Highlights and Breaking News

PLEN03_92 | Jes Olesen Award Lecture: Peripherin: A novel early diagnostic and prognostic plasmatic biomarker in Amyotrophic Lateral Sclerosis

A. Bombaci
Vita-Salute San Raffaele University, Milan, Italy

Background: Motor neuron diseases (MND) are heterogeneous and complex neurodegenerative disorders. Biomarkers could facilitate early diagnosis, prognosis determination, and patient stratification. Among the most studied biomarkers are neurofilaments, with peripherin (PRPH), a specific type predominantly expressed in peripheral nervous system, gaining attention. To date, no studies have evaluated PRPH in human plasma.

Methods: sandwich-ELISA was used to quantify plasma peripherin from 120 MND (100 ALS, 4 PMA, 15 PLS), 73 MND-mimics and 38 healthy-controls (HCs). Plasma was collected at diagnosis or some months earlier. 41 ALS were evaluated longitudinally. ALSFRS_r, MRC, spirometry, genetic tests, disease progression rate (PR), blood examinations, and neuropsychological tests were performed. Statistical analyses included Kruskal-Wallis, Mann-Whitney, Cox-regression, and Kaplan-Meier curves.

Results: Plasma PRPH levels differed significantly among groups ($p < 0.0001$), showing higher values in MND participants than MND mimics and HCs. Moreover, PRPH levels were elevated in PLS compared with HSP patients ($p = 0.0001$). Differences persisted after adjusting for age and sex. ROC curve demonstrated that PRPH discriminated MND from MND mimics (AUC = 0.85). Elevated PRPH correlated positively with ALSFRS_r and lower motor neuron index, while inversely with disease progression rate. Higher PRPH levels at the beginning of the disease were associated with longer survival.

Discussion: Plasma PRPH is raised in MND, particularly ALS, from the earliest stages, distinguishing MND from mimics and

correlating with clinical parameters and survival. This suggests PRPH may reflect an endogenous response of lower motor neuron to injury. Further multicentre studies are required to refine the diagnostic and prognostic utility of PRPH in MND.

Disclosure: Nothing to disclose.

SUPPLEMENT ABSTRACTS

Symposia

Saturday, June 27 2026

EAN/MDS-ES: Tremor syndromes: From pathophysiology to emerging treatment approaches**SYMP01_1 | Pathophysiology of tremor syndromes**

R. Helmich
*Neurology Department, Radboud University Medical Centre,
Donders Institute, Nijmegen, the Netherlands*

Tremor syndromes are defined by clinical features, including tremor characteristics and accompanying symptoms. The pathophysiology of clinical tremor syndromes involves the mechanisms that give rise to the tremor. Knowledge about the pathophysiology of tremor is relevant, because it helps to understand clinical heterogeneity (e.g., in the response to treatment) and because it aids the development of new, mechanism-guided therapies. Here, I will discuss the pathophysiology of the most common tremor syndromes, including Parkinson's tremor, essential tremor, and dystonic tremor. To this end, I will discuss evidence from studies that have used neuroimaging and neurophysiology outcomes, with or without interventions (e.g., pharmacological, stereotactic surgery). I will discuss how rhythmic activity in the cerebello-thalamo-cortical circuit plays a key role in almost all tremor syndromes. These activities are governed by differing cerebral mechanisms, both within the cerebello-thalamo-cortical circuit (e.g., cerebellar atrophy), and outside the cerebello-thalamo-cortical circuit (e.g., triggering circuits like the basal ganglia and counter-acting circuits like recently discovered "anti-tremor networks").

Disclosure: Rick Helmich is consultant for Neurocrine Biosciences.

The treatment of Medium Vessel Occlusions (MeVO) represents on of the next frontiers in acute ischemic stroke intervention, moving beyond the established boundaries of large vessel mechanical thrombectomy (MT). While the 2015 “thrombectomy revolution” solidified MT as the gold standard for proximal occlusions, the management of more distal M2/M3, A2/A3, and P2/P3 segments remains a complex clinical challenge. This presentation evaluates the transition of intra-arterial (IA) thrombolysis from a historical “rescue” therapy to a potential primary tool for achieving micro-vascular patency in primary or secondary MeVos. From initial IA Lytics trial in the pre-EVT era the field is now reequipped with evidence for treatment of secondary MeVOs after LVO MT. Past and current evidence is reviewed and the role of patient selection, including intraoperative imaging is reviewed. The session concludes with a practical framework for clinical application, including dosing, timing and exact mode of administration, thereby providing a comprehensive roadmap for optimizing reperfusion in the distal cerebral vasculature.

Disclosure: TECNIO Trial funded by Boehringer Ingelheim. Research contracts with Siemens and Cercare for intra-operative Imaging.

modern environments shape our heart and brain health**

J. Reis
Hopital Universitaire de Haute-pierre CHU Strasbourg, France

The studies of human biorhythms have become an important and emerging discipline in the sixties along with an interest for the sleep quality and duration. The media assumption of its

decrease is debated. Sleep epidemiological studies are mostly based on self-reported sleep duration via questionnaires (self-reported wearable devices). They were first conducted in WEIRD (Western, Educated, Industrialized, Rich and Democratic) countries before considering nowadays non-WEIRD countries and even gather-hunter populations. Finally, the first question concerns sleep quality: which are the optimal sleep duration and pattern? The perceived sleep efficacy as well as duration/pattern are both individual and cultural. We will question genetic, age and sex variability, the effects of societal, cultural as well the geographical latitude on the sleep duration's characteristics. The description of the Insufficient Sleep Syndrome, characterized by a quantitative deficit of sleep seems triggered by specific lifestyles. Initially observed among New-York Yuppies, it seems nowadays related to some particular behaviors (e.g., work addiction). As well as imposed shift-work, these conditions lead considering some recent societal constraints, our "modern environments". These Zeitgebers include the effects of urbanization and technological revolution as well as lifestyle; they override the universal Zeitgeber which are light and the Day-Night alternance. Understanding the health consequences of poor sleep quality, needs a global view of biorhythms as sleep may be considered as the perfect clinical marker of bio-rhythmicity, or our Body Time. Amidst health risks, brain health, and cardio-vascular and metabolic problems are prominent.

EAN/WMS: Molecular therapies in neuromuscular disorders: From genes to clinical impact

SYMP05_1 | Spinal muscular atrophies: From molecular mechanisms to therapeutic breakthroughs

S. Corti

Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy

Spinal muscular atrophy (SMA) is a severe neurodegenerative disorder caused by mutations in the SMN1 gene, resulting in progressive motor neuron loss and muscle atrophy. Over the past decade, SMA has transitioned from being an untreatable condition to a model of successful molecular therapy, fundamentally transforming patient outcomes and quality of life.

This lecture will provide an integrated overview of the molecular pathogenesis of SMA and the revolutionary therapeutic strategies that have emerged. Gene replacement therapy using onasemnogene abeparvovec, an AAV9-mediated approach delivering functional SMN1 gene copies, has demonstrated remarkable efficacy, particularly when administered in pre-symptomatic or early symptomatic stages. The lecture will discuss clinical trial data, long-term outcomes, and practical considerations for implementation.

Splicing modulators, including nusinersen and risdiplam, represent groundbreaking RNA-targeted approaches that enhance SMN2 exon 7 inclusion to increase functional SMN protein production. Comparative analysis of antisense oligonucleotide and small-molecule strategies will be presented, highlighting their distinct pharmacological profiles and clinical applications across different SMA phenotypes.

The critical importance of therapy timing and personalization will be emphasized, drawing from newborn screening programs and natural history studies that underscore the window of therapeutic opportunity. Patient selection criteria, biomarkers for treatment response monitoring, and individualized treatment algorithms based on SMN2 copy number and disease severity will be discussed.

Finally, new and emerging therapies, including next-generation gene therapies, combination treatment strategies, and neuroprotective approaches targeting muscle and neuronal pathways beyond SMN restoration, will be explored as the future frontier of SMA management.

Disclosure: Participation in SAB of Novartis, Roche, Biogen.

SYMP05_2 | Advances in molecular therapies for muscular dystrophies: Targeting the underlying defects

G. Comi

Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy

Muscular dystrophies represent a heterogeneous group of inherited disorders characterized by progressive muscle weakness and degeneration. Recent advances in molecular medicine have revolutionized the therapeutic landscape, shifting from purely symptomatic management toward disease-modifying interventions that address the underlying genetic defects.

This lecture will provide a comprehensive overview of cutting-edge molecular therapies currently in development or clinical use. Gene and RNA-based therapies, including exon-skipping antisense oligonucleotides, stop-codon read-through agents, and adeno-associated virus (AAV)-mediated gene replacement strategies, have demonstrated promising results in conditions such as Duchenne muscular dystrophy and limb-girdle muscular dystrophies. The lecture will discuss the mechanistic principles, clinical trial outcomes, and real-world evidence supporting these approaches.

Targeted molecular approaches will be explored, focusing on precision medicine strategies tailored to specific genetic mutations and disease subtypes. Particular attention will be given to the development of personalized therapeutic protocols and the importance of genetic diagnosis in treatment selection.

Finally, the lecture will address current challenges and future directions, including immunological responses to viral vectors, limited tissue biodistribution, long-term safety concerns, and the need for biomarkers to monitor therapeutic efficacy. Emerging technologies, such as CRISPR-based gene editing and next-generation delivery systems, will be discussed as potential solutions to overcome existing limitations.

EAN/EANO: The changing landscape of neuro-oncology: New frontiers of treatments

SYMP10_1 | Anatomical-physiological basis of the blood-brain barrier in brain tumours

A. Di Stefano
Spedali Riuniti di Livorno, Livorno, Italy

The blood-brain barrier (BBB) represents one of the most distinctive anatomical and physiological features of the central nervous system and plays a pivotal role in the pathogenesis, diagnosis, and treatment of brain tumours. While the BBB is essential for maintaining neural homeostasis by regulating molecular trafficking between the systemic circulation and the brain parenchyma, it also constitutes the principal obstacle to

the effective delivery of therapeutic agents to intracranial neoplasms. Indeed, many potentially active anticancer drugs fail to demonstrate clinical efficacy not because of inadequate target engagement, but because insufficient concentrations reach the tumour tissue. Understanding the anatomy and physiology of the BBB is therefore fundamental to modern neuro-oncology. This lecture will review the structural organization of the BBB, focusing on the neurovascular unit, a dynamic multicellular system composed of endothelial cells, pericytes, astrocytic end-feet, neurons, microglia, and extracellular matrix components. Particular attention will be given to the specialized properties of brain endothelial cells, including tight junction proteins such as claudin-5, occludin, and zonula occludens-1, the suppression of transcytosis pathways, and the expression of active efflux transporters including P-glycoprotein and breast cancer resistance protein. Together, these mechanisms tightly regulate molecular exchange, preserve ionic and metabolic homeostasis, and limit immune cell trafficking within the central nervous system.

The presentation will then examine how these physiological barriers are altered in brain tumours. In gliomas, particularly glioblastoma, the normal BBB undergoes profound but heterogeneous remodeling, giving rise to the so-called blood-tumour barrier (BTB). Contrary to the common perception of a uniformly disrupted barrier, permeability changes within gliomas are highly variable across different tumour regions. Tumour angiogenesis, driven in part by vascular endothelial growth factor (VEGF), results in abnormal endothelial differentiation, pericyte dysfunction, and increased vascular permeability. Nevertheless, infiltrative tumour cells frequently invade surrounding brain tissue where the BBB remains structurally and functionally intact. This preserved barrier at the tumour margins is a major contributor to treatment failure and disease recurrence.

The BBB in brain metastases exhibits distinct biological features, often showing greater permeability than primary gliomas, although substantial inter- and intra-tumour heterogeneity persists. These alterations have important clinical consequences, contributing to vasogenic edema, increased intracranial pressure, and the radiological appearance of contrast enhancement on magnetic resonance imaging (MRI).

The lecture will also discuss current approaches for assessing BBB integrity in clinical practice. Gadolinium-enhanced MRI remains the most widely used surrogate marker of BBB disruption; however, contrast enhancement does not necessarily reflect the full extent of tumour infiltration. Advanced imaging techniques, including dynamic contrast-enhanced and dynamic susceptibility contrast MRI, provide additional insights into vascular permeability and tumour physiology, although their ability to predict drug penetration remains limited.

Finally, the therapeutic implications of BBB and BTB biology will be explored. The differential permeability of the BBB explains why certain agents, such as temozolomide, achieve clinically meaningful concentrations within the brain, whereas many targeted therapies do not. Emerging strategies aimed at overcoming or bypassing the BBB include convection-enhanced delivery, focused ultrasound combined with microbubbles, nanoparticle-based drug delivery systems, and local cellular immunotherapies such as CAR-T approaches. Increasingly, the heterogeneity of the BTB is being recognized not only as an obstacle but also as a potential therapeutic opportunity.

A deeper understanding of BBB anatomy and physiology is essential for the development of next-generation neuro-oncological

therapies. Future advances may enable patient-specific characterization of BBB status, allowing treatment selection to be guided not only by tumour biology but also by the dynamic properties of the tumour microenvironment and its vascular barriers.
Disclosure: Nothing to disclose.

SYMP10_2 | Disrupting BBB to enhance treatment delivery

A. Idbaih
Sorbonne Université, AP-HP/La Pitié Salpêtrière, ICM

The blood–brain barrier (BBB) represents a major obstacle to drug delivery in treatment of central nervous system (CNS) disorders including brain cancer such as glioblastoma. The BBB is a highly selective biophysical and biochemical barrier that regulates molecular transport from the blood flow stream to the brain parenchyma.

In the setting of brain tumors, several strategies have been developed to overcome, bypass, and/or disrupt the BBB, to improve the bioavailability and the efficacy of therapeutic agents against tumor cells.

First, strategies aim at increasing drug delivery using systemic or local routes. High-dose intravenous chemotherapy has significantly improved outcomes in selected brain malignancies. Intra-arterial delivery approaches have also been explored. In addition, locally implanted biodegradable agents within the surgical cavity have demonstrated antitumor efficacy in recurrent glioblastoma.

Second, approaches focus on increasing drug penetration through drug or BBB modulation. Drug modulation strategies include several modalities, among which nanoparticle encapsulation is one of the most advanced, with encouraging signals of efficacy. Finally, direct BBB modulation represents a promising approach, including inhibition of efflux pumps and transient disruption of tight junctions. Ultrasound-mediated BBB opening is currently being evaluated in a phase III clinical trial in brain tumors.

Overall, the BBB remains a major limiting factor in the treatment of CNS diseases, including brain tumors. Strategies aimed at overcoming, bypassing, or disrupting the BBB have the potential to enhance local therapeutic efficacy while reducing systemic toxicity.

EAN/EPNS: How to deal with cerebrovascular diseases in children and adolescents

FW02_1 | Stroke across pediatric age

I. Kopyta
Department of Child Neurology, Medical University of Silesia, Katowice, Poland

Stroke is a rare condition in the pediatric population, but it can affect children of all ages, most commonly -newborns and young infants. Neonatal stroke is excluded from the definition of pediatric arterial ischemic stroke due to its specific risk factors

and prognosis. The diagnosis of PAIS (Pediatric arterial ischemic stroke) can be made in the case of sudden neurological symptoms, at age between 29 days and 18 years, with vascular pathology detected by neuroimaging, correspond in its location to clinical symptoms. The incidence of PAIS is estimated at 3–13/100,000 per year; the risk factors are arteriopathies (acquired and congenital, with a progressive, stationary or remitting course), heart diseases and thrombophilia. Confirmation of PAIS is based on the results of a neuroimaging and the method of choice is magnetic resonance imaging with MRA of the cerebral and neck vessels. If the probable delay in MRI performance exceeds 25 min, then CT imaging should be performed. A child diagnosed with PAIS is currently a potential candidate for thrombolytic therapy and thrombectomy. Antiplatelet therapy is an alternative in the case of exceeding the therapeutic window and is a method used in secondary prevention. Most children with PAIS will present the permanent neurological deficits; approximately 3% of children with PAIS die during the acute phase of the disease. A key issue in improving prognosis and increasing access to modern therapeutic methods for children with PAIS is improving awareness on PAIS.

Disclosure: Nothing to disclose.

FW02_2 | Arteriopathies in pediatric stroke

R. Tudorache
Pediatric Neurology Discipline, Neuroscience Department, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, and Université Paris Cité, France

Pediatric arterial ischemic stroke (PAIS) has been associated with a wide range of underlying conditions. In developed countries, the most common etiologies include cerebral arteriopathies, congenital or acquired heart diseases, and severe systemic infections. Cerebral arteriopathy is a major contributor to PAIS, accounting for nearly half of all cases and significantly increasing the risk of both initial and recurrent stroke. These arteriopathies may be congenital, reflecting abnormal vascular development, or acquired as a result of disruption of vascular homeostasis. The term encompasses a broad spectrum of vascular imaging abnormalities, including cervicocervical arterial dissection, moyamoya, vasculitis, post-varicella

This is an open access article under the terms of the [Creative Commons Attribution](https://creativecommons.org/licenses/by/4.0/) License, which permits use, distribution and reproduction in any medium, provided the original work is properly cited.

© 2026 The Author(s). *European Journal of Neurology* published by John Wiley & Sons Ltd on behalf of European Academy of Neurology.

angiopathy, and idiopathic focal cerebral arteriopathy. Their classification has undergone several revisions over the past two decades. Among intracranial arteriopathies, focal cerebral arteriopathy (FCA) is the most frequently identified subtype, accounting for up to 25% of cases. FCA is a dynamic entity that may exhibit progression or relapse and is characterized by inflammatory arterial stenosis, often developing secondary to infection, particularly viral infections such as upper respiratory tract infections or varicella. The vascular involvement typically affects the carotid T, especially the proximal segment of the middle cerebral artery. Diagnosis relies on clinical presentation and neuroimaging. Brain MRI is the first-line imaging modality in pediatric stroke, enabling early differentiation from stroke mimics, while in cases of suspected FCA, vessel wall imaging is particularly useful. Therapeutic approaches remain heterogeneous. Antithrombotic therapy is most commonly used for secondary stroke prevention, while corticosteroids have been proposed to limit disease progression, with several studies currently ongoing.

Timely evaluation of a first-time seizure

FW03_1 | Timely evaluation of a first seizure - insights from the SWISS FIRST Study

B. Jin

Sleep-Wake-Epilepsy-Center, Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland

Early diagnosis of a first unprovoked epileptic seizure and estimation of seizure recurrence risk is challenging and important to decide about initiating antiseizure medication. In SWISS FIRST, a prospective, observational, multicenter study across seven hospitals in Switzerland, we assessed adult patients suspected for first unprovoked epileptic seizure and their development over two years. We determined diagnostic accuracy of baseline EEG and MRI based on their diagnosis two years after first event. We developed a binary logistic regression model for seizure recurrences on the baseline EEG and MRI and clinical characteristics of the patients.

We recruited 636 patients with suspected first unprovoked epileptic seizure. 238 were finally diagnosed with epilepsy. Sensitivity for epileptiform activity in EEG was 31.5%, specificity was 97.3%. Potential epileptogenic lesions were present in 40.3% amongst epilepsy patients, but also abundantly in patients with only a first unprovoked seizure (31%) and non-epileptic seizure

FW04_3 | Repetitive TMS of the precuneus for the treatment in AD

A. Antal
Department of Neurology, UMG, Göttingen, Germany

Non-invasive Brain Stimulation (NiBS) techniques such as repetitive Transcranial Magnetic Stimulation (rTMS) and transcranial Electrical Stimulation (tES), including Direct Current and Alternating Current Stimulation (tDCS, tACS), allow to modulate neuronal excitability, oscillatory activity and to boost cortical functions, hereby possibly offering a therapeutic potential to slow down cognitive decline. Cognitive decline reaches medical attention for about 8–25% of individuals aged over 65, when suffering from Mild Cognitive Impairment (MCI). Around 15% of MCI patients develop dementia within two years, supporting a medical need for early diagnosis and treatment. Recent investigations propose rTMS of the precuneus as a potential therapeutic tool to improve network activity and cognitive functions in older individuals with cognitive impairments. However, several subject-specific factors, for example, anatomical and physiological differences, gender, brain state before and during stimulation, and also methodological factors, such as the type of the task applied in combination with the stimulation, can confound the effects of stimulation. This talk aims to provide an overview of the commonly utilized rTMS protocols, elucidating their individual merits and drawbacks.

The cerebellum beyond motor function: Uncovering cognitive-affective roles

FW06_1 | The 3 facets of the cerebellar syndrome: Emphasis on the cerebellar cognitive affective syndrome

M. Manto
Brussels, Belgium

FW06_2 | The role of the cerebellum in emotions

D. Timmann
Department of Neurology and Center for Translational Neuro- and Behavioral Sciences (C-TNBS), Essen University Hospital, University of Duisburg-Essen, Essen, Germany

The link between the cerebellum and emotional behavior will be discussed, beginning with an overview of known anatomical connections between the cerebellum and limbic structures, including the amygdala, PAG, hippocampus, and prefrontal cortex. Second, early animal studies demonstrating the involvement of the cerebellum in autonomic functions related to the expression of emotions will be summarized, including blood circulation and respiration. Third, functional brain imaging studies in healthy human participants examining emotional tasks will be reviewed, along with observations of altered emotional control in patients with cerebellar disorders, including degenerative ataxias and focal lesions. These findings will be complemented by structural and functional imaging evidence of disrupted cerebello–limbic interactions in patients with neuropsychiatric disorders, in particular anxiety disorders.

Finally, we will focus on fear, an important emotion for survival. The cerebellum contributes not only to innate affective and defensive behaviors but also to learned fear responses. Early rodent lesion studies showed that fear-conditioned bradycardia is markedly reduced after vermal lesions. To date, only a few studies have examined fear conditioning in patients with cerebellar disease, in which behavioral deficits appear to be milder. Most evidence for cerebellar involvement in human fear conditioning comes from neuroimaging studies in healthy participants. Threat-prediction-related activations extend beyond the vermis, with prominent involvement of the lateral cerebellum. There is initial evidence that the cerebellum contributes to prediction-error signals driving fear extinction via interactions with the VTA. These findings demonstrate that cerebellar control extends beyond autonomic functions and includes higher-order processes such as reward processing.

Disclosure: Dagmar Timmann received funding from the German Research Foundation (project number 316803389 – SFB1280), the European Union’s Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement No 956414, and the Bernd Fink Foundation.

FW06_3 | A functional atlas of the cerebellum

C. Nettekoven

Department of Experimental Psychology, University of Oxford, Oxford, UK

Once considered primarily a motor structure, the cerebellum is now known to contribute to cognitive processes. Cerebellar damage can therefore produce cognitive disturbances in addition to motor deficits. However, limited knowledge of cerebellar functional organization continues to constrain the interpretation of cerebellar involvement in neurological disease.

This limitation largely reflects the absence of a comprehensive functional map of the human cerebellum. Although different cerebellar regions are engaged during motor, cognitive, and emotional tasks, these regions remain difficult to reliably delineate using existing atlases, particularly in the presence of substantial inter-individual variability.

In this talk, I will present the first comprehensive functional atlas of the human cerebellum, derived by integrating multiple large-scale functional MRI datasets spanning a wide range of motor, cognitive, and language tasks. Using a data-driven modelling approach, we identified distinct cerebellar regions with characteristic functional profiles and connectivity patterns. The atlas reveals a clear functional topography, with anterior cerebellar regions predominantly involved in motor control, posterior regions, particularly lobule VIIA (Crus I and II)—engaged in higher-order cognitive processes.

Importantly, the atlas enables precise mapping of cerebellar function at the individual level, addressing the limitations of group-based maps. I will discuss how this framework improves our ability to interpret cerebellar activation and lesion effects, and how it can inform the study of cognitive and affective symptoms in neurological disorders along with potentially improve surgical planning. By providing a unifying functional reference, this work supports a more integrated view of the cerebellum as a key contributor to both motor and non-motor brain function.

Disclosure: Nothing to disclosure.

FIGURE 1 Cerebellar functional atlas. Symmetric atlas at medium level of granularity. The labels of each region consists of a capital for the domain (M, A, D, S), a number for region (1–4), and a lower- case letter for the subregion (a–d).

University of Science and Technology*

The use of artificial intelligence (AI) in headache care and research is rapidly expanding. AI has the potential to enhance clinical task such as diagnosis, treatment selection and prediction of disease trajectories. To date, several key areas have received the most attention in the headache literature. First, large language models have been used for automated extraction of patient-level data, as well as to support the training of healthcare providers and patient education. Second, a variety of AI models have been used to diagnose and classify headache disorders using both clinical and paraclinical data. There are also some indications that such models could improve diagnostic accuracy among non-neurologists. Third, AI models have shown promise in optimizing treatment selection and predicting treatment responses in primary headache disorders. Finally, predictive models that can forecast day-to-day headache occurrence, as well as longer-term disease trajectories, show encouraging results. While the current body of literature demonstrates promising developments, there remains a substantial need for external validation and clinical trials to enable the translation of these models into clinically applicable tools.

EAN/EANS: Spontaneous intracranial hypotension: The headache neglected by neurologist

FW09_1 | Clinical spectrum and imaging essentials in Spontaneous Intracranial Hypotension

T. Dobrocky
*Diagnostic and Interventional Neuroradiology, University of
Bern, Inselspital, Bern, Switzerland*

Spontaneous intracranial hypotension (SIH) is an important and frequently underrecognized cause of secondary headache with a broad and sometimes misleading clinical spectrum. Although orthostatic headache is the classic presentation, patients may develop atypical symptoms including non-orthostatic headache, cranial nerve palsies, cognitive and behavioral changes, movement disorders, or impaired consciousness, often leading to delayed diagnosis. Over the past years, substantial progress has been made in elucidating the underlying etiologies of SIH, particularly distinct types of spinal cerebrospinal fluid (CSF) leaks and CSF-venous fistulas. In parallel, standardized diagnostic algorithms integrating brain MRI and advanced spinal imaging have been established, transforming SIH into a well-defined and treatable condition. Neuroimaging is central to diagnosis and management, with characteristic brain MRI findings and targeted spinal techniques such as dynamic myelography enabling precise leak localization and guiding therapy. This session

reviews the clinical spectrum of SIH and highlights imaging essentials for accurate diagnosis and effective treatment.

Technologies to identify and preserve residual brain functions in the ICU

FW10_1 | TMS-EEG to probe brain networks in unconsciousness

S. Casarotto
Dept. Biomedical and Clinical Sciences, University of Milan;
IRCCS Fondazione Don Carlo Gnocchi ONLUS, Milan

Introduction: Attributing consciousness to others always implies an inferential process, which is particularly challenging when evaluating patients who remain in prolonged unresponsive wakefulness syndrome (UWS) after severe brain injury. Behavioral evaluations alone may be misleading due to impaired sensory-motor functions. Neural responses to verbal commands can indicate intentional processing, but require intact language, executive functions, and sustained attention. Auditory paradigms with increasing complexity may reveal residual perceptual awareness without requiring active participation, though they still depend on attention and preserved sensory pathways. Measures of intrinsic brain activity, such as perturbational complexity, can inform about capacity for consciousness even when sensory-motor channels are compromised.

Methods: This study applied a multilayer neurophysiological assessment in 16 UWS patients hospitalized in an Intensive Rehabilitation Unit.

Results: Twelve patients recovered at least minimal behavioral signs of responsiveness. Before this occurred, intrinsic brain activity suggested a capacity for consciousness in all these patients, 25% of whom also showed neural responses to verbal commands and 8% perceptual activations. Clinical evoked potentials revealed significant sensory-motor impairments in most patients, likely contributing to negative findings of behavioral, task-based and perceptual evaluation.

Discussion: These results demonstrate feasibility and sensitivity of multilayer neurophysiological assessment in subacute rehabilitation. This approach is necessary to evaluate residual consciousness beyond behavioral responsiveness, progressively moving from task-based modulation of brain activity to perceptual awareness to intrinsic brain dynamics. The accurate detection of covert capacity for consciousness is crucial to guide treatment, since 75% of patients who remain in prolonged UWS may show late recovery.

Disclosure: I am currently advisor and share-holder of Intrinsic Powers, a spin-off of the University of Milan.

EAN/MDS-ES: Repurposing GLP-1 receptor agonists: New frontiers for neuroprotection in neurological diseases

FW12_1 | Beyond glycemic control: Uncovering the neuroprotective role of GLP-1 receptor agonists

F. Ferrari

Department of Health Sciences, Università del Piemonte Orientale, Novara Italy

Introduction: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs), developed for type 2 diabetes mellitus and obesity, are emerging as neuroprotective candidates in neurological disorders [1,2]. This lecture provides a mechanistic overview of their central nervous system (CNS) actions.

Methods: Literature review focused on GLP-1 RAs pharmacology, intracellular signaling and downstream pathways relevant to neuroprotection.

Results: GLP-1 receptors are broadly expressed in CNS and their activation engages cyclic AMP-dependent and phosphoinositide 3-kinase signaling, producing pleiotropic effects [3,4]: (i) attenuation of neuroinflammation via microglial polarization to anti-inflammatory phenotype, NFkB and NLRP3 inflammasome inhibition, suppression of TNF-alpha, IL-1-beta and IL-6, and prevention of neurotoxic reactive astrocyte conversion; (ii) anti-apoptotic activity through Bcl-2 upregulation and Bax/caspase-3 suppression; (iii) mitochondrial biogenesis via PGC-1-alpha and sirtuin-1, with reduction of oxidative stress; (iv) neurotrophic and synaptic support through brain-derived neurotrophic factor/TrkB signaling, AMPA receptor trafficking, postsynaptic density protein-95 upregulation, hippocampal neurogenesis and long-term potentiation; (v) proteostasis restoration via ULK1-dependent autophagy, reducing amyloid-beta, hyperphosphorylated tau and alfa-synuclein aggregates; (vi) preservation of blood-brain barrier and neurovascular unit. Additional body-to-brain signaling via vagal afferents contributes to indirect central neuroprotection.

Conclusion: GLP-1 RAs display multifaceted, converging neuroprotective mechanisms targeting the triad of neurodegeneration:

neuroinflammation, mitochondrial dysfunction and proteinopathy. Their established safety profile and pleiotropy make them strong candidates for repurposing in neurology.

FW13_2 | Revised Recommendations on the use of pharmacological therapies for neuropathic pain relief

X. Moisset

Université Clermont Auvergne, CHU Clermont-Ferrand, Inserm, Neuro-Dol, Clermont-Ferrand, France

Neuropathic Pain remains a major clinical challenge, with many patients experiencing insufficient pain relief and treatment-related adverse effects. The Neuropathic Pain Special Interest Group undertook a comprehensive update of its treatment recommendations, incorporating new randomized controlled trials and advances in evidence synthesis.

In this presentation, we will summarize the pharmacological findings of a large systematic review and meta-analysis including double-blind, randomized, placebo-controlled trials published up to February 2024. Across 284 pharmacological trials involving tens of thousands of participants, treatments were evaluated using standardized efficacy and safety outcomes, including responder rates, numbers needed to treat (NNT), and

numbers needed to harm (NNH), with evidence certainty assessed using the GRADE framework.

Participants will gain an updated overview of evidence-based pharmacological strategies for neuropathic pain. Strong recommendations support the use of tricyclic antidepressants, $\alpha 2\delta$ -ligands (gabapentinoids), and serotonin–noradrenaline reuptake inhibitors as first-line treatments. Second-line options include topical therapies such as high-concentration capsaicin patches, capsaicin cream, and lidocaine 5% plasters. Third-line strategies include botulinum toxin A and opioids in selected situations. The presentation will also highlight the magnitude of treatment effects, safety considerations, and how these therapies compare in terms of benefit–risk balance.

Beyond summarizing the evidence, the session will provide practical guidance on how to translate these updated recommendations into everyday clinical decision-making. Attendees will leave with a clear understanding of current pharmacological treatment hierarchies for neuropathic pain and the strengths and limitations of the available evidence.

FW16_3 | Digital solutions for diagnostics and treatment of psychiatric disorders in neurorehabilitation

K. Rauen

Institute of Emergency Medicine, University Hospital Zurich & Neuroscience Center Zurich, University of Zurich, Switzerland

Digital solutions are increasingly accepted as add-on tools for diagnostics and treatment in patients and their caregivers. Despite rapid developments and rising approvals only 39% of Digital Health Applications target psychiatric disorders and none of them addresses psychiatric burden in neurological patients during neurorehabilitation. Today, most digital solutions target depression (27%), anxiety (23%), insomnia (10%), cognition (7%), and various psychiatric conditions. It is well known that neurological patients after stroke or traumatic brain injury (TBI) particularly suffer from brain-injury induced depression, cognitive dysfunction and/or sleep disorders with raising evidence that brain-injury induced affective disorders differ in their pathophysiology and clinical presentation from Major Depressive Disorder (MDD). Consecutively, current digital solutions may not adequately address neurological patients' needs and often require caregivers' support. Therefore, it is time to close the gap on brain-injury specific Digital Health Applications for patients during and beyond neurorehabilitation aiming for better neuropsychiatric and quality of life outcomes. Here, we pinpoint (i) the communalities and differences of the brain-injury induced affective disorder and MDD, (ii) the specific personalized needs regarding neurobiological, functional and psychiatric characteristics to improve affective, cognitive and sleep burden during neurorehabilitation, and (iii) future digital solutions to enable effective, scalable, and patient-centered advances for better long-term outcomes as well as good quality of life for our neuropsychiatric patients during and beyond neurorehabilitation.

FW16_4 | Network-targeted brain stimulation for neurorehabilitation of cognition and behaviour

S. Filipović

Institute for Medical Research, University of Belgrade, Serbia

Non-invasive brain stimulation (NIBS) has been increasingly studied as a tool to promote neurorehabilitation for cognitive and behavioural impairments. A considerable body of evidence suggests that NIBS can have a beneficial effect, especially when coupled with other rehabilitation approaches. However, although encouraging, the results so far have not been unequivocal. One reason for the apparent lack of more substantial effects is the dominant single-target focus in most clinical studies. NIBS techniques (such as transcranial magnetic stimulation – TMS, or transcranial direct current stimulation – tDCS) were typically applied over either the injured area or the homologue (contralateral) healthy area, or, in the case of cognitive impairments, over the dorsolateral prefrontal cortex (DLPFC). However, it is increasingly recognised that this approach is not effective enough to reset physiological mechanisms into a sustainable and robust recovery mode. Injury- or disease-induced structural changes, beyond a loss of function directly associated with the lesion site(s), also disrupt large-scale distributed brain networks (such

as the default mode, salience, central executive, and sensorimotor). These disruptions can be a significant factor behind symptoms and impairments, but, even more importantly, they often prevent the recovery of functions, whether by restoration or by compensation. There is a growing understanding that individualised multi-locus targeting, guided by functional and structural connectivity determined by functional imaging techniques (e.g., fMRI, DTI, EEG), can provide a breakthrough towards meaningful and enduring clinical applications.

SPS02_2 | Harmonising practices: Bridging biological aspects and social contexts across Europe

U. Volpe
Unit of Clinical Psychiatry, Department of Clinical Neurosciences/DIMSC, Università Politecnica delle Marche, Ancona, Italy

Achieving sustained improvements in brain and mental health requires approaches that integrate biological knowledge with social, cultural, and systemic determinants of health. Across Europe, advances in neuroscience, genetics, and clinical neurobiology coexist with persistent disparities in mental health outcomes, access to care, and implementation of evidence-based interventions. These gaps highlight the need for harmonised approaches that connect biological insights with social realities, healthcare systems, and public health strategies.

A unified brain health perspective can be applied across diverse European contexts by addressing interactions between biological vulnerability and social determinants across the lifespan. Biological risk factors—such as neurodevelopmental trajectories, genetic susceptibility, inflammation, and stress-related neurobiological changes—are shaped by environmental exposure, socioeconomic conditions, education, migration, discrimination, and healthcare access. Understanding these interactions

This is an open access article under the terms of the [Creative Commons Attribution](https://creativecommons.org/licenses/by/4.0/) License, which permits use, distribution and reproduction in any medium, provided the original work is properly cited.

© 2026 The Author(s). *European Journal of Neurology* published by John Wiley & Sons Ltd on behalf of European Academy of Neurology.

is essential for effective prevention, early intervention, and service planning.

Also, cross-national differences will be considered in mental health policies, service organisation, and preventive strategies, and how these influence the translation of neuroscientific knowledge into routine practice. Particular attention is given to the challenge of aligning neurobiological advances with population-level and community-based interventions, and to the importance of interdisciplinary collaboration across neurology, psychiatry, public health, and social sciences.

Ultimately, advancing brain health in Europe requires preventive, equity-oriented strategies that integrate biological and social perspectives while remaining adaptable to local contexts.

SPS02_3 | A child neurology perspective on the origins of neurodevelopmental disorders and their impact in adolescence

L. Haataja

Department of Pediatric Neurology, Helsinki University Hospital, Helsinki, Finland

Children and adolescents with neurodevelopmental disabilities represent a growing population of individuals with varying functional everyday impairments. These health conditions cause impairments in motor, cognitive, language, behavioral and/or sensory functioning. In 2023, WHO and UNICEF reported that there are approximately 317 million children and adolescents affected by developmental disabilities globally. In the Global Burden of Disease study (2019) the prevalence of these conditions ranged from 7.5% among children under 5 years to 13.9% for those aged 15–19 years.

The origins of neurodevelopmental disorders are diverse and often multifactorial combinations of genetic, epigenetic and environmental factors affect critical periods of neurogenesis and connectivity. Furthermore, adverse perinatal incidents, like preterm birth and birth asphyxia, play a major role in adverse neurodevelopmental outcomes.

Neurodevelopmental disabilities are associated with poor academic outcomes, bullying, loneliness, discrimination, unemployment and somatic health problems like obesity, diabetes, cardiac and respiratory diseases, and mental health conditions. The vicious circle may be accelerated by the fact that the diagnoses of neurodevelopmental disorders are often based on various combinations of symptoms, blurring the line between so-called typical and atypical development, and, at present, the neuro-anatomic correlation is to a large degree not detected by the currently available imaging tools in clinics.

There is an immense global need for increasing evidence-based awareness of neurodevelopmental disorders and developing community-based strategies for providing opportunities to support individual needs and interventions and secure equal rights to individuals affected by these disorders as members of society.

Dauren Ramankulov EAN Scientific Department Coordinator
Clinical guidelines are essential for ensuring high-quality, cost-efficient healthcare. They reflect scientific knowledge, guide clinical practices, and identify gaps in research, ultimately improving healthcare outcomes. However, the challenge lies in balancing quality, efficiency, accessibility, and sustainability. In response to this challenge, the Cost-Conscious Healthcare (CoCoCare) training programme was launched in 2018 at Maastricht University and later adopted by the European Academy of Neurology (EAN) in 2023. This year-long educational initiative targets neurology residents and early-career neurologists, equipping them with the skills to develop evidence-based, economically sustainable clinical guidelines. The programme combines e-learning, workshops, webinars, self-directed learning, and practical guideline development, culminating in project presentations at the EAN Congress. Over 140 participants from more than 25 European countries have completed the programme, which has received positive feedback for fostering cost-conscious decision-making and promoting active participation in guideline development. CoCoCare's fourth edition, launched at the 2026 EAN Congress, continues to nurture a new generation of experts poised to lead future guideline development within the EAN framework. Graduates gain mentorship, congress grants, and professional recognition, enhancing their careers and contributing to the long-term sustainability and quality of neurological care across Europe.

SPS05_3 | Broad rim lesions as new biomarker for rapid disease progression in Multiple Sclerosis

V. Konstantinidis

Department of Neurology, Erasmus MC, Rotterdam, The Netherlands

The high diversity in individual clinical disease courses of multiple sclerosis (MS) is likely caused by heterogeneity in proportional contribution of underlying biology. Our understanding of mechanisms driving progressive disease in MS is limited, hampering the development of effective therapies. In our work, we aim to study differentiating underlying mechanisms by extensive biological characterization of people with opposite MS disease trajectories. In the current study, we investigated with an international team MS white matter lesion pathology of selected Netherlands Brain Bank (NBB) donors with slow versus rapid MS progression (26 vs. 18 individuals, respectively).

Donors with a rapid disease progression were characterized by high prevalence of a distinct histological MS lesion type marked by a hypocellular demyelinated core surrounded by extensive hypercellular myeloid cell rims. This broad rim lesion (BRL) type was characterized by cellular and transcriptional signatures of innate immune activation, inflammatory cytokine production and apoptosis. Within the entire NBB cohort, presence of BRL associated with rapid disease progression, homozygous carrier-ship of the rs10191329 severity-associated common genetic risk variant and higher levels of cerebrospinal fluid neurofilament light chain. Myeloid cell fractions in BRL rims stained positive for translocator protein 18-kDa (TSPO). An independent TSPO positron emission tomography study (114 individuals) revealed variation in white matter lesion myeloid cell rim size, and validated the association between lesions with a broad rim and disability progression in individuals with MS.

Our findings offer crucial insights into mechanisms behind MS progression, identifying BRL as a biomarker for rapid disease progression. Presence of BRL could potentially guide participant selection for future therapeutic trials targeting central nervous system intrinsic inflammation in progressive MS. Overall, our findings demonstrate the potential of translational studies comparing individual disease trajectories to reveal novel aspects of MS biology.

SPS05_4 | Innovative pharmacological therapies to promote the recovery of patients with disorders of consciousness

L. Sanz

Service of Neurology, Department of Clinical Neurosciences, CHUV, Lausanne, Switzerland

Disorders of consciousness is a group of neurological conditions resulting from heterogeneous etiologies yet with a common clinical phenotype. There are only very scarce therapeutic options at hand to improve clinical outcomes and promote the recovery of consciousness among these patients at the moment, despite the fact that even slim beneficial effects may result in tremendous implications both for the patients' quality of life and the financial burden on healthcare systems. Growing evidence suggests that early interventions may carry the most significant chances of efficacy by targeting brain plasticity and neurotransmitter imbalances shortly after injury, already in the ICU setting. Othman and colleagues have explored the use of pharmacological stimulants (methylphenidate and apomorphine) among patients with disorders of consciousness in the ICU and demonstrated preliminary evidence of increased arousal after the administration of these drugs, which may facilitate later recovery.

Pupillary responsiveness was identified as a potential marker of patients responding to these treatments, which may help identify candidates and guide therapy. On a similar note, Alnagger et al. are investigating the use of novel experimental pharmacological agents to enhance recovery of consciousness, using different mechanisms of action. They designed a virtual clinical trial using advanced computational modeling of brain activity to test the effect of psilocybin and lysergic acid diethylamide (LSD), two psychedelics, on brain dynamics of simulated patients, and demonstrated the potential future role of these innovative treatments in disorders of consciousness.

Breakthroughs in treatment neurology – Part 2

SPS10_3 | Disease-modifying therapies in frontotemporal dementia: Breakthrough clinical trials and emerging treatment paradigms

R. Vandenberghe

University Hospitals Leuven, Leuven, Belgium

The term “frontotemporal dementia” (FTD) covers a variety of rare diseases with distinct phenotypes, etiologies, and neuropathological features. All FTD diseases have in common that there is no symptomatic or disease-modifying therapy of proven efficacy and no in vivo biomarkers that accurately reflect the underlying neuropathological hallmark lesions. Current trials mostly target the forms with known genetic causes where the disease mechanism is clear. Progranulin (PGRN) mutations lead to a loss of function with a decrease in PGRN protein levels. At the time of writing, more than five industry-sponsored trials are ongoing in FTLT due to PGRN mutations. The main mechanisms of action under study are PGRN gene replacement via various delivery modes and PGRN protein substitution. We will review the therapeutic strategies, the opportunities and challenges. For the two other

main genetic causes (c9orf72 and MAPT) the therapeutic path forward is currently less clear for various reasons. In sporadic FTLT, an investigator-initiated study of a myeloperoxidase (MPO) inhibitor, verdiperstat, is ongoing in the semantic variant of primary progressive aphasia.

Progress in clinical development of novel therapies in FTLT also depends on readiness of clinical trial networks organized around hubs at a transnational, European level. Furthermore, due to the historical absence of treatment options, persons who are potentially interested to participate in trials may not have received a diagnosis or may not receive the information. The search for novel therapies for FTLT has intensified over the past five years offering hope to patients and families.

The neurology of a changing planet

SPS11_1 | Effects of heat on human physiology – A perspective on climate change and human resilience

H. Pallubinsky

Department of Nutrition and Human Movement Sciences, NUTRIM Institute for Nutrition and Translational Research in Metabolism, Maastricht University, the Netherlands

According to the World Health Organization (WHO), heat is among the most dangerous of natural hazards for humans. Projections anticipate the death toll to rise sharply in the upcoming decades, unless effective prevention plans and long-term strategies are implemented on a wide scale. Understanding how heat affects the human body, who is most vulnerable, and how resilience can be strengthened is therefore critical.

The effects of heat exposure on the human body are dependent on environmental parameters (e.g., ambient temperature, solar radiation, humidity, air velocity), duration of exposure, and individual characteristics such as sex, age, fitness, and health status. Ageing and chronic disease, such as cardiovascular diseases or type 2 diabetes, increase vulnerability to heat strain. Moreover, people living with certain neurological conditions, such as epilepsy, may be negatively affected by climate change, as seizures may be triggered by heat stress.

However, importantly, heat should not be viewed solely as a threat. Repeated exposure induces a range of thermophysiological adaptations, including enhanced sweating, improved skin blood flow, reduced core temperature, and greater cardiovascular stability. Heat therapy, or heat training, has also been shown to induce health benefits, such as enhanced cardiovascular function and improved glucose homeostasis. This talk presents heat as a double-edged sword. It argues for a shift toward individualized and context-aware strategies that both protect

vulnerable populations and harness the adaptive potential of heat to strengthen human resilience and reduce health risks.

Disclosure: None.

SPS11_2 | Environmental neuroscience: Insights from experimental models and human tissue

E. Aronica

Department of (Neuro)pathology, Amsterdam UMC Location University of Amsterdam, Amsterdam Neuroscience, Amsterdam, The Netherlands

Climate change and environmental degradation are critical determinants of brain health. Heat stress, air pollution, chemical toxicants, and other environmental exposures increase the risk and progression of neurological disorders. Environmental Neuroscience integrates epidemiology, experimental models, and human tissue studies to uncover how these exposures affect neural structure and function.

The neural exposome, reflecting cumulative exposures across the lifespan, provides a framework to understand how physical, chemical, biological, and social stressors shape neurological vulnerability. Exposures trigger oxidative stress, inflammation, blood–brain barrier disruption, metabolic imbalance, and epigenetic modulation, converging on networks that regulate neuronal excitability, glial activation, and neurovascular integrity. Experimental approaches, including in vitro systems, organ-on-chip platforms, and in vivo models, allow controlled investigation of heat, particulate matter, and chemical exposures. Multi-tier strategies, from computational screening to rodent models, assess dose dependency, interactions, and gene–environment effects. Human brain tissue studies confirm exposure accumulation and validate mechanisms.

A key convergent pathway involves hypothalamic thermoregulation. Warm-sensitive neurons and ion channels (TRPV1, TRPC4, SCN1A/Nav1.1) maintain thermal homeostasis; dysfunction increases neuronal excitability, seizure susceptibility, and promotes glial activation, extracellular matrix remodeling, and inflammatory signaling. These mechanisms occur across neurological conditions, including neurodegenerative disorders and epilepsy.

Understanding these pathways is essential for identifying vulnerable populations and guiding preventive and therapeutic strategies. Environmental Neuroscience provides a vital framework to mitigate climate-related neurological risk.

Autonomic Nervous System Diseases 1

OPR-001 | Development of autonomic dysreflexia card

E. Hagen

Department of Clinical Medicine, Aarhus University, Aarhus, Denmark

Background and Aims: Autonomic dysreflexia (AD) is a potentially life-threatening medical emergency, most commonly occurring in individuals with spinal cord injury (SCI) at or above the T6 neurological level. AD is characterized by a sudden increase in systolic blood pressure of >20 mmHg above a person's baseline, which is the result of an unopposed sympathetic response to noxious or non-noxious stimuli below the injury. To facilitate prompt recognition and targeted intervention of AD by clinicians, rapid access to essential information, including patient-specific information, is critical.

Methods: Through joint online surveys and meetings, the International Spinal Cord Society (ISCoS) and the European Society of Physical and Rehabilitation Medicine (ESPRM)

have systematically developed an International AD Medical Emergency Card highlighting causes, management, and prevention of AD.

Results: The International AD Medical Emergency Card has been uploaded on ESPRM and ISCoS platforms. It contains Personal information, General information concerning AD, Management of AD and QR codes linking to international standards, guidelines and a review. It is a pocket size-Instructions for completing and editing the Medical Emergency Card has been developed, as well as a translation process. The card is bilingual, in English and a national language.

Conclusion: The International AD Medical Emergency Card has been developed and will be updated regularly. It is presently in English and Greek and translations to other languages is underway.

Disclosure: Nothing to disclose.

OPR-002 | Diagnosing prodromal synucleinopathies: What is the role of cardiac metaiodobenzylguanidine scintigraphy?

G. Chiaro¹; Z. Jiang¹; A. Rogeau²; J. Bomanji³; V. Iodice⁴

¹National Autonomic Centre, The National Hospital for Neurology and Neurosurgery, London, UK; ²Department of Nuclear Medicine, Pitié-Salpêtrière Hospital, APHP Sorbonne Université, Paris, France; ³Institute of Nuclear Medicine, University College London Hospital NHS Foundation Trust, London, UK; ⁴NIHR University College London Hospitals Biomedical Research Centre, London, UK

Background and Aims: Cardiac metaiodobenzylguanidine (MIBG) scintigraphy differentiates Lewy body disorders (LBD), such as Parkinson's disease and dementia with Lewy bodies, from multiple system atrophy (MSA). Reduced cardiac MIBG uptake reflects postganglionic sympathetic denervation typical of LBD, while uptake is usually preserved in MSA. Abnormal uptake has also been reported in pure autonomic failure (PAF). We aimed to characterize cardiac MIBG uptake in patients with an initial diagnosis of PAF (iPAF) and evaluate its role as a prognostic tool in stratifying risk of phenoconversion.

Methods: As part of our longitudinal natural history study, consecutive patients with iPAF underwent prospective clinical and autonomic evaluations, including cardiac MIBG scintigraphy.

FIGURE 1 Colour version of the card in full size for printing on a colour printer. There are 8 sections. Four in Greek and four in English.

This is an open access article under the terms of the [Creative Commons Attribution](https://creativecommons.org/licenses/by/4.0/) License, which permits use, distribution and reproduction in any medium, provided the original work is properly cited.

© 2026 The Author(s). *European Journal of Neurology* published by John Wiley & Sons Ltd on behalf of European Academy of Neurology.

Patients were followed until conversion to LBD or MSA, or until last follow-up in 2025.

Results: Among 106 patients with iPAF, 63 (59%) remained clinically stable for ≥ 3 years; 62 (98%) had abnormal MIBG uptake. The single patient with normal uptake was under 50 years old with severe urogenital dysfunction. Thirty-four patients (32%) converted to LBD; 33 (97%) showed abnormal MIBG uptake up to 9 years before phenoconversion. Eight patients (8%) converted to MSA, all with normal uptake up to 1 year before phenoconversion. One patient with parkinsonism of uncertain diagnosis also had normal uptake.

Conclusion: Cardiac MIBG scintigraphy was highly sensitive for detecting cardiac sympathetic denervation in a large cohort of iPAF and accurately predicted disease trajectories up to 9 years before phenoconversion, supporting its value for risk stratification and counseling.

Disclosure: Nothing to disclose.

OPR-003 | Cardiovascular reflex tests as early indicators of disease-modifying treatments eligibility in asymptomatic hereditary transthyretin amyloidosis carriers: Introducing the “Two or more rule”

G. Carrozzo¹; M. Gianoli²; S. Longhi³; I. Cani²; I. Ruotolo³; M. Schiavo³; C. Fasano⁴; R. D'Angelo²; R. Rinaldi²; S. Domenichini²; A. Cerere²; G. Calandra-Buonaura⁵; P. Guaraldi²

¹Department of Biomedical and NeuroMotor Sciences (DIBINEM), University of Bologna, Bologna, Italy; ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; ³Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy; European Reference Network for Rare, Low Prevalence and Complex Diseases of the Heart – ERN GUARD-Heart; ⁴AOU Careggi and Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy; ⁵Department of Biomedical and NeuroMotor Sciences (DIBINEM), University of Bologna, Bologna, Italy; IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy

Background and Aims: Hereditary transthyretin amyloidosis (ATTRv) is a progressive multisystem disorder in which autonomic dysfunction may precede both neuropathy and cardiomyopathy. Early identification of autonomic involvement is crucial, as disease-modifying treatments (DMTs) are most effective in the earliest disease stages.

Methods: In this monocentric, cross-sectional study, 47 asymptomatic ATTRv carriers and 47 healthy controls underwent cardiovascular reflex testing (CRTs), including head-up tilt test (HUTT), Valsalva manoeuvre (VM), deep breathing (DB), cold face (CF), and handgrip (HG). Forty carriers also underwent ^{99m}Tc-DPD scintigraphy.

Results: ATTRv carriers exhibited a significantly reduced overshoot during VM ($p < 0.001$) and attenuated blood pressure responses during HUTT, despite the absence of overt orthostatic hypotension. Overall, 21 of 47 carriers (44.7%) demonstrated at least one abnormal CRT and 7 of 21 were initiated on DMTs. All treated individuals presented with two or more abnormal CRTs, most frequently involving overshoot and Valsalva ratio (VR), or the combination of overshoot, VR, and DB abnormalities.

Conclusion: CRTs therefore appear to be sensitive markers of early autonomic dysfunction in ATTRv carriers. The presence of two or more abnormal CRTs (e.g., overshoot < 15 mmHg, VR < 1.24 , $\Delta I-E$ in DB < 10 bpm) identifies a subgroup at higher risk and may represent a practical threshold for advanced evaluation and early therapeutic intervention. Integrating this “two-or-more rule” into routine monitoring may enable timely treatment initiation and improve long-term outcomes in presymptomatic carriers of ATTRv.

Disclosure: Nothing to disclose.

OPR-004 | Autonomic involvement in small fiber neuropathy

M. Nolano¹; V. Provitera²; I. Borreca²; A. Areniello²; G. Caporaso²; D. Dell'Aversana³; F. Masciarelli³; G. Ciccarelli³; F. Vitale³; R. Lombardi⁴; S. Mazzetti⁵; A. Elia⁵; D. Cazzato⁶; R. Eleopra⁵; S. Tozza³; F. Manganelli³; G. Lauria⁷; G. Devigili⁵
¹Neurology Department, Skin Biopsy Laboratory, Istituti Clinici Scientifici Maugeri IRCCS, Telese Terme, Italy; ²Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II of Naples, Naples, Italy; ³Neurology Department, Skin Biopsy Laboratory, Istituti Clinici Scientifici Maugeri IRCCS, Telese Terme, Italy; ⁴Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II of Naples, Naples, Italy; ⁵Neuroallogology Unit, Fondazione IRCCS Istituto Neurologico “Carlo Besta,” Milan, Italy; ⁶Movement Disorders Unit, Fondazione IRCCS Istituto Neurologico “Carlo Besta,” Milan, Italy; ⁷Clinical Neurophysiology Unit, Fondazione IRCCS Istituto Neurologico “Carlo Besta,” Milan, Italy; ⁷1. Neuroallogology Unit, Fondazione IRCCS Istituto Neurologico “Carlo Besta,” Milan, Italy; 2. Medical Genetics and Neurogenetics Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy

Background and Aims: The diagnosis of small fiber neuropathy (SFN) is based on sensory symptoms and signs, supported by sensory dysfunction assessment using quantitative sensory testing and/or evidence of intraepidermal nerve fiber (IENF) loss. However, autonomic impairment is frequently part of the clinical picture.

Methods: We assessed sensory and autonomic symptoms, as well as cardiovascular and sudomotor dysfunction, using the SFN-SIQ and COMPASS-31 questionnaires, cardiovascular reflex tests (Ewing score), sympathetic skin response (SSR), dynamic sweat test (DST), and IENF density at the distal leg. A total of 337 patients with SFN (age 49.0 ± 14.27 years; 237 women) from three centers were included.

Results: According to etiology, patients were classified into five groups: dysimmune ($n = 103$), metabolic ($n = 39$), toxic ($n = 5$), genetic ($n = 22$), and idiopathic ($n = 168$). No significant differences in functional or morphological assessments were observed among groups, except for higher COMPASS-31 scores in patients with dysimmune etiology. In the overall population, a COMPASS-31 total score > 30 was found in 59.3% of patients, while an Ewing score ≥ 2 was observed in 26.9%. SSR was absent in 7 patients and showed reduced amplitude in 10.6%. DST at the distal leg demonstrated hypohidrosis in 79.1% of patients compared with cut-off values derived from 210 healthy controls. IENF loss was detected in 81% of patients. Overall, sensory and

autonomic symptom severity (SFN-SIQ and COMPASS-31 total scores) was higher in women, who also exhibited greater sudomotor impairment.

Conclusion: These findings indicate that autonomic involvement is common in SFN and support the inclusion of postganglionic sudomotor function assessment in the diagnostic criteria for SFN.

Disclosure: Nothing to disclose.

OPR-005 | To tilt or to stand? Comparing the accuracy of current diagnostic tests for orthostatic hypotension in Parkinson's disease

N. Campese¹; A. Van Der Stam²; G. Goebel³; F. Leys¹; J. Ndayisaba¹; R. Granata¹; S. Kiechl¹; W. Poewe¹; R. Thijs⁴; A. Fanciulli¹

¹Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria; ²Radboud University Medical Center, Donders Institute for Brain, Cognition and Behavior, Department of Neurology, Center of Expertise for Parkinson & Movement Disorders, Nijmegen; ³Institute of Clinical Epidemiology, Public Health, Health Economics, Medical Statistics and Informatics, Medical University of Innsbruck, Innsbruck (Austria); ⁴Department of Neurology, Leiden University Medical Centre, Leiden

Background and Aims: Classic orthostatic hypotension (cOH) affects approximately 30% of persons with Parkinson's disease (pwPD), being associated with functional read-outs like orthostatic intolerance, syncope and falls. cOH is defined by a systolic and/or diastolic blood pressure drop $\geq 20/10$ mmHg within 3 min of an orthostatic challenge, be it an active standing test (AST) or a passive head-up tilt-test (HUT). However, the diagnostic accuracy of these tests in pwPD remains unclear.

Methods: In a retrospective cohort of 173 pwPD, who underwent both the AST and the HUT at the Medical University of Innsbruck between 2007 and 2020, we compared the diagnostic accuracy for cOH of HUT and AST.

Results: Both AST and HUT showed acceptable sensitivity for cOH in pwPD [63% (confidence interval, CI 48%–77%) vs. 73% (CI 59%–85%)] with moderate agreement between the two tests (Cohen's k 0.43, CI 0.26–0.60). Compared to AST, the HUT warranted a 10% sensitivity gain for cOH. We found no differences in the frequency of orthostatic intolerance, syncope and falls across persons with cOH at both the AST and the HUT and those with cOH at either the AST or the HUT only ($p=1$, $p=0.26$ and $p=0.69$ respectively).

Conclusion: Identifying and managing cOH improves the quality of life and prevents adverse outcomes in pwPD. The HUT shows higher sensitivity for cOH compared to AST but a proportion of pwPD shows cOH only at either the AST or the HUT. In clinical practice, AST and HUT represent therefore complementary tests, with similar sensitivity for cOH-related functional read-outs.

Disclosure: Academic study without external financial support. The authors have no conflict of interest to declare.

Cognitive Neurology/Neuropsychology

OPR-006 | Substrates of consolidated resilience and impact on cognitive outcomes in multiple sclerosis

D. Mistri¹; M. Margoni²; P. Valsasina¹; A. Meani¹; N. Tedone¹; M. Rubin³; G. Guido³; F. Esposito⁴; M. Rocca³; M. Filippi⁵

¹Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ²Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ⁴Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Consolidated resilience integrates cognitive reserve and cognitive resilience. Its relevance in multiple sclerosis (MS) and the underlying functional mechanisms remain unexplored.

Methods: Structural and functional 3.0 T MRI scans were acquired from 522 MS patients and 304 healthy controls (HCs). Consolidated resilience scores were estimated in patients using a partial least-squares path model, combining proxies of cognitive reserve (education and intelligence quotient) and cognitive resilience (residuals from the regression of cognitive scores on T2-hyperintense white matter lesion volumes and normalized brain volumes standardized to HCs). After a median follow-up of 2.0 years (interquartile range = 1.1; 2.9 years), 179 patients underwent cognitive and MRI reassessment. Resting state (RS) functional connectivity (FC) was estimated using independent component analysis. Linear mixed models tested the interaction between consolidated resilience and RS FC changes in cognitive networks in predicting variations in cognitive scores.

Results: At follow-up, higher consolidated resilience was associated with better verbal and visuospatial memory, processing speed and verbal fluency (all $p < 0.001$). Significant three-way interactions (consolidated resilience $\times$ RS FC changes $\times$ time) were observed in verbal memory (executive control network [$\beta = -1.36$, $p = 0.029$], left frontoparietal network [$\beta = -0.79$, $p = 0.034$] and default mode network [$\beta = -0.71$, $p = 0.035$]) and processing speed changes (salience network [$\beta = -1.43$, $p < 0.001$], executive control network [$\beta = -0.92$, $p = 0.030$], left frontoparietal network [$\beta = -0.66$, $p = 0.034$] and default mode network [$\beta = -0.83$, $p = 0.003$]).

Conclusion: Consolidated resilience moderated the association between cognitive functioning and FC changes. In highly resilient patients, better cognitive performance was associated with stable or decreased FC, whereas in patients with lower resilience, better cognitive outcomes correlated with increased FC.

OPR-007 | Glymphatic dysfunction by DTI-ALPS links to GFAP, brain atrophy, white matter hyperintensity progression, and processing speed decline in ONDRI cohort

D. Andriuta¹; J. Ramirez²; L. Woods²; E. Gibson²; M. Kang²; S. Berberian²; F. Gao²; M. Wood Alexander²; J. Rabin²; C. Scott²; D. Broberg³; R. Bartha³; R. Swartz⁴; M. Masellis⁴; S. Black⁴

¹Department of Neurology, Amiens University Medical Center, Amiens, France; ²Dr. Sandra Black Centre for Brain Resilience & Recovery, Sunnybrook Research Institute, Toronto, Canada; ³Western University/Robarts Research Institute, London, Canada; ⁴Division of Neurology, Sunnybrook Health Sciences Centre, Toronto, Canada

Background and Aims: Glymphatic clearance is implicated in neurocognitive disorders, but its role in human is unclear. The diffusion tensor image analysis along the perivascular space (DTI-ALPS) index provides a noninvasive MRI marker

of glymphatic function. We examined the association between baseline DTI-ALPS and 1-year changes in gray matter (GM) and white matter hyperintensity (WMH) volumes. Secondary aims were to assess whether plasma GFAP mediates DTI-ALPS effects on GM atrophy and the effect of DTI-ALPS on processing speed decline via GM volume.

Methods: We studied 304 participants from the Ontario Neurodegenerative Disease Research Initiative (ONDRI): AD/MCI ($n=120$), cerebrovascular disease (CVD, $n=139$), and frontotemporal dementia (FTD, $n=45$). MRI-derived GM, WMH, perivascular space, DTI-ALPS indices, total intracranial volumes were measured. Plasma GFAP was quantified. Processing speed was assessed with a composite z-score from the Digit Symbol Modalities Test and Trail Making Test A. Linear regression and mediation analyses were performed.

Results: Baseline DTI-ALPS was significantly associated with 1-year GM loss ($\beta=0.111$, $p=0.048$) and WMH increase ($\beta=-0.148$, $p=0.013$). Baseline plasma GFAP mediated the effect of DTI-ALPS on GM atrophy (indirect effect: 845.94; 95% CI [73.89, 3370.62]). Baseline left DTI-ALPS influenced 1-year processing speed decline via GM volume (indirect effect: 0.1385; 95% CI [0.042, 0.3016]).

Conclusion: Glymphatic dysfunction, measured by DTI-ALPS, is linked to structural brain changes and cognitive decline in mixed neurodegenerative and cerebrovascular disorders. Plasma GFAP mediates GM atrophy, highlighting astroglial involvement. DTI-ALPS, combined with plasma GFAP, may serve as a noninvasive biomarker to guide mechanistic studies and therapeutic strategies targeting glymphatic pathways.

Disclosure: The authors report no disclosures of relevance to the manuscript. The ONDRI study was conducted in part with the support of the Ontario Brain Institute, an independent non-profit corporation, funded partially by the Ontario government (GRANT# ONDRI/OBI-34739).

OPR-008 | Structural and functional brain correlates of fatigue in neuromyelitis optica spectrum disorder

M. Grosselle¹; N. Tedone¹; P. Valsasina¹; P. Preziosa^{1,2,3}; M. Rubin^{1,2,3}; L. Moiola²; M. Filippi^{1,2,3,4,5}; M. Rocca^{1,2,3}

¹Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ²Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Vita-Salute San Raffaele University, Milan, Italy; ⁴Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background and Aims: Fatigue in NMOSD remains poorly understood. We investigated structural and functional MRI correlates of fatigue in NMOSD patients.

Methods: Twenty-five NMOSD patients and 60 healthy controls (HC) underwent 3T brain structural and functional MRI scans, and fatigue assessment using the Modified Fatigue Impact Scale (MFIS). In patients, associations were evaluated between MFIS and regional distribution of T2-hyperintense lesions, microstructural white matter (WM) damage, regional grey matter (GM) atrophy, and seed-based resting-state (RS) functional connectivity (FC) abnormalities within main brain networks.

Results: Higher MFIS scores were associated with lower GM volume in the right superior frontal gyrus, right posterior cingulate cortex, left inferior frontal gyrus, and right parahippocampal gyrus (r range = $-0.37/-0.40$, $p < 0.001$ uncorrected). Higher MFIS was also associated with increased RS FC within the two primary motor cortices (BA4), as well as between the right BA4 and the left postcentral gyrus, and between the left BA4 and the right temporal cortex (r range = $0.36/0.47$, $p < 0.001$ uncorrected). Finally, higher MFIS scores were associated with: (1) increased RS FC between the right insula and the right inferior frontal gyrus ($r = 0.46$, $p < 0.001$), (2) decreased RS FC within the left posterior cingulate cortex of the default-mode network, and (3) decreased RS FC between the left caudate and bilateral thalami (r range = $-0.45/-0.48$, $p < 0.001$). No associations were found between fatigue and distribution of T2-hyperintense lesions or WM microstructural abnormalities.

Conclusion: Fatigue in NMOSD is primarily related to large-scale brain network dysfunction rather than focal WM damage, supporting a network-based MRI biomarker framework for this symptom.

OPR-009 | Blood biomarkers of Alzheimer's disease and progression of brain atrophy and cerebrovascular burden in cognitively healthy older adults

M. Valletta¹; D. Liborio¹; E. Laukka¹; G. Kalpouzos¹; J. Oltra¹; D. Rizzuto¹; M. Canevelli²; C. Fredolini³; C. Qiu¹; B. Winblad⁴; L. Fratiglioni¹; G. Grande¹

¹Aging Research Center, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden;

²Department of Human Neuroscience, Sapienza University, Rome, Italy; ³Affinity Proteomics Stockholm, Science for Life Laboratory, Royal Institute of Technology (KTH), Solna, Sweden;

⁴Division of Neurogeriatrics, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Solna, Sweden

Background and Aims: Blood biomarkers of Alzheimer's disease (AD) have been linked to structural brain alterations in clinical cohorts, but evidence in cognitively healthy populations remains limited. We investigated the associations between AD blood biomarkers and changes in brain volumes and cerebrovascular burden in cognitively healthy community-dwelling older adults.

Methods: In a cohort of 372 dementia-free older adults from Sweden, baseline blood levels of amyloid- $\beta_{42/40}$ (A $\beta_{42/40}$), phosphorylated tau (p-tau)181 and 217, total tau (t-tau), neurofilament light chain (NfL), and glial fibrillary acidic protein (GFAP) were measured and their z-scores derived. Brain MRI was performed at baseline and after 3 and/or 6 years. Associations between AD blood biomarkers and changes in

FIGURE 1 Annual rate of change in total brain tissue (TBTv), ventricular and hippocampus and amygdala volumes, by baseline levels of p-tau217, NfL and GFAP.

FIGURE 2 Annual rate of change in white matter hyperintensities (WMH) volume by baseline levels of p-tau217, NfL and GFAP.

volumes of total brain tissue (TBTv), ventricles, hippocampus, amygdala and white matter hyperintensities (WMH) were examined using linear mixed models.

Results: Higher p-tau181 and p-tau217 were associated with faster hippocampal volume loss (beta*year -0.036 , 95% CI -0.063 , -0.009 ; and beta*year -0.051 , 95% CI -0.080 , -0.021 , respectively), and p-tau217 was additionally associated with amygdala volume decline. Elevated GFAP was linked to faster TBTv decline, ventricular enlargement, and hippocampal shrinkage. Higher NfL levels were associated with steeper TBTv decline, ventricular enlargement, hippocampal and amygdala shrinkage, and faster WMH accumulation.

Conclusion: In cognitively healthy older adults, elevated blood levels of p-tau isoforms were linked to decline in AD-specific regions, whereas NfL and GFAP were associated with widespread atrophy and NfL also with WMH accumulation. These findings suggest that altered AD blood biomarkers may capture the earliest stages of dementia-related brain changes in the general population.

Disclosure: Nothing to disclose.

OPR-010 | Precuneus and posterior cingulate functional connectivity in multiple sclerosis: Age, onset timing and cognitive implications

N. Tedone¹; P. Valsasina²; A. Gallo³; P. Pantano⁴; M. Margoni⁵; P. Preziosa⁶; M. Filippi⁷; M. Rocca⁶

Background and Aims: Precuneus and posterior cingulate cortex (PCC) are cognitive hubs frequently involved in multiple

sclerosis (MS). We explored the effects of age and age at onset on static (sFC) and time-varying functional connectivity (TVFC) of precuneus/PCC and their association with cognition.

Methods: We enrolled 279 right-handed MS patients and 130 matched healthy controls (HC) from three Italian sites. All subjects underwent Rao's battery and 3T resting-state fMRI assessment. sFC was computed with seed-to-voxel correlation; TVFC with sliding-window correlation using bilateral precuneus and PCC as seeds.

Results: Compared with HC, MS patients showed limited sFC increase between the precuneus/PCC and parieto-frontal regions, and widespread sFC decrease within the default-mode network. Time-varying analysis revealed localized TVFC increase of the precuneus/PCC with lingual and cerebellar regions. In MS, a modulation of age on connectivity (significant at disease-by-age interaction analysis) was found: older age was associated with decreased sFC between the precuneus and cerebellum, and between PCC and anterior cingulate cortex. Similarly, older age was associated with decreased TVFC between the precuneus and left caudate (associated with better visual memory performance [$\rho = -0.19$, $p = 0.002$]) and between PCC and right superior frontal gyrus. Older age at disease onset was associated with decreased TVFC between the PCC and right thalamus, right angular gyrus, right middle frontal and left postcentral gyri, these latter two were associated with worse fluency performance ($\rho = 0.13-0.15$, $p = 0.02-0.03$).

Conclusion: In MS, age and age at disease onset significantly influenced sFC and TVFC of the precuneus and PCC, contributing to explain cognitive performances.

Neuro-Oncology

OPR-011 | Leptomeningeal metastases from primary brain tumors: Still a neglected complication

E. Pronello¹; F. Bruno¹; A. Pellerino¹; L. Bertero²; E. Marchesani¹; B. Raschio¹; M. Borgognone¹; A. Gastino³; D. Garbossa⁴; R. Soffietti⁵; R. Rudà¹

¹Division of Neuro-Oncology, Department of Neuroscience “Rita Levi Montalcini”, University of Turin, Turin, Italy; ²Pathology Unit, Department of Medical Sciences, University of Turin, Italy; ³Division of Radiotherapy, Department of Oncology, University and City of Health and Science, Turin, Italy, Turin, Italy; ⁴Division of Neurosurgery, Dept. of Neuroscience “Rita Levi Montalcini”, University and City of Health and Science Hospital, Turin, Italy; ⁵Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Turin, Italy

Background and Aims: Leptomeningeal metastases (LM) from primary brain tumors are rare and aggressive with information about optimal management limited to small retrospective series. We report the characteristics and outcomes of a large cohort of patients with LM from primary brain tumors treated at our Institution.

Methods: Clinico-therapeutic and outcome data of adult patients with LM from primary brain tumors were retrospectively collected. LM were classified according to EANO–ESMO criteria. Time-to-LM was defined as the interval from first surgery to LM diagnosis, and overall survival from LM (OS-LM) as the interval from LM diagnosis to death or censoring. Statistical analyses included chi-square tests and Cox regression models.

Results: 111 patients diagnosed between 1994 and 2025 were included (median age 50 years). The most frequent histologies were glioblastoma IDH-wildtype (33.7%), astrocytoma IDH-mutant (16.8%), medulloblastoma (15.8%), and ependymoma (15.8%). LM were synchronous with the primary tumor in 15.8% of cases and occurred mainly at local tumor progression. Diagnosis was based on clinico-radiological findings in 72.6%. Median time-to-LM was 17.0 months and significantly differed by histology ($p < 0.001$), with the shortest interval in glioblastoma. Median OS-LM was 4.0 months overall and was strongly influenced by histology ($p < 0.001$). On multivariable analysis, Karnofsky Performance Status ≥ 70 and LM from ependymomas were independently associated with longer OS-LM.

Conclusion: LM represent a dismal complication of primary brain tumors. In this cohort, tumor histology and performance status were the main determinants of time-to-LM and survival, whereas EANO–ESMO class and treatment modalities did not significantly impact OS-LM. Molecular analysis in the different subgroups are ongoing.

Disclosure: Nothing to disclose.

OPR-012 | IDH-mutant gliomas treated with vorasidenib: Early seizure control correlates with [18F]-DOPA PET response and D-2-hydroxyglutarate plasma reduction

F. Bruno¹; E. Pronello¹; A. Pellerino¹; P. Botta¹; F. Scalvini¹; F. Ponzetto²; L. Leoni²; A. Melis²; M. Zotta³; G. Mengozzi²; S. Morbelli³; R. Rudà¹

¹Division of Neuro-Oncology, Department of Neuroscience “Rita Levi Montalcini”, University and City of Health and Science Hospital, Turin, Italy; ²Clinical Biochemistry Laboratory, Department of Medical Sciences, City of Health and Science Hospital and University of Turin, University of Turin, Italy, Turin, Italy; ³Division of Nuclear Medicine, Department of Medical Sciences, City of Health and Science Hospital and University of Turin, University of Turin, Italy, Turin, Italy

Background and Aims: Given the role of IDH mutations and D-2-hydroxyglutarate (D2HG) in epileptogenesis, the impact of IDH inhibitors on seizure control is appealing. This prospective study assessed patterns and timing of seizure response in grade 2 IDH-mutant glioma patients receiving vorasidenib after surgery.

Methods: Seizures were recorded at the end of each 28-day cycle. MRI, [18F] fluorodopa (F-DOPA) PET, and D2HG plasma levels were performed at baseline and every 3 cycles.

Results: Of 56 patients, 12 (7 astrocytomas, 5 oligodendrogliomas) had persistent seizures prior to vorasidenib (mean frequency: 4/month); 9/12 had measurable F-DOPA PET uptake; median D2HG plasma concentration was 39.7 ng/mL. Over a median treatment duration of 11.6 months, 6/12 achieved seizure freedom within 1 cycle, whereas 5/12 improved gradually. One patient, after initial improvement, worsened by cycle 4. All patients showed stable disease (SD) per RANO criteria on MRI after 3 and 6 cycles. 8/9 patients with seizure reduction showed reduced PET uptake by cycle 3 (mean changes: SUVmax -6.3% ; TBRmax -7.5% ; MTV -4.7 cm^3) and 6 (SUVmax -20.9% ; TBRmax -10.9% ; MTV -35.9 cm^3), translating into 3 partial responses and 5 SD by PET RANO. All 11 patients with durable seizure response showed reduced D2HG at cycle 3 (mean change: -51%) and cycle 6 (-60%). In contrast, the only patient, who experienced seizure worsening over time, showed D2HG reduction at cycle 3 (-53%), but no further reduction, and PET progression disease, at cycle 6.

Conclusion: These findings suggest that F-DOPA PET and D2HG plasma levels may correlate with seizure improvement after vorasidenib.

¹Department of Neurology, Cancer Center Clinica Universidad de Navarra, Pamplona, Spain; ²Program in Solid Tumors, Center for Applied Medical Research, Pamplona, Navarra, Spain; ³Department of Neuro-Oncology, The University of Texas MD Anderson Cancer Center, Houston, USA

Background and Aims: Oncolytic immunovirotherapy is an emerging therapeutic approach in neuro-oncology. DNX-2401, a tumour-selective oncolytic adenovirus with enhanced infectivity, has demonstrated clinical activity in adults with recurrent glioblastoma. DNX-2440 is a next-generation construct incorporating the OX40-ligand to enhance antitumour immune responses through T cell co-stimulation and modulation of the immunosuppressive tumour microenvironment. The primary objective was to evaluate the safety and feasibility of DNX-2440, with secondary exploration of preliminary clinical activity.

Methods: This open-label, single-centre, phase I dose-escalation study used a 3+3 design in patients with first or second glioblastoma recurrence. Participants underwent stereotactic biopsy followed by single intratumoral DNX-2440 administration. Two dose levels were evaluated: 4×10^9 and 4×10^{10} viral particles. Eligibility required a single measurable lesion of at least 10 mm in two perpendicular diameters and a maximum tumour volume of 25 cc.

Results: Sixteen patients were enrolled, including 6 women and 10 men, with a median age of 55 years (range 39–80) and a median KPS of 80 (range 70–90). No dose-limiting toxicities occurred during escalation, with 3 patients treated per dose level. Remaining patients received 4×10^{10} vp in the expansion cohort. DNX-2440 was well tolerated, with no treatment-related serious adverse events. Clinical benefit, including tumour reduction and prolonged survival, was observed in 3 patients. Correlative studies assessed systemic immune responses and characterised the tumour immune microenvironment.

Conclusion: Single intratumoral DNX-2440 administration is feasible, with a favourable safety profile and hints of antitumour activity, supporting further investigation of oncolytic virotherapy as an immunomodulatory strategy in glioblastoma.

Background and Aims: This study aimed to describe clinical features and long-term outcomes of patients with glycine receptor (GlyR) antibody-mediated progressive encephalomyelitis with rigidity and myoclonus (PERM).

Methods: We retrospectively analyzed 41 patients with PERM and GlyR antibodies (22 diagnosed in our laboratory, 19 previously reported patients identified through a systematic literature review) with sufficient clinical data and ≥ 12 months of follow-up. Neurologic disability was assessed using the modified Rankin Scale (mRS). Relapses were defined as events occurring > 6 months after onset requiring immunotherapy.

Results: Median age was 58 years (IQR: 43–66 years), and 36 (88%) were male. Median time from symptom onset to admission was 2 weeks (IQR: 1–4 weeks). Predominant presentations included brainstem symptoms, mainly dysphagia and trismus, in 23 patients (56%); muscle stiffness and myoclonus in 9 (22%); dysesthesias or pruritus in 7 (17%); and cacosmia with dysgeusia in 2 (5%). Five patients (12%) never developed stiffness. All received immunotherapy. Eleven patients died, 8 (20%) from complications of PERM. Ten patients relapsed but responded well to immunotherapy. At last follow-up [median time 24 months (IQR: 18–72 months)] 23 (70%) of the 33 patients who did not die from PERM presented good functional status (mRs score < 3).

Age and admission to the intensive care unit independently predicted poor outcomes (mRS score ≥ 3).

Conclusion: GlyR antibody-mediated PERM is a rapidly progressive and severe disease that predominantly affects men and frequently presents with brainstem involvement. Its distinct demographic and clinical features support considering it separately from stiff-person spectrum disorders.

Disclosure: J. Dalmau receives royalties from Athena Diagnostics for the use of Ma2 as an autoantibody test and from Euroimmun for the use of NMDA, GABAB receptor, GABAA receptor, DPPX, and IgLON5 as autoantibody tests and has received an unrestricted research grant from Euroimmun. F. Graus holds a patent licensed to Euroimmun for the use of IgLON5 in an autoantibody test, for which he receives royalties and receives honoraria from MedLink Neurology for his role as associate editor. The other authors report no relevant disclosures.

OPR-015 | Reinforcing peritumoral GABAergic inhibition modulates glioma progression and enhances immunotherapy efficacy

M. Scalera¹; E. De Santis²; F. Rossi¹; N. Meneghetti³; A. Mazzoni³; A. Flori⁴; F. Raimondi²; P. Miglionico²; M. Pasqualetti⁵; M. Costa¹; E. Vannini¹

³Scuola Superiore Sant'Anna, Pisa, Italy; ⁴Bioengineering Unit, Fondazione Gabriele Monasterio Regione Toscana CNR;

⁵University of Pisa, Biology Department, Pisa, Italy

Background and Aims: Gliomas disrupt cortical excitatory-inhibitory balance, contributing to neurological dysfunction and tumor progression. Parvalbumin (PV)-expressing GABAergic interneurons are key regulators of network stability within the peritumoral microenvironment. This study aimed to determine whether chemogenetic modulation of peritumoral PV-interneurons and pharmacological enhancement of GABAergic signaling influence glioma growth, cortical function, and survival in murine models.

Methods: PV-Cre mice were implanted with GL261 glioma cells. To selectively modulate peritumoral PV-interneurons, AAV-hSyn-DIO-hM4D(Gi)-mCherry or AAV-hSyn-DIO-hM3D(Gq)-mCherry were bilaterally injected into the motor cortex adjacent to the tumor site. From day 12 to day 22 post-tumor induction, mice received clozapine-N-oxide (CNO) or vehicle twice daily. As readouts, we evaluated tumor volume by magnetic resonance imaging, longitudinal motor performance, and animal survival. To evaluate a pharmacological strategy, GL261- and CT-2A-bearing mice were treated with the GABAB receptor agonist baclofen, alone or combined with anti-PD-L1 immunotherapy. In vivo and in vitro assays were performed to assess direct drug effects.

Results: PV-interneuron inactivation exacerbated neurological symptoms and epileptiform activity without affecting tumor size or survival. Conversely, PV-interneuron activation reduced tumor proliferation, preserved motor and network function, and partially maintained visual acuity and contrast sensitivity. Baclofen modestly reduced tumor volume and motor decline in GL261 but not CT-2A gliomas, consistent with indirect microenvironment-mediated effects. Notably, baclofen

combined with anti-PD-L1 therapy synergistically reduced tumor burden, achieved complete tumor eradication in 66% of mice, and significantly extended survival.

Conclusion: Enhancing peritumoral GABAergic inhibition stabilizes cortical networks, limits glioma progression, and potentiates immunotherapy, representing a promising adjuvant strategy for glioma treatment.

Disclosure: Nothing to disclose.

OPR-016 | Vascular complications in IDH-wildtype glioblastoma: Incidence, timing, and clinical impact

T. Urbanic Purkart; M. Lochmann; T. Gattringer
Neurology, Medical University of Graz, Graz, Austria

Background and Aims: Patients with high-grade glioma (HGG) are at elevated risk for venous thromboembolism (VTE) and cerebrovascular events; however, the frequency, timing, and underlying mechanisms remain insufficiently characterized. This study aimed to determine the incidence and potential risk factors for vascular complications in a well-defined glioblastoma cohort.

Methods: We retrospectively analyzed 337 consecutive patients with histopathologically confirmed IDH-wildtype glioblastoma (WHO 2021) treated at the neuro-oncological outpatient clinic of University Hospital Graz. Demographic data, treatment characteristics, and vascular events were systematically collected using the electronic hospital documentation system, covering all acute vascular events within the regional catchment area.

Results: Vascular complications occurred in 25.2% of patients ($n=85$), including VTE (18.4%), ischemic stroke (4.2%), intracerebral hemorrhage (3.6%), cerebral sinus venous thrombosis (0.6%), and myocardial infarction (0.6%). Most events occurred early: 31.8% within 1 month and 74.1% within 6 months of diagnosis; 22.4% occurred during first-line therapy. Vascular events were associated with a case fatality rate of 12.9%. Complications were treated according to current guidelines; VTE was mainly managed with low-molecular-weight heparins and, less frequently, with direct oral anticoagulants, without major intracerebral bleeding. Overall survival did not differ significantly between patients with and without vascular events, and no analyzed risk factor was significantly associated with outcome. TP53 mutations were less frequent in patients with vascular events.

Conclusion: Incidence rates were consistent with previous retrospective studies. The temporal clustering of events in the postoperative period and during radiochemotherapy confirms known high-risk phases. Vascular complications may affect treatment continuity and increase case fatality rates, warranting prospective risk stratification studies.

Disclosure: Nothing to disclose.

Maria delle Croci Hospital, AUSL Romagna, Italy; ⁸Demyelinating Diseases Centre, Neurology Operative Unit, Department of Clinical and Experimental Medicine, University of Pisa, Neuroscience Department, Pisa University Hospital; ⁹Clinical Centre for Multiple Sclerosis, II Neurology Clinic, University of Campania "L. Vanvitelli"; ¹⁰Neurology Unit, Department of Medical Specialties, Azienda USL Toscana Centro, Prato, Italy; ¹¹IRCCS Institute of Neurological Sciences of Bologna, Multiple Sclerosis Rehabilitation Operative Unit, Bologna, Italy; ¹²Department of Neurosciences, San Camillo Forlanini Hospital, Rome, Italy; ¹³Department of Economics, European University Institute, ¹⁴Florence Centre for Data Science, Florence, Italy

Background and Aims: Effectiveness of available disease-modifying treatments (DMTs) on disability progression in multiple sclerosis (MS) is marginal, hence therapeutic options for secondary progressive (SP) MS are limited to Siponimod (SIP) in Europe. Cyclophosphamide (CY), a small highly immunosuppressive molecule with high blood-brain-barrier penetration, is a potential optimal treatment, although yet never compared to SIP.

Methods: SPMS patients recruited at the Tuscany region MS Referral Centre of the Careggi University-Hospital (Florence, Italy) treated with intravenous CY-pulses according to a standardized protocol were included as index-cases and compared to SIP-treated controls from the same MS Centre or extracted from the Italian Multiple Sclerosis Register. To correct for unbalances between the two groups, an overlap weighting approach based on propensity scores was used, censoring results at month 36. The primary endpoint was disability Worsening-Free Survival (WFS). Key secondary endpoints were Progression-Free Survival (PFS), No-Evidence of Disease Activity-2 (NEDA-2) and Time To First-Relapse (TTFR). Safety outcomes included mortality for any cause and incidence of neoplasms. Disability outcomes were assessed through Cox regression models.

Results: 123 CY-treated and 81 SIP-treated SPMS patients were included thus far. WFS was remarkably higher in the CY-treated compared to the SIP-treated cohort (Survival Probability Causal Effect, SPCE, close to significance, Figure 1); NEDA-2 (Figure 2) and disability improvement were significantly more frequently obtained and TTFR delayed (Figure 3) in the CY-cohort. No difference was observed in terms of safety.

FIGURE 1 (a) Cox estimated distribution of WFS following treatment with Cyclophosphamide (CY; red) or Siponimod (SIP; green). WFS at Year 3 was 75% in CY and 60% in SIP group. (b) WFS SPCE was positive and close to significance.

FIGURE 2 (a) Cox estimated distribution of NEDA-2 following treatment with Cyclophosphamide (CY; red) or Siponimod (SIP; green). NEDA-2 at Year 3 was 65% in CY and 37% in SIP group. (b) NEDA-2 SPCE was positive and statistically significant

FIGURE 3 (a) Cox estimated distribution of TTFR following treatment with Cyclophosphamide (CY; red) or Siponimod (SIP; green). TTFR at Year 3 was 96% in CY and 81% in SIP group. (b) TTFR SPCE was positive and statistically significant.

Conclusion: The preliminary analysis of the first three years of this study in SPMS suggests a superior effectiveness of CY vs. SIP on disability progression and NEDA-2.

Background and Aims: Compartmentalized central nervous system (CNS) inflammation involving B cells is implicated in gray matter injury and disease progression in multiple sclerosis (MS). Products secreted by B cells of MS patients can kill oligodendrocytes and neurons, a cytotoxicity conferred by their exosome-enriched extracellular vesicle (Ex-En) fraction.

Methods: To explore the potential molecular mediators of this cytotoxicity, we profiled proteomic and transcriptomic cargo of Ex-En isolated from B cells of treatment-naïve MS patients and matched healthy controls.

Results: MS B cell-derived Ex-En appeared enriched in cell-death associated proteins (including fibrinogen, complement C9, APP, and SPARC) and deficient in cell-survival associated proteins (such as galectin-3). Abnormal enrichment for cell-death proteins was supported by Gene Set Enrichment Analysis. Protein pathway analysis revealed densely connected pro-death modules in the MS B cell-derived EVs, contrasting with homeostatic signatures in controls. Transcriptomic analysis further revealed that Ex-En of MS B cells appeared to carry reduced levels of miRNAs (miR-182, miR-212, miR-1270) known to inhibit apoptosis.

Conclusion: Our findings indicate that B cell-derived exosomes of MS patients, previously shown to impair neuronal and glial survival, harbor an abnormal cytotoxic molecular profile that may contribute to CNS-compartmentalized injury and progressive MS biology.

Background and Aims: This study aimed to model lifespan trajectories of upper cervical cord atrophy in healthy controls (HC) and identify multiple sclerosis (MS)-specific patterns of cord atrophy in a large multicenter cohort.

Methods: We analyzed 3D T1-weighted brain MRIs and clinical data from 480 HC and 1295 MS patients. Mean upper cervical cord cross-sectional area (MUCCA) was measured between C1 and C2/3 intervertebral disk using the active surface method and normalized for head size (nMUCCA). nMUCCA was modelled across the lifespan in HC using linear regression accounting for age, age², sex, scanner and interactions, and thereafter, applied to the MS cohort to derive nMUCCA Z-scores. Analyses were stratified by sex and age at onset (pediatric-onset [POMS], adult-onset [AOMS], late onset [LOMS]).

Results: In HC, nMUCCA showed a non-linear relationship with age, increasing until the late 30s ($p \leq 0.033$) and declining after age 50 ($p \leq 0.008$). In MS, nMUCCA Z-scores decreased up to late 40s ($p \leq 0.001$). Sex did not significantly influence atrophy patterns in either group. POMS patients exhibited significantly lower Z-scores compared to AOMS and LOMS ($p < 0.001$), although age-related MS-driven decline did not differ among onset groups. Lower nMUCCA Z-scores were

associated with longer disease duration and greater clinical disability (all $p < 0.001$).

Conclusion: In MS, upper cervical cord atrophy exceeded effects of normal ageing, especially during midlife, independent of the effect of sex and age at disease onset, and was associated with longer disease duration and disability. Upper cord atrophy holds promise as a sensitive biomarker for tracking MS progression beyond ageing effects.

Background and Aims: Prognosticating disease progression is difficult in MS. We investigated how serum neurofilament light chain (NfL) and glial fibrillary acidic protein levels (GFAP) can support assessment of progression-risk and reflect protective effects of disease-modifying therapy (DMT) against long-term 'progression independent of relapse activity' (PIRA).

Methods: Patients from two large real-world MS cohorts, the Swiss MS Cohort (SMSC) and the EPIC study (University of California, San Francisco), were included. Clinical data and

biomarker Z scores were collected from 18629 visits at 6/12-month intervals.

Results: SMSC and EPIC consisted of 1709 and 620 patients, yielding 13375 and 5254 samples (Table 1). Elevated NfL (Z score >1.5; 93rd percentile) was associated with a 2-fold risk of relapse within the next year in SMSC (OR 2.00, 95% CI 1.63–2.45; $p < 0.0001$) and a 1.69-fold risk in EPIC (1.69, 1.24–2.32; $p = 0.00094$, Figure 1), while GFAP was not. Elevated GFAP (Z score >1.0; 84th percentile) prognosticated a 45% higher risk of PIRA at next visit in SMSC (1.45, 1.21–1.75; $p < 0.0001$). This was confirmed in EPIC (1.36, 1.07–1.71; $p = 0.011$, Figure 1). In SMSC, every yearly GFAP Z score unit reduction during the first 2 years of fingolimod or B-cell depleting therapy was associated with a 54% (HR 0.46, 95% CI 0.26–0.84; $p = 0.012$) and 67% (0.33, 0.18–0.61; $p = 0.00036$) lower risk of PIRA (Figure 2), respectively. No such associations were observed for NfL Z scores.

Conclusion: NfL and GFAP are powerful complementary tools for prognostication of relapse activity and PIRA in MS. DMT-associated GFAP-reduction predicted lower PIRA-risk. Together, these biomarkers may improve prognostic accuracy and personalized treatment.

Disclosure: This investigation was supported by Swiss National Science Foundation (grant 320030_189140), award from Progressive MS Alliance (PA-2007-36872), and grant funding from Novartis and Roche. The Swiss MS Cohort study received funding from the Swiss MS Society and grant funding from Biogen, Celgene, Merck, Novartis, Roche, and Sanofi. The EPIC cohort and biomarker assessment was funded through grants R35NS111644 from the National Institutes of Health/National Institute of Neurological Disorders and Stroke, Valhalla Foundation, Westridge Foundation and grant funding from Roche. The UCSF MS biorepository was supported by grant Si-2001-35701 from the US National Multiple Sclerosis Society. EPIC biomarker measurements research/study was in part funded by F. Hoffmann-La Roche Ltd as part of Integrative Neuroscience Collaborations Network.

TABLE 1 Characteristics of included patients.

	SMSC (1709 patients)	EPIC (620 patients)
Baseline		
Sex, female	1126 (66.0%)	432 (69.7%)
Age, years	46.6 [32.1–50.1]	42.0 [35.0–50.0]
MS subtype		
RMS	1539 (90.1%)	536 (86.8%)
SPMS	170 (9.9%)	82 (13.2%)
Disease duration, years	6.3 [2.0–13.6]	6.3 [2.3–12.8]

Oral	560 (32.8%)	85 (13.7%)
High-efficacy	803 (47.0%)	124 (20.0%)
Samples	13375	5254
NfL Z score	0.3 [−0.6–1.1]	0.4 [−0.4–1.2]
GFAP Z score	0.2 [−0.7–0.9]	0.4 [−0.2–1.3]
Days between sample timepoints	346.0 [190.0–375.0]	385.0 [355.0–518.0]

Data are n (%) or median [IQR].

FIGURE 1 Serum NfL prognosticated subsequent relapses (logistic mixed models, 2.0- and 1.69-fold risk), while serum GFAP was independently associated with progression independent of relapse activity (PIRA; 1.45- and 1.36-fold risk) in both cohorts.

FIGURE 2 Patients with GFAP Z score reduction after DMT start had lower risk of future PIRA than those without. Kaplan-Meier curves for subsequent PIRA stratified by biomarker slope within 2 years of DMT start. HR/p values from multivariable Cox models.

OPR-022 | Genetic and early-life vulnerability in functional neurological disorder: A large-scale retrospective cohort study

E. Ipavic¹; T. Pollak²; T. Nicholson²; M. Edwards²; R. Berlot¹

¹Department of Neurology, University Medical Centre Ljubljana, Slovenia; ²Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UK

Background and Aims: Contemporary models of functional neurological disorder (FND) emphasise biological vulnerability affecting motor, sensory, and integrative processing as a predisposing factor. While early-life influences were traditionally viewed within psychological frameworks, little is known about early-life biological vulnerabilities that may predispose to FND or shape its clinical presentation.

Methods: Using TriNetX, a large electronic health records dataset, we assessed rates of genetic, congenital, perinatal, and neurodevelopmental diagnoses, selected to capture a broad range of early-life conditions, including those that may lead to sensory and motor system vulnerability. Comparisons were performed between 188,868 individuals with FND and demographically matched migraine and depression cohorts, and between matched cohorts of 42,015 individuals with motor FND and functional seizures.

Results: Compared with migraine and depression, FND was associated with increased odds of heritable connective tissue disorders, heritable neuromuscular disorders, and congenital malformations, including those of the musculoskeletal system and sensory organs (Table 1). Apart from attention-deficit/hyperactivity disorder, which was more prevalent in the depression

TABLE 1 Genetic, congenital, perinatal, and neurodevelopmental factors in functional neurological disorder (FND) compared to matched cohorts with migraine and depression.

Motor disorders	481 (0.2)	2.88 (1.41-6.08)	<0.001		34 (0.1)	3.37 (1.81-6.68)	<0.001

FIGURE 1 Congenital and developmental factors in functional motor disorder versus functional seizures. OR >1 indicate higher odds in the motor subtype, whereas OR <1 indicate higher odds in the seizure subtype.

cohort, neurodevelopmental disorders were consistently enriched in FND, alongside increased rates of perinatal adversity related to short gestation, low birth weight, and newborn respiratory distress. Motor FND showed stronger associations with connective tissue, neuromuscular, and musculoskeletal conditions, whereas functional seizures were more enriched for chromosomal abnormalities and neurodevelopmental disorders (Figure 1).

Conclusion: Genetic and early-life biological factors may predispose to functional symptoms. Distinct associations were observed for functional motor and seizure presentations. Our findings support a more biologically informed understanding of FND.

OPR-023 | Risk of epilepsy in people with adult-onset hydrocephalus: Insights from the UK Biobank

J. Buonocore¹; F. Fortunato²; E. Fratto¹; I. Sammarra²; A. Gambardella²; A. Quattrone¹; A. Quattrone¹

¹Neuroscience Research Center, University "Magna Graecia", Catanzaro, Italy; ²Institute of Neurology, Department of Medical and Surgical Sciences, University "Magna Graecia", Catanzaro, Italy

Background and Aims: Epileptic seizures frequently occur in Alzheimer's disease (AD) and other neurodegenerative dementia; conversely, little is known about epilepsy risk in idiopathic adult-onset hydrocephalus.

Methods: We analyzed data from the UK Biobank cohort. Diagnoses of "hydrocephalus" and "epilepsy" were identified through ICD-10-coded health records, excluding congenital and secondary cases. The association between these two diseases was investigated using logistic regression (adjusted for age and sex); subsequently, we performed a nested case-control study to evaluate the hazard ratio (HR) for incident epilepsy in people with adult-onset hydrocephalus using Cox proportional hazards models with a dedicated sensitivity analysis including different sets of covariates such as demographic, lifestyle, vascular, and genetic factors.

Results: Our cohort included 483,790 controls, 5028 individuals with epilepsy, and 320 with adult-onset hydrocephalus. Hydrocephalus was strongly associated with epilepsy (OR: 9.6, 95% CI: 6.4–13.8, $p < 0.001$). Adjusted Cox models demonstrated a markedly increased risk of incident epilepsy in people with adult-onset hydrocephalus, with HR values ranging from 14.62 (95% CI: 7.91–27.00, $p < 0.001$) to 23.80 (95% CI: 12.87–44.03, $p < 0.001$) across models, after adjusting for multiple covariates. Results were also consistent after excluding people with comorbid neurodegenerative dementias such as Alzheimer's disease.

Conclusion: We demonstrated a markedly increased risk of epilepsy in adult-onset hydrocephalus, independent of vascular and neurodegenerative comorbidities and not attributable to shunt-related complications. These findings underscore the importance of increased diagnostic vigilance, as seizures may be under-recognized in this population, and support further research to clarify mechanisms and optimize management strategies.

Disclosure: Nothing to disclose.

OPR-024 | Mental health outcomes among refugees and internally displaced people in Africa: A systematic review

O. Uwishema
Department of Research and Education, Oli Health Magazine Organization, Kigali, Rwanda

Background and Aims: Refugees and internally displaced people in Africa are exposed to conflict, violence, and displacement-related stressors that substantially increase the risk of mental health disorders. However, a comprehensive continent-wide synthesis of mental health outcomes in these populations is lacking. This study aimed to systematically review the prevalence, risk factors, and interventions related to mental health among displaced populations in Africa.

Methods: This systematic review followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses 2020 guidelines and was registered with the International Prospective Register of Systematic Reviews. Five databases and grey literature were searched up to January 20, 2025. Eligible studies assessed mental health outcomes among refugees, internally displaced persons, or asylum seekers in African countries. Risk of bias was evaluated using Joanna Briggs Institute tools and the revised Cochrane Risk of Bias tool.

Results: Seventy-eight studies from over 20 African countries were included. Depression, post-traumatic stress disorder, anxiety, and general psychological distress were the most frequently reported conditions, with prevalence estimates ranging from 6.8 percent to over 80 percent. Common risk factors included exposure to violence, gender-based violence, prolonged displacement, and socioeconomic hardship. Protective factors included social support, community cohesion, and access to basic services. Intervention studies were limited but suggested potential benefits of group therapy, task-shifting approaches, and culturally adapted psychosocial interventions.

Conclusion: Displaced populations in Africa experience a high burden of mental health disorders, while access to evidence-based interventions remains limited. Strengthening culturally appropriate mental health services and integrating them into humanitarian and national health systems is urgently needed.

OPR-025 | Changing incidence patterns for multiple sclerosis in a large population-based study in the province of Palermo, southern Italy

P. Ragonese¹; S. Iacono²; G. Schirò²; W. Mazzucco³; C. Norrito³; S. Mazzola³; M. Zarcone³; G. Sorbello⁴; M. Andolina⁴; G. Callari²; S. Realmuto⁵; G. Vazzoler⁶; S. Cottone⁶; L. Baiamonte⁴; P. Aridon⁴; G. Salemi⁴; L. Grimaldi²

¹Departmental School of Medicine and Health Sciences, Saint Camillus International Medical University, Rome, Italy; ²Neurology and Multiple Sclerosis Center, Foundation Institute "G. Giglio", Cefalù, PA, Italy; ³Neurology and Multiple Sclerosis Center, Foundation Institute "G. Giglio", Cefalù, PA, Italy; ⁴Department of Health promotion, Maternal and Infant care, Internal Medicine, and Medical Specialties (PROMISE), University of Palermo, Italy; ⁵Department of Biomedicine, Neurosciences, and Advanced Diagnostics (BIND), University of Palermo, Italy; ⁶Neurology Unit, Azienda Ospedaliera Ospedali Riuniti Villa Sofia Cervello, Palermo, Italy; ⁶Neurology Unit, ARNAS Civico, Palermo, Italy

Background and Aims: The global epidemiology of multiple sclerosis (MS) is changing over time and the understanding of its epidemiological features in low-prevalence areas is crucial for tailoring healthcare strategies and optimizing therapeutic interventions (1).

Methods: We collected demographic and clinical information of people with MS (pwMS) starting from 01st January 2000 to 31st December 2024 living in the Province of Palermo, southern Italy (pop. 1,268,000 inhabitants). The observational time was divided into five-year intervals. We calculated crude and sex and age-adjusted incidence rates in the analysed time frame. MS prevalence was estimated on the prevalence day, December 31st, 2024.

FIGURE 1 Crude and age and sex adjusted incidence rates for MS in the Province of Palermo

Results: A total of 2423 pwMS were diagnosed as of 31st December 2024, giving a prevalence of 201/100.000 person (95% CIs: 193–209). The annual incidence rate increased from 4.1/100.000 person/year to 7.6/100.000 person/year over time ($p=0.007$; Figure 1). Incidence rate was higher in women, reaching the peak of 9.7/100.000 person/year after 2020 (Figure 2A). While the incidence of early-onset MS was almost similar across eras ($p=0.9$), we observed an increasing trend of incidence rate for adult-onset ($p=0.011$) and late-onset MS ($p=0.001$; Figure 2B).

Conclusion: Incidence and prevalence of MS in Palermo Province are higher than previously reported, making this province a high-risk area. Our population-based study confirms increasing incidence rates of late-onset MS over time, confirming the impact that cases with late-onset MS are achieving in the clinical and pharmaco-economical management of this disease.

Disclosure: Nothing to disclose.

OPR-026 | Drivers of rising prevalence in major motor neurodegenerative diseases: Temporal trends in Sweden and France (2003–2021)

O. Guinebrethière¹; F. Yang²; F. Fang²; T. Nedelec¹

¹Sorbonne University, Paris Brain Institute – ICM, CNRS, Inria, Inserm, AP-HP, Hôpital de la Pitié Salpêtrière, Paris, France; ²Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Background and Aims: The prevalence of Parkinson's disease (PD), multiple sclerosis (MS), and motor neuron diseases (MND) is rising globally. However, it is unclear to what degree this reflects increased incidence versus improved survival after diagnosis.

Methods: We performed two nationwide, population-based cohort studies including all individuals in Sweden (2001–2016) and France (2009–2022). Pooled mixed-effects models determined temporal trends in prevalence, crude and age-sex-standardized incidence, and life expectancy at diagnosis.

Results: Prevalence of PD, MS, and MND increased significantly between 2003 and 2021. While crude incidence of PD and MS remained stable (PD: IRR=0.998; MS: IRR=0.992), standardized incidence decreased for PD (IRR=0.986) but not MS (IRR=0.995). For MND, both crude and standardized incidence increased (IRR=1.018 and 1.008, respectively). Life expectancy at diagnosis increased for PD between 2003 and 2013 (+0.95 months/year) then decreased 2013–2022 (−1.20 months/year), while increasing throughout for MS (+2.35 months/year) and MND (+0.34 months/year).

OPR-027 | Global SPG11 genotype-phenotype landscape: Integrated analysis of 560 patients

A. Daponte¹; M. Lima²; G. Koutsis¹; G. Karadima¹; C. Kartanou¹; A. Gabas³; R. Lee³; K. Gunanayagam³; R. Kaiyrzhanov³; A. Cortese³; N. W. Wood³; E. Kara³; H. Houlden³; R. Maroofian³

¹1st Department of Neurology, Eginitio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; ²Second Department of Neurology, Aristotle University of Thessaloniki, Thessaloniki, Greece; ³Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology, London, UK

Background and Aims: SPG11 is the most frequent cause of autosomal recessive hereditary spastic paraplegia (HSP). However, its clinical spectrum and genotype-phenotype correlations remain incompletely defined.

Methods: We assembled a multicenter international cohort of 75 genetically confirmed SPG11 patients with detailed epidemiological and clinical data and performed a literature review of published SPG11 cases. We analyzed clinical, radiological and genetic features to investigate genotype-phenotype associations.

Results: The merged dataset comprised 560 SPG11 patients (75 in-house; 485 literature) with >200 unique variants, without mutational hotspot. Mean age at onset was ~16 years. In addition to spastic paraparesis, the most frequent feature was cognitive impairment/intellectual disability (91%), with the vast majority presenting with complicated HSP (96%), while only 4% exhibited

TABLE 1 Epidemiological, clinical and radiological characteristics of the international SPG11 cohort compared with the combined dataset (75 in-house patients and 485 cases extracted from the literature). Values are presented as percentages.

	INTERNATIONAL COHORT (n=75)	COMBINED COHORT (n=560)
EPIDEMIOLOGY		
Sex (Male/Female)	~ 1:1 (40/35)	~ 1:1
Mean age of onset	16.8 years (Range 2-58)	15.9 years (Range 1-78)
Consanguinity	31%	41% (172/416)
Positive Family History	37%	29% (119/416)
CLINICAL FEATURES		
Spastic paraparesis/pyramidal signs	100%	97%
Cognitive impairment	80%	91%
Dysarthria	56%	43%
Cerebellar signs	47%	30%
Peripheral neuropathy	15%	17%
Distal amyotrophy (ALS mimics)	12%	18%
Parkinsonism	16%	10%

Cerebellar Atrophy	7% (3/44)	9% (38/422)

FIGURE 1 Country-specific of secular trends in incidence rates of Amyotrophic Lateral Sclerosis, Multiple Sclerosis and Parkinson's disease assuming a linear relationship with time in France and Sweden (2003–2022).

FIGURE 2 Secular trends in life expectancy at diagnosis of patients with (A) PD, (B) MS, and (C) MND compared with the general population.

FIGURE 3 Varying dynamics explaining increases in prevalence across diseases.

Conclusion: These findings reveal fundamentally different prevalence drivers with critical implications for disease etiology and healthcare planning. MS prevalence is survival-driven through therapeutic advances, with no evidence of changing population-level risk factors. MND shows true incidence increases, suggesting emerging or intensifying environmental or lifestyle risk factors. PD demonstrates declining age-adjusted incidence, with prevalence growth historically driven by improved survival. These distinct mechanisms demand disease-specific strategies.

Disclosure: Nothing to disclose.

FIGURE 1 Sagittal T1-weighted brain MRI from two SPG11 patients showing marked thinning of the corpus callosum (TCC), as representative examples of the most common radiological finding in SPG11 (arrows).

a pure HSP phenotype. Distinct SPG11-associated phenotypic subtypes overlapping with other neurodegenerative diseases, included a predominately ataxic phenotype (30%), a parkinsonism/dystonia subtype (10%) and an amyotrophic lateral sclerosis (ALS)-like phenotype (18%). Additional manifestations included dysarthria (43%), neuropathy (17%), and epilepsy, optic atrophy and psychiatric symptoms (~5% each). Brain MRI was abnormal in 95%, most commonly showing thin corpus callosum (89%), white-matter hyperintensities (63%) and cortical atrophy (31%). Ten recurrent variants were identified; some with specific clinical patterns. The most frequent worldwide, c.733_734del ($n=50$), was associated with increased cerebellar/extrapyr- amidal manifestations; whereas, the recurrent missense variant c.5381T>C was linked to strikingly later-onset (mean 52 years) and milder phenotype.

Conclusion: This integrated analysis provides the largest SPG11 genotype-phenotype dataset to date, refining the SPG11 landscape. Despite extensive allelic diversity, recurrent variants are associated with distinct clinical features, potentially facilitating diagnosis and prognosis in SPG11-HSP.

Disclosure: Nothing to disclose.

OPR-028 | Genome sequencing as a diagnostic tool for common hereditary spinocerebellar ataxias with repeat expansions

E. Perraki; M. Bieg; A. Kaune; K. Kandaswamy; K. Bruesehafer; J. Pinto-Basto; P. Bauer
Centogene, Rostock, Germany

Background and Aims: Spinocerebellar ataxias (SCAs) is a group of autosomal dominant neurodegenerative disorders. Several common SCAs are caused by CAG repeat expansions, a type of variant that is a challenge for short read next-generation sequencing. We used genome sequencing (GS) with the application of ExpansionHunter (EH) for CAG repeat detection in SCA1, 2, 3, 6, 7, and 17.

Methods: The study cohort comprised 301 adult ataxia patients. PCR-free GS was performed on an Illumina platform. CAG repeat loci associated with SCA1, 2, 3, 6, 7, and 17 were sized using EH. Expanded CAG alleles of all loci were reviewed, and

orthogonal confirmation was performed using PCR-based fragment length analyses.

Results: EH detected expanded CAG alleles in all SCA loci (Table 1). The presence of all expanded alleles was confirmed orthogonally. 4/5 SCA1 calls had repeat size deviation of 2-18 repeats between methods and one expanded allele was reclassified to “normal expanded” due to repeat interruptions. 4/8 SCA2 and 3/4 SCA6 expanded calls resulted in the same repeat size between methods, while 4/8 SCA2 and 1/4 SCA6 calls deviated by 1–2 CAGs. SCA3, SCA7 and SCA17 calls had repeat size deviation of 7–15, 1–27 and 1–4 repeats between methods, respectively, with the PCR-based method showing higher repeat size.

TABLE 1 The GS results via EH for the different SCA loci and their orthogonal confirmation results. One of the SCA1 calls was reclassified to normal due to the presence of interruptions in the CAG repeats (*).

Disorder	Number of patients identified in the cohort	EH range of expanded alleles	Confirmation of expanded allele	PCR-based range of expanded alleles
SCA1	5	49-53	5/5*	48-71
SCA2	8	38-44	8/8	38-43
SCA3	5	13-20	5/5	67-77
SCA6	4	22-25	4/4	21-25
SCA7	1	45-70	3/3	75-108
SCA17	2	41-69	2/2	42-58

Conclusion: Our data show that EH application for SCA repeat expansion detection can increase the diagnostic utility of GS. Orthogonal confirmation remains relevant for positive EH calls: whilst shorter range CAG expansions show the same or ± 1 CAG size between GS and conventional fragment length analysis, larger expanded alleles require orthogonal method for accurate repeat sizing.

OPR-029 | Parkinsonian manifestations in primary mitochondrial diseases: Evidence from a large Italian multicenter cohort

I. Arena¹; C. La Morgia²; C. Lamperti³; G. Primiano⁴; P. Lopriore⁵; G. Urbano⁶; F. Magri⁷; D. Ronchi⁷; M. Percetti⁷; A. Di Fonzo⁷; G. Cecchi⁵; F. Santorelli⁸; A. Ardisson³; T. Mongini⁶; S. Servadei⁴; V. Carelli²; M. Mancuso⁵; O. Musumeci⁹

¹BIOMORF Department, University of Messina; ²IRCCS Istituto delle Scienze Neurologiche di Bologna; ³UO Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico “Carlo Besta”, Milan, Italy; ⁴Fondazione Policlinico Universitario A. Gemelli, IRCCS, Rome, Italy; ⁵Department of Clinical and Experimental Medicine, Neurological Clinic, University of Pisa; ⁶Department of Neurosciences, University of Torino; ⁷Dino Ferrari Center, Department of Pathophysiology and Transplantation, University of Milan; ⁸Molecular Medicine for Neurodegenerative and Neuromuscular Diseases Unit, IRCCS Stella Maris Foundation; ⁹Unit of Neurology and Neuromuscular Disorders, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy

Background and Aims: Parkinsonism represents a common hypokinetic manifestation in individuals with primary mitochondrial diseases (PMDs) and has been reported in association with both mitochondrial and nuclear DNA variants. Despite this, its phenotypic features, associated comorbidities, and genetic landscape remain insufficiently defined. This study aimed to characterize the clinical and genetic profile of parkinsonism in a large, multicenter PMD cohort through a detailed phenotyping approach.

Methods: Patients were identified from the Italian Mitochondrial Disease Registry (Genomit). Available clinical records were reviewed to collect demographic, genetic, imaging, and comorbidity data.

Results: Sixty-six patients with genetically confirmed PMDs were included, of whom 45 carried nuclear DNA variants and 21 mitochondrial DNA variants. The most frequently implicated genes were POLG ($n=15$), TWNK ($n=10$), OPA1 ($n=9$). Parkinsonism onset occurred at a median age of 62.2 years, notably later than the median age at PMD onset (40.0 years), although in approximately 20% of cases both conditions manifested within 1 year. The most prevalent clinical syndrome was CPEO plus with several other mitochondrial syndromes observed less frequently. DAT-SCAN imaging mostly demonstrated bilateral dopaminergic deficits in over half of cases, along with additional abnormalities such as substantia nigra alterations and asymmetric dopamine uptake.

Conclusion: In PMDs, parkinsonism typically emerges later than the underlying mitochondrial disorder. These findings expand the clinical characterization of parkinsonism in PMDs and support the need for larger, longitudinal studies to better delineate genotype–phenotype relationships and disease evolution.

Disclosure: Nothing to disclose.

clinical and molecular spectrum remains unclear. This study characterizes phenotypic and genotypic variability in multinational patients with Twinkle-related disorders.

Methods: A retrospective cohort study included patients from specialized centers in Italy, France, Germany, Spain, Denmark, Hungary, and the United States, establishing the Twinkle-Related Disorders International Consortium for Trial Readiness (TReDIC). Data from medical records included clinical features, age at onset, disease progression, and genetic testing results. Phenotypes were classified as infantile-onset cerebellar ataxia, parkinsonism, primary mitochondrial myopathy, multisystem involvement, asymptomatic carriers, undetermined, or other. All diagnoses were genetically confirmed, with variants documented. Outcomes included phenotype prevalence, symptom chronology, and mutational patterns.

Results: The study analyzed 189 patients (116 females), mean onset 40.3 years; 70.4% were alive at analysis. Primary mitochondrial myopathy was predominant (85.2%). Common features included progressive external ophthalmoplegia (84.7%), skeletal myopathy (55.6%), hearing loss (17.5%), and psychiatric symptoms (15.3%). At onset, 76.8% had neuromuscular symptoms, 19.6% CNS involvement, and 3.6% multi-organ; after >8 years, proportions shifted to 54.4%, 23.3%, and 23.3%. Seventy-three TWNK variants (16 novel), mostly missense, clustered in critical functional regions.

Conclusion: This multinational cohort clarifies the broad phenotypic spectrum, progression patterns, and clinically relevant mutational hotspots in Twinkle-related disorders. International collaborations like TReDIC are essential to improve understanding and support future clinical trial design in this rare disease context.

Disclosure: Nothing to disclose.

Background and Aims: Cerebellar ataxia, neuropathy, vestibular areflexia syndrome (CANVAS), caused by biallelic AAGGG expansions in RFC1, is increasingly recognised as one of the most common causes of ataxia and sensory neuropathy. Despite previous studies failed to detect a decrease in RFC1 transcript and protein expression, the recessive mode of inheritance and the identification of patients carrying compound heterozygous null variants suggest a loss-of-function mechanism underlying this disease. **Methods:** We assessed the effects of AAGGG expansions on RFC1 expression and function, leveraging reporter assays, brain tissue, patient-derived cell lines, and a Drosophila model.

Moreover, we investigated the association between RFC1 expansions and chemotherapy-induced neuropathy in a cohort of cancer patients who underwent oxaliplatin treatment.

Results: AAGGG expansions cause a length-dependent impairment of transcription efficiency in reporter assays and decrease RFC1 expression in human cerebellum and iPSC-neurons. Patient-derived cell lines showed an increased apoptotic response after exposure to platinum compounds. CRISPR/Cas9-mediated excision of the AAGGG repeat restored RFC1 expression and the DNA damage response. Furthermore, neuronal-specific knockdown of RFC1 in flies led to reduced survival, motor impairment, and increased DNA damage. Finally, individuals carrying RFC1 expansions and exposed to oxaliplatin treatment presented a higher risk to develop a clinically significant neuropathy compared to non-carriers.

Conclusion: Our data suggest that AAGGG expansions cause a cell- and tissue-specific decrease in RFC1 expression with consequent impairment of DNA damage response. The rescue of RFC1 expression and DNA repair after repeat-excision lays the groundwork for future therapeutic avenues.

Disclosure: Nothing to disclose.

Background and Aims: Cues are specific references that support motor performance by improving speed, timing, and amplitude while reducing variability. This study aimed to investigate the effects of external auditory cueing on bradykinesia-related kinematic deficits and their neural correlates during a hand-tapping task in people with Parkinson's disease (pwPD) and healthy controls (HC).

Methods: Twenty-six pwPD and 20 HC performed a right hand-tapping fMRI task either in a self-paced condition (NOCue) or following an auditory cue (Cue). Hand-tapping kinematics were objectively quantified using an optical-fiber glove.

Results: PwPD showed reduced hand-tapping amplitude and a greater sequence effect on amplitude than HC during NOCue condition. Cueing attenuated the sequence effect on amplitude in pwPD. During the NOCue condition, pwPD showed reduced activity of pallidum relative to HC. No group differences emerged during Cue condition. During Cue relative to NOCue condition, pwPD showed higher activity of pallidum, parietal, temporal, sensorimotor, insular, and cerebellar regions, alongside reduced activation in of paracentral gyrus and cerebellum. Higher activity of pallidum and lower activity of paracentral gyrus correlated with better motor performance and higher positive effects of cueing.

Conclusion: Our results demonstrated that auditory cueing reduces bradykinesia in pwPD by facilitating basal ganglia activity and reducing the need of movement programming.

Background and Aims: Standard neuropsychological assessments of post-stroke attentional deficits often suffer from limited ecological validity and insufficient sensitivity to complex behavioral patterns. Immersive virtual reality (iVR) combined with eye tracking (ET) offers a high-dimensional characterization of attentional functioning; however, the structural substrates underlying these digital oculomotor biomarkers remain insufficiently understood. This study uses lesion-based connectomics to link ET-derived metrics with focal brain damage.

Methods: Fifty patients with acquired brain injury underwent iVR-based assessments of spatial attention. Random forest classifiers were trained to identify attentional deficits from ET metrics. Structural lesion impact was quantified using the Lesion Quantification Toolkit (LQT), estimating parcelwise gray matter lesion load (Schaefer–Yeo atlas) and white matter disconnection severity (HCP-1065 tractography atlas). Principal component analysis was applied to derive latent oculomotor dimensions. To explore prognostic relevance, longitudinal changes in oculomotor behavior were related to baseline structural disconnectivity.

Results: Classification models achieved high diagnostic performance ($F1=0.88$). Lesion quantification revealed that the principal oculomotor component characterizing spatial neglect—reflecting increased gaze bias and reduced visual exploration—was associated with cumulative damage within dorsal and ventral attention networks, notably involving the right frontal aslant tract and superior longitudinal fasciculi. Ongoing longitudinal analyses aim to determine whether these structural-functional associations predict recovery trajectories.

Conclusion: By integrating iVR-based eye tracking with lesion-informed connectomics, this study provides a novel framework for characterizing attentional deficits and their neural

FIGURE 1 iVR tasks. (A) Free viewing: 4 conditions (lateral/bilateral x left/right) with fixation cross. (B) Alertness: target detection. (C) Spatial selective attention: target localization and selection.

FIGURE 2 Structural correlates of the oculomotor latent factor (PC1). (A) Linear association between cumulative structural damage across the Sal-VAN/DAN and the PC1. (B) Region-wise permutation-based Spearman correlations. (C) Brain renderings

substrates. The findings suggest that network-level structural integrity plays a key role in shaping oculomotor manifestations of spatial attention deficits and may inform future digital diagnostic and prognostic tools.

Background and Aims: Attentional deficits, notably hemispatial neglect, are highly disabling consequences of acquired brain injury (ABI) that significantly impair recovery. Current rehabilitation lacks a granular understanding of the underlying behavioral dynamics. This study develops a predictive Deep Neural Network (DNN) framework to model attentional-motor behavior and assess deficits via synthetic lesions, aiming to provide a foundational tool for automated diagnosis and personalized neurorehabilitation (See Figure 1).

Methods: We integrated a Convolutional Neural Network (CNN) for foveated visual perception with a Deep Reinforcement Learning (DRL) agent using Proximal Policy Optimization (PPO) to resolve a visuospatial selective attention task (Figure 2). Lesion models were generated by selectively deactivating neurons across neural networks layers. A Multilayer Perceptron (MLP) was trained on 17 behavioral metrics (e.g., mean step size, velocity variance) to predict lesion location and magnitude. Behavioral data were validated against a cohort of 43 ABI patients and 19 healthy controls.

Results: The DRL agent successfully mimicked healthy human exploration patterns and trajectories. The MLP demonstrated

FIGURE 1 Schematic representation of the different phases of the project.

FIGURE 2 Overview of the deep neural network framework designed to mimic healthy human behavior during a visuospatial selective attention task.

discriminative performance in identifying in-silico lesion patterns. While group-level behavioral metrics showed convergence between in-silico and in-vivo data, direct transfer of the MLP’s predictive performance to patient data remains limited and need further improvements.

Conclusion: This project establishes a robust methodology for computational cognitive modeling. It demonstrates that synthetic lesions in DNNs can reflect specific behavioral impairments, offering a promising path toward data-driven diagnostic tools and the optimization of individualized rehabilitation strategies in clinical neurology.

OPR-035 | Investigating the relationship of trunk and postural control with pulmonary functions in subacute stroke patients

N. Duruturk¹; S. Ozkan²

¹Baskent University, Physical Therapy and Rehabilitation Department, Ankara, Türkiye; ²Physiocare Rehabilitation Center, Ankara, Türkiye

Background and Aims: Stroke is a disease with high mortality and morbidity that not only causes weakness in the extremities, loss of balance and disturbances in trunk and postural control, but also affects respiratory function. The aim of this study was to investigate the relationship between trunk and postural control and pulmonary function in stroke patients.

Methods: 32 volunteer patients who were diagnosed with hemiplegia and who met the inclusion criteria participated in the study. Functional independence of the participants was evaluated using Modified Rankin Scale (mRS) and their cognitive function was assessed with the Standardized Mini Mental State Examination. Respiratory function was evaluated with spirometric measurements, inspiratory muscle strength was evaluated with intraoral pressure measurements, trunk control was evaluated using the Trunk Impairment Scale (TIS), postural

control was evaluated using the Postural Assessment Scale for Stroke Patients (PASS-T), computerized postural sway evaluation, and static posture analysis.

Results: A significant correlation was found between the TIS scores and inspiratory muscle strength ($p < 0.05$). A significant correlation was also found between the PASS-T scores and inspiratory muscle strength and pulmonary function ($p < 0.05$). All of the center of pressure parameters measured were significantly correlated with the PEF(L/s) and FEF25–75 (L/s) ($p < 0.05$).

TABLE 1 Demographic characteristics of the participants.

Sex	n	%
Female	20	62.5
Male	12	37.5
Age (years)	Mean	SD
Age (years)	58.56	12.31
Height (cm)	169	8.3
Weight (kg)	79.00	11.54
BMI (kg/m ²)	27.70	3.87
Time elapsed since stroke diagnosis (months)	6.03	3.89
Affected side (left/right) (n)	14/18	
Stroke Type (ischemic/hybrid/hemorrhagic) (n)	11/21	
Smoking status	n	%
Smoker	8	25
Non-smoker	32	68.8
Quit	2	6.3

TABLE 2 Relationship between functional independence and trunk-postural control and inspiratory muscle strength and respiratory functions.

[illegible]

Conclusion: In conclusion, this study showed that trunk and postural control are associated with inspiratory muscle strength and pulmonary function. It is recommended that evaluation of trunk and postural control and respiratory functions, as well as exercise training to improve these parameters, should be included in rehabilitation programs for individuals with stroke.

Background and Aims: In multiple sclerosis (MS) patients, aerobic exercise may exert a neuroprotective role on the brain by stimulating neurogenesis in the dentate gyrus (DG) of the hippocampus and in the subventricular zone (SVZ), but further evidence is needed. We assessed the effects of aerobic exercise

on the volume of the hippocampus and its subfields and on diffusivity measures of the SVZ in progressive MS.

Methods: We retrospectively analyzed data from 84 patients with progressive MS enrolled at four sites in the CogEx MRI sub-study. Thirty-nine patients performed aerobic training, while 45 undertook a balance- and stretching-based sham intervention. Both groups trained twice weekly for twelve weeks. At baseline, post-intervention and 6-month follow-up, patients underwent MRI assessment on a 3.0 T scanner. FreeSurfer's longitudinal pipeline was used to analyze hippocampal subfields' volumes. Fractional anisotropy and mean diffusivity were extracted from the SVZ and the thalamus (as control region).

Results: No baseline differences were observed between the aerobic and the sham exercise groups ($p \geq 0.070$). The DG showed a significant volume increase post-intervention in the aerobic group (mean change = 0.63%, 95% confidence interval [95% CI] = 0.04%; 1.22%, $p = 0.035$), but not in the sham exercise group (mean change = -0.26%, 95% CI = -0.81%; 0.28%, $p = 0.337$). Between-group difference in DG volume change was significant ($p = 0.029$). No significant changes were found in the other hippocampal subfields or SVZ diffusivity metrics ($p \geq 0.057$). No changes in either group were found between post-intervention and 6-month follow-up ($p \geq 0.061$).

Conclusion: Aerobic exercise increases DG volume in progressive MS patients but does not modify microstructural integrity of the SVZ.

Disclosure: Funding. This study was supported in part by funds from MSCanada (grant EGID 3185). Ancillary funding was provided by the Consortium of Multiple Sclerosis Centres, the Danish Multiple Sclerosis Society, and the US National Multiple Sclerosis Society.

OPR-037 | Migraine in older adults: A multicenter real-world analysis from the Italian RICE registry

G. Paparella¹; L. Iannone²; G. Paparella¹; S. Scannicchio¹; C. Abbatantuono¹; L. Clemente¹; M. Delussi³; M. Fanelli⁴; M. de Tommaso¹

¹Neurophysiopathology Unit, Department of Translational Biomedicine and Neuroscience (DiBrain), University of Bari Aldo Moro, Bari, Italy; ²Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; ³Department of Education, Psychology, Communication (For.Psi.Com.), University of Bari Aldo Moro, Bari, Italy; ⁴Section of Molecular Pathology, Department of Precision and Regenerative Medicine and Ionian Area (DiMePRE-J), University of Bari Aldo Moro, Bari, Italy

Background and Aims: Primary headaches, particularly migraine, are prevalent disorders insufficiently characterized in the growing elderly population. This multicentre study provides a evaluation of headache diagnoses, with a focus on migraine, across different age groups in tertiary headache centers participating in the Italian RICE registry.

Methods: We retrospectively analyzed 3472 patients evaluated at thirty Headache Centers between 2021 and 2025. Patients were stratified into four age groups: young adults (18–30 years),

adults (31–45 years), middle-aged (46–59 years), and elderly (≥ 60 years). Data collected included International Headache Society (IHS) headache diagnoses (ICHD3) and demographic and clinical features. Statistical analyses included chi-square tests and Kruskal–Wallis ANOVAs.

Results: Of the total sample, 643 patients (18.5%) were elderly, 1285 (37.0%) middle-aged, 988 (28.5%) adults, and 556 (16.0%) young adults. The distribution of diagnoses differed significantly across groups [$\chi^2(117)=254$, $p<0.001$]. Elderly patients were more likely to receive a diagnosis of chronic migraine ($z=3.41$). Migraine with aura was more prevalent in younger individuals ($z=5.32$). Among other primary headaches, tension-type headache was more frequent in the elderly ($z=2.47$). Medication overuse headache (MOH) occurred more often in middle-aged patients ($z=4.64$). Older patients reported a longer disease duration, but with less intense pain severity, and fewer associated symptoms (all $p<0.01$).

Conclusion: Headache diagnoses vary significantly with age. In elderly patients, chronic migraine predominates and it is characterized by longer attacks with reduced associated symptoms. MOH represents a relevant concern in middle-aged individuals. These findings highlight the need for age-specific diagnostic and therapeutic strategies, particularly in older adults.

OPR-038 | Onabotulinum toxin type-A for the management of medically refractory SUNHA: A preliminary retrospective single centre experience

M. Guarinoni¹; A. Andreou²; M. Murphy¹; B. Hill¹; G. Lambru¹
¹Headache and Facial Pain Service, Guy's and St Thomas' NHS Foundation Trust, London, UK; ²Headache Research-Wolfson Sensory, Pain and Regeneration Centre, Institute of Psychology, Psychiatry and Neuroscience, King's College London, London, UK

Background and Aims: Short-lasting unilateral neuralgiform headache attacks (SUNHA) are rare primary head and facial pain disorders that share clinical features and treatment challenges with trigeminal neuralgia (TN). Onabotulinum Toxin A (OnaBoNT) demonstrated promising efficacy in refractory TN. Based on this rationale, we began offering OnaBoNT to SUNHA patients refractory to medical management. Here we aim to evaluate the effectiveness of OnaBoNT in patients with refractory SUNHA.

Methods: Medically refractory SUNHA patients diagnosed between January 2024 and January 2026, were offered OnaBoNT using a “follow-the-pain protocol”, performed 3–4 months apart. Efficacy outcomes were retrospectively assessed using the Patient Global Impression of Change (PGIC) scale, percentage of symptom improvement, and duration of benefit. Side effects were collated.

Results: Of the 214 patients with SUNHA evaluated during the study period, outcomes were available for 18 individuals who received at least one OnaBoNT treatment (Tables 1 and 2). A median dose of 112.5U [IQR 80–145U] was administered per treatment cycle. At 3- and 6-month follow-ups, 9/18 (50%) and 6/12 (50%) patients respectively reported a PGIC of ≥ 6 and a $\geq 50\%$ pain reduction (median: 90%, IQR: 80%–100%). The mean duration of benefit was 9.5 weeks (3–16 weeks). The six responders to

the first two treatments displayed a sustained improvement up to their last treatment cycle (range: 5–13 cycles). Mild transient facial asymmetry was reported in 5/18 (28%) patients.

L. Novarese, Moncrivello, Vercelli, Italy

Background and Aims: Migraine is common in people with multiple sclerosis (PwMS) and substantially contributes to disability and impaired quality of life. Although calcitonin gene-related peptide (CGRP)-targeting therapies have reshaped migraine prevention, evidence on their use in PwMS remains scarce, particularly in patients receiving concomitant disease-modifying therapies (DMTs).

Methods: We retrospectively collected data from 17 Italian MS centers on adult PwMS with comorbid migraine treated with anti-CGRP monoclonal antibodies or atogepant in addition to stable DMTs. Monthly headache days (MHDs) and analgesic intake were compared between treatment initiation and last available follow-up. MS activity was assessed through relapses, Expanded Disability Status Scale (EDSS), and MRI findings. A $\geq 50\%$ reduction in MHDs defined treatment response. Multivariate regression models were used to explore predictors of clinical improvement.

Results: Fifty-four patients were included (46 women; mean age 42.3 years; 85% relapsing MS). Baseline MHDs averaged 19.9 ± 7.0 and declined to 11.4 ± 9.4 at follow-up ($p < 0.001$), with a parallel decrease in analgesic use ($p < 0.001$). A responder rate

of 53.7% was observed. MS disease activity remained stable, with no significant changes in relapse frequency, EDSS, or MRI activity. Higher baseline headache burden was associated with

FIGURE 1 Number of MHD and EDSS score at baseline, and the last follow-up during treatment with CGRP-mAbs in combination with DMT for multiple sclerosis.

greater reduction in MHDs ($\beta=0.64$, $p<0.001$), whereas longer MS duration predicted poorer response (OR=1.70, 95% CI 1.11–2.63). Mild adverse events occurred in four patients, without treatment discontinuation.

Conclusion: In this real-world multicenter cohort, anti-CGRP therapies provided meaningful migraine improvement in PwMS while maintaining MS stability. Disease duration and baseline headache frequency may influence therapeutic response.

Disclosure: Nothing to disclose.

OPR-040 | Randomised controlled trial with translational validation: Migraine induced by vascular KATP channel activation is independent of HCN channel activity

Z. Zhuang¹; J. Thuraiayah¹; L. Kokoti¹; R. Moreno¹; E. Gozalov¹; Z. Hakimzadeh¹; M. Al-Karaghali¹; A. Clement²; D. Kristensen²; J. Abdulla³; S. Christensen²; M. Ashina⁴

¹Department of Neurology, Danish Headache Centre, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; ²Translational Research Centre, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; ³Department of Cardiology, Amager-Hvidovre Hospital, Copenhagen, Denmark; ⁴Centre for Discoveries in Migraine, Danish Headache Centre, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark

Background and Aims: Vascular ATP-sensitive potassium (KATP) channel activation can trigger migraine, but the mechanisms remain unclear. Proposed pathways involve either direct neuronal activation via hyperpolarisation-activated cyclic nucleotide-gated (HCN) channels or signalling at the vessel-to-neuron interface. We tested whether HCN channel blockade alters KATP channel-induced migraine.

Methods: We conducted a single-centre, randomised, double-blind, placebo-controlled, 2-way crossover study in individuals with migraine without aura and mechanistically aligned pre-clinical experiments in a validated mouse model. Participants received intravenous levocromakalim followed by oral ivabradine or placebo on separate days. The primary outcome was the 12-h incidence of levocromakalim-induced migraine; secondary outcomes included area under the curve (AUC) for headache intensity and haemodynamic responses. In mice, von Frey testing was used to assess whether ivabradine, given as pre- or rescue treatment, modified levocromakalim-induced hypersensitivity.

Results: Twenty-seven participants completed the human study and were included in the analysis. Ivabradine had no effect on the incidence of levocromakalim-induced migraine (22/27 after ivabradine and 22/27 after placebo; $p>0.99$) or on AUC for

headache intensity ($p=0.11$). Haemodynamic responses did not differ between study days. In mice, multiple doses of ivabradine neither prevented nor reversed tactile hypersensitivity caused by repeated levocromakalim administration.

Conclusion: HCN channel blockade does not affect migraine or nociceptive behaviour triggered by vascular KATP channel activation, suggesting that HCN channels are not required for translating vascular KATP channel activation into migraine pain. Instead, our findings support a model in which migraine is initiated via signalling at the vessel-to-neuron interface.

Background and Aims: Although amyloid deposition is a core pathological feature of Alzheimer's disease (AD), its spatial expression varies widely across individuals. The probabilistic amyloid hypothesis predicts that APOE ε4 constrains amyloid accumulation toward more stereotyped spatial patterns. Whether APOE ε4 gene dose increases the predictability and homogeneity of amyloid topography across disease stages remains unknown.

Methods: We performed voxel-wise similarity and spatial homogeneity analyses of amyloid-PET data in amyloid-positive participants from ADNI (CU, MCI, dementia). Participants were stratified by APOE ε4 genotype. Individual amyloid-PET maps were correlated with two independent canonical AD amyloid reference maps. Within-group spatial homogeneity was quantified using inter-subject voxel-wise correlation matrices. Replication was performed in an independent cohort from the Geneva Memory Center.

Results: APOE ε4 genotype predicted amyloid-PET pattern similarity to canonical AD maps, independent of age, sex, and

global amyloid burden. Similarity increased in a dose-dependent manner from non-carriers to heterozygotes and homozygotes. APOE $\epsilon 4$ carriers also showed significantly greater within-group spatial homogeneity of amyloid deposition, with the highest convergence observed in homozygotes. These effects were most pronounced in CU and MCI stages but persisted across the AD continuum. All findings replicated across cohorts, PET tracers, and canonical reference maps.

Conclusion: The APOE $\epsilon 4$ gene dose is associated with increasingly predictable and homogeneous amyloid topographies, supporting a gradient of pathological determinism in AD. These results provide in vivo support for the probabilistic model of AD and suggest that APOE $\epsilon 4$ homozygosity drives the topographical predictability and homogeneity of amyloid deposition, with implications for targeted anti-amyloid interventions.

Background and Aims: Frontotemporal lobar degeneration (FTLD) includes several syndromes with specific regional susceptibility. How molecular architecture shapes degeneration across functional networks remains unclear. Stepwise functional connectivity (SFC) captures how disease epicenters communicate across network distances. We investigated whether

transcriptomic profiles of key FTLD-associated genes align with SFC patterns.

Methods: Variant-specific atrophy epicenters were identified using voxel-based morphometry in patients with behavioral variant FTD (bvFTD, $n=11$), semantic variant PPA (svPPA, $n=18$), nonfluent variant PPA (nfvPPA, $n=14$), and semantic behavioral variant FTD (sbvFTD, $n=15$). Regional SFC topological distances from epicenters were derived using resting-state fMRI in 50 healthy controls. Spatial correlations were computed between SFC distance and gene expression maps from Allen Human Brain Atlas. Genes enriched near epicenters underwent pathway analysis.

Results: Epicenters were located in the left anterior insula (bvFTD), left anterior inferior temporal gyrus (svPPA), left supplementary motor area (nfvPPA), and right temporal pole (sbvFTD). GRN and MAPT were enriched near epicenters, whereas C9orf72 expression increased with SFC distance. Pathway analysis identified two molecular clusters: bvFTD/nfvPPA-associated genes were linked to mitochondrial metabolism, oxidative stress, and proteostasis; svPPA/sbvFTD-associated genes were associated with neuromodulation and synaptic plasticity.

Conclusion: Regional transcriptomic patterns reflect functional network architecture in FTLD, suggesting molecular vulnerability shapes network-specific degeneration. GRN and MAPT enrichment near epicenters indicates local susceptibility, while C9orf72 patterns suggest distinct propagation. Variant-associated clusters may reflect differential vulnerability to tau or TDP-43 pathology, potentially explaining clinical and anatomical differences.

Background and Aims: Diffusion tensor imaging analysis along the perivascular space (DTI-ALPS) is a non-invasive MRI-based proxy of glymphatic dysfunction, a mechanism implicated in the accumulation of protein aggregates in several neurodegenerative disorders. This study aimed to evaluate glymphatic function using DTI-ALPS in GRN-mutated frontotemporal dementia (FTD), comparing them to sporadic cases and healthy controls (HC), and investigate its clinical relevance and relationship with white-matter (WM) damage.

Methods: Eighteen GRN-mutated patients with an FTD syndrome (10 behavioural variant FTD [bvFTD], 5 non-fluent primary progressive aphasia [nfvPPA], 3 other PPA variants), 43 sporadic FTD patients, and 32 age- sex-matched HC underwent 3T MRI. The DTI-ALPS index was calculated for each participant. Group comparisons were performed using age- sex- and fractional anisotropy (FA)-adjusted ANCOVA. Associations with cognitive performance, behavioural symptoms, and sleep disturbances were assessed. WM microstructural integrity was evaluated using tract-based spatial statistics with voxel-wise FA.

Results: GRN-patients showed significantly lower DTI-ALPS values than HC ($p < 0.001$) and sporadic FTD patients with bvFTD ($p = 0.027$) and semantic variant of PPA ($p = 0.003$). Within the GRN-group, lower DTI-ALPS was associated with poorer executive performance, higher impairment on selected Frontal Behavioural Inventory items, and the presence of insomnia ($p = 0.025$). DTI-ALPS values positively correlated with FA in the anterior and superior corona radiata, internal and external capsules, corpus callosum, and left superior longitudinal fasciculus ($p < 0.05$, Family-Wise Error corrected for multiple comparisons).

Conclusion: Glymphatic dysfunction is more pronounced in GRN-FTD than in sporadic FTD and is associated with WM damage, executive, behavioural alterations, and sleep disturbances, supporting a gliovascular contribution to GRN-mediated neurodegeneration.

OPR-044 | Metabolically defined lesion clusters show differential associations with clinical disability in multiple sclerosis

R. Rumbak¹; A. Petrova¹; A. Kloss-Brandstätter²; F. Niess¹; B. Strasser¹; L. Hingerl¹; T. Berger³; G. Grabner⁴; P. Rommer³; W. Bogner¹; E. Niess¹; A. Dal-Bianco³

¹High-field MR Center, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria; ²Department of Engineering & IT, Carinthia University of Applied Sciences, Villach, Austria; ³Department of Neurology, Medical University of Vienna, Vienna, Austria; ⁴Department of Medical Engineering, Carinthia University of Applied Sciences, Klagenfurt, Austria

Background and Aims: Lesion burden on conventional magnetic resonance imaging correlates only weakly with clinical disability in multiple sclerosis (MS). We investigated whether metabolically defined lesion clusters identified by 7T MR

spectroscopic imaging show differential associations with clinical disability.

Methods: In this cross-sectional observational study, 50 people with MS underwent 7T MR spectroscopic imaging. After quality control, 304 white matter lesions from 45 participants were analysed using metabolite ratios reflecting lesion metabolic state. Data-driven clustering identified metabolically distinct lesion clusters. Lesion burden within each cluster was correlated with clinical disability measures, including the Expanded Disability Status Scale (EDSS), Symbol Digit Modalities Test (SDMT), Timed 25-Foot Walk (T25FW), and 9-Hole Peg Test (9-HPT), using age-adjusted models.

Results: Three reproducible metabolic lesion clusters were identified (Figure 1). Cluster 1, consistent with newly emerging, actively inflammatory and expanding lesions, showed the strongest clinical associations, with higher lesion count correlating with worse SDMT performance ($r = -0.34$, $p = 0.027$). Cluster 2, reflecting metabolically exhausted lesions with ongoing tissue damage, was associated with impaired motor function, including slower T25FW ($r = 0.31$, $p = 0.044$) and 9-HPT ($r = 0.29$, $p = 0.031$). Cluster 3, characterized by metabolically stable lesions with features consistent with partial repair, showed no significant associations with disability ($p > 0.1$). Associations between cluster-specific lesion burden and disability are illustrated in Figure 2.

FIGURE 1 Longitudinal examples of metabolically clustered lesions (Clusters 1–3) across coregistered FLAIR + SWI, MP2RAGE, and quantitative T1 maps from baseline to 8-year follow-up.

FIGURE 2 Linear regression models assessed the effect of lesion count (A) and log-transformed lesion volume (cm^3) on disability.

Conclusion: These findings indicate that lesion metabolic state, rather than lesion presence alone, determines clinical relevance, supporting metabolic imaging as a tool for improved stratification of disease impact.

Background and Aims: Cognitive decline in early MS remains understudied. We investigated longitudinal cognitive trajectories and baseline magnetic resonance imaging (MRI) predictors following the first demyelinating event.

Methods: Patients were enrolled within 3 months of symptom onset and followed for 5 years. Baseline MRI metrics included brain matter fractions and neurite orientation dispersion and density imaging (NODDI) parameters, specifically neurite density index (NDI), orientation dispersion index (ODI) and isotropic volume fraction (Viso). The Brief Visuospatial Memory Test-Revised (BVM-T-R), California Verbal Learning Test (CVLT) and Symbol Digit Modalities Test (SDMT) were collected at each visit. Quadratic and single-knot piecewise linear mixed models evaluated the impact of baseline MRI metrics on cognitive trajectories.

Results: 100 patients (mean age 32.3 ± 7.5 years, 33% male) were included, 35% of whom had MS at baseline. BVM-T-R and CVLT improved until year 3 by 0.15 (SE: 0.03; $p < 0.001$) and 0.21 (SE: 0.04; $p < 0.001$) z-scores/year, respectively, before declining. SDMT remained steady throughout the study period. A 1% decrease in deep grey matter fraction (DGMF) predicted 0.92 ($p = 0.009$, SE = 0.35) and 1.11 ($p = 0.022$, SE = 0.48) z-scores/year declines in BVM-T-R and CVLT, respectively, while a 0.1-unit increase in cortical grey matter isotropic volume fraction (CGMViso) predicted a 0.47 z-score/year decline in BVM-T-R ($p = 0.003$, SE = 0.15).

Conclusion: After the first demyelinating event, patients showed initial cognitive improvement followed by decline in multiple domains. Baseline DGMF and CGMViso predicted this decline, highlighting their value as prognostic markers for cognitive trajectories in early MS.

Background and Aims: The choroid plexus (ChP) regulates cerebrospinal fluid production and central nervous system homeostasis. In multiple sclerosis (MS), ChP enlargement occurs early in the disease course, yet its normative lifespan trajectory and disease-specific associations remain unclear. We defined normative ChP volume trajectories across the healthy lifespan and assessed ChP enlargement in MS to evaluate associations with demographic, clinical, MRI, and genetic variables, including Human Leukocyte Antigen (HLA) and non-HLA polygenic risk scores (PRSs).

Methods: This monocentric retrospective study included 461 healthy controls (HC) and 727 MS patients (age 18–70 years) who underwent 3T brain MRI and neurological assessment. ChP volumes were quantified using ASCHOPLEX, normalized for head size, and modeled in HC to compute z-scores for MS patients. PRSs were calculated from established MS susceptibility loci, encompassing both HLA and non-HLA regions.

Results: In HC, normalized ChP volume (NChPV) was predicted by normalized brain volume, lateral ventricle volume, and its squared term ($R^2=0.54$), remaining stable until age 35, then increasing nonlinearly ($p\text{-FDR}<0.002$). MS patients had significantly higher NChPV z-scores than controls ($p\text{-FDR}<0.001$), independent of age or phenotype. NChPV z-scores rose during the first five years after onset ($p\text{-FDR}=0.012\text{--}0.015$) before plateauing. Higher z-scores were associated with greater T2-hyperintense white matter lesion volume ($p<0.001$) and HLA genetic burden ($p=0.027$) but not non-HLA PRSs ($p\geq 0.177$).

Conclusion: We provided normative ChP trajectories and showed early, sustained ChP enlargement in MS, linked to inflammatory lesion burden and HLA-mediated genetic risk. The ChP may represent a non-invasive biomarker of MS susceptibility and neuroinflammation.

¹Laboratory of Genetics and Molecular Bases of Complex Diseases, Health Research Institute of Hospital Clínico San Carlos (IdISSC), Madrid, Spain; ²Department of Neurology, Hospital Universitario de Getafe, Getafe, Spain; ³Department of Neurology, Hospital Clínico San Carlos, Health Research Institute of Hospital Clínico San Carlos (IdISSC), Madrid, Spain

Background and Aims: A non-selective agonist of sphingosine-1-phosphate (S1P) receptors, FTY720, inhibits lymphocyte migration and mitigates subsequent inflammation. Mounting evidence supports the participation of S1P signaling in additional processes besides cell migration, but FTY720 mechanisms are not fully understood at present and possible effects on mitochondrial integrity are now explored. This study aims to investigate whether the S1P analog FTY720 modulates mitochondrial homeostasis in lymphocytes from healthy donors. Specifically, we evaluated its in vitro effects on peripheral blood mononuclear cells (PBMCs) isolated from controls.

Methods: Mitochondrial respiration and glycolytic activity were assessed by Seahorse XFp extracellular flux analysis. Mitochondrial mass, membrane potential, reactive oxygen species (ROS) production, and glycolytic mediators were evaluated by flow cytometry, and electron transport chain (ETC) complexes by Western Blot.

Results: FTY720 blocked early and late activation of PBMCs and inhibited basal and PHA-stimulated respiration (basal, maximal, and ATP-linked respiration) and glycolytic capacities (basal/maximal/glycolytic reserve). We observed significantly decreased mitochondrial depolarization and coupling in basal and stimulated conditions, with parallel increased ROS levels, together with lower fold-change of complex III of the ETC upon PHA stimulation. Both in basal and PHA-stimulated conditions, we found consistently reduced levels of fission/fusion (DRP1, FIS1, OPA1, MFN2) proteins and a reduced fold-change in mitochondrial mass of B cells. Upon PHA stimulation, lactate transporters (MCT1 and 4) remained at unstimulated levels, while PFKFB3 showed increased prestimulated levels already in the absence of PHA.

FIGURE 1 Respirometry of control lymphocytes incubated with FTY720. (A) Oxygen consumption rate and (B) extracellular acidification rate profiles and associated parameters in unstimulated and PHA-stimulated PBMCs in the presence of 5µM FTY720 or vehicle.

FIGURE 2 Changes in mitochondrial polarization, coupling, ROS and complex III levels upon in vitro PHA-stimulation of control lymphocytes incubated with FTY720.

FIGURE 3 Changes in mitochondrial fusion and fission protein levels of lymphocytes incubated with FTY720. Representative Western blots and quantification of (A) OPA-L, (B) MFN2, (C) DRP1, and (D) FIS1 proteins from PBMCs.

Conclusion: FTY720 modulates mitochondrial activity of PBMCs isolated from healthy donors, indicative of additional pathways contributing to its therapeutic effects.

³Department of Neurology, Medical University of Graz, Graz, Austria; ⁴Research Unit for Neuronal Plasticity and Repair, Department of Neurology, Medical University of Graz, Graz, Austria;

⁵Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Graz, Austria; ⁶Diagnostic and Research Institute of Human Genetics, Medical University of Graz, Graz, Austria

Background and Aims: Multiple sclerosis (MS) is a chronic inflammatory autoimmune disease of the central nervous system characterized by demyelination and neurodegeneration. Mitochondrial DNA copy number (mtDNA-CN) is a proposed biomarker of mitochondrial health, with reduced mtDNA-CN being related to disease duration and worsening in MS. However, its temporal dynamics and association with brain atrophy remain unclear. This study investigates longitudinal changes in mtDNA-CN in peripheral blood and its relationship with brain volume loss in people with MS (pwMS).

Methods: This study included 123 pwMS (mean ($\pm$ SD) age 33.2 ± 8.5 years, 59.3% female, median disease duration 3.1 years [IQR: 1.0–7.9]), median Expanded Disability Status Scale (EDSS) score 1.0 [IQR: 0.0–2.0] and 47 healthy controls (HC; mean ($\pm$ SD) age 34.1 ± 10.7 years, 72.3% female). In a subgroup of 62 pwMS, a second sample was collected after 2.6 ± 1.6 years. mtDNA-CN was quantified by real-time quantitative polymerase chain reaction in peripheral blood. Magnetic resonance imaging was performed on a 3-T Tim Trio system and longitudinal brain volume changes were assessed using SIENA.

Results: The mtDNA-CN was significantly lower in MS compared to HCs ($p < 0.05$). mtDNA-CN was unrelated to age, sex, disease duration and EDSS. No significant longitudinal change in mtDNA-CN was observed in the subgroup analysis. Of note, lower mtDNA-CN at baseline correlated with a higher percentage of annualized brain volume loss during the follow-up period ($\rho = 0.266$, $p < 0.05$).

Conclusion: These findings confirm lower mtDNA-CN in pwMS and suggest that mtDNA-CN might serve as a biomarker for the rate of brain atrophy in pwMS.

Background and Aims: MSCopilot®, a Software as a Medical Device, remotely assesses key functions such as cognition, dexterity, vision and walking. French studies showed that MSCopilot® tests correlate with the Extended Disability Scale Score (EDSS) and the 4-item MS Functional composite (MSFC-4) when assessed in-clinic. The international MS-DETECT study (NCT05816122) evaluates MSCopilot®'s ability to detect disability worsening during 18–24 months. This analysis compares individual MSFC-4 scores with MSCopilot® digital biomarkers measured in-clinic or at home.

Methods: MSFC-4 scores were assessed in-clinic during the inclusion visit. MSCopilot® tests were performed with and without supervision in-clinic and at home, respectively. Association between the digital scores and their clinical counterparts was assessed using Pearson correlation coefficients.

Results: 244 patients (68.4% female, mean age 49.15 ± 8.74 , mean disease duration 17.57 ± 8.04 and mean EDSS: 3.8 ± 1.3) were included in this analysis. We collected 973 in-clinic and 870 remote MSCopilot® evaluations (243/218 cognition, 244/219 dexterity, 244/215 vision and 242/218 walking). Significant correlations were found between individual MSFC-4 items and digital tests: cognition ($r = 0.71/0.62$), dexterity ($0.45/0.47$), vision ($0.36/0.37$) and walking ($0.54/0.66$) tests. Composite MSFC-4 scores significantly correlated with MSCopilot®'s measured in-clinic (0.71) and remotely (0.74).

Conclusion: MSCopilot® digital tests, whether performed in-clinic or at home, correlated with their clinical counterparts. These findings emphasize their potential use in detecting disease worsening thus leading to improved clinical monitoring of MS.

Ageing and Dementia 1

OPR-050 | Cortical thickness signature of early-onset Alzheimer's disease across preclinical and prodromal stages in a real-world memory clinic

A. Zilioli¹; R. Mohanty²; A. Rosenberg²; A. Matton²; T. Granberg²; G. Hagman²; M. Spallazzi¹; M. Kivipelto²; E. Westman²

¹Department of Neurology, University-Hospital of Parma, Parma, Italy; ²Division of Clinical Geriatrics, Center for Alzheimer Research, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden

Background and Aims: The cortical thinning signature of early-onset Alzheimer's disease (EOAD) is well characterized in dementia, but its expression at earlier stages remains unclear. We aimed to determine when EOAD-related cortical atrophy becomes detectable and assess ATN biomarker contribution.

Methods: We studied individuals <65 years who underwent 3T structural MRI and cerebrospinal fluid-based ATN profiling. Cortical thickness was derived from T1-weighted images using FreeSurfer. EOAD signature regions were defined through vertex-wise comparisons between AD dementia and ATN-negative subjective cognitive decline (SCD). Regional cortical thickness and hippocampal volume were evaluated across SCD

and mild cognitive impairment (MCI) groups stratified by ATN status. Brain–cognition associations were assessed.

Results: The cohort included 507 individuals (mean age 57.7 ± 5.3 years), of whom 185 within the AD continuum. EOAD dementia showed marked thinning in parietal and lateral temporal cortices. In MCI with AD biomarkers, cortical thickness was significantly reduced across EOAD signature regions, including the inferior and superior parietal lobules, precuneus, and lateral temporal cortex, together with hippocampal volume (all $p < 0.01$; Cohen's $d \leq -0.50$). In SCD, cortical thinning was observed only

FIGURE 1 Cortical thinning pattern in EOAD dementia compared to the reference group of ATN-negative SCD.

FIGURE 2 Regional cortical thickness and hippocampal volume in MCI subgroups. (A) SCD ATN negative, (B) MCI ATN negative, (C) MCI non AD-change, (D) MCI A+T-, (E) MCI A+T+.

FIGURE 3 Regional cortical thickness and hippocampal volume in SCD groups. (A) SCD ATN negative, (B) SCD non AD change, (C) SCD A+T-, (D) SCD A+T+.

in A+T+ individuals, involving the precuneus and the banks of the superior temporal sulcus (all $p < 0.05$; $d \leq -0.60$), with no differences in A+T− SCD. In MCI-AD, reduced cortical thickness correlated with poorer global cognition and episodic and visuospatial memory (all $p < 0.05$), while no associations emerged in SCD.

Conclusion: EOAD-related cortical thinning at preclinical and prodromal stages depends on combined amyloid and tau pathology.

Disclosure: Nothing to disclose.

OPR-051 | Automatic primary progressive aphasia variant classification from transcripts and diffusion magnetic resonance imaging

³Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ⁴Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁶Unit of Neurology 5, Clinical Neuropathology Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; ⁷Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Primary Progressive Aphasia (PPA) comprises three main clinical variants, nonfluent/agrammatic (nfvPPA), semantic (svPPA), and logopenic (lvPPA), each with distinct linguistic profiles and neurodegeneration patterns. Differential diagnosis relies heavily on subjective clinical judgment, limiting standardization. This study developed a multimodal pipeline combining speech-derived linguistic features with diffusion MRI markers for automated PPA classification.

Methods: This study included data from 91 healthy controls and 94 PPA patients (38 nfvPPA, 36 svPPA and 20 lvPPA). Connected speech was recorded during Picnic scene description task and automatically transcribed using Microsoft Azure after preprocessing optimization. Linguistic features were extracted via Python pipelines; diffusion features derived from atlas-based fractional anisotropy measures. A multinomial logistic regression classifier was trained with nested cross-validation. Transcriptions were compared against manual gold-standard using word error rate (WER). A web-based application integrating transcription with clinician-supervised revision and automatic feature extraction was implemented.

Results: Automatic transcription achieved mean WER of $12 \pm 7\%$ (controls) and $19 \pm 10\%$ (PPA). Linguistic features

captured variant-specific patterns (reduced output and slowed speech in nfvPPA; increased pauses and word-finding difficulty in lvPPA; fluent but semantically less informative speech in svPPA). The multimodal classifier achieved balanced accuracy of $87 \pm 6.9\%$, outperforming speech-only and imaging-only models. Per-variant accuracy was 93% (nfvPPA), 95% (svPPA), with lower performance for lvPPA.

Conclusion: This multimodal framework integrates speech and diffusion MRI to support standardized PPA variant differentiation with strong diagnostic performance. The interactive web platform improves transcription accuracy through clinician oversight, supporting harmonized diagnosis and longitudinal monitoring.

Geneva University Hospitals, Geneva, Switzerland; ³Division of Nuclear Medicine and Molecular Imaging, Diagnostic Department, Geneva University Hospitals, Geneva, Switzerland; ⁴Laboratory for Translational Research in Neurodegeneration, University of Geneva, Geneva, Switzerland; ⁵Department of Psychiatry and Neurochemistry, Institute of Neuroscience & Physiology, The Sahlgrenska Academy at the University of Gothenburg, Mölndal, Sweden; ⁶Banner Alzheimer's Institute and University of Arizona, Phoenix, USA

Background and Aims: Synaptic dysfunction is the biological substrate of cognitive decline in Alzheimer's disease (AD). While amyloid- β and tau are known to interact in driving synaptic damage, their independent contributions remain unclear.

Methods: 109 cognitively unimpaired individuals and patients with mild cognitive impairment or dementia from the Geneva Memory Center with available CSF synaptic biomarkers (neurogranin, SNAP25, GAP43) were included and classified according to amyloid (A) and tau (T) status. Group comparisons and correlations between synaptic and AD biomarkers were performed. Multiple linear regression models assessed the independent associations of amyloid and tau with synaptic biomarkers. Model I included CSF A β 42 and CSF p-tau181, whereas Model II included amyloid PET centiloid and CSF p-tau181. Mediation analyses explored the relationships between amyloid, tau and synaptic biomarkers. All analyses were replicated in the Alzheimer's Disease Neuroimaging Initiative (ADNI) cohort ($n=787$).

Results: Synaptic biomarkers concentrations were significantly higher in A+/T+ participants ($n=27$) compared with A-/T- ($n=52$) and A+/T- ($n=30$) groups ($p<0.001$). CSF p-tau181 showed the strongest correlations with synaptic biomarkers (rs up to 0.83, $p<0.001$). In Model I, GAP43 was positively associated with CSF A β 42 ($\beta=0.31$, 95% CI 0.23–0.40, $p<0.001$; partial $R^2=0.321$) and p-tau181 ($\beta=0.94$, 95% CI 0.84–1.04, $p<0.001$; partial $R^2=0.809$). In Model II, lower centiloid ($\beta=-0.31$, 95% CI -0.46 to -0.16, $p<0.001$; partial $R^2=0.225$) and higher p-tau181 ($\beta=0.94$, 95% CI 0.84–1.04, $p<0.001$; partial $R^2=0.758$) predicted higher GAP43. Mediation analyses indicated tau as the mediator of the direct association between amyloid burden and GAP43.

Conclusion: These results indicate tau pathology as the main driver of synaptic damage across the Alzheimer's disease continuum.

Disclosure: Nothing to disclose.

OPR-053 | Residual cerebrospinal fluid NPTX2 predicts dementia progression beyond neurogranin and core pathology in prodromal Alzheimer's disease

F. Massa¹; F. De Cesari¹; G. Bozzo¹; A. Panza¹; M. Urbinati¹; V. Pelagotti¹; A. Lechiara²; E. Mobilia²; F. Bozzano²; D. Visigalli²; L. Lorenzini¹; M. Losa¹; A. Brugnolo¹; N. Girtler¹; D. Arnaldi¹; A. Uccelli²; G. Pesce²; M. Pardini¹

FIGURE 1 Kaplan–Meier curves for time-to-progression to AD dementia across tertiles of Res_NPTX2.

Background and Aims: In Alzheimer's disease (AD) core markers have limited ability in predicting progression from mild cognitive impairment (MCI) to dementia. Synaptic cerebrospinal fluid (CSF) biomarkers may add prognostic information, spanning processes from injury to adaptive network capacity. We tested whether a residual component of CSF neuronal pentraxin-2 (NPTX2), a synaptic protein linked to network homeostasis, beyond neurogranin (Ng) reflecting synaptic injury and core AD biomarker burden predicts dementia progression.

Methods: We retrospectively studied 104 patients with typical MCI-AD supported by core CSF biomarkers. CSF NPTX2 and Ng were quantified by commercial immunoassays. Early vs. late MCI sub-stages were defined by proximity to progression (LMCI ≤ 2 years, EMCI > 2 years or stable). A residual NPTX2 component (Res_NPTX2) was defined after regressing standardized (z-transformed) NPTX2 on Ng, a core AD biomarker burden composite (phosphorylated tau181 divided by amyloid- β 42/amyloid- β 40), and age. Associations with Mini-Mental State Examination (MMSE) and time to progression were tested using linear regression, Kaplan–Meier and Cox analyses, including ≤ 2 -year administrative censoring.

Results: Ng correlated with NPTX2 ($\rho=0.67$, $p<0.001$). Res_NPTX2 was higher in early than late MCI ($p=0.0006$) and associated with better MMSE at baseline ($p=0.008$) and less decline over time (Δ MMSE, $p=0.002$). During follow-up, 55/104 (52.9%) progressed to dementia. Higher Res_NPTX2 predicted lower hazard of progression (HR=0.63; $p=0.007$). Res_NPTX2 tertiles separated Kaplan–Meier curves (log-rank $p=0.006$), with stronger discrimination within 2 years (High vs. Low HR=0.18; $p=0.008$).

Conclusion: A residual CSF NPTX2 component beyond Ng and core biomarker burden identifies clinically meaningful heterogeneity and improves near-term prognostic stratification for dementia progression in MCI due to AD.

Disclosure: Nothing to disclose.

¹Department of Clinical and Experimental Sciences, Neurology Unit, University of Brescia, Brescia, Italy; ²Department of Continuity of Care and Frailty, Neurology Unit, ASST Spedali Civili Brescia University Hospital, Brescia, Italy; ³Neurobiorepository and Laboratory of advanced biological markers, University of Brescia and ASST Spedali Civili Hospital, Brescia, Italy; ⁴Department of Psychiatry and Neurochemistry, Institute of Neuroscience & Physiology, the Sahlgrenska Academy at the University of Gothenburg, Mölndal, Sweden; ⁵Clinical Neurochemistry Laboratory, Sahlgrenska University Hospital, Mölndal, Sweden; ⁶Banner Alzheimer's Institute and University of Arizona, Phoenix, USA

Background and Aims: TREM2 (Triggering Receptor Expressed on Myeloid Cells 2) modulates microglial responses to neurodegeneration and plasma soluble TREM2 has been linked to white matter hyperintensity burden. However, whether plasma TREM2 relates to tract-specific white matter disconnection in Alzheimer's disease (AD) is unknown. To determine whether plasma TREM2 is associated with white matter tract disconnection in AD and whether such associations show anatomical specificity.

Methods: Fifty-seven AD patients (age 72 ± 6 years, 42% male) underwent 3T MRI and plasma collection. TREM2 was measured using the NULISA CNS Disease Panel. White matter hyperintensities were segmented on FLAIR and MPRAGE images and tract-specific disconnection probability was estimated for white matter tracts using volBrain DeepLesion, an automated deep learning-based pipeline. Tracts were grouped into limbic, association, callosal and projection categories. Partial

FIGURE 1 Plasma TREM2 and uncinete fasciculus disconnection in Alzheimer's disease. Scatter plot shows age- and sex-adjusted residuals.

FIGURE 2 Forest plot of TREM2 associations with white matter tract disconnection.

correlations adjusted for age and sex tested associations between plasma TREM2 and each outcome.

Results: Plasma TREM2 showed a trend association with total WMH volume ($r=0.28$, $p=0.07$). Strikingly, TREM2 was selectively associated with limbic tract disconnection: uncinete fasciculus ($r=0.46$, $p=0.002$), rostral cingulum ($r=0.40$, $p=0.007$), frontal-parahippocampal cingulum ($r=0.34$, $p=0.024$), and parahippocampal-parietal cingulum ($r=0.32$, $p=0.040$). Overall, 4/12 limbic tracts reached significance (mean $r=+0.38$), compared to 0/4 callosal and 0/6 projection tracts (Figure 2). Higher TREM2 consistently predicted greater disconnection in memory-critical pathways (Figure 1).

Conclusion: Plasma TREM2 is specifically associated with limbic white matter disconnection in AD. This anatomical selectivity mirrors the regional vulnerability of AD and implicates microglial activation in disrupting memory-relevant circuits. Plasma TREM2 may serve as an accessible biomarker of limbic network integrity in AD.

Disclosure: Nothing to disclose.

OPR-055 | Serum inflammatory proteomic signatures stratify disease activity in chronic inflammatory demyelinating polyneuropathy

A. Bhandage¹; F. Stascheit²; H. Preßler²; S. Hoffmann²; A. Meisel³; A. Rostedt Punga⁴

¹Department of Medical Sciences, Clinical Neurophysiology, Uppsala University, Uppsala, Sweden; ²Department of Neurology with Experimental Neurology and Neuroscience Clinical Research Center, Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt Universität zu Berlin, Berlin, Germany; ³Department of Neurology with Experimental Neurology and Center for Stroke Research Berlin, Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt Universität zu Berlin, Berlin, Germany; ⁴Department of Medical Sciences, Clinical Neurophysiology, Uppsala University and Clinical Neurophysiology, Uppsala University Hospital, Uppsala, Sweden

Background and Aims: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an immune-mediated neuropathy characterized by marked clinical heterogeneity and variable treatment response. Objective blood-based biomarkers reflecting disease activity and therapeutic responsiveness remain an unmet need, particularly in the context of immunoglobulin therapy, which may confound immune profiling. We aimed to identify serum inflammatory proteomic signatures associated with clinical phenotype, disease activity, and treatment exposure in CIDP.

Methods: In this case-control study, a multiplex proximity extension assay (PEA) and ELISA were used to quantify inflammatory proteins in serum from patients with CIDP and age- and sex-matched healthy controls, as well as from neurological disease controls including multiple sclerosis and IVIG-treated myasthenia gravis. Multivariable regression with correction for multiple testing, principal component analysis, and correlation analyses were performed to define disease-specific protein signatures and their associations with clinical characteristics, disease stability, and longitudinal outcomes.

Results: Distinct inflammatory proteomic patterns differentiated 51 patients with CIDP from 192 healthy controls and 105 neurological disease controls, indicating immune signatures beyond treatment-related effects. Specific protein clusters were associated with clinical phenotype, unstable disease, and subsequent clinical improvement, whereas others reflected immunoglobulin-modifiable pathways. Integrative analyses further suggested links between systemic inflammatory activity and markers of axonal injury.

Conclusion: This study identifies clinically relevant serum inflammatory signatures in CIDP and supports their potential as translational biomarkers for patient stratification, disease monitoring and therapy optimization.

Disclosure: F.S., A.R.P., S.H., and A.M. report speaker fees, consultancy honoraria, advisory board participation, or institutional research support from companies active in neuromuscular therapeutics, including Alexion, argenx, UCB, and others. OPR-056 | Patient-reported carpal tunnel syndrome outcomes with and without surgery during COVID-19: A real-world follow-up study

G. Rusin^{1,2}; A. Fryźlewicz¹; J. Antczak^{1,2}

¹Department of Neurology, University Hospital in Cracow, Poland; ²Department of Neurology, Jagiellonian University Medical College, Cracow, Poland

Background and Aims: During the COVID-19 period, some patients postponed or declined planned surgery for carpal tunnel syndrome (CTS). We assessed whether surgery was associated with better longitudinal outcomes on symptom severity and functional status.

Methods: We analyzed follow-up data from 73 patients (17.8% men, mean age 59.5 ± 12.0) first assessed pre-COVID and re-contacted later. Surgery status was self-reported (operated $n=29$; non-operated $n=44$). Overall, 40 (54.8%) used ≥ 1 additional option (rehabilitation, nocturnal splinting, reduced manual work). Baseline Padua severity was similar: median 3 (IQR 3–3) in both groups. Primary outcomes were Boston Carpal Tunnel Questionnaire subscales: Symptom Severity Scale (SSS) and Functional Status Scale (FSS). Between-group differences in improvement were tested, and multivariable linear models evaluated follow-up SSS/FSS adjusted for baseline score, follow-up interval, age, and Padua score.

Results: Both groups improved significantly over time. SSS improved from 2.77 ± 0.78 to 1.64 ± 0.80 in non-operated and from 2.94 ± 0.83 to 1.58 ± 0.65 in operated patients (both $p < 0.001$). FSS improved from 2.47 ± 0.95 to 1.70 ± 0.81 in non-operated

FIGURE 1 Change in symptom severity scale from baseline to follow-up by surgery status.

FIGURE 2 Change in functional status scale from baseline to follow-up by surgery status.

and from 2.58 ± 0.95 to 1.65 ± 0.75 in operated patients (both $p < 0.001$). Mean SSS improvement was 1.13 ± 1.12 vs. 1.36 ± 1.17 ($p = 0.40$; Figure 1). Mean FSS improvement was 0.77 ± 1.26 vs. 0.93 ± 1.11 ($p = 0.562$; Figure 2). In adjusted models, surgery was not independently associated with follow-up SSS ($\beta = -0.10$, 95% CI -0.49 to 0.28 ; $p = 0.60$) or FSS ($\beta = -0.04$, 95% CI -0.45 to 0.36 ; $p = 0.83$).

Conclusion: In this cohort, symptom and function scores improved over time regardless of surgery status. Surgery was not associated with greater longitudinal improvement in SSS or FSS after adjustment, suggesting that non-surgical factors and follow-up timing may substantially influence patient-reported outcomes.

Disclosure: Nothing to disclose.

OPR-057 | Diaphragmatic dysfunction after lung transplantation: Longitudinal assessments and intraoperative neurophysiological monitoring of the phrenic nerve

G. Libelli¹; M. Vergari²; A. Priori³; F. Cogliamarian²

¹Department of Medicine and Surgery, University of Parma, Ospedale Maggiore, Parma, Italy; ²Department of Neurophysiology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ³Department of Neurology, ASST Santi Paolo e Carlo, Ospedale San Paolo, Milan, Italy

Background and Aims: The diaphragm is the main respiratory muscle, controlled by the phrenic nerve, essential for breathing. Diaphragmatic dysfunction affects up to 43% of lung transplant (LTx) patients due to phrenic nerve injury from surgical factors, causing respiratory complications. This thesis combines two investigations: a prospective cohort study of longitudinal diaphragmatic function pre- and post-LTx, and an intraoperative neurophysiological monitoring sub-study of phrenic nerve damage dynamics.

Methods: Thirty patients were assessed for respiratory function, diaphragm ultrasound, and phrenic conduction preoperatively, at discharge, 6 and 12 months. Three patients underwent intraoperative testing at multiple surgical points, focusing on ice slush effects.

Results: Despite good clinical recovery (spirometry, 6MWT), phrenic cMAP amplitude reduced at discharge and 6 months but normalized by 12 months, underscoring multimodal monitoring needs. Intraoperative tests showed immediate cMAP drop with ice slush ($p < 0.05$) suggesting cryogenic axonal

FIGURE 1 Longitudinal changes in phrenic nerve cMAP amplitude and respiratory parameters in 30 lung transplant patients.

FIGURE 2 Intraoperative neurophysiological monitoring of phrenic nerve during lung transplantation. Immediate cMAP amplitude reduction after ice slush application, indicating cryogenic axonal damage.

FIGURE 3 Statistical representation of phrenic cMAP reduction post-ice slush ($p = 0.0029$) and latency prolongation, indicating cryogenic nerve damage despite partial subsequent recovery.

damage, emphasizing the utility of intraoperative neurophysiological monitoring in detecting and potentially mitigating nerve damage.

Conclusion: This study highlights the importance of routine diaphragm assessment during and after surgery to identify phrenic nerve damage mechanisms, guide strategies to reduce respiratory complications, and ultimately improve management protocols and optimize transplant outcomes.

Disclosure: Nothing to disclose.

OPR-058 | Anti-PLP1 antibody as a biomarker in acute and chronic polyradiculoneuropathies

G. Taieb¹; T. Nguyen¹; J. El-Bechir²; C. Roué²; S. Masciocchi³; M. Gasltaldi³; A. Jentzer⁴; J. Devaux¹

¹Department of Neurology, Centre Hospitalier Universitaire Montpellier, Hôpital Gui de Chauliac, Montpellier, France; ²Institut de Génomique Fonctionnelle, Université de Montpellier, CNRS, INSERM, Montpellier, France; ³Neuroimmunology Laboratory and Neuroimmunology Research Section, IRCCS Mondino Foundation, Pavia, Italy; ⁴Laboratory of Immunology, Centre Hospitalier Universitaire Montpellier, Montpellier, France

Background and Aims: Up to 24% of patients with combined central and peripheral demyelination (CCPD) harbor IgG antibodies against proteolipid protein 1 (PLP1), a key component of CNS and PNS myelin. Given peripheral demyelination in these cases, we assessed anti-PLP1 prevalence in Guillain-Barré syndrome (GBS) and chronic inflammatory demyelinating polyradiculoneuropathy (CIDP).

Methods: Sera from GBS ($n=66$), CIDP ($n=46$), and CCPD ($n=16$) were tested for IgG/IgM against PLP1 using live cell-based assays on HEK293 cells as well as oligodendrocyte and myelinating Schwann cell/dorsal root ganglion cocultures. Clinical features of seropositive and seronegative patients were compared. Controls included autoimmune nodopathies ($n=25$), Charcot-Marie-Tooth disease ($n=20$), and healthy donors ($n=23$).

Results: Anti-PLP1 antibodies were found in 17% of GBS patients (IgG: $n=3$; IgM: $n=8$), associated with greater disability (ONLS 8 vs. 5; $p=0.019$), sensory-motor subtype (91% vs. 47%; $p=0.008$), AIDP (91% vs. 51%; $p=0.014$), and higher CSF protein (0.88 vs. 0.6 g/L; $p=0.011$). In CIDP, 24% were seropositive (IgG: $n=1$; IgM: $n=10$), linked to older age (66 vs. 55 years; $p=0.003$), greater disability (ONLS 6 vs. 4; $p=0.041$), and reduced IVIg response (36% vs. 70%; $p=0.05$). Four CCPD patients (25%) were positive. All controls were negative. Antibody binding to oligodendrocytes confirmed reactivity.

Conclusion: Anti-PLP1 antibodies, mainly IgM, correlate with severe demyelinating GBS and typical CIDP with greater disability and poorer IVIg response. These antibodies likely target conformational epitopes on myelin. Further studies are needed to confirm these findings and to determine the pathogenic actions of these antibodies.

Disclosure: Nothing to disclose.

OPR-059 | Evaluating peripherin as a biomarker of axonal damage in chemotherapy-induced peripheral neuropathy

M. Awadelkareem¹; R. Bellanti¹; D. Bennett¹; M. Lunn²
¹Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford OX3 9DU, UK; ²Department of Neuromuscular Diseases, Queen Square Institute of Neurology, University College London, London, UK

Background and Aims: Chemotherapy-induced peripheral neuropathy (CIPN) is a common, often dose-limiting adverse effect of several chemotherapeutic agents, preferentially affecting sensory neurons. Sensitive biomarkers of early axonal injury are currently lacking. Neurofilament light chain (NfL) is not specific to sensory neurons. As an initial, proof-of-concept approach, we investigated whether peripherin, an intermediate filament enriched in peripheral sensory axons, could serve as a biomarker of CIPN using human induced pluripotent stem cell (iPSC)-derived sensory neuron cultures, aiming to inform subsequent evaluation in patient samples.

Methods: Human iPSC-derived sensory neurons were exposed to a range of concentrations of vincristine or paclitaxel. Culture media were collected at 24, 48, and 72 h and analysed for peripherin using Simoa and NfL using an electrochemiluminescence assay. Axonal integrity was quantified by an axonal degeneration index using immunostaining and confocal microscopy. To explore mechanistic linkage, parallel cultures were treated with a small-molecule SARM1 inhibitor to block the Wallerian degeneration pathway.

Results: Peripherin release into culture media increased in a dose- and time-dependent manner with both vincristine and paclitaxel, correlating with the progression of the axonal

degeneration index and levels of NfL. Levels of both biomarkers were lower in cultures treated with SARM1 inhibitor, indicating reduced axonal degeneration.

Conclusion: In vitro, peripherin shows promise as a biomarker of chemotherapy-related axonal damage. Work is underway to measure peripherin and NfL in large, deeply phenotyped patient cohorts of CIPN. We will determine whether axonal fluid biomarkers correlate with clinical features and existing outcome measures, and evaluate their individual and combined contributions to clinical evaluation.

Coma and Chronic Disorders of Consciousness

OPR-060 | Reconstructing treatment preferences for patients with disorders of consciousness: A longitudinal qualitative study

N. Kok¹; J. Van Gurp¹; W. Van Erp²

¹Radboudumc, Department of IQ Health, Section Ethics of Healthcare, Nijmegen, The Netherlands; ²Radboudumc, Department of Primary Care, Nijmegen, The Netherlands

Background and Aims: For patients with neurological conditions that impair their capacity to participate in shared decision-making, guidelines recommend that physicians help surrogates to reconstruct these patients' treatment preferences. This study's objective was to explore the way physicians reconstruct preferences for patients with disorders of consciousness (DoC).

Methods: This 2-year longitudinal qualitative case study took place in the specialized Dutch chain of care patients with DoC. Eligible patients (>18 years of age) had a Coma Recovery Scale-revised based diagnosis of unresponsive wakefulness syndrome or minimally conscious state. Interactions between physicians and surrogates were audio-recorded. Additionally, we interviewed healthcare professionals.

Results: Characteristics of included patients are reported in Table 1. Across 16 observed healthcare trajectories, 46 physician-surrogate interactions were audio-recorded and 32 healthcare professionals were interviewed. We identified five recurring activities physicians' support of surrogates in reconstructing treatment preferences (Table 2): (1) clarifying responsibilities, (2) exploring clues that point to patient's preferences, e.g., the patient's described personality or identity and verbal advance directives, (3) discussing the preferences revealed by the patient's behavior, (4) establishing the minimal level of functioning thought to result in an acceptable quality of life, and (5) discussing sources of surrogate bias. More interactions involved an exploration of patients' personality or identity (51.2%) than prior expressed wishes (25.6%). Inferring preferences from the patient's behavior was important for continuing or withdrawing life-sustaining treatment.

Methods: In a prospective longitudinal cohort ($n=250$) with impaired consciousness after traumatic or non traumatic brain

Results: Late LOR latency was dissociated from same day behavioral responsiveness yet independently predicted improvement

A PLR and late LOR: Mixed-effects modeling of current consciousness ('today')
 PLR is associated with same-day PFCM score, but not LOR

B Sedation-dependent effect of late LOR on consciousness recovery ('next week')
 Late LOR predicts PFCM 7 days later in non-sedated patients

C Etiology-dependent effect of late LOR on consciousness recovery ('next week')
 Late LOR and 7-day recovery in the fully sedated model

European Journal of Neurology, 2026

FIGURE 3 Longitudinal NPi values across ICU days and levels of consciousness. Daily NPi recordings are shown for 250 DoC patients.

in FOUR scores seven days later, beyond baseline FOUR and time since injury. The prognostic relationship was modified by sedation status and etiology, with effects most evident in non-sedated patients and predominantly among those with anoxic-ischemic injury (etiology interactions exploratory). In contrast, PLR based metrics, including Neurological Pupil Index and PLR latency, did not predict later gains in consciousness despite being within normal ranges early after injury.

Conclusion: Conclusion: Late LOR latency captures recovery related pupillary dynamics that anticipates clinically meaningful improvement in consciousness.

OPR-062 | Baseline pupillometry reveals dissociation between the pupillary light reflex and late light off response in acute brain injury

S. Stückler¹; P. P. Laigaard¹; A. Eigenbrodt¹; M. Hassani¹;
N. Kühl²; D. Kondziella¹

¹Department of Neurology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; ²Department of Applied Mathematics and Computer Science, Cognitive Systems, Danish Technical University (DTU), Lyngby, Denmark

Background and Aims: We investigated whether distinct components of the automated pupillary reflex – including the

pupillary light-off response (LOR) – measured in the intensive care unit (ICU) reflect level of consciousness after acute brain injury, beyond summary metrics such as the Neurological Pupil Index (NPI).

Methods: In a prospective cohort of 250 ICU patients with acute brain injury and impaired consciousness, alongside 30 age- and sex-matched healthy controls, we performed standardized automated pupillometry during the early ICU period. Within a single measurement, we quantified the pupillary light reflex (PLR), decomposed LOR into early and late components, and computed late LOR latency (T50: time to 50% dilation ≥ 3 s after light offset), normalized to controls. Associations with concurrent level of consciousness, measured by the Full Outline of UnResponsive-ness (FOUR) score, were assessed using mixed effects models adjusted for ICU Day, baseline severity, sedation, and injury etiology.

Results: In acute coma, PLR and early LOR components were largely preserved. In contrast, late LOR latency was markedly attenuated despite normal NPi-values and showed substantial interindividual variability. Unsupervised hierarchical clustering of raw pupillary waveforms demonstrated a selective loss of delayed pupillary dilation early after injury. PLR latency showed a strong association with same day FOUR scores, whereas late LOR latency was not correlated with concurrent behavioral responsiveness.

Conclusion: Pupillometry reveals dissociable features of the pupillary reflex arc in coma which are not captured by conventional metrics, indicating that PLR and late LOR index distinct aspects of brainstem–arousal network function early after brain injury.

Background and Aims: Prolonged disorders of consciousness (PDOC) include the unresponsive wakefulness syndrome and the minimally conscious state. Long-term outcomes following specialized intensive neurorehabilitation are largely unknown, complicating personalized decision-making. This study aimed to determine the 2-year outcomes of PDOC patients in the Netherlands regarding consciousness, mortality, disability, functioning, and independence.

Methods: Prospective cohort study including PDOC patients ≥ 16 years admitted to the nationwide Dutch PDOC chain of care (2019–2023). Baseline measurements at admission to Early Intensive Neurorehabilitation (EIN): Coma Recovery Scale-Revised (CRS-R), Disability Rating Scale (DRS), Functional Independence Measure (FIM). Follow-up at 14, 28, 40, 52, and 104 weeks post-admission. Mortality, recovery of consciousness, functional outcomes, and independence (FIM ≥ 78) were analysed using descriptive statistics and generalized estimating equations.

Results: Of 129 enrolled patients (mean age 38 years; 52% male), 43% regained consciousness during EIN, with an additional 19% within 2 years. Overall, 62% recovered consciousness. Functional independence increased from 4% at 14 weeks to 41% at 2 years among conscious survivors. The most substantial improvements in DRS and FIM occurred between 14–28 weeks post-admission, with continued, though smaller, gains up to 2 years. Mortality was 26%, predominantly following a decision to withhold or withdraw life-sustaining treatment.

Conclusion: PDOC patients demonstrate significant recovery of consciousness and functional independence during the first 2 years of specialized rehabilitation, predominantly within the first 9 months. These findings emphasize the importance of early, intensive, and prolonged neurorehabilitation and support informed decision-making in severe acquired brain injury.

Disclosure: Nothing to disclose.

Background and Aims: Cerebellum plays an increasingly recognized role in gait modulation and freezing of gait (FoG) in Parkinson's disease (PD). This study investigated gait kinematics, cerebellar structural and functional connectivity (FC) changes in PD patients with and without FoG (PD-FoG, PD-NO-FoG).

Methods: Thirty PD-FoG, 30 PD-NO-FoG (with postural instability and gait disorders), and 30 healthy controls (HC) underwent clinical, gait analysis and MRI evaluations. Seed-based FC used cerebellar vermis as region of interest, based on volumetric findings.

Results: PD-FoG showed lower balance confidence and greater impact of symptoms on daily activities than PD-NO-FoG, while cognitive performance was similar. PD groups exhibited reduced stride length, foot-strike angle, and gait velocity. PD-FoG displayed higher asymmetry, slower Timed-Up-and-Go (TUG) relative to HC, and slower turning velocity, greater stride variability, and shorter turning stride length than PD-NO-FoG; while PD-NO-FoG showed reduced trunk mobility and gait rhythm relative to HC. MRI analyses revealed reduced cerebellar lobule-VI volume in PD vs. HC. PD-FoG showed increased volumes of lobule-VIIIb, vermis-X, and vermis-Crus-II then PD-NO-FoG. Resting-state FC analyses demonstrated increased vermis connectivity with frontal and cerebellar areas (VI, IX, vermis-VII, and Crus-I) in PD-FoG relative to HC, while PD-NO-FoG showed enhanced FC between vermis and postcentral, middle temporal, and occipital cortices. In PD-FoG, increased cerebellar FC correlated with increased cerebellar volume,

which also correlated with worse gait parameters; reduced frontal areas FC correlated with worse depression.

Conclusion: PD-FoG patients displayed specific alterations. Increased FC of cerebellum suggests an attempt to hyper-control movement that may result in increased volume related to overuse.

OPR-065 | NIO752, a tau-targeting antisense oligonucleotide, in progressive supranuclear palsy: Phase I results and phase III design

C. Serban¹; G. Höglinger²; A. Boxer³; H. Gunduz-Bruce⁴; N. Pezous¹; L. Kovacic¹; A. Pethe⁵; A. Graf¹; M. Brys⁵

¹Novartis Pharma AG, Basel, Switzerland; ²Neurology, LMU Hospital, Munich, Germany; ³Fein Memory and Aging Center, Department of Neurology, University of California, San Francisco, USA; ⁴Novartis BioMedical Research, Cambridge, USA; ⁵Novartis Pharmaceuticals, East Hanover, USA

Background and Aims: Progressive supranuclear palsy (PSP) is a rare, debilitating primary tauopathy with no effective therapies. NIO752, an antisense oligonucleotide (ASO), inhibits MAPT mRNA translation, reducing production of all tau protein isoforms and pathogenic aggregation into neurofibrillary tangles, and thereby potentially attenuating tau-mediated neurodegeneration. NIO752 is being investigated in PSP for its potential to slow clinical progression. Here we present results from

the first-in-human Phase I study (NCT04539041) of NIO752 in PSP and Phase III development plans.

Methods: In the Phase I, randomized, double-blind, placebo-controlled, multiple dose-escalation study, eligible patients had a PSP diagnosis for <5 years classified as probable PSP Richardson syndrome (PSP-RS). Patients received intrathecal NIO752 or placebo. The Phase III randomized, double-blind, placebo-controlled, parallel group study will enroll patients with possible/probable PSP-RS for <5 years to receive NIO752 or placebo. The goal is to evaluate efficacy and safety of NIO752.

Results: In the Phase I study, 59 patients were enrolled to receive NIO752 ($n=45$) or placebo ($n=14$). Median time since diagnosis was 1.6 years (range: 0.3–4.8 years). NIO752 had an acceptable safety profile; most adverse events were mild to moderate and consistent with the nature of PSP. Serious adverse events were reported in treatment and placebo cohorts at similar rates. Pharmacokinetic profile and exploratory biomarker data will also be presented.

Conclusion: NIO752 is the first MAPT ASO investigated as a potential PSP treatment. Phase I results support proceeding to Phase III to establish the potential of NIO752 as a disease-modifying therapy in PSP-RS.

OPR-066 | Efficacy and safety of dimethyl fumarate in Friedreich ataxia: A phase 2, randomized, double-blind, placebo-controlled DMF-FA-201 trial

C. Pane; M. Gramaglia; A. Sarnataro; A. Bonfini Rendina; G. Puorro; A. Marsili; C. Giannini; C. Linguetta; V. Giordano; L. Aliberti; G. Esposito; A. De Mare; A. Cittadini; A. Marra; F. Saccà

University of Naples Federico II, Napoli, Italy

Background and Aims: FA is an autosomal recessive neurodegenerative disease. Compared to controls, FXN gene expression is 20% in patients and 50% in healthy carriers. Treatment of multiple sclerosis patients with DMF is known to increase FXN expression by 70%. Objective of the study was to evaluate the efficacy and safety of Dimethyl fumarate (DMF) in patients with Friedreich Ataxia (FA).

Methods: We conducted a phase II trial with a randomized, placebo-controlled, 12 weeks phase, and an identical extension open-label phase (Figure 1). Primary endpoint was the efficacy of DMF on FXN gene transcription. Secondary objectives were: frataxin protein, stimulation of the nrf2 pathway and mitochondrial biogenesis, safety and tolerability, and clinical measures of disease (Figure 2). EudraCT number: 2021-006274-23.

Results: 140 patients (female, 57.5%; mean [SD] age, 36.1 [12.6] years; disease duration 16.8 [6.9] years), were randomized (DMF $n=20$, placebo $n=20$). At the end of the core phase, 33 patients continued to the open-label extension. DMF increased FXN gene expression after 12 weeks of treatment (difference compared to

FIGURE 1

FIGURE 2

FIGURE 3

placebo +119.0%, 95% CI +55.3, +182.7, $p=0.018$; Figure 3). In the DMF-DMF group FXN expression increased to +205% after 24 weeks compared to baseline ($p<0.001$). Secondary endpoints showed a non-significant trend towards improvement after treatment. Frequent adverse events were gastrointestinal, flushing, eosinophilia, lymphopenia, and elevated liver enzymes.

Conclusion: DMF significantly increases transcription of the FXN gene, with long-term stability, to a degree that restores expression levels to those of healthy carriers. The drug appeared safe, with adverse events consistent with DMF pharmacovigilance.

³Stereotactic Neurosurgery and Radiosurgery Unit, Department of Neurosciences, Azienda Ospedaliera Universitaria Integrata, Verona, Italy; ⁴Neurology Unit, Department of Neurosciences, Azienda Ospedaliera Universitaria Integrata, Verona, Italy; ⁵Neurosurgery Section, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona, Verona, Italy

Background and Aims: MR-guided focused ultrasound (MRgFUS) is an established treatment for essential tremor when targeting the ventral intermediate nucleus (VIM), whereas its efficacy in dystonic tremor (DT) remains uncertain. Emerging evidence suggests that a more anterior targeting may improve clinical outcomes. Based on the involvement of distinct circuits, we explored a dual-target approach combining VIM and Ventralis oralis (Vo) targeting.

Methods: Initial treatment targeted the VIM using standard stereotactic coordinates. In cases of partial tremor control, additional targeting of the most anterior (i.e., pallidal) portion of the Vo was performed. Efficacy was assessed by changes in CRST A + B scores of the treated hand at 1 and 6 months, while functional outcomes were evaluated using CRST Part C. Safety was assessed through systematic collection and grading of adverse events (AEs).

Results: Fifteen patients (6 female; mean age 68.3 ± 5.8 years) with DT underwent dual-target thalamotomy. Significant improvements in tremor severity were observed at both follow-up timepoints, reflected by reductions in CRST A + B scores of the treated hand (-56% and -60% at 1 and 6 months, respectively). Functional improvement was observed on CRST Part C (-60% and -61% at 1 and 6 months). A total of 22 AEs were recorded

FIGURE 1 Boxplots of the Clinical Rating Scale for Tremor (CRST) scores at T0, T1, and T2, showing a significant post-treatment reduction in CRST A + B for the treated hand, CRST C, and total CRST scores.

across all timepoints, all of which were mild. At the last available follow-up, only two AEs persisted (worsening of pre-existing

FIGURE 2 Axial T2 MRI sequence showing dual lesion at 1-month follow-up.

gait instability and finger hypoesthesia), both occurring in the same patient.

Conclusion: These preliminary findings suggest that a dual-target MRgFUS thalamotomy approach is feasible in patients with DT and is associated with an acceptable safety profile.

Disclosure: Nothing to disclose.

OPR-068 | Motor outcomes and network effects of adaptive deep brain stimulation programming in Parkinson's disease

Background and Aims: In Parkinson's disease (PD), adaptive deep brain stimulation (aDBS) of the subthalamic nucleus (STN) may enhance clinical benefits and reduce side effects compared with conventional DBS (cDBS). In single-drive aDBS (SD-aDBS), bilateral stimulation is modulated using local field potentials (LFPs) recorded from one hemisphere, making interhemispheric coupling a critical determinant of appropriate

stimulation. Here, we investigated the effects of chronic cDBS and SD-aDBS on subthalamic interhemispheric coupling in PD. **Methods:** Twelve PD patients were treated in a randomized, double-blind crossover design with cDBS and SD-aDBS (AlphaDBS, Newronika) for two consecutive weeks per condition, with dopaminergic medication unchanged. In SD-aDBS, stimulation amplitude was adjusted every minute using a linear proportional algorithm based on patient-specific beta-range STN-LFP amplitude. Motor symptoms were assessed using the MDS-UPDRS-III at baseline (stim-OFF/meds-OFF) and after each treatment period (stim-ON/meds-ON). ON- and OFF-time percentages were derived from Hauser diaries. Continuous STN-LFP recordings were decomposed into periodic and aperiodic spectral components. Interhemispheric coupling was quantified using Pearson's r^2 for aperiodic offset and slope, and low-beta (12–20 Hz) and high-beta (21–30 Hz) oscillatory amplitudes.

Results: cDBS and SD-aDBS yielded comparable motor improvement (mean MDS-UPDRS-III change: 59% vs. 58%), with greater ON-time during SD-aDBS. Ten of twelve patients blindly preferred SD-aDBS. Interhemispheric coupling was significant under both conditions. Low-beta interhemispheric coupling was higher during cDBS than SD-aDBS and, during SD-aDBS, positively correlated with OFF-time.

Conclusion: Chronic cDBS and SD-aDBS differentially modulate subthalamic interhemispheric coupling, with a greater reduction during SD-aDBS. This mechanism may contribute to its additional clinical value.

FIGURE 1 Immunolocalization of oligomeric α -syn and mitochondria. (A) Representative immunofluorescence of oligomeric α -syn (Syn33, green) and HSP60 (red) in ONs from healthy controls and PD. Nuclei: DAPI (blue). Scale bar: 10 μ m.

Methods: ONs obtained by nasal brush from 41 well-phenotyped patients with PD ($n=24$ PD de novo [PDdn] and $n=17$ under treatment [PDtr]) and 29 healthy controls were examined through real-time polymerase chain reaction (RT-PCR), immunofluorescence, and Western blot. An integrative set of experiments using SH-SY5Y neuronal cells was also performed. **Results:** PD ONs accumulated α -synuclein oligomers in association with an aberrant subcellular distribution of mitochondrial markers COX IV and HSP60. DJ-1 ONs expression was permanently reduced in PD, revealing the mitochondrial dysfunction and justifying the defective Nrf2-mediated cytoprotective response. The Nrf2/SOD-1 pathway was indeed downregulated in PD ONs, although with stage-specific differences. In PDdn ONs, Nrf2 mostly presented in the inactive cytosolic localization with a major reduction of SOD-1 expression, whereas in PDtr, the Nrf2 active nuclear fraction increased, and the SOD-1

FIGURE 2 Graphs showing immunofluorescence intensity of oligomeric α -syn in each group, quantified with ImageJ. Data are mean $\pm$ SEM. Asterisks indicate significant differences by unpaired t test or 1-way ANOVA with Tukey post hoc. *** $p < 0.001$.

expression raised. In SH-SY5Y cells, we demonstrated that dopamine administration increases the Nrf2 nuclear fraction, acting as a possible pathway's inducer.

Conclusion: Human-derived ONs may recapitulate PD pathogenic milestones, exhibiting stage-specific interactions among α -synuclein oligomers, mitochondrial metabolism, and cytoprotective response. These findings highlighted mitochondrial dysfunction as primary target for therapeutic interventions and a potential axis for the biological stratification of patients. Moreover, they supported the translational value of ONs, as a source of biomarkers or models, which is critical in the current changing paradigm of PD toward a biological-based approach.

Autonomic Nervous System Diseases 2

OPR-070 | Haemodynamics of supine graded exercise and orthostatic blood pressure in autonomic failure

A. van der Stam; E. Barnes; Z. Jiang; G. Chiaro; V. Iodice
National Autonomic Centre, National Hospital for Neurology and Neurosurgery, London, UK

Background and Aims: The prevalence of exercise-induced hypotension and exacerbation of post-exercise orthostatic hypotension across phenotypes of autonomic failure is currently not well documented. In this work, we aimed to fill this gap as both symptoms can significantly impair mobility, quality of life and rehabilitation efforts.

Methods: We performed a retrospective analysis of blood pressure (BP) and heart rate (HR) recorded with Dinamap during supine rest, supine graded cycling exercise (25W, 50W, 75W) and an active standing test before and after exercise. Additionally, the orthostatic intolerance ratio (OIR) was calculated. Participants ($n=140$) were diagnosed with Parkinson's disease/Lewy body dementia (PD/LBD, $n=32$), multiple system atrophy (MSA, $n=16$), pure autonomic failure (PAF, $n=41$), autoimmune autonomic ganglionopathy (AAG, $n=13$), peripheral autonomic neuropathy ($n=27$), or rare disorders featuring autonomic failure ($n=11$).

Results: Systolic BP (SBP) did not increase during exercise in 69 (52%) people (Figure 1, Table 1). Different patterns were observed in post-exercise supine recovery of SBP (Figure 2). The magnitude of the SBP drop upon standing did not increase post-exercise compared to pre-exercise, but the absolute SBP

FIGURE 1 Systolic blood pressure during supine graded exercise, split into those who had an increase in systolic blood pressure during exercise (INC) and those who had a decrease during exercise (DEC) (-19.6 mmHg per exercise increment, $p < 0.001$).

FIGURE 2 Recovery of supine systolic blood pressure during a 10-min post-exercise rest. Measurements were taken at 1, 2, 5 and 10 min after cessation of exercise, and compared to the pre-exercise supine baseline. * $p < 0.05$; ** $p < 0.001$.

TABLE 1 Blood pressure response during and after supine graded exercise. Includes supine and standing SBP, change in SBP and the Orthostatic Intolerance Ratio (OIR). * $p < 0.05$; ** $p < 0.001$.

	SBP decrease during exercise	Supine SBP (10 min post-exercise)	Standing SBP (post vs pre-exercise)	Delta SBP	OIR
PD/LBD	11 (38%)	+	+	+	+
MSA	10 (67%)	+	+	+	+
PAF	20 (73%)	+	+	+	+
Peripheral	0 (33%)	+	+	+	+
AAG	7 (54%)	+	+	+	+
Other	3 (20%)	+	+	+	+

was lower in those with alpha-synucleinopathies (Table 1). The OIR only worsened in those with MSA (Table 1). HR increased during exercise and did not fully recover during 10 min of post-exercise supine rest.

Conclusion: An abnormal BP response to exercise is common in autonomic failure, and the baroreflex impairment in alpha-synucleinopathies exacerbates orthostatic hypotension post-exercise. Both should be considered when advising on physical activity and rehabilitation in clinic.

Disclosure: Nothing to disclose.

OPR-071 | Autonomic involvement across the spectrum of genetic prion diseases

F. Vitali¹; G. Chiaro¹; T. Mok²; S. Mead²; V. Iodice¹
¹National Autonomic Centre, National Hospital for Neurology and Neurosurgery, London, UK; ²NHS National Prion Clinic, National Hospital for Neurology and Neurosurgery, University College London Hospitals NHS Foundation Trust, London, UK

Background and Aims: Genetic prion diseases (gPrDs) are fatal neurodegenerative disorders caused by pathogenic PRNP mutations. Among them, fatal familial insomnia (FFI) and PrP systemic amyloidosis (PrP-SA) show prominent autonomic nervous system involvement. FFI is marked by selective thalamic degeneration, leading to sleep disruption and cardiovascular sympathetic dysregulation. PrP-SA, in contrast, involves

systemic amyloid deposition affecting peripheral organs and nerves, resulting in early gastrointestinal dysfunction, sensorimotor neuropathy, and widespread autonomic failure.

Methods: This study aimed to assess cardiovascular autonomic involvement across gPrDs, focusing on FFI and PrP-SA. We retrospectively evaluated 5 patients with FFI, 6 with PrP-SA, and 3 asymptomatic PRNP variant carriers. Cardiovascular autonomic function was assessed using standardized autonomic testing (AFT) with Finapres® NOVA plus and 24-h blood pressure monitoring.

Results: At the time of assessment (median age 44 years; IQR: 33–52), all symptomatic patients ($n = 11$) reported autonomic symptoms, predominantly affecting cardiovascular, gastrointestinal, and urogenital systems. FFI patients exhibited sympathetic overactivity – supine hypertension, nocturnal hypertension, and resting tachycardia – alongside AFT evidence of cardiovagal and adrenergic impairment. In contrast, PrP-SA showed combined sympathetic and parasympathetic failure, characterized by neurogenic orthostatic hypotension, reduced heart rate variability, and poorer postural tolerance than FFI patients. Asymptomatic carriers displayed subtle AFT abnormalities despite the absence of clinical symptoms.

Conclusion: FFI and PrP systemic amyloidosis exhibit distinct autonomic phenotypes – central dysregulation in FFI and peripheral autonomic failure in PrP-SA. Routine autonomic assessment may facilitate early detection and targeted symptom management across the spectrum of gPrDs.

Disclosure: Nothing to disclose.

OPR-072 | Linking autonomic dysfunction, immune adrenergic signaling, and neurofilament light chain in multiple sclerosis

M. Sredanović¹; K. Jerčinović²; K. Tešija¹; A. Savić Mlakar³; Ž. Vogrinč⁴; I. Adamec¹; Ž. Cvetić³; T. Tunjić⁴; T. Gabelić¹; B. Barun¹; K. Bendelja³; M. Krbot Skorić¹; M. Habek¹
¹University Hospital Center Zagreb; ²School of Medicine, University of Zagreb, Zagreb, Croatia; ³Center for Research and Knowledge Transfer in Biotechnology, University of Zagreb; ⁴University Hospital Center Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia

Background and Aims: To investigate the association between autonomic dysfunction and immune cell neurotransmitter receptor expression in people with multiple sclerosis (pwMS), and to explore relationships with serum neurofilament light chain levels (sNfL) as a marker of disease activity.

Methods: Autonomic dysfunction was assessed in 68 pwMS using the Composite Autonomic Scoring Scale (CASS). Expression of Adrenoceptor Beta 2 (ADRB2), Nicotinic Acetylcholine Receptor $\alpha 7$, Dopamine Receptors D3 and D5, Interleukin-1 receptors (IL1R1, IL1R2, IL1R8), and Interleukin-23 receptor was measured on T- and B-lymphocyte subsets, natural killer (NK) cells, and monocytes. Serum neurofilament light chain levels were quantified using the Roche Elecsys NfL assay.

Results: PwMS with objective autonomic dysfunction showed significantly lower ADRB2 expression on total T cells ($p = 0.037$), cytotoxic T cells ($p = 0.016$), including memory and naïve subsets, B lymphocytes ($p = 0.019$), and NK cells ($p = 0.026$), compared with pwMS with normal autonomic function. No differences

were observed for other neurotransmitter or cytokine receptors. sNfL levels did not differ between groups; however, sNfL negatively correlated with ADRB2 expression on cytotoxic T cells ($r = -0.294$, $p = 0.015$), including effector/memory and naïve non-regulatory subsets.

Conclusion: Autonomic dysfunction in pwMS is associated with reduced ADRB2 expression across multiple immune cell populations, suggesting altered adrenergic neuroimmune regulation. The inverse relationship between ADRB2 expression on cytotoxic T cells and sNfL levels points to a potential link between impaired adrenergic signaling and inflammatory disease activity in multiple sclerosis.

OPR-073 | Pattern and progression of sudomotor dysfunction in alpha synucleinopathies

Z. Jiang; G. Chiaro; V. Iodice
National Autonomic Centre, The National Hospital for Neurology and Neurosurgery, London, UK

Background and Aims: Pure autonomic failure (PAF) is an alpha-synucleinopathy with a 30%–40% risk of phenoconversion to Parkinson's disease (PD), dementia with lewy bodies (DLB), or multiple system atrophy (MSA). While several biomarkers have been proposed to predict phenoconversion, sudomotor dysfunction remains underexplored. This study examined the distribution and longitudinal progression of sweat loss in patients with PAF.

Methods: As part of an ongoing natural history study, consecutive patients diagnosed with PAF were systematically phenotyped and followed longitudinally until phenoconversion or death. Sudomotor function was assessed using thermoregulatory sweat testing (TST) and dynamic sweat testing (DST). Combined results were used to localize sudomotor dysfunction as preganglionic, postganglionic, or mixed.

Results: 69 PAF patients underwent sudomotor testing: 40/69 (58%) completed TST and 45/69 (65%) completed DST. On TST, 29/40 (73%) demonstrated global anhidrosis, 8/40 (20%) length-dependent sweat loss, 2/40 (5%) regional anhidrosis, and 1/40 (2%) unilateral anhidrosis. Among those with global anhidrosis, 22/29 (76%) remained PAF, 3/29 (10%) developed DLB, and 4/29 (14%) developed MSA. Patients without global anhidrosis either remained PAF or phenoconverted to PD/DLB. DST showed reduced sweating in 43/45 patients (95.5%) and a predominantly length dependent distribution in patients with stable PAF compared with MSA, with no difference in the rate of sweat output decline over time.

Conclusion: Global anhidrosis is the most common sudomotor pattern in MSA and is associated with a non-length-dependent impairment of postganglionic sudomotor fibres. In contrast, a

FIGURE 1 Pattern of anhidrosis.

length-dependent sudomotor deficit is more suggestive of a restricted postganglionic alpha-synucleinopathy, such as PAF.

Disclosure: Nothing to disclose.

Ageing and Dementia 2

OPR-074 | Plasma ApoE proteotyping on Lumipulse for ApoE epsilon4 determination: A clinically practical tool in the era of anti-amyloid therapies

F. Coraglia¹; G. Cecchetti²; G. Rugarli¹; E. Spinelli¹; A. Ghirelli¹; S. Pisano³; E. Canu³; F. Caso⁴; G. Magnani⁴; M. Filippi⁵; F. Agosta¹

¹Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ²Vita-Salute San Raffaele University, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁴Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: To determine whether plasma-based quantification of apolipoprotein E4 (ApoE4) and total apolipoprotein E (PanApoE) using a Lumipulse immunoassay can reliably identify APOE epsilon4 carrier status as a practical alternative to genetic testing in patients along the Alzheimer's disease (AD) continuum.

Methods: We retrospectively included 110 patients with cognitive impairment evaluated at a tertiary memory clinic. APOE genotyping classified individuals as epsilon4 non-carriers, heterozygous, or homozygous carriers. Plasma ApoE4 and PanApoE were measured using the Lumipulse 600 G platform, and the ApoE4 to PanApoE ratio was calculated. Additional plasma biomarkers were assessed, including AB40, AB42, pTau181, pTau217, NfL, GFAP, and sTREM2. Diagnostic accuracy for epsilon4 carrier identification was assessed using receiver operating characteristic analyses, deriving area under the curve values and optimal Youden thresholds.

Results: The ApoE4 to PanApoE ratio increased stepwise with epsilon4 allele dose, with complete separation between carrier status. For identifying epsilon4 carriers, the ratio achieved perfect discrimination, with an area under the curve of 1.00 and no misclassified individuals at the optimal cut-off. ApoE4 concentration alone showed substantially lower accuracy. No significant differences were observed in other plasma AD biomarkers between epsilon4 carriers and non-carriers.

Conclusion: The ApoE ratio measured on the Lumipulse platform accurately reflects APOE epsilon4 status and allele dose. This prototype-based approach may represent a rapid and accessible alternative to genotyping to support risk stratification and decision-making in the anti-amyloid treatment era.

Besta Neurological Institute and Foundation (IRCCS), Milano, Italy; ⁹Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; ¹⁰Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Frontotemporal lobar degeneration (FTLD) includes heterogeneous neuropathological and clinical profiles often overlapping with Alzheimer's disease (AD). Neuroimaging is essential for differential diagnosis alongside biomarkers and clinical assessment. We validated a deep learning approach for classifying behavioral variant frontotemporal dementia (bvFTD), AD, and healthy controls (HC) using single high-resolution T1-weighted MRI scans.

Methods: 3T T1-weighted MRI scans from 120 bvFTD, 147 AD, and 202 HC from five institutions were analyzed, plus 651 scans (293 AD, 358 HC) from ADNI. 3D convolutional neural networks (CNNs) were implemented in PyTorch using raw MRI volumes. Data were stratified by center and split into training (64%), validation (16%), and test (20%) sets, with random augmentation. Two architectures were evaluated: fully convolutional and convolutional-pooling networks. Performance was measured by balanced accuracy and F1-score. Grad-CAM maps were generated for the best model to identify regions driving class-specific predictions.

Results: The best model was the fully convolutional network, achieving 72% balanced accuracy and 77.7% F1-score with class-specific F1-scores of 67% (bvFTD), 76% (AD), and 82% (HC). Grad-CAM highlighted the right frontal lobe for bvFTD, bilateral parietal cortices for AD, and periventricular regions for HC, demonstrating anatomically plausible patterns.

Conclusion: Our findings support structural MRI as a potential biomarker for early disease screening using end-to-end CNN models. While performance was lower for bvFTD, likely

reflecting heterogeneity and sample imbalance, anatomically plausible patterns were identified. CNN-based MRI analysis may serve as a complementary tool for early differential diagnosis of neurodegenerative disorders.

Background and Aims: To report feasibility, safety, and early biological outcomes of lecanemab and donanemab therapy for early Alzheimer's disease (AD) in a real-world tertiary setting.

Methods: This observational study included consecutive patients treated with anti-amyloid antibodies at the San Raffaele Memory Center (Milan, Italy) between September 2024 and October 2025. All patients fulfilled clinical and biomarker criteria for mild cognitive impairment or mild dementia due to AD. Lecanemab (10 mg/kg biweekly) and donanemab (350–1400 mg monthly titration) were administered under EMA-aligned protocols with standardized MRI monitoring. Safety outcomes included amyloid-related imaging abnormalities (ARIA) and infusion-related reactions (IRR). Biological effects were assessed using amyloid-PET Centiloid quantification, plasma biomarkers, and cognitive measures at 6 months.

Results: Twenty-nine treatment courses were delivered (9 lecanemab, 20 donanemab). ARIA-E occurred in 2 (10%) and ARIA-H in 3 (15%) donanemab-treated patients, all resolving with corticosteroids. One mild asymptomatic ARIA-H (11%) was observed with lecanemab. IRRs occurred in 6 patients (21%), all mild-to-moderate. At 6 months, cortical amyloid burden decreased by -61 ± 30 Centiloids ($p < 0.001$); 75% of donanemab-treated patients achieved PET negativity (< 11 CL). Plasma GFAP (-20 ± 26 pg/mL) and pTau181 (-0.8 ± 0.9 pg/mL) declined, while NfL showed a mild increase ($+4.4 \pm 4.7$ pg/mL). Cognitive scores (MMSE, CDR-SB) remained stable. No discontinuations occurred for safety or logistical reasons.

Conclusion: Anti-amyloid antibodies can be safely implemented in real-world tertiary centers. Amyloid clearance and plasma biomarker dynamics mirror pivotal trials, supporting the feasibility of disease-modifying therapy for AD in structured clinical practice.

OPR-077 | Frailty is associated with structural and metabolic brain changes in cognitively unimpaired adults

M. Toccaceli Blasi¹; J. Contador²; G. Bruno¹; A. González-Escalante²; I. Cumplido²; O. Grau-Rivera²; D. Váñez García²; J. Jisper²; G. Salvadó Blasco²; M. Canevelli¹; M. Suárez-Calvet²
¹Department of Human Neuroscience, "Sapienza" University, Rome, Italy; ²Barcelonaβeta Brain Research Center (BBRC), Pasqual Maragall Foundation, Barcelona, Spain

Background and Aims: Frailty is a multidimensional syndrome that entails an increased risk of dementia. Characterizing early frailty-related brain changes in cognitively unimpaired (CU) individuals may help to clarify its role in subsequent cognitive decline, particularly beyond Alzheimer's pathology.

FIGURE 1 Forest plots of linear regression models, corrected by age, sex, CSF Aβ42/40, and total intracranial volume if necessary, exploring the impact of frailty on cortical thickness.

Methods: We investigated the relationship between frailty and 3T-MRI, and [18F] FDG PET biomarkers in CU middle-aged adults from the ALFA+ cohort with available cerebrospinal fluid (CSF) Alzheimer's disease (AD) biomarkers. Frailty was assessed using a 35-item Frailty Index (FI), and its relationship with predicted brain age, global and regional cortical thickness (CTh), brain volume, white matter hyperintensities (WMH), and cerebral hypometabolism was investigated using linear regression models.

Results: Out of the 418 included participants, 57 (13.64%) were classified as frail. Frailty was associated with older predicted brain age, decreased mean, fronto-temporal and Jack's signature CTh, and hippocampal volume, as well as mean, parieto-temporal and posterior cingulate [18F] FDG uptake. Frailty was also associated with augmented white matter hyperintensities (WMH), especially in fronto-parietal and basal ganglia regions. These associations remained significant also after adjusting for CSF Aβ42/40 levels.

Conclusion: Independent of amyloid pathology, frailty was associated with atrophy, vascular damage, and hypometabolism in AD and aging regions in CU adults. These findings highlight frailty as an early contributor to brain vulnerability, potentially preceding dementia.

Disclosure: Nothing to disclose.

OPR-078 | MRI-based atrophy subtypes in a young memory clinic cohort: Associations with clinical and biomarker profiles

A. Zilioli¹; R. Mohanty²; A. Rosenberg²; A. Matton²; T. Granberg²; G. Hagman²; M. Spallazzi¹; D. Ferreira²; M. Kivipelto²; E. Westman²

¹Department of Neurology, University-Hospital of Parma, Parma, Italy; ²Division of Clinical Geriatrics, Center for Alzheimer Research, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden

Background and Aims: MRI-based brain atrophy subtypes are increasingly recognized in Alzheimer's disease (AD) dementia, but their relevance across the real-world memory clinic spectrum remains unclear. We aimed to identify atrophy subtypes in a young memory clinic cohort and examine their associations with demographics, cerebrospinal fluid (CSF) biomarkers, and cerebrovascular burden.

Methods: We included consecutive patients (subjective cognitive impairment [SCI] to dementia) evaluated at the Karolinska

Memory Clinic (2018–2023) with available 3T MRI. Subtypes were defined using FreeSurfer volumetric measures and a validated algorithm combining categorical classification (typical, limbic predominant, cortical predominant, minimal atrophy) with continuous indices of typicality and severity. Cognitive, APOE $\epsilon 4$, CSF biomarkers (A β 42, A β 42/40, p-tau181, total tau, neurofilament light [NFL]), and cerebrovascular burden were compared across subtypes. Analyses were replicated in A β -positive and anti-A β -therapy-eligible patients.

Results: Among 809 patients (median age 60years; 56.1% female), 38.2% had SCI, 44.4% MCI, and 17.4% dementia. Limbic predominant and typical subtypes showed higher male prevalence, APOE $\epsilon 4$ frequency, cerebrovascular burden, poorer memory, and greater A β positivity (all $p \leq 0.02$). The cortical predominant subtype was more frequent in females, whereas minimal atrophy was associated with milder cognitive impairment and higher depressive symptoms. In A β -positive patients ($n = 231$), typical and limbic subtypes showed higher p-tau181 and NFL levels and lower A β 42/40 ratios (all $p < 0.05$). Results were consistent across continuous atrophy measures and in patients eligible for anti-A β therapy ($n = 89$).

Conclusion: MRI-based atrophy subtypes display distinct clinical and biomarker profiles across the memory clinic spectrum, supporting their diagnostic value and relevance for biologically targeted AD trials.

Disclosure: Nothing to disclose.

FIGURE 1 Summary of demographic, cognitive assessment, CSF, and vascular profiles among the MRI-based atrophy subtypes.

FIGURE 2 Scatterplots of correlation between typicality (hippocampus/cortex ratio) and CSF biomarkers in the A β -positive cohort.

FIGURE 3 Scatterplots of correlation between severity (brain volume/CSF ratio) and CSF biomarkers in the A β -positive cohort.

⁹Neuro-Oncology Unit, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain; ¹⁰Department of Neurosciences, Psychology, Drug Research and Child Health (NEUROFARBA), University of Florence, Florence, Italy; ¹¹Neurology Unit, University Hospital of Sassari, Sassari, Italy; ¹²IRCCS Istituto delle Scienze Neurologiche di Bologna (S.R., R.R., M. Guarino), Italy; ¹³ASST-Spedali Civili di Brescia, Montichiari, Italy;

¹⁴Neurology Department, Centre d'Esclerosi Múltiple de Catalunya (Cemcat), Hospital Universitari Vall d'Hebron, Vall d'Hebron Institut de Recerca, Barcelona, Spain; ¹⁵Neurology

Background and Aims: Immune-related adverse events (irAEs) can occur after the administration of immune-checkpoint inhibitors (ICI). De novo demyelinating irAEs (DEM-irAEs) are rare, poorly characterized and often challenging. We aimed to define the demographic, clinical, therapeutic and prognostic features of DEM-irAEs.

Methods: We conducted a multicentric retrospective study including patients with DEM-irAEs evaluated between 2011 and 2024 in nine European neurology units. Additional cases were identified through a systematic literature review according to PRISMA guidelines. Statistical analyses were performed using R software version 4.0.3.

Results: We identified 80 patients with DEM-irAEs. Median age was 59 years (range: 9–84), with male predominance (52/80, 65%). DEM-irAEs developed after a median of 18 weeks (range: 2–178) following ICI initiation (anti-PD1 $n=49$, 61%; anti-PD-L1 $n=4$, 5%; anti-CTLA4 $n=5$, 6%; anti-PD1 plus anti-CTLA4 $n=22$, 28%). Clinical manifestations included optic neuritis ($n=17$, 8 bilateral), myelitis ($n=29$, including 24 LETM), acute disseminated encephalomyelitis ($n=6$), atypical DEM-irAEs ($n=7$), and overlapping syndromes ($n=21$). CSF-restricted oligoclonal bands (12/50, 24%) and glial autoantibodies were uncommon (11/80, 14%). Immunotherapy was administered in 74/80 (93%) of patients, mainly steroids ($n=61$), IVIg ($n=16$), plasmapheresis ($n=23$), rituximab ($n=8$), and cyclophosphamide ($n=8$). Outcomes were complete response in 15 patients (24%), partial response in 25 (40%), and no response in 22 (35%). Compared with AQP4-NMOSD ($n=42$) and MOGAD ($n=22$), DEM-irAEs showed greater attack severity and worse outcomes ($mRS>2$; $p<0.01$).

Conclusion: DEM-irAEs represent a rare and heterogeneous complication of ICI treatment. Long-term immunosuppression should be considered in selected cases, as approximately one-quarter of patients relapse, and outcomes appear worse than in AQP4-NMOSD and MOGAD.

Disclosure: Nothing to disclose.

OPR-080 | Circumventricular organ permeability to NMO IgG allows AQP4 targeting in the mouse brain

C. Peynet¹; S. Joly¹; A. Chan¹; A. Ben-Zvi²; V. Pernet¹

¹Neurology, Inselspital, Bern, Switzerland; ²Developmental Biology and Cancer Research, The Institute for Medical Research-Israel-Canada, Jerusalem, Israel

Background and Aims: The penetration of circulating aquaporin-4 (AQP4) IgG into the CNS is a major event in neuromyelitis optica (NMO)-induced astrocytopathy. After intravenous injection in rodents, recombinant AQP4 IgG predominantly accumulates in circumventricular organs (CVOs), such as the median eminence. Physiologically, protein passage through the fenestrated blood vessels of CVOs importantly contributes to brain-periphery communication. The aim of the present study

was to determine whether the median eminence is an entry site for AQP4 IgG in the mouse CNS, leading to AQP4 targeting.

Methods: AQP4 expression was examined in the brain of C57BL/6Jrj female mice by immunofluorescence on coronal sections. The biodistribution of recombinant human anti-AQP4 antibody (rAb-53) was observed 24 h after intravenous injection (7.5 mg/kg body weight). Vascular endothelial cells and tanycytes were labeled using podocalyxin and vimentin, respectively.

Results: AQP4 was present in perivascular astrocytic endfeet and in ependymal cells lining the 3rd ventricle, but not in tanycyte cell bodies which occupy a more ventral position. After intravenous injection, a high level of rAb-53 was detected within the parenchyma and around podocalyxin-positive blood vessels of the median eminence. Ependymal cells, but not tanycyte cell bodies, were also positive for rAb-53. High-resolution microscopy revealed perivascular colocalization of AQP4 and rAb-53, thus suggesting antigen-antibody interaction.

Conclusion: Our data demonstrate that AQP4 IgG reaches AQP4 in astrocytes and ependymal cells through the leaky vasculature of the median eminence in the mouse brain, suggesting that CVOs are potential entry sites for pathogenic antibodies in NMO.

OPR-081 | GAD65 epitope predictive for Stiff-person syndrome

E. Leisgang¹; I. Talucci²; S. Seefried¹; A. Wiessler³; C. Kurth¹; C. Villmann³; H. Maric⁴; C. Sommer¹

¹Department of Neurology, University Hospital Würzburg, Würzburg, Germany; ²Northwestern University, Evanston, USA; ³Institute for Clinical Neurobiology, University of Würzburg, Würzburg, Germany; ⁴Rudolf Virchow Center for Integrative and Translational Bioimaging, University of Würzburg, Würzburg, Germany

Background and Aims: Stiff-person-syndrome (SPS) is a rare but treatable neurological autoimmune disease associated with GAD65-autoantibodies (aAb). However, GAD65aAb may also be associated with other diseases, like epilepsy or ataxia. We therefore aimed at determining SPS-specific GAD65 epitopes.

Methods: Epitope binding was screened in sera ($n=46$) and cerebrospinal fluid ($n=4$) from a SPS patient cohort ($n=30$) via microarray binding assay including full positional scans. Controls included healthy controls ($n=7$), a GAD65-aAb-positive diabetes cohort ($n=10$) and a GlyR α 1-aAb SPSD cohort ($n=24$).

Results: 80% (24/30 patients) showed aAb binding to at least one out of five epitopes (E1–E5) and a single dominant epitope

J. Brenner¹; A. Tolido¹; Y. Crijnen¹; C. Ruhe¹; T. Brand¹; S. Olijslagers²; M. Mandarakas³; E. van den Berg¹; M. Titulaer¹
¹Erasmus University Medical Center Rotterdam, The Netherlands; ²Catharina Hospital Eindhoven, The Netherlands; ³UNSW Medicine and Health Sydney

FIGURE 1 Epitope mapping in Stiff person syndrome cohort reveals five distinct epitopes. Heatmap representing overview of initial screening results for GAD65 epitopes with microarray binding assay including baseline, follow up and CSF samples.

FIGURE 2 Correlation among disease and GAD65 epitope E1, E2, E3, E4 and E5. Horizontal line refers to median, error bars indicate interquartile range. Prior to conducting the one-way ANOVA, the assumption of homogeneity of variances was tested.

(E1) was recognized in 56% of all SPS samples. For 20% (6/30 patients) no aAb binding epitopes could be determined. In 14 patients epitopes were analysed before and after plasmapheresis (PE). Here we found a baseline polyclonal antibody response that disappeared after PE, only the response to E1 remained. No correlation between epitope profile and clinical phenotype was visible within the SPS spectrum. Statistical analysis validated E1 as the SPS-specific GAD65 epitope, not recognized by any of the tested controls ($p < 0.0001$).

Conclusion: Epitope screening, mapping and characterization defined five distinct GAD65 epitopes shared within SPS patients. Amongst all, E1 stands out as the strongest predictor for SPS due to its prevalence and consistency. Epitopes in SPS GAD65-aAbs and diabetes GAD65-aAbs were clearly distinct. This knowledge has the potential for more precise SPS diagnostics and broad implications for SPS pathophysiological research.

Disclosure: Nothing to disclose.

Background and Aims: Studies on the long-term cognitive abilities and psychosocial outcomes of individuals with anti-LGI1 encephalitis are scarce. Recently, a disease-specific Patient-Reported Outcomes Score for (autoimmune) Encephalitis (PROSE; score 0–100) was developed. We assessed cognitive and psychosocial recovery in a large national cohort, including the first patient-data using PROSE.

Methods: All adults diagnosed with anti-LGI1 encephalitis in the Netherlands were invited to participate, provided they could self-report and participate in cognitive testing. Patients were evaluated cross-sectionally, and those within 1.5 years of diagnosis were also followed prospectively. Functional (mRS, CASE), cognitive (comprehensive test-battery covering major cognitive domains) and self-reported outcomes (PROSE, SF-36, EQ-5D-5L, WHO-5, WHO-DAS-II, FSS, BDI, HADS) were assessed at various disease stages.

Results: We included 106 patients with anti-LGI1 encephalitis (mean age 68 years, 33% female). Two years after diagnosis, 50% of patients ($n = 37/74$) had fully recovered and returned to their regular life, while 40% had significant cognitive impairments (< -1.5 SD below norm) in at least one domain, most commonly verbal memory (average z-score > 2 years -1.12 , $SD = 0.90$). Cognitive recovery plateaued around 24 months post-treatment, whereas psychosocial recovery often continued for at least 3 years after treatment (PROSE mean score < 1 year: 30, > 3 years: 26).

Conclusion: Anti-LGI1 is a serious neurological condition. Around 50% fully recovers but many experience lasting cognitive and psychosocial difficulties, and would benefit from long-term monitoring and targeted rehabilitation. We outline the recovery trajectory of anti-LGI1 encephalitis and present the first patient data on the disease-specific PROSE.

Disclosure: J. Brenner and M.J. Titulaer, on behalf of the Erasmus University Medical Centre, hold intellectual property rights for the PROSE.

Background and Aims: In anti-NMDA receptor encephalitis (NMDARe) delayed and slow improvement complicates assessment of treatment refractoriness, creating a larger knowledge gap in prolonged impaired consciousness. We aimed to assess these features and outcomes in patients with prolonged vegetative state. **Methods:** Retrospective cohort study of NMDARe patients who remained in vegetative state for ≥ 9 months. Outcomes were: death; achieving command-following, mRS=2, or recovery (mRS=0 with return to premorbid activities).

Results: Forty-five patients were identified (38 female; median age 22 [IQR 19–31]). All had impaired consciousness 9 (5–16) days after symptom onset. All received first-line immunotherapy; 41 (91%) second-line, and 18 (40%) third-line. Twenty-one (47%) had ovarian teratomas. Median durations were: vegetative state 399 days (307–698), ICU stay 275 days (189–354), and hospitalization 474 days (349–715). Thirteen (28%) patients were resuscitated from dysautonomic cardiac arrest. After a median of 5 years (2.5–6.8), 15 (33%) recovered, 13 (29%) substantially improved (mRS ≤ 2), 11 (24%) had mRS=3–5, and 6 (13%) died. Five began command-following 11 months (1.5–21) after last immunotherapy. Estimated cumulative incidences at 5 and 10 years were 66% and 76% for achieving mRS=2, and 32% and 54%, respectively, for recovery. Teratomas were associated with lower probability of achieving mRS=2, whereas older age and higher NEOS2 score were associated with increased mortality.

Conclusion: In NMDARe, recovery from prolonged impaired consciousness is more common than expected. Early assessment of treatment response or refractoriness may underestimate delayed improvement, prolonged therapy needs, or spontaneous recovery. Futility decisions should be individualized with multidisciplinary input after extended follow-up.

OPR-084 | Investigating intravenous efgartigimod in juvenile generalized myasthenia gravis: Results from the ADAPT JR study

A. Kostera-Pruszczyk¹; A. N. Schwaede²; N. L. Kuntz²; S. Ramdas³; A. Bogatyreva⁴; J. Giacobbe⁴; F. Menezes⁴; L. Lan⁴; J. Noukens⁵; T. van Bragt⁵; E. Harmen Niks⁶

¹Department of Neurology, Medical University of Warsaw, Warsaw, Poland; ²Division of Neurology, Department of Pediatrics, Ann & Robert H. Lurie Children's Hospital of Chicago, Northwestern University Feinberg School of Medicine, Chicago, USA; ³Department of Paediatric Neurology, John Radcliffe Hospital, Oxford, UK; ⁴MDUK Oxford Neuromuscular Centre, Department of Paediatrics, University of Oxford, Oxford, UK; ⁵argenx, Ghent, Belgium; ⁶Curare Consulting BV, Liempde, The Netherlands; ⁶Department of Neurology, Leiden University Medical Center, Leiden, The Netherlands

Background and Aims: Efgartigimod is a human immunoglobulin G1 (IgG1) antibody Fc fragment that blocks the neonatal Fc receptor. Phase 3 trials (ADAPT/ADAPT+) demonstrated that intravenous (IV) efgartigimod is efficacious and well tolerated in adults with generalized myasthenia gravis (gMG). However, there remains an unmet need for treatments in patients with juvenile gMG. We present interim results from a Phase 2/3 trial assessing efgartigimod IV in juvenile participants with anti-acetylcholine receptor antibody-positive (AChR-Ab+) gMG (ADAPT JR; NCT04833894).

Methods: ADAPT JR will ultimately recruit ≥12 participants (aged 2–17 years), using a staggered design starting with an adolescent cohort (aged 12–17 years). The study comprises a single-dose confirmatory Part A (≥8 weeks) and a multiple-dose treatment-response confirmatory Part B (≥18 weeks).

Results: Eleven adolescent participants were enrolled as of February 2025. Efgartigimod treatment decreased both total IgG and AChR-Ab levels. In Part B, the mean (SE) total Myasthenia Gravis Activities of Daily Living (MG-ADL) score change between cycle baseline to Week 4 was −3.5 (0.94) and −4.0 (1.34) during Cycles 1 and 2, respectively. Quantitative Myasthenia Gravis (QMG) scores exhibited a similar trend. Minimal symptom expression (MSE; MG-ADL, 0–1) was achieved by 72.7% (Cycle 1) and 80.0% (Cycle 2) of participants. Efgartigimod was well tolerated.

Conclusion: Efgartigimod treatment was well tolerated in adolescents and resulted in decreased levels of both total IgG and AChR-Abs, similar to those observed in adult studies. Clinically meaningful improvements in MG-ADL and QMG occurred, with many participants achieving MSE. Efgartigimod may address an unmet need in juvenile gMG therapy.

OPR-085 | Patient acceptable symptom state in MG patients: A cross-sectional study

P. Szczudlik; E. Sobieszczyk; K. Badowski; D. Orzechowski; B. Szyluk; A. Kostera-Pruszczyk
Department of Neurology, Medical University of Warsaw, ERN EURO NMD, Poland

Background and Aims: To assess patient acceptable symptom state (PASS) in tertiary center cohort.

Methods: Cross-sectional study of 101 MG patients, age 60.7 ± 18.5 years, 67.3% F, 42.6% with EOMG, conducted between Feb2024 to Jun2025.

Results: 91% of patients received AChEI, 72.3% glucocorticoids (CS), 20.8% AZA, 19.8% MFM, 2% MTX, 44.6% were treated with IVIG (23.8% previous year), 12.9% with PLEX (5.9% previous year). 13.9% had history of myasthenic crisis, 15% had ocular symptoms only. 40.6% of patients were PASS-positive, with MG-ADL 4.4 ± 3.8 vs. 8.3 ± 4.1 in PASS-negative, MGQoL15 was 16.3 ± 10.5 vs. 32.2 ± 12.3, respectively ($p < 0.05$). Patients treated with CS had lower MGQoL15 (27.22 ± 13.7 vs. 16.9 ± 11.6, $p < 0.05$) as compared with untreated, with no significant differences in MG-ADL, age or sex between groups. Patients treated with IVIG or PLEX within last 12 months had worse MGQoL15 (29.9 ± 15.2 vs. 23.0 ± 13.7, $p < 0.05$) and MG-ADL (8.1 ± 5.1 vs. 5.5 ± 4.0, $p < 0.05$). Females, as compared with males were more often PASS-negative; (51.5% vs. 27.3%), had higher MG-ADL

(6.8+4.5 vs. 4.4+3.6) and MGQoL (26.8+14.0 vs. 19.7+14.2) $p<0.05$. There were no differences between PASS-positive and negative in age, history of myasthenic crisis. More patients with only ocular or no symptoms were PASS-positive (67%) compared with gMG (35%, $p<0.01$), with better MGQoL15 (9.7+10.3 vs. 28.2+12.8, $p<0.001$). Threshold for PASS-positive answer was ≤ 4.0 points in MG-ADL (sensitivity 58%, specificity 75%).

Conclusion: Nearly 60% of patients do not accept their MG state. Treatment with CS had negative impact on PASS-status despite no differences in MG-ADL, sex or age, compared with those who not CS-treated.

Disclosure: Nothing to disclose.

OPR-086 | From evidence to practice: Clinical audit of uptake of heart failure therapy in adult Duchenne muscular dystrophy at a tertiary centre

L. Sese¹; M. Guillermo²

¹Neuromuscular Complex Care Centre, National Hospital for Neurology and Neurosurgery, London, UK; ²Department of Paediatric Cardiology, Great Ormond Street Hospital for Children, London, UK

Background and Aims: Duchenne muscular dystrophy (DMD) is a progressive X-linked neuromuscular disorder that leads to dilated cardiomyopathy and heart failure with reduced ejection fraction (HFrEF) in most patients by adulthood. Despite consensus recommendations, the extent of guideline-directed medical therapy (GDMT) utilization remains varied across institutions. The objective of the study is to evaluate the proportion of patients who are receiving GDMT under specialist care at an accredited Duchenne centre.

Methods: A retrospective audit was conducted of patients aged ≥ 18 years with confirmed DMD and HFrEF under the care of an accredited Duchenne centre in January 2025. Prescription rates for key GDMT classes which include renin-angiotensin-aldosterone-system inhibitors (RAASi), beta-blockers, mineralocorticoid receptor antagonists (MRA), and sodium-glucose-co-transporter-2 inhibitors were analysed.

Results: A total of 49 patients met inclusion criteria (mean age 23.5 ± 3.9 years; mean BMI 25.8 ± 8.4 kg/m²; mean LVEF $29.7 \pm 9.1\%$). Genetic variants in the dystrophin gene included deletions ($n=32$), duplications ($n=11$), nonsense ($n=5$), and point mutations ($n=1$). 29 (59%) were on long-term corticosteroids, and 28 (57%) used chronic non-invasive ventilation. Medication

FIGURE 1 GDMT compliance.

utilisation was high: RAASi 96%, beta-blocker 100%, MRA 88%, and SGLT2 inhibitor 82% patients. Others included ivabradine in 24% and loop diuretics in 10%.

Conclusion: This audit demonstrated excellent adherence to GDMT among adults with DMD-related HFrEF under an accredited Duchenne centre, with near-universal prescription of beta-blockers and renin-angiotensin system inhibitors. SGLT2i and MRA use were also notably high which shows proactive adoption of evidence-based HF management.

Disclosure: Nothing to disclose.

OPR-087 | Rituximab in acetylcholine receptor antibody-positive generalised myasthenia gravis: A single-centre experience

M. Noushad; C. Allen; A. Pinto; F. Fatehi; G. Burke
Wessex Neuroscience Centre, Plymouth, UK

Background and Aims: This study evaluated the effectiveness of rituximab in acetylcholine receptor antibody (AChR-Ab)-positive generalised myasthenia gravis (MG) patients with explosive onset, steroid intolerance, or treatment resistance at Wessex Neurological Centre (2018–2025).

Methods: Retrospective analysis of 40 AChR-Ab-positive generalised MG patients (mean age 60 ± 17 years; 58% male; mean baseline Myasthenia Gravis Activities of Daily Living [MG-ADL] 10 ± 6 , Myasthenia Gravis Composite [MGC] 15 ± 9) receiving rituximab (median initial dose 2000 mg). Outcomes included MG-ADL/MGC at baseline and 3–24 months, CD19 B-cell counts, IgG, prednisolone dose. Repeated-measures ANOVA assessed changes; McNemar tests compared pre/post RTX hospitalisations/plasmapheresis; $p<0.05$ significant (JASP software).

Results: MG-ADL ($F(6,54)=4.67$, $p=0.001$) and MGC ($F(6,42)=3.68$, $p=0.005$) improved significantly over time, though post-hoc pairwise differences were non-significant after Bonferroni correction. CD19 counts depleted markedly ($F(6,12)=10.71$, $p=0.001$); Rituximab led to clinically meaningful improvement, with 71% of patients achieving MCID (≥ 2 -point MG-ADL and ≥ 3 -point MGC reduction) at one or more visits, alongside sustained B-cell depletion and reduced rescue

FIGURE 1 MG ADL reduction.

FIGURE 2 MGC reduction.

FIGURE 3 Prednisolone dose reduction.

therapies. IgG remained stable ($p=0.93$). Prednisolone dose reduced ($F(6,42)=5.49$, $p=0.001$). Hospital admissions dropped from 47.5% to 20% pre/post RTX ($p=0.013$); plasmapheresis from 50% to 25% ($p=0.021$). No serious adverse events with RTX.

Conclusion: Rituximab achieved sustained B-cell depletion, clinical improvement, and reduced rescue therapies/steroids in refractory AChR-MG without impacting IgG, supporting its role in difficult-to-treat cases.

Disclosure: Nothing to disclose.

OPR-088 | Natural progression of oxidative phosphorylation pathology in mitochondrial myopathy

T. Bernardino Gomes¹; V. Di Leo¹; C. Warren¹; A. Khan²; I. Barrow³; G. Hudson⁴; D. M. Turnbull¹; C. Lawless¹; A. E. Vincent¹

¹Mitochondrial Research Group, Translational and Clinical Research Institute, Newcastle University, UK; ²Centre for Doctoral Training in Cloud Computing and Big Data, Newcastle University, UK; ³NIHR Biomedical Research Centre, Translational and Clinical Research Institute, Newcastle University, UK; ⁴Mitochondrial Research Group, Biosciences Institute, Newcastle University, UK

Background and Aims: Mitochondrial myopathies are progressive and disabling disorders. Although their hallmark muscle oxidative phosphorylation (OXPHOS) pathology is widely measured in diagnosis and research, its longitudinal behaviour remains poorly characterised, limiting mechanistic insight and the interpretability of OXPHOS markers. Building on our previous characterisation of cross-sectional intra-individual variability in muscle OXPHOS pathology (PMID:41419999), we now aim to assess its natural history using comparable methods.

Methods: Imaging mass cytometry was used to quantify myofibre deficiency across OXPHOS complex (C) I, III, IV and V. Repeat muscle biopsies from a genetically confirmed mitochondrial myopathy cohort were analysed using our previous methods (PMID:41419999), with rates of change estimated from per-patient bootstrapped differences.

Results: Myofibre deficiency in CI or CIV, and a combined CI-IV-V-deficient profile, were the most prevalent abnormalities. Longitudinal differences were heterogeneous, with CI, CIV and CV often changing in tandem and preserving baseline relationships, while CIII deficiency was rare and changed inconsistently. Some patients exhibited stable or declining pathology over time. Both the magnitude and direction of change were patient-specific and showed no association with major genotype-phenotype groups, demographics or biopsy-related factors.

Conclusion: These data show a slow, heterogeneous progression of muscle OXPHOS pathology in mitochondrial myopathy and indicate that extended follow-up or large effect sizes are likely to be required for its use as a reliable indicator of disease modification. Apparent declines in some patients further indicate that endogenous or exogenous biological factors and/or sampling effects must be considered in future longitudinal research.

Disclosure: Nothing to disclose. This work was funded by the Wellcome Trust, UK.

OPR-089 | Incidence of lipid storage myopathy in Southwestern Sweden

U. Lindgren¹; A. Oldfors²; C. Hedberg-Oldfors³

¹Department of Neurology and Department of Clinical Pathology, both Sahlgrenska University Hospital, and Department of Laboratory Medicine, Institute of Biomedicine, University of Gothenburg, Gothenburg, Region Västra Götaland, Sweden; ²Department of Laboratory Medicine, Institute of Biomedicine, University of Gothenburg, and Department of Clinical Pathology, Sahlgrenska University Hospital, Gothenburg, Region Västra Götaland, Sweden; ³Department of Clinical Genetics and Genomics and Department of Clinical Pathology, both Sahlgrenska University Hospital, and Department of Laboratory Medicine, Institute of Biomedicine, University of Gothenburg, Gothenburg, Region Västra Götaland, Sweden

Background and Aims: Lipid storage myopathies (LSM) are a group of genetic and acquired rare disorders affecting the lipid metabolism. Symptoms typically derive from organs with a high energy demand and onset can occur from birth to late adulthood. This study aimed to describe the incidence and primary causes of adult-onset LSM in a tertiary muscle biopsy centre serving >1.4 million adult inhabitants during 12 years.

Methods: A registry search identified patients with a histopathological diagnosis of adult-onset LSM (Figure 1) 2014–2025 at Sahlgrenska University Hospital, Gothenburg, Sweden. We retrospectively reviewed histopathology, genetic data and medical records.

Results: A total of 31 patients were included (17 women, 14 men). Median age at biopsy was 55 years (range 23–79 years). The primary cause of LSM was identified in 24 patients. Sixteen patients had sertraline-associated MADD (Figure 2A). Three patients had a genetically confirmed disease with variants in ETFDH, PNPLA2 and CPTII respectively. One patient was a symptomatic carrier of an ETFDH variant. Other causes included one patient with a pituitary tumour, and three patients with inflammatory myopathy. Seven patients lacked sufficient data to establish the cause of LSM. The mean incidence of LSM in adults in Region Västra Götaland, Sweden, was 1.45 patients per million inhabitants per year (Figure 2B). The mean incidence of sertraline-associated MADD was 1.76 patients per 100 000 inhabitants treated with sertraline per year.

Conclusion: Sertraline-associated MADD was the most common primary cause of LSM in this study and is important to consider in patients diagnosed with lipid storage myopathy without genetic cause.

Disclosure: Nothing to disclose.

OPR-090 | Brain and CSF volume changes in AI-assisted MRI volumetry in spontaneous intracranial hypotension

A. El Rahal¹; P. Scheffler¹; K. Wolf¹; F. Volz¹; N. Lützen²; C. Zander³; H. Urbach²; J. Beck¹

¹Department of Neurosurgery, Medical Center University of Freiburg, Germany; ²Department of Diagnostic and Interventional Neuroradiology, Medical Center University of Freiburg, Freiburg, Germany; ³Department of Diagnostic and Interventional Radiology, Medical Center University of Freiburg, Freiburg, Germany

Background and Aims: Surgical closure of spinal CSF leaks in SIH patients is associated with quantifiable MRI changes, such as increased intraventricular CSF volume and region-specific expansion and contraction of cerebral lobes, which could help monitoring these patients on MRI follow-up. The pathophysiological significance and prognostic value of brain and CSF volume changes remain to be elucidated. AI-assisted image quantification could be a useful, time-efficient tool for analyzing these changes on a larger scale.

FIGURE 1 Muscle biopsy showing lipid storage myopathy. (A) Vacuoles (arrows), fibre size variation (asterix) and internal nuclei (arrowheads) are seen (Haematoxylin/eosin). (B) Multiple lipid droplets are stained with Sudan black (arrows).

FIGURE 2 (A) Primary causes and (B) Incidence of adult-onset lipid storage myopathy in 31 adult patients diagnosed at Sahlgrenska University Hospital, Gothenburg, Sweden 2014–2025.

FIGURE 1 Illustration of volume changes by area. Areas in orange are expanding, areas in blue are contracting.

FIGURE 2 Illustration of volume changes within the ventricular system. Areas in red are expanding, areas in blue are contracting.

FIGURE 3 Boxplots compare preoperative and postoperative HIT-6 scores at (a), EQ-VAS scores at (b), and EQ-5D-SL scores at (c). The dotted lines represent the evolution of each patient's scores.

Methods: We analyzed 107 patients with SIH who underwent surgical closure of a spinal CSF leak. We used AI-assisted volumetry of pre- and postoperative MRIs using the AssemblyNet segmentation model to quantify CSF and brain region volumes, which were correlated with patient-reported clinical outcome measures.

Results: Patients demonstrated a significant increase in lateral ventricle volume ($+2.83 \text{ cm}^3$, $+17.8\%$) as well as third ($+0.22 \text{ cm}^3$, $+30.1\%$) and fourth ventricle volume ($+0.20 \text{ cm}^3$, $+14.1\%$), after SIH surgery ($p < 0.001$ for all). There was an increased frontal lobe volume ($+6.23 \text{ cm}^3$, $+3.1\%$, $p < 0.050$), and there were small but significant relative volume decreases in temporal horn volume, brainstem, and occipital lobe volume. Clinical scores improved significantly postoperatively but showed low correlation with volumetric changes.

Conclusion: Surgical closure of spinal CSF leaks in SIH patients is associated with quantifiable MRI changes: increased intraventricular CSF volume and region-specific expansion and contraction of cerebral lobes, which could help monitor these patients on MRI follow-up. AI-assisted image quantification could be a useful, time-efficient tool for analyzing these changes at scale.

OPR-091 | Artificial intelligence analysis of patient videos for neurological diagnosis: A systematic review

C. Tatit¹; S. Vallamchetla¹; A. Patel¹; A. Safa¹; F. Colella²; A. Mahadeen¹; A. Kissinger-Knox¹; Y. Khand¹; C. Tao³; A. Abdelhameed³; M. Roberts³; W. Tatum¹; B. Freund¹

¹Department of Neurology, Mayo Clinic, Jacksonville, USA;

²Department of Biomedical Sciences, Humanitas University,

Milan, Italy; ³Department of AI and Informatics, Mayo Clinic, Jacksonville, USA

Background and Aims: Neurological diagnosis frequently depends on visual assessment during examination and video review for paroxysmal and movement disorders. However, clinician interpretation remains subjective, variable, and unsuited to growing tele-neurology data volumes. Computer vision and deep learning advances enable quantitative analysis, potentially converting qualitative neurological signs into reproducible digital biomarkers.

Methods: Following a registered PROSPERO protocol (CRD420251070499), we searched databases from inception to June 2025 for studies using AI on video to detect, classify, or quantify neurological disorders. From included papers, we extracted clinical aim, video modality, model type, validation approach, diagnostic metrics. Risk of Bias assessment was conducted following the Newcastle–Ottawa Scale tool. Heterogeneity precluded meta-analytic synthesis.

Results: Thirty studies including 22,532 participants met inclusion criteria. Performance varied by condition: acute stroke/TIA identification reached 85.8% accuracy; post-stroke motor deficit quantification reported 78%–83% accuracy, while facial weakness detection reached 94.3% accuracy. Neonatal seizure detection achieved $>90\%$ specificity. Movement-disorder applications (bradykinesia, tremor, gait, tics) reported 73%–97% accuracies. Pediatric and fetal tasks reported 0.80–0.90 AUCs for early cerebral palsy and congenital malformations. Most studies were moderate quality with limited external validation.

FIGURE 1 PRISMA flow diagram illustrating the screening process.

FIGURE 2 Illustration of the typical video-based AI workflow.

FIGURE 3 Graphical synthesis of included studies.

Conclusion: AI based video analysis shows potential to support neurological evaluation across acute, chronic, and developmental disorders, but translation to clinical practice is limited by small datasets, heterogeneous protocols, and scarce real-world evaluation. Prospective multicenter evidence with standardized

methodology and robust external validation are required to support the integration of AI-video analysis in neurological care.

Disclosure: Nothing to disclose.

OPR-092 | Speech-based biomarkers for scalable detection of Alzheimer's disease, mild cognitive impairment, and Parkinson's disease

L. Gervaise¹; D. Avalos²; O. Kauffman²; R. Etemad-Sajadi³; S. Ghosh⁴

¹Virtuosus Artificial Intelligence SA, Lausanne, Switzerland;

²Swiss Data Science Center (SDSC), EPFL, Lausanne,

Switzerland; ³Hospitality Innovation and Data Analytics, EHL Hospitality Business School, Lausanne, Switzerland;

⁴Department of Brain and Cognitive Sciences, McGovern Institute for Brain Research at MIT, Cambridge, USA

Background and Aims: Early detection of neurodegenerative disorders is limited by the cost, accessibility, and burden of standard clinical assessments. Speech analysis offers a low-burden, non-invasive, and scalable alternative. This study evaluates a unified speech-based framework for detecting Alzheimer's disease (AD), Mild Cognitive Impairment (MCI), and Parkinson's disease (PD) from spontaneous speech, with an emphasis on robustness across clinical sites, recording conditions, and speech varieties.

Methods: Spontaneous speech recordings were analyzed from multiple clinical and research cohorts, including six datasets for cognitive impairment and five for PD, each treated as an independent domain. Audio was standardized and processed using a shared self-supervised speech encoder. To reduce site-, language-, and recording-related bias, domain-adversarial learning was applied. For cognitive impairment, binary (AD vs. healthy control), three-class (healthy/MCI/AD), and ordinal ($\geq$ MCI, $\geq$ AD) classifiers were trained using a two-phase strategy combining pretraining and multitask learning. PD detection used binary classification, including a model adapted to Swiss-dialect speech. Performance was evaluated using five-fold cross-validation.

Results: For cognitive impairment, AD versus healthy classification achieved a sensitivity of 0.794 and specificity of 0.911, while MCI versus healthy reached a sensitivity of 0.851 and specificity of 0.782; three-class AD/MCI/healthy classification showed a macro-sensitivity of 0.723 and macro-specificity of 0.860. For Parkinson's disease, baseline detection achieved a sensitivity of 0.659 and specificity of 0.937, while dialect-adapted models improved sensitivity to 0.845 and specificity to 0.831.

FIGURE 1 Schematic representation of the neural, physiological, and acoustic levels involved in speech production, from cortical and brain-stem control to vocal tract articulation and the resulting acoustic signal.

FIGURE 2 Overview of the unified speech analysis framework, in which a shared model processes spontaneous speech and supports multiple classification tasks for cognitive impairment and Parkinson's disease.

TABLE 1 Sensitivity and specificity of speech-based models for Alzheimer's disease, mild cognitive impairment, and Parkinson's disease.

Task	Sensitivity	Specificity
AD vs Healthy	0.794	0.911
MCI vs Healthy	0.851	0.782
AD / MCI / Healthy (macro)	0.723	0.86
Parkinson's Disease (baseline)	0.659	0.937
Parkinson's Disease (dialect-adapted)	0.845	0.831

Conclusion: Speech-based biomarkers enable scalable, low-burden screening and monitoring of neurodegenerative diseases and show robust performance across disorders, centers, and speech varieties, supporting their potential integration into routine neurological practice.

Surgery and Neuroscience, University of Siena, Siena, Italy; ⁸Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Multiple sclerosis (MS) shows marked heterogeneity in clinical presentation and progression patterns. Here, we used machine learning (ML) to investigate the combined ability of demographic, clinical and MRI variables in: (i) identifying MS patients from healthy controls (HC); (ii) classify MS phenotypes; and (iii) predict disability, assessed using the Expanded Disability Status Scale (EDSS) score.

Methods: From the Italian Neuroimaging Network Initiative, we selected 1554 MS patients (1143 relapsing/411 progressive MS) and 520 age-matched HC. Participants underwent neurological evaluation and T2-/3D T1-weighted MRI, from which lesion volume (LV), normalized whole-brain and tissue compartment volumes were calculated. Different ML models (including support vector machines and multi-layer perceptron) were implemented for the above-mentioned classification tasks. SHAP analysis ranked the most important variables.

Results: The described ML tools were able to classify MS patients vs. HC with an accuracy ranging from 94% to 96%. Measures consistently showing top contributions included T2 LV and normalized cerebellar/brainstem volumes. ML models were able to classify relapsing from progressive MS patients with 92% accuracy. Top discriminating variables were EDSS score, age, normalized cortical grey matter volume, and normalized hippocampal/thalamic volumes. Finally, ML models were able to predict EDSS score with 0.74–0.76 intra-class correlation. The top variables contributing to EDSS prediction were T2 LV, sex, normalized cortical grey matter and thalamic volumes.

Conclusion: ML models were able to differentiate MS patients from HC, classify MS subtypes and predict disability with high accuracy, supporting the potential of ML in advancing personalized MS care.

OPR-094 | Primary brain calcification: Survey on the efficacy of medical therapy on movement and psychiatric disorders in an Italian cohort

G. Bonato¹; F. Pistonesi²; A. Antonini²; M. Carecchio²

¹Movement Disorders Unit, Neuroscience Department, University of Padova, Padova, Italy; ²Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, University of Milan, Milan, Italy; ²Movement Disorders Unit, Neuroscience Department, University of Padova, Padova, Italy

Background and Aims: Primary Brain Calcification (PBC) is a neurodegenerative disorder characterized by brain calcium deposition, causing movement disorders, psychiatric/cognitive disturbances. Evidence on symptomatic treatment efficacy is limited. We here assess response to medical therapy in a cohort of PBC patients.

Methods: Patients diagnosed with PBC through CT-scan and blood tests at Padova University underwent clinical evaluation and pharmacological anamnesis; treatment response was rated by neurologists and subjective patients' perception as absent, partial, or satisfying.

Results: 35 PBC subjects with movement disorders underwent pharmacological (32) and/or rehabilitation treatment (24), with a multidrug approach in 65.5%. Parkinsonism was the most common phenotype (75%); all patients received Levodopa, dopamine agonists in 13 (54%), MAO/COMT-inhibitors in 6 (25%). Dystonia was treated with anticholinergics or botulinum toxins in 7 cases (22%), benzodiazepine/antiepileptics were added in resistant cases without further benefit; anticholinergic and carbamazepine were effective in 2 PKD subjects. Essential/dystonic tremor was treated with beta-blockers or antiepileptics (4 subjects, 12.5%). Levodopa trial was adopted in tremor or dystonia as second line treatment, and in 13 subjects with

FIGURE 1 Therapy response according to patients and clinician's survey in different movement disorders.

cerebellar symptoms. Overall, 28% of patients had a satisfying response and 37% a partial response. Cerebellar symptoms, dysarthria, and atypical parkinsonism responded significantly worse ($p=0.03$) (Figure 1). Psychiatric symptoms required treatment in most patients (33), achieving satisfactory control in 80%; main drugs were SSRIs, atypical antipsychotics, anxiolytics and benzodiazepines.

Conclusion: Symptomatic medical treatment provides significant benefit in over half of PBC patients, except for cerebellar features, supporting the need for systematic therapeutic evaluation. Systematic assessment will help in defining therapy guidelines in the future.

Disclosure: Data partially submitted for 2026 Italian movement disorders congress. Nothing to disclose.

OPR-095 | Continuous subcutaneous foslevodopa/foscarbidopa infusion in advanced Parkinson's disease: results from a prospective real-world study

G. Pinola¹; V. Leta²; M. Tosi²; C. Leuzzi²; G. Gaudio²; A. Braccia²; F. Pirone²; S. Rinaldo²; R. Cancilla²; N. Golfre Andreasi²; L. Romito²; G. Devigili²; R. Cilia²; A. Elia²; R. Eleopra²

¹Neurology and Stroke Unit, Ospedale di Circolo e Fondazione Macchi, Varese, Italy; ²Parkinson and Movement Disorders Unit, Department of Clinical Neurosciences, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy

Background and Aims: In advanced Parkinson's disease (APD), motor fluctuations and dyskinesias often persist despite optimized oral therapy, supporting the transition toward continuous dopaminergic delivery. Recently, continuous subcutaneous foslevodopa/foscarbidopa (LDp/CDp) became available, but real-world data remain limited. This study aimed to evaluate the effectiveness and tolerability of continuous subcutaneous LDp/CDp infusion in patients with APD in a real-world setting.

Methods: This prospective observational study included APD patients referred to the outpatient clinics for device-aided therapies at Fondazione IRCCS Istituto Neurologico "Carlo Besta", consecutively screened from March 2025 over the following 18 months and followed-up for 6 months after treatment initiation. Motor complications were assessed using the Movement Disorder Society–Unified Parkinson's Disease Rating Scale part

FIGURE 1 Flowchart of patients screened and initiated on continuous subcutaneous Foslevodopa/Foscarbidopa infusion therapy.

FIGURE 2 Longitudinal changes in motor-diary outcomes and LEDD.

IV (MDS-UPDRS IV), the MDS–Unified Dyskinesia Rating Scale (MDS-UDysRS) and 3-day Hauser diaries. Non-motor symptoms were assessed using validated scales. Levodopa equivalent daily dose (LEDD), adverse events and treatment discontinuations were recorded.

Results: Out of ninety-nine patients screened, 45 patients were initiated on LDp/CDp and followed up in outpatient clinics. Treatment discontinuation occurred in 9 (20.0%) patients, mainly due to local infusion-site reactions. Among patients who continued therapy, MDS-UPDRS IV, MDS-UDysRS scores and daily on-time with dyskinesias significantly decreased, while on-time without dyskinesias increased. Oral LEDD was reduced, while total LEDD increased, reflecting continuous 24-h dopaminergic delivery. Non-motor symptoms showed a tendency toward improvement.

Conclusion: Continuous subcutaneous LDp/CDp infusion reduced motor complications and improved on-time quality with acceptable tolerability in a real-world cohort of APD, supporting its use in clinical routine with appropriate patient selection and follow-up.

Disclosure: Nothing to disclose.

OPR-096 | Unraveling multiple system atrophy through skin biopsy: Biomarkers of autonomic dysfunction and α -synuclein aggregation

S. Mazzetti¹; L. Maldera²; A. Luppino¹; G. Gaudiano¹; A. Elia¹; G. Simmini³; R. Lombardi⁴; V. Leta¹; A. Ciullini⁵; F. Colucci¹; D. Cartelli⁴; E. Salvi²; R. Cilia¹; F. Moda⁵; R. Eleopra¹; G. Devigili¹

¹Parkinson's and Movement Disorders Unit, Department of Clinical Neurosciences, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; ²Data Science Center, Fondazione IRCCS Istituto Neurologico "Carlo Besta," Milan, Italy;

³Dementia and Degenerative Diseases of CNS Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;

⁴Neuroalgology Unit, Fondazione IRCCS Istituto Neurologico "Carlo Besta," Milan, Italy; ⁵SSD Laboratory Medicine, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy

Background and Aims: Multiple System Atrophy (MSA) is a progressive neurodegenerative disorder characterized by marked clinical heterogeneity. Identifying accessible biomarkers that mirror underlying neuropathology and differentiate MSA subtypes remains an unmet need. This study explores the skin as an accessible window, aiming to identify peripheral signatures that distinguish MSA phenotypes and capture clinically meaningful differences.

Methods: We conducted a cross-sectional study in 49 patients with clinically established MSA (22 MSA-P, 27 MSA-C). Participants underwent comprehensive clinical and instrumental evaluations, including brain magnetic resonance imaging, DaTSCAN, cardiovascular autonomic testing, and sudomotor assessment. Peripheral biomarkers included α -synuclein seed amplification assay (SAA) performed on olfactory mucosa, and skin biopsy analyses assessing phosphorylated α -synuclein (p-syn) deposits and synaptic terminal density. High-resolution confocal images were analyzed using an automated image software to quantify synaptic markers.

Results: MSA-C was associated with more severe orthostatic hypotension (OH) compared with MSA-P. A postganglionic cholinergic sudomotor impairment was observed across nearly all patients. Synaptic terminals co-expressing vasoactive intestinal peptide and tyrosine hydroxylase were significantly denser in MSA-P than in MSA-C, suggesting phenotype-specific compensatory or regenerative mechanisms; p-syn deposits exhibited a distal-to-proximal gradient in both somatic and autonomic fibers and correlated significantly with OH. Integrating p-syn pathology with SAA results increased sensitivity to 90% in differentiating MSA subtypes, with synaptic loss accounting for most remaining negative cases.

Conclusion: By using a multimodal approach that integrates clinical, molecular, and morphological data, this study provides novel insights into MSA heterogeneity and support the skin as a meaningful source of disease-relevant biomarkers to refine MSA characterization.

Disclosure: Nothing to disclose.

OPR-097 | Local field aperiodic spectral power modulated by deep brain stimulation in Parkinson's disease

M. Bočková

Brain and Mind Research Program, Central European Institute of Technology, Masaryk University, Brno, Czech Republic

Background and Aims: Aperiodic spectral broadband power has been described recently as reflecting Parkinson's disease (PD) severity. It has therefore become an increasing focus of research interest in the context of the new adaptive deep brain stimulation (aDBS) approach. We aimed to study the influence of DBS on the main parameters of the aperiodic spectral component of local field potentials (LFPs).

Methods: LFPs were recorded from the subthalamic nucleus (STN) in patients with PD ($n = 22$) during a simple experimental paradigm that included 5 min of resting state and a short gait

task during DBS “off” and “on” conditions (“off” medication). Classical spectral analysis was performed using Fast Fourier Transform (FFT); the analysis of the aperiodic component was performed by fitting oscillations and a one-over-F (FOOOF) approach. In a subset of the patients ($n=14$), it was possible to evaluate the symptom progression over time after 1 year by analyzing the control measurement.

Results: The severity of hypokinetic/rigid symptomatology, measured by MDS-UPDRS, correlated significantly with both of the aperiodic components characteristics of the STN LFPs: the slope and the offset. These parameters were significantly modified by DBS, as evaluated with a Wilcoxon signed-rank test during the resting state and during the gait task. Aperiodic power remained stable over time during the control measurements.

Conclusion: The aperiodic component in LFPs may reflect pathological activity of the neuronal network and might serve as a new potential clinical marker in PD. The variable relation to conventional beta oscillopathy indicates the involvement of multiple neural mechanisms.

Disclosure: Nothing to disclose.

OPR-098 | Clinical progression and genetic pathways in body-first and brain-first Parkinson's disease

M. Passaretti¹; D. Veréb¹; M. Mijalkov¹; Y. Chang²; H. Zhao²; B. Zufiria-Gerbolés¹; J. Sun¹; G. Volpe²; N. Rivera³; M. Bologna⁴; J. Pereira¹

¹Department of Clinical Neuroscience, Karolinska Institutet, K8 Klinisk neurovetenskap, K8 Neuro Pereira, 171 77, Stockholm, Sweden; ²Department of Physics, University of Gothenburg, Gothenburg, Sweden; ³Immunology and Respiratory Medicine Division, Department of Medicine Solna, Karolinska Institutet, Center for Molecular Medicine, Karolinska University Hospital, Karolinska University Hospital, Solna, Stockholm, Sweden; ⁴Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy

Background and Aims: Recently, two main Parkinson's disease (PD) phenotypes have been proposed: “body-first,” where α -synuclein pathology begins in the peripheral nervous system and spreads symmetrically from bottom-up, and “brain-first,” where pathology starts in the brain and spreads asymmetrically downwards. However, no studies have assessed these phenotypes across both prodromal and clinical PD stages, tracked their pathological progression in vivo or identified potential underlying biological mechanisms.

Methods: We analyzed 910 prodromal and 1120 clinical PD cases with comprehensive longitudinal clinical, imaging, and genetic data from the Parkinson Progression Marker Initiative over a 12-year period.

Results: Both prodromal and clinical groups with body-first symptoms exhibited worse longitudinal motor progression and attention decline compared to brain-first cases. The body-first and brain-first phenotypes were stable over time, identifiable using unsupervised deep learning, and predicted conversion to clinical PD in prodromal cases. Additionally, body-first cases displayed more pronounced changes in the caudal locus coeruleus (LC), symmetrical alterations in the striatum and glymphatic system, consistent with the traditional Braak's bottom-up

progression of α -synuclein pathology and the more symmetric distribution proposed for body-first PD. In contrast, brain-first cases exhibited changes in the rostral LC and asymmetric alterations in the striatum and glymphatic system, suggesting a top-down progression. Genetic analysis identified new specific single-nucleotide polymorphisms associated with PD phenotypes (e.g., TRIM40, IP6K2) linked to worse outcomes in prodromal cases.

Conclusion: Recognising body-first and brain-first PD as distinct entities with unique clinical, imaging, and genetic profiles paves the way for targeted and personalised therapeutic strategies that address the specific pathophysiological mechanisms of PD.

Disclosure: Nothing to disclose.

OPR-099 | Activity of brainstem nuclei of PD patients during noninvasive vagal nerve stimulation: An fMRI study

V. van Midden¹; A. Vovk²; R. Berlot¹; Z. Pirtošek¹; M. Kojić¹

¹Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia; ²Centre of Clinical Physiology, Medical Faculty, University of Ljubljana, Ljubljana, Slovenia

Background and Aims: Transcutaneous auricular vagus nerve electrostimulation (taVNS) is under investigation as add-on therapy for Parkinson's disease (PD). fMRI studies in healthy cohorts show taVNS activates nucleus tractus solitarius (NTS) and locus coeruleus (LC). Whether this applies to PD is unknown. We aimed to quantify taVNS effects on LC and NTS activation in PD, using fMRI.

Methods: We enrolled 40 PD patients in our double-blind, sham-controlled, within-subject, fMRI study (NCT05967598). 32 were analyzed. During a single ON-medication visit, each participant received taVNS at 100 Hz (taVNS100), taVNS at 25 Hz (taVNS25), and sham, in randomized order during which fMRI was obtained. Activity of LC and NTS was analysed using LME models accounting for stimulation type, degeneration-onset side (Deg_onset_side), and UPDRS-III-tertiles. After

FIGURE 1 In left-onset PD, taVNS100 exceeded both taVNS25 ($p=0.005$) and sham ($p=0.029$). No NTS differences were detected in right-onset PD.

FIGURE 2 LC activity was decreased during taVNS100 regardless of the side of the participants degeneration onset.

FIGURE 3 Correlation between the NTS and LC ROI signal.

imaging, we assessed gait using motion sensors across stimulation conditions.

Results: NTS activation showed a main effect of taVNS type ($p=0.021$) and an interaction with Deg_onset_side ($p=0.011$), with taVNS100 increasing NTS activity versus taVNS25 ($p=0.018$). In left-onset PD, taVNS100 exceeded taVNS25 ($p=0.005$) and sham ($p=0.029$), while no NTS differences appeared in right-onset PD. LC activity showed a stimulation-type effect ($p=0.034$), driven by reduced LC activity during taVNS100 versus sham ($p=0.033$). UPDRS-III-tertiles did not affect nuclei responses. LC activity was predicted by NTS activity with a Deg_onset_side interaction ($p=0.007$), showing a negative NTS–LC correlation in left-onset PD. Stimulation had no effect on gait.

Conclusion: taVNS100 reduced LC activity and elevated NTS activity in patients with left Deg_onset_side. This suggests taVNS has PD specific effects on brainstem-nuclei activation, which are driven by disease asymmetry.

Disclosure: Nothing to disclose.

OPR-100 | Genetic determinants of apixaban plasma exposure and clinical outcomes in ischemic stroke patients

A. Olšerová¹; T. Šrámková¹; J. Paulasová Schwabová¹; S. Kmetonyová¹; K. Benešová¹; J. Macek²; P. Janský¹; V. Matoška³; A. Tomek¹

¹Department of Neurology, Second Faculty of Medicine, Charles University, Motol University Hospital, Prague, Czech Republic;

²Pharmakl s.r.o., Prague, Czech Republic; ³Laboratory of molecular diagnostics, Hospital Na Homolce, Prague, Czech Republic

Background and Aims: Apixaban is a direct factor Xa inhibitor used for stroke prevention in patients with atrial fibrillation. Its absorption and elimination are influenced by drug transporters and metabolic enzymes encoded by the ABCG2, ABCB1, CYP3A5, and SULT1A1 genes. Genetic polymorphisms in these pathways may contribute to variability in apixaban plasma exposure, but data in ischemic stroke patients remain limited. This study evaluated the impact of selected genetic polymorphisms on minimal apixaban plasma concentrations (Cmin) and clinical outcomes.

Methods: This retrospective monocentric study included consecutive ischemic stroke patients treated with apixaban. Genotyping for ABCG2 rs2231142, ABCB1 rs4148738, CYP3A5 rs776746, and SULT1A1 rs9282861 was performed, and Cmin was measured 12h after administration. Clinical follow-up assessed recurrent ischemic stroke, clinically relevant bleeding, thromboembolic events, and mortality.

FIGURE 1 ABCB1 genotyping – graphical visualization of melting curves using HRM analysis with the LightScanner Master Mix system, where red curves represent patients without the ABCB1 rs4148738 allele (wild type), grey curves indicate heterozygotes, and blue curve.

Results: Eighty-three patients were included (53% male, mean age 70.4 years), with a mean follow-up of 47.2 months (326 patient-years); 37.3% received a reduced dose. Carriers of ABCG2 rs2231142 more frequently had apixaban plasma levels below the therapeutic range ($p=0.016$). No significant associations were observed for ABCB1, CYP3A5, or SULT1A1, and genetic variants were not independently associated with clinical outcomes.

TABLE 1 Distribution of genotypes and apixaban plasma levels in patients treated with apixaban.

Genotype	Patients, n (%)	Median apixaban plasma level (ICP, ng/ml)
CYP3A5 rs17746 - WT	71 (82.8)	111.34 (70.79–193.00)
CYP3A5 rs17746 - Heterozygous	6 (7.2)	93.77 (70.88–159.89)
CYP3A5 rs17746 - Homozygous	0	NA
CYP3A5 rs17746 - Variant allele carrier	6 (7.2)	93.77 (70.88–159.89)
ABCG2 rs2231142 - WT	60 (72.5)	130.48 (77.81–193.00)
ABCG2 rs2231142 - Heterozygous	22 (28.5)	187.28 (93.87–302.40)
ABCG2 rs2231142 - Homozygous	1 (1.2)	138
ABCG2 rs2231142 - Variant allele carrier	23 (27.7)	187.28 (93.87–302.40)
SULT1A1 rs9282861 - WT	29 (34.9)	111.34 (70.79–193.00)
SULT1A1 rs9282861 - Heterozygous	54 (65.1)	108.87 (75.80–155.80)
SULT1A1 rs9282861 - Homozygous	0	NA
SULT1A1 rs9282861 - Variant allele carrier	54 (65.1)	108.87 (75.80–155.80)
ABCB1 rs4148736 - WT	29 (34.9)	98.09 (74.58–129.99)
ABCB1 rs4148736 - Heterozygous	29 (34.9)	120.76 (89.87–174.80)
ABCB1 rs4148736 - Homozygous	70 (85.1)	90.00 (61.30–136.82)
ABCB1 rs4148736 - Variant allele carrier	58 (69.1)	114.27 (82.14–165.28)

Apixaban plasma levels are presented as median (interquartile range, ICP). * Plasma level is a constant value due to a single patient.

FIGURE 2 Kaplan–Meier curve for the occurrence of bleeding complications in carriers of SULT1A1 rs9282861.

Conclusion: The ABCG2 rs2231142 polymorphism is associated with subtherapeutic apixaban plasma levels in ischemic stroke patients, suggesting a potential role for pharmacogenetic guidance of apixaban dosing.

Disclosure: Nothing to disclose.

OPR-101 | Streamline-based lesion-symptom mapping reveals network substrates of post-stroke disability

C. Weiller¹; E. Vaidelyte²; F. Hertel¹; M. Reisert³; H. Urbach⁴; E. van den Hoven¹; M. Rijntjes¹

¹Department of Neurology, Freiburg, Baden-Württemberg, Germany; ²Department of Neurology & Neurorehabilitation, University Center for Medicine of Aging and Rehabilitation Basel, Felix Platter Hospital, Basel, Switzerland; ³Department of Radiology, Freiburg, Baden-Württemberg, Germany, ⁴Department of Neurology, Freiburg, BW, Germany

Background and Aims: Although many factors are associated with post-stroke disability (including initial severity, age, education, co-morbidity, and social support), the underlying anatomical determinants remain unclear.

Methods: We applied a novel method, whole-brain streamline-based lesion-symptom mapping (SLSM) (Figure 1) in 493 patients with stroke and a single ischaemic lesion on acute MRI (<1 week). This approach was used to delineate fibre bundles predicting the modified Rankin Scale (mRS) at the chronic stage (>3 months).

Results: SLSM identified afferent (spinothalamic) and efferent (corticospinal tract) projection fibres, interhemispheric transcallosal fibres, and three association fibre bundles as predictors of chronic mRS (Figure 2). The association bundles corresponded to dorsal and ventral pathways, as well as streamlines linking the temporal, parietal, and occipital lobes, consistent with the middle longitudinal fasciculus (“caudal pathway”).

Conclusion: SLSM is a new technique that constructs whole-brain connectomes at the single-streamline level without predefined tract templates. Disability after stroke is not only explained by damage to afferent and efferent projections. Dorsal and ventral pathways converge in frontal and posterior hubs to integrate sequential processing with deeper structural analysis (“syntax”). The caudal pathway supports multimodal integration in the angular gyrus and abstraction in the anterior temporal lobe (“semantics”). This framework enables abstraction and generalisation, crucial abilities when adapting to novel situations during recovery.

Disclosure: CW, FH, EvdH, MR are supported by EBRAINS2.0.

Background and Aims: Oral anticoagulants (OACs), including vitamin K antagonists (VKAs) and direct oral anticoagulants (DOACs), reduce ischemic stroke risk in atrial fibrillation (AF), yet 1%–2% of patients still experience breakthrough strokes annually, not fully explained only by poor adherence. Clarifying underlying mechanisms is essential to improve prevention strategies.

Methods: ASPERA (NCT06823466) is a multicenter ambispective study; this analysis includes the retrospective arm of AF patients with neuroimaging-confirmed ischemic stroke despite ongoing therapeutic OAC between 2020 and 2025, with collection of baseline characteristics, comorbidities, treatments, and 90-day outcomes.

Results: Among 1649 patients (median age 80.4 years, 52.2% females) most were treated with DOACs (77.3%). Causal factors for breakthrough ischemic stroke included drug-to-drug interactions potentially affecting OAC efficacy (26.4%), competing etiologies (24.3%), and active cancer (4.4%). Overall, 180 (10.9%) had more than one potential cause and 724 (43.9%) of patients had at least one of those factors. Patients with almost one identifiable factor had a higher prevalence ($p < 0.01$) of arterial hypertension (87.3% vs. 76.3%), diabetes mellitus (30.1% vs. 24.3%), and dyslipidemia (58.1% vs. 45.8%) and a higher rate of minor stroke (NIHSS ≤ 5) presentation (33.8% vs. 26.7%, $p = 0.002$) compared with those without. These patients also showed higher 90-day mortality (22.7% vs. 18.4%, $p = 0.032$) and stroke recurrence rates (4.8% vs. 2.4%, $p = 0.007$).

Conclusion: Approximately half of patients experiencing ischemic stroke despite ongoing oral anticoagulation have an identifiable mechanism that may have contributed to the event. Improved recognition and characterization of these factors may help reduce the risk of breakthrough stroke and warrant investigation in prospective studies.

Disclosure: Nothing to disclose.

OPR-103 | Maraviroc for stroke recovery (MASTER): Protocol and status of a phase 2 double-blind placebo-controlled randomized clinical trial

N. Broc; G. Byczynski; E. Dirren; E. Carrera
Stroke Research Lab, Division of Neurology, Department of Clinical Neuroscience, Geneva University Hospital, Geneva

Background and Aims: Despite advances in acute stroke care, stroke remains the leading cause of acquired disability, and no pharmacological therapy is currently available to enhance recovery beyond the acute phase. Preclinical studies suggest that inhibition of the C-C chemokine receptor 5 (CCR5) may promote functional recovery by enhancing peri-infarct cortical plasticity. However, its role in human stroke recovery remains unknown.

Methods: MASTER (MARaviroc for STroke REcovery) is a phase II, single-centre, randomized, double-blind, placebo-controlled trial. Eighty patients with moderate, incomplete upper limb motor impairment will be enrolled within 7 days of acute ischemic stroke and randomized (1:1) to receive oral maraviroc (300 mg twice daily) or placebo for 90 days, in addition to standard rehabilitation. The primary outcome is upper limb motor recovery at day 90, assessed using the Fugl-Meyer Assessment for the Upper Extremity (FMA-UE). Secondary outcomes include measures of motor skill learning and imaging markers of peri-infarct plasticity at day 90, evaluated using MRI

FIGURE 1 Study schematic for the MASTER trial. Patients are included following verification of inclusion and exclusion criteria. Randomization (R) is 1:1 to placebo (Mannitol) or Maraviroc group.

FIGURE 2 Box-plot of Fugl-Meyer scores for the upper extremity (FMA-UE) at baseline.

connectivity and spectroscopy. Additional clinical outcomes will be assessed longitudinally up to 6 months post-stroke.

Results: To date, 21 of 80 patients have been enrolled. Treatment compliance ranges from 69% to 100%. The cohort has a median age of 77 years, 43% are women, and median baseline NIHSS and FMA-UE scores are 5 and 50, respectively. Eight participants have completed the primary outcome assessment.

Conclusion: MASTER explores a novel pharmacological approach to enhance post-stroke motor recovery and to investigate its underlying mechanisms with the help of advanced MRI.

Background and Aims: Sex-specific outcomes after breakthrough ischemic stroke on oral anticoagulation (OAC) are unexplored. We compared 90-day outcomes by sex and explored modifiers.

Methods: ASPERA-R (NCT06823466) was an international, multicenter, retrospective study enrolling adults (>18 years) with breakthrough ischemic stroke on OAC for AF. Primary outcome was 90-day return to baseline neurological (mRS 0–1 maintained if pre-stroke 0–1; or same/lower mRS if pre-stroke ≥ 2). Secondary outcome were 90-day mRS shift, recurrent ischemic stroke/TIA, myocardial infarction, all-cause and vascular death. Safety outcomes included 90-day moderate-to-severe bleeding, intracranial hemorrhage (ICH), 24-h hemorrhagic transformation, and 24-h symptomatic ICH. We applied inverse probability weighting and regression models to compare outcomes. Prespecified subgroup analysis tested sex-specific interactions.

Results: We included 1649 patients (women 52.2%; mean age 78.0 ± 10.7). Women were older (80.2 ± 9.6 vs. 76.3 ± 10.8 ; SMDunw = 0.376), had higher baseline NIHSS (13 [IQR 9–19] vs. 9 [IQR 4–17]; SMDunw = 0.227), and worse pre-stroke mRS (SMDunw = 0.237). After weighting, women were less likely to return to baseline neurological function (35.2% versus 42.7%; adjusted risk ratio 0.82, 95% CI 0.71–0.96; $p = 0.015$), had worse mRS distribution (adjusted OR 1.17, 95% CI 1.01–1.37; $p = 0.043$) and higher recurrent ischemic stroke/TIA (4.8% vs. 2.8%; adjusted HR 1.70, 95% CI 1.01–2.86; $p = 0.045$). Women showed a trend toward more moderate-to-severe bleeding (4.6% vs. 2.8%; adjusted HR 1.63, 95% CI 0.96–2.72; $p = 0.070$). Subgroup analyses revealed significant sex interactions for OAC type, competing etiology, endovascular treatment, and OAC restart.

Conclusion: Women had worse 90-day outcomes than men after breakthrough ischemic stroke on OAC for AF, highlighting the need for sex-aware management.

Background and Aims: Breakthrough ischemic stroke during oral anticoagulation (OAC) for atrial fibrillation (AF) remains a major therapeutic challenge, particularly in patients with cancer, who have competing thrombotic and bleeding risks. We investigated the impact of cancer on 90-day outcomes after ischemic stroke during OAC.

Methods: We analyzed patients with AF experiencing ischemic stroke on continuous OAC enrolled in the international retrospective ASPERA-R study (35 stroke centers, 9 countries). Inverse probability weighting adjusted baseline imbalances. Weighted Cox, ordinal logistic, and generalized linear models estimated adjusted 90-day risks for primary (ischemic stroke or TIA), secondary (mRS shift, vascular/all-cause death), and safety outcomes (moderate-to-severe bleeding, intracranial hemorrhage, 24-h hemorrhagic transformation).

Results: Among 1649 patients (mean age 78.0 ± 10.7 years; 45.8% male), 247 (15.0%) had cancer (35.2% active, 64.8% remission). After weighting, cancer was associated with a higher 90-day risk of new ischemic stroke or TIA (8.2% vs. 2.8%; aHR 2.56, 95% CI 1.59–4.13; $p < 0.001$) and worse mRS distribution (aOR 1.29, 95% CI 1.08–1.54; $p = 0.005$). Active cancer conferred a >4-fold higher ischemic risk (HR 4.48, 95% CI 2.46–8.13; $p < 0.001$) and higher moderate-to-severe bleeding risk (HR 2.77, 95% CI 1.30–5.88; $p = 0.008$). Cancer in remission increased ischemic (HR 2.60, 95% CI 1.59–5.25; $p = 0.001$) but not bleeding risk. Hematological malignancies showed higher risks of ischemic events (HR 3.06, 95% CI 1.69–5.54; $p = 0.001$) and moderate-to-severe-bleeding (HR 3.47, 95% CI 1.57–7.70; $p = 0.006$) than solid tumors.

Conclusion: Cancer, particularly active and hematological malignancies, substantially worsens 90-day prognosis after breakthrough stroke on OAC, underscoring the need for refined risk stratification and tailored secondary prevention.

Disclosure: Nothing to disclose.

OPR-106 | Neuronal antibody discovery in unexplained cerebellar ataxia: Preliminary results

J. Kerstens¹; E. Erdag Turgeon¹; M. van Duijn¹; S. Franken¹; M. Nagtzaam¹; M. Jin¹; M. Rouvroye²; S. Veenbergen³; R. van Steenhoven¹; J. de Vries¹; P. Sillevius Smitt¹; B. van de Warrenburg⁴; M. Titulaer¹

¹Department of Neurology, Erasmus MC University Medical Center, Rotterdam, The Netherlands; ²Department of Gastroenterology and Hepatology, Amsterdam University Medical Center, Amsterdam, The Netherlands; ³Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands; ⁴Department of Neurology, Radboud University Medical Center, Nijmegen, The Netherlands

Background and Aims: Over 40 autoantibodies associated to autoimmune cerebellar ataxia (ACA) have been discovered and this number is still growing. Antibody identification allows for definitive diagnosis and access to potentially beneficial immunotherapy. This is especially relevant for patients in whom an immune-mediated cause is not initially suspected, for example because of a chronic rather than subacute disease course.

Methods: We retrospectively identified patients with suspected ACA tested at the national referral center for antibody diagnostics and autoimmune encephalitis (cohort A) and patients with unexplained chronic cerebellar ataxia seen at the largest tertiary ataxia referral center in the Netherlands (cohort B). Patients positive for known ACA-associated antibodies were excluded. Serum or cerebrospinal fluid (CSF) samples were screened for antibodies by immunohistochemistry (IHC). Positive samples were tested on human induced pluripotent stem cell-derived live neurons (LN). Samples positive with both techniques were grouped according to clinical features and IHC/LN staining patterns and evaluated by immunoprecipitation/mass spectrometry (IP/MS) to identify novel antibody targets.

Results: After exclusion of 235 patients who tested positive for known antibodies (all cohort A), we enrolled 351 patients in cohort A (229 serum and CSF, 99 serum, 23 CSF) and 143 in cohort B (all serum). IHC and LN were both positive in 11/351 (3.1%) and 3/143 (2.1%) patients, respectively. Four patients of the IHC/LN double positive subgroup in cohort A had similar staining patterns and were tested by IP/MS (analysis pending).

Conclusion: The search for novel ACA-associated antibodies is not yet exhausted and should also include patients with a chronic disease course.

OPR-107 | Antibody functionalities during herpes-simplex-virus-1 infection are associated with disease severity and predict post-herpes autoimmune encephalitis

M. Spatola¹; L. Marmolejo¹; C. Milano¹; J. Planagumà¹; E. Aguilar¹; R. Bello-Morales²; J. Dalmau¹; T. Armangué³
¹Neuroimmunology Program, Fundació de Recerca Clínica Barcelona-Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), University of Barcelona, Spain and Caixa Research Institute (CRI), Barcelona, Spain; ²Universidad Autónoma de Madrid, Madrid, Spain; ³Neuroimmunology Program, FRCB-IDIBAPS, University of Barcelona, Spain; Caixa Research Institute (CRI), Barcelona, Spain; and Pediatric Neuroimmunology Unit, Neurology Service, Sant Joan de Déu (SJD) Children's Hospital, University of Barcelona, Barcelona

Background and Aims: Herpes-simplex-virus-1 (HSV1) can cause recurrent cold sore (periphHSV) or encephalitis (HSE), which may be complicated by autoimmune encephalitis (postHSE-AE). The immunological mechanisms underlying HSE and postHSE-AE remain unclear.

Methods: We deeply characterized HSV1-antibody responses in paired serum/CSF of 45 HSE patients (12 who developed postHSE-AE, 33 who did not; at onset and 1 month), and in serum of 12 periphHSV. Profiles included Ig classes/subclasses, Fc receptor binding, and Antibody-Dependent Cellular/Neutrophil Phagocytosis (ADCP/ADNP), Complement Deposition (ADCD) and NK-cells activation (ADNKA). Antibody features were compared across groups and compartments, and correlated with disease severity and development of postHSE-AE. Neuronal death was quantified in HSV1-infected cultures treated with IgG from HSE, periphHSV or healthy controls.

Results: In HSE, HSV1-specific responses in CSF were low at onset, but significantly increased at 1 month, while serum responses remained elevated. LASSO/PLSDA analyses identified ADCD in serum and ADCP in CSF as features that differed most across compartments. Higher CSF-ADCP correlated with HSE severity. Compared to HSE, periphHSV patients showed higher serum ADNKA and FcγR3A binding despite similarly high IgG titers. Patients who developed PostHSE-AE exhibited higher titers, ADCD, ADNP and FcγR binding. IgG from HSE patients caused increased neuronal death in-vitro compared to IgG from periphHSV or healthy controls.

Conclusion: Our results indicate that, during HSE, HSV1-responses are compartmentalized and characterized by phagocytosis-activating antibodies in CSF that correlate with HSE severity and predict PostHSE-AE. NK-activating antibodies in periphHSV may protect the brain from HSE. Antibodies from HSE cause increased neuronal death, which likely promotes the development of autoimmune encephalitis.

OPR-108 | Frequent early cognitive impairment in both pediatric multiple sclerosis and myelin oligodendrocyte glycoprotein antibody-associated disease

M. Buijze¹; S. Molenaar¹; R. Verkerk²; M. Quist¹; W. van der Vlugt²; R. Neuteboom¹

¹Department of Neurology, Division of Pediatric Neurology, MS Center ErasMS, Erasmus Medical Center, Rotterdam, The Netherlands; ²Department of Neurology, Division of Neuropsychology, Erasmus Medical Center, Rotterdam, The Netherlands

Background and Aims: The characterization of early cognitive impairment (CI) in pediatric multiple sclerosis (MS) remains limited due to methodological heterogeneity across previous studies. Moreover, standardized data for pediatric Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease (MOGAD) are scarce. Therefore, we aim to evaluate early cognitive dysfunction in both diseases and comprehensively characterize their neurocognitive profiles.

Methods: A cross-sectional study of children with MS and MOGAD (excluding acute demyelinating encephalomyelitis) assessed neurocognition within 2 years after disease onset using a standardized, comprehensive test battery covering all cognitive domains. Test results were converted to Z-scores. CI was defined as having Z-scores below -1.5 in ≥ 2 domains. Children were compared according to CI status and domain specific impairment was evaluated using composite domain Z-scores.

Results: Fifty-one participants were analyzed (MS $n=31$, MOGAD $n=20$). Full-scale intelligence was normal in both groups. Poor performance on the Bourdon-Vos Test indicated reduced sustained attention and processing speed. MS patients additionally showed lower scores on tasks of visuospatial processing and visuospatial memory. Overall, 48% of MS children and 45% of MOGAD children met criteria for CI. Domain-specific impairments were most prominent in complex attention, with significantly reduced composite Z-scores (MS: -1.26 ± 2.45 , $p < 0.001$; MOGAD: -1.08 ± 2.13 , $p = 0.006$). Only fatigue was significantly associated with the presence of CI (PedsQL fatigue Z-score: -2.55 vs. -0.75 , $p = 0.02$).

Conclusion: In both pediatric MS and MOGAD, early CI is prevalent with prominent difficulties in complex attention. Visuospatial functioning appears to be an additional vulnerable area for children with MS.

Disclosure: Michiel Buijze, Sandy Molenaar, Rosa Verkerk, Maud Quist and Willemijn van der Vlugt report no disclosures. Rinze Neuteboom participated in clinical trials with Roche, Novartis, Sanofi, Teva, Amgen and Livanova.

OPR-109 | Pathophysiology of pain in stiff person syndrome: An MRI and autoantibody study

S. Seefried¹; M. Pham²; C. Sommer¹

¹Department of Neurology, University Hospital Würzburg, Würzburg, Germany; ²Department of Neuroradiology, University Hospital Würzburg, Würzburg, Germany

Background and Aims: Stiff-person syndrome (SPS) is a rare autoimmune neurological disorder characterized by stiffness,

spasms, anxiety, and pain. Pain is frequent but insufficiently understood and treated. Autoantibodies interfering with GABAergic inhibition may contribute to neuromuscular hyperexcitability and nociceptive processing. This study aimed to comprehensively characterize pain in SPS and to investigate its association with autoantibodies, peripheral nociceptor involvement, and central GABAergic dysfunction.

Methods: Thirty patients with SPS underwent detailed neurological examination and standardized pain assessment (NRS, GCPS, mRS). Structural brain MRI and proton MR spectroscopy of the insular cortex were performed. Serum autoantibodies were analyzed, peripheral blood mononuclear cells were stimulated to antibody-producing B cells, and serum binding to rat spinal cord and brain sections was assessed.

Results: Patients reported high levels of acute and chronic pain. Greater serum binding to GABAergic interneurons in the spinal cord was associated with higher pain intensity. Burning and electrifying pain, predominantly affecting the back and legs, were frequently reported. SPS patients showed reduced cortical thickness in the bilateral superior frontal gyrus, which correlated negatively with pain severity. Insular GABA levels were reduced compared with healthy controls and showed an association with autoantibody titers.

Conclusion: Pain is a prominent and clinically relevant feature of SPS and appears to be linked to autoantibody-associated peripheral nociceptor involvement and central GABAergic dysfunction. Improved understanding of pain mechanisms may support more targeted therapeutic strategies to reduce pain and disability in SPS.

Disclosure: Nothing to disclose.

OPR-110 | Long-term outcomes in anti-LGI1 encephalitis: A nationwide Dutch cohort study

T. Brand¹; Y. Crijnen¹; A. van Sonderen²; M. de Bruijn³; J. Brenner¹; T. Bienfait¹; J. Kerstens¹; R. van Steenhoven¹; P. Sillevius Smitt¹; S. Veenbergen⁴; J. de Vries¹; M. Titulaer¹

¹Department of Neurology, Erasmus MC, University Medical Centre Rotterdam, Rotterdam, The Netherlands; ²Department of Neurology, Haaglanden Medical Centre, The Hague, The Netherlands; ³Department of Neurology, Elisabeth Tweesteden Hospital, Tilburg, The Netherlands; ⁴Department of Immunology, Erasmus MC, University Medical Centre Rotterdam, Rotterdam, The Netherlands

Background and Aims: Anti-leucine-rich glioma-inactivated 1 (LGI1) encephalitis is one of the most prevalent autoimmune encephalitides, yet data regarding long-term outcomes and treatment efficacy remain scarce. This study aims to assess long-term clinical outcomes, characterize relapses and compare the efficacy of different therapeutic approaches.

Methods: In this nationwide cohort study, patients diagnosed with anti-LGI1 encephalitis between August 2010 and January 2026 were included. Retrospective and prospective clinical data were collected. Primary outcomes included the modified Rankin Scale (mRS) and the Clinical Assessment Scale for Autoimmune Encephalitis (CASE).

Results: 215/240 patients were eligible for analysis. An interim analysis ($N=100$) demonstrated a median follow-up of 60 months (IQR 42–84; range 8–211). At least one relapse occurred in 24%,

with significantly lower incidence among those treated with rituximab. Median time to first relapse following immunotherapy was 6 months (IQR 4–37; range 3–83). Relapses typically mirrored the symptoms of the initial episode, albeit with reduced severity: median maximal mRS during the initial disease episode was 3 (IQR 2–3; range 1–5), compared to 2 (IQR 2–3; range 2–3) at the time of first relapse. At 2 years post-diagnosis, the median mRS score was 1 (IQR 1–2; range 0–3) and symptomatic epilepsy was present in 6% of patients.

Conclusion: This study will provide novel insights into long-term prognosis. Ongoing analyses aim to identify predictors for relapse and functional outcome. Furthermore, we seek to provide guidance on optimal treatment strategies regarding immunotherapy and duration of anti-seizure medication to improve patient care.

Disclosure: Peter A.E. Sillevius Smitt holds a patent for the detection of anti-DNER and received research support from Euroimmun. Maarten J. OPR-111 | Duchenne muscular dystrophy drives T cell remodeling

Y. Torrente¹; C. Villa²; A. Farini¹

¹Neurology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ²Stem Cell Laboratory, Department of Pathophysiology and Transplantation, Dino Ferrari Centre, Università degli Studi di Milano, Milan, Italy

Background and Aims: Duchenne muscular dystrophy (DMD) is characterized by progressive muscle degeneration, yet systemic immunological consequences remain poorly understood. Recent fatalities following AAV-mediated gene therapy highlight critical gaps in baseline immune dysfunction knowledge. This study aimed to comprehensively characterize systemic immune profiles in glucocorticoid-free DMD patients using multi-omic approaches.

Methods: We performed single-cell transcriptomic and epigenomic profiling coupled with systemic cytokine analysis in glucocorticoid-free DMD patients. Immune cell populations

FIGURE 1 DMD muscles showed marked increases in CD4+ and CD8+ T cells and myeloid dendritic cells, while B cells were notably absent, suggesting selective immune cell recruitment driven by the inflammatory muscle.

FIGURE 2 DMD patients exhibited significantly higher T cell exhaustion scores.

FIGURE 3 Circulating CD8+ T cells from DMD patients and healthy controls, revealing specific T cell subsets expressing multiple markers of both exhaustion and senescence.

were characterized across bone marrow, dystrophic muscle, and peripheral blood compartments. Cell-cell communication networks were analyzed, and findings were validated through meta-analysis across independent cohorts.

Results: DMD exhibited distinct immune microenvironments: bone marrow harbored transcriptionally primed yet phenotypically naïve lymphocytes with stress-responsive signatures (ATF3, FOSB) and metabolic reprogramming. Dystrophic muscle showed chronic T cell exhaustion with epigenetic imprinting. Paradoxically, circulating CD8+ memory T cells maintained TCF1+TIGIT– stem-like features despite tissue exhaustion. Systemic profiling revealed elevated

pro-inflammatory mediators (IL-6, TNF receptors, interferons) with impaired chemokine networks. Bone marrow networks centered on monocyte-mediated T cell priming, while muscle networks involved FAP-myofiber-macrophage triads driving remodeling.

Conclusion: Pre-existing immune priming in DMD—characterized by stress-responsive transcription, enhanced OXPHOS metabolism, and preserved T cell stemness—may predispose patients to exaggerated therapeutic responses, providing essential groundwork for predicting complications and designing immunomodulatory strategies.

Disclosure: Nothing to disclose.

Epilepsy 1

OPR-112 | AutoStim mode versus traditional vagus nerve stimulation in drug-resistant epilepsy: Long-term real-world outcomes from a large vagus nerve stimulation cohort

C. Silvestri¹; C. Algoet¹; K. Van Rooy¹; L. Hogeveen¹; E. Carrette¹; S. Gadeyne¹; A. Mertens¹; F. Dewaele²; J. Vandersteene²; A. Meurs¹; P. Boon¹; K. Vonck¹
¹Brain, Department of Neurology, Reference Center for Refractory Epilepsy, Ghent University Hospital, Ghent, Belgium;
²Department of Neurosurgery, Ghent University Hospital, Ghent, Belgium

Background and Aims: Vagus nerve stimulation (VNS) is an adjunctive therapy for drug-resistant epilepsy. Newer devices incorporating AutoStim deliver additional stimulation in response to ictal tachycardia (1–3). However, comparative data between AutoStim-enabled and conventional VNS remain limited. This study compared long-term clinical outcomes of VNS with AutoStim ON versus AutoStim OFF.

Methods: We conducted a retrospective observational cohort study of adults implanted with VNS between 2010 and 2024 at Ghent University Hospital (minimum follow-up of 12 months) (Table 1). Patients were classified according to exposure to AutoStim during follow-up. The AutoStim ON group included patients in whom AutoStim was activated at any time, while the AutoStim OFF group comprised patients treated exclusively with conventional VNS (ON: *n* = 142; OFF: *n* = 94). Outcomes included seizure frequency reduction, responder and best-responder rates (≥50% and ≥90% reduction), seizure freedom, total daily antiseizure medication load (TDL), and mortality. Mixed-effects negative binomial regression and analysis of covariance were applied.

Results: Responder rates were higher in the AutoStim ON group (51% vs. 41%, *p* = 0.011), as were best-responder rates (22% vs. 13%, *p* = 0.002) (Figure 1). Seizure freedom occurred in 17% versus 12% of patients, respectively (*p* > 0.05). Stimulation parameters did not differ significantly between groups (Table 2). Among responders, antiseizure TDL remained stable or decreased in the AutoStim ON group. Mortality was lower in the AutoStim ON group (6% vs. 15%, *p* = 0.03).

Conclusion: In this wide real-world cohort, VNS with AutoStim ON was associated with better seizure outcomes, stable

TABLE 1 Demographic description of the cohort. *Chi-square and Mann-Whitney tests applied. °8/21 (38.1%) patients had SE recurrence after VNS implantation on Open Loop Group, 11/40 (27.5%) in the Closed loop.

	AutoStim ON (n=142)	AutoStim OFF (n=94)	<i>p</i> -value*	Total (n=236)

OPR-113 | Medial pulvinar stereo-electroencephalography biomarkers associated with deep brain stimulation response in focal drug-resistant epilepsy

I. Bratu¹; R. Carron²; A. Clement¹; S. Medina Villalon¹; F. Bartolomei¹; F. Pizzo¹
¹Department of Epileptology and Cerebral Rhythmology, Timone Hospital, Marseille, France; ²Medico-surgical Unit of Epileptology, Functional and stereotactic neurosurgery, Timone Hospital, Marseille, France

Background and Aims: Thalamic deep brain stimulation (DBS) represents an emerging therapeutic option for patients with focal drug-resistant epilepsy who are ineligible for or have failed resective surgery. To optimize outcomes and guide DBS lead placement, thalamic stereo-electroencephalography (SEEG) has been proposed.

Methods: This monocentric retrospective study aimed to identify interictal and ictal SEEG biomarkers of the medial pulvinar (PuM) associated with favourable PuM-DBS response. Six patients (four female, two male) underwent SEEG including PuM sampling, were deemed unsuitable for resective surgery, and subsequently received bilateral PuM-DBS. In total, eight PuM were sampled in SEEG: four bilaterally (two patients) and four unilaterally (four patients). The SEEG exploration covered both the PuM and the ipsilateral epileptogenic-zone network (EZN) in four patients, whereas in the other two the EZN was bilateral but PuM sampling was unilateral. All SEEG signal analyses were performed on the PuM sampling contacts available in each patient. Interictal SEEG analysis included spike-rates and non-linear functional connectivity (h2), while ictal analyses combined visual inspection with quantitative biomarkers: Epileptogenicity Index (EI), Connectivity Epileptogenicity Index (cEI), Permutation Entropy Index (PEI) and Delta Entropy (ΔE).

Results: Two patients were responders ($\geq 50\%$ seizure reduction at 1 year). PuM spike-rates, connectivity, EI and cEI values did not differentiate responders from non-responders. In contrast, entropy-based measures were significantly higher in responders: PEI (FDR- $p=0.024$) and ΔE (FDR- $p=0.034$).

Conclusion: Ictal PuM complexity disruption, quantified through entropy-based SEEG metrics (PEI and ΔE), may represent a candidate biomarker of response to medial pulvinar DBS and warrants validation in larger cohorts.

Disclosure: Nothing to disclose.

Background and Aims: New onset refractory status epilepticus (NORSE) is an extremely severe form of status epilepticus. We aim to assess how extensive is seizure-induced acute brain damage in patients with cryptogenic NORSE (cNORSE) compared to etiology-defined status epilepticus (eSE), chronic epilepsy, and healthy controls.

Methods: This international cross-sectional cohort study includes 78 patients with cNORSE, 211 with eSE, 100 subjects with chronic epilepsy and 36 healthy participants. We measured neurofilament light chain (NfL) and S100-beta (S100B), respectively for neuronal and astroglial damage, in serum and cerebrospinal fluid (CSF).

Results: In cNORSE, NfL concentrations were tenfold higher in CSF and fourfold higher in serum compared with eSE ($p<0.0001$). Serum levels of NfL in cNORSE were twentyfold higher than in epilepsy and healthy controls' groups. Serum and CSF NfL values were strongly correlated (Spearman's $\rho=0.75$, $p<0.001$) and NfL levels rose sharply from week 1 to week 3 after cNORSE onset ($p<0.001$). On the contrary, S100B concentrations in serum and CSF did not differ between cNORSE and eSE. NfL levels discriminated cNORSE from other cohorts with an area under the receiver operating characteristic (ROC) curve between 0.79 (95% CI 0.68–0.90) versus eSE and 0.99 (95% CI 0.78–1.00) versus non-SE groups.

Conclusion: Acute neuroaxonal injury in cNORSE is extraordinarily severe, disproportionate to glial damage, and far greater than in other forms of status epilepticus. The rapid early rise in NfL highlights a narrow therapeutic window, underscoring the need for early, aggressive, and neuroprotective interventions.

Disclosure: This work includes data from project SE-BIO funded by LICE (Lega Italiana Contro l'Epilessia) and PREDICT, project code GR-2021-12374594 funded by the Italian Ministry of Health. The NORSE/FIRES biorepository is supported by the Daniel Raymond Wong Neurology fund and the NORSE/FIRES Research Fund at Yale.

Background and Aims: Brain tumor-related epilepsy (BTRE) is a disabling complication of brain tumors and often remains poorly controlled despite multiple antiseizure medications (ASMs). Cenobamate (CNB) showed high efficacy in drug-resistant focal epilepsy, but evidence in BTRE is limited. This study evaluated the effectiveness and safety of CNB as add-on therapy in a real-world multicenter cohort of patients with BTRE.

Methods: We conducted a multicenter retrospective observational study across tertiary epilepsy centers in Italy. Adult patients with drug-resistant BTRE treated with adjunctive CNB were included. Monthly seizure frequency was assessed at baseline and follow-up. Outcomes were seizure frequency changes, responder rates, and safety. Effectiveness was analyzed in the intention-to-treat (ITT) population.

Results: Twenty patients (10 females; median age 48 years) were included. Tumor histologies were meningioma (35%), astrocytoma (20%), glioblastoma (15%), ganglioglioma (15%), oligodendroglioma (10%), and DNET (5%). Median follow-up duration was 12 months (IQR: 9.8–12). In the ITT cohort ($n = 20$), monthly seizure frequency significantly decreased from a median of 6 seizures (IQR 18.75) at baseline to 1 seizure (IQR 2.55) at last follow-up ($p = 0.006$). Median seizure reduction was 49.7%, with 50% of patients achieving a $\geq 50\%$ reduction, 30% achieving a $\geq 75\%$ reduction, and 20% becoming seizure-free. One patient discontinued treatment before the 3-month follow-up, and one patient with glioblastoma died before the 6-month follow-up. Adverse events were predominantly mild to moderate in severity.

Conclusion: In this cohort of patients with drug-resistant BTRE, CNB add-on therapy was associated with a substantial reduction in seizure frequency and acceptable tolerability, supporting CNB as a promising option in this challenging population.

Background and Aims: Epilepsy is markedly more prevalent in individuals with intellectual disability (ID) than in the general population and is often associated with drug resistance and increased adverse effects [1]. This study aimed to evaluate the efficacy and safety of perampanel (PER) as the sole add-on therapy in patients with epilepsy and ID.

Methods: We performed a subanalysis of the PEROC study, an Italian multicenter, retrospective, longitudinal study assessing PER as the only add-on treatment [2]. Patients were stratified according to ID status into three groups: no ID (no-ID), mild ID (mID) and moderate/profound ID (mpID). Retention rate, responder rate ($\geq 50\%$ seizure reduction), seizure freedom and adverse events (AEs) were evaluated at 3, 6, and 12 months after PER introduction.

Results: The study included 356 patients: 277 no-ID, 44 mID, 35 mpID. Retention rates were slightly lower in mpID (57.1%) than mID (78.6%) and no-ID (72.7%), without significant differences ($p < 0.05$). Responder rates were comparable across groups, reaching 69.1%, in no-ID, 72% in mID, 75% in mpID at 12 months ($p = 0.848$). Seizure-freedom was higher in no-ID compared with mID and mpID at 3 (38.1%, 21.4%, 17.4%; $p = 0.046$) and 6 (42.3%,

20.7%, 19.2%; $p=0.011$) months, but no difference resulted at 12 months (46.3%, 40.5%, and 35%, respectively; $p=0.579$). AEs (mainly irritability, dizziness, drowsiness) occurred in 28.7% no-ID, 30.2% mID and 37.1% mpID patients, without significant difference ($p=0.585$).

Conclusion: Peramppanel as the only add-on therapy showed good effectiveness and tolerability in patients with ID, achieving meaningful seizure control and satisfactory retention rates in this challenging population.

Disclosure: Nothing to disclose.

OPR-117 | Performance of ictal electrical source imaging from routine clinical EEG to define the epileptogenic zone

S. Lagarde¹; N. Roehri²; L. Spinelli²; C. Benar³; S. Momjian⁴; F. Bartolomei⁵; M. Seeck²; S. Vulliemoz⁶

¹EEG and Epilepsy Unit, University Hospitals and Faculty of Medicine, University of Geneva, Switzerland; ²Epileptology Department & Institute of Systems Neurosciences, University Hospitals of Marseille and Aix-Marseille University, Marseille, France; ³EEG and Epilepsy Unit, University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland; ⁴Institute of Systems Neurosciences, Aix-Marseille University, Marseille France; ⁵Neurosurgery Department, University Hospitals and Faculty of Medicine, University of Geneva, Switzerland; ⁶Epileptology Department and Institute of Systems Neurosciences, University Hospitals of Marseille and Aix-Marseille University, Marseille, France; ⁶EEG and Epilepsy Unit, University Hospitals and Faculty of Medicine, University of Geneva, and CIBM, Centre D'Imagerie Biomédicale, Geneva, Switzerland

Background and Aims: Epilepsy surgery is the treatment of choice for drug-resistant focal epilepsy, provided the epileptogenic zone (EZ) is accurately identified. Electrical source imaging (ESI) allows three-dimensional cortical projection of EEG activity and may improve EZ localisation. Ictal analysis is more specific than interictal analysis. This study evaluates the diagnostic performance of ictal ESI using a standard clinical EEG montage in presurgical assessment.

Methods: Seventy-five patients underwent EEG recording with 37 electrodes. Individualised head models (BEM) were generated. Ictal ESI was performed using sLORETA and eLORETA. Seizure onset, time window (1–5 s), and frequency band were visually selected. Ictal power and dynamic functional connectivity (FC) were computed using Granger causality (sPDC). EZ was defined by the resection area or SEEG. Diagnostic performance was assessed using ROC analysis.

Results: A total of 213 seizures were analysed (median age 29 years); 73 patients underwent surgery, with 58.6% seizure-free at follow-up. MRI was positive in 54 cases, and 37 patients had mesiotemporal epilepsy. sLORETA and eLORETA showed comparable performance (AUROC 0.853 and 0.858, respectively). For eLORETA, sensitivity was 0.752, specificity 0.816, and accuracy 0.813. Performance was higher in seizure-free patients and in mesiotemporal epilepsy. Diagnostic accuracy varied with discharge morphology, highest for sinusoidal rhythmic patterns. FC metrics showed limited added value (AUROC 0.66). Patients with poor surgical outcome exhibited a more diffuse ictal power distribution.

FIGURE 1 ROC curve eLORETA vs. sLORETA, ictal discharge power.

FIGURE 2 ROC curve for directional ictal connectivity (sPDC) using eLORETA.

FIGURE 3 Violin plot, skewness of ictal frequency power distribution in eLORETA, depending on whether the patient is seizure-free or not.

Conclusion: Ictal ESI using standard EEG provides good accuracy for EZ localisation, particularly in seizure-free patients. Power-based ESI outperforms FC metrics, supporting its clinical relevance in presurgical evaluation.

Disclosure: Nothing to report.

OPR-118 | Discontinuation of ocrelizumab in multiple sclerosis: Re-occurrence of disease activity

F. Koenen¹; F. Axhausen²; S. Wolff²; P. Mühlenbrock²; S. Gingele¹; K. Jendretzky¹; S. Nay¹; L. Grote-Levi¹; P. Schwenkenbecher¹; S. Meuth³; T. Skripuletz¹; S. Pfeuffer¹
¹Department of Neurology, Hannover Medical School, Hannover, Germany; ²Department of Neurology, University Hospital of Giessen and Marburg, Justus-Liebig-University-Giessen, Giessen, Germany; ³Department of Neurology, University of Münster, Münster, Germany

Background and Aims: Discontinuation of B-cell depleting therapies such as ocrelizumab in people with multiple sclerosis (pwMS) is increasingly discussed due to infection risk and hypogammaglobulinemia. However, prospective data on disease reactivation, disability progression, and optimal treatment duration after cessation are limited.

Methods: In this prospective two-centre observational cohort study, pwMS treated with ocrelizumab for ≥ 12 months without inflammatory disease activity in the preceding year were enrolled between 2018 and 2023. Patients who discontinued ocrelizumab were compared with continuers using 4:1 propensity score matching. Primary outcomes were time to combined inflammatory activity (CIA; relapse and/or new T2 lesions) and progression independent of relapse activity (PIRA). Receiver operating characteristic (ROC) analyses explored associations between treatment duration, discontinuation length, and disease activity.

Results: Among 655 eligible pwMS, 290 patients (58 discontinuers, 232 continuers) were included after matching. Median post-discontinuation follow-up was 28.5 months. Discontinuation was not associated with a significantly increased risk of CIA (hazard ratio [HR] 0.91, 95% CI 0.08–10.79) or PIRA (HR 4.8, 95% CI 0.38–60.2; Figure 1) compared with continuation. Disease activity remained largely stable during the first 24 months after discontinuation, with a numerical increase thereafter. ROC analyses suggested a plateau of anti-inflammatory benefit

after approximately 29–30 months of ocrelizumab treatment and a rising risk of disease reactivation beyond 30–32 months off-treatment.

Conclusion: In clinically stable pwMS, ocrelizumab discontinuation after about 30 months appears safe in the short term for 25–43 months. Careful monitoring is warranted beyond 2 years off-treatment to detect potential delayed disease reactivation.

Background and Aims: Epstein–Barr virus (EBV) has been implicated in the pathogenesis of multiple sclerosis (MS). Elevated immunoglobulin G (IgG) titers against EBV nuclear antigen 1 (EBNA1) represent the most consistent serological marker of MS risk, with levels remaining persistently elevated following disease onset.

Methods: We conducted high-dimensional profiling of virus-specific antibody-associated immune features in 60 individuals with relapsing-onset MS followed over time and in 54 age- and sex-matched EBV-seropositive healthy controls.

Results: EBNA1-specific IgG in MS patients exhibited a distinct proinflammatory Fc signature, characterized by increased affinity for Fcγ receptors (FcγRs) and enhanced Fc-mediated effector functions, including antibody-dependent phagocytosis, complement activation, and natural killer cell engagement. This signature was not observed for antibodies against other common viral antigens and showed a strong association with MS. Increased FcγR binding by IgG specific for both EBNA1 and the

lytic EBV glycoprotein 350 correlated with disease activity, defined as clinical relapse and/or presence of contrast-enhancing brain lesions.

Conclusion: Both Fab- and pro-inflammatory functional Fc-mediated features contribute to the association between EBNA1-specific antibody responses and MS. Fc effector functions of EBV-specific antibodies may actively participate in promoting focal disease activity in MS.

Disclosure: Nothing to disclose.

Background and Aims: Kappa-deleting recombination excision circles (KRECs) and T-cell receptor excision circles (TRECs) are measures of newly generated B- and T-cells respectively. Given their potential as immune aging biomarkers, we evaluated their association with disease activity and disability in people with Multiple Sclerosis and assessed their relationship with Disease-Modifying Therapies (DMTs).

Methods: We included treatment-naïve relapsing–remitting MS patients from a 24-month prospective multicenter study

FIGURE 1 Project Overview.

FIGURE 1 Longitudinal KRECs changes under different DMTs at baseline and after 12 months.

FIGURE 2 Longitudinal TRECs changes under different DMTs at baseline and after 12 months.

involving 9 European centers (MultipleMS). TRECs ($n=471$) and KRECs ($n=472$) levels were determined by qPCR at baseline and at 1-year. Associations with age, baseline Expanded Disability Status Scale (EDSS), and time to first relapse in the 24 months before and after baseline were assessed through linear models and Cox regression. Longitudinal TRECs and KRECs changes under different DMTs and in untreated patients were assessed by Wilcoxon tests on cell-count-adjusted values.

Results: Both TRECs ($p=4.65 \times 10^{-13}$) and KRECs ($p=0.004$) significantly decreased with age, with a stronger effect observed for TRECs. Neither TRECs nor KRECs correlated with baseline EDSS, although a negative trend was observed in patients with EDSS < 3.0. No associations were found with time to first relapse. DMTs had distinct effects on immune output: TRECs significantly decreased under fingolimod, remained stable with alemtuzumab and cladribine, and increased with other therapies at 1 year. KRECs declined markedly under fingolimod and anti-CD20 therapies, more mildly under dimethyl fumarate and teriflunomide, and increased under natalizumab.

Conclusion: TRECs and KRECs primarily reflect immune ageing in MS and are differentially modulated by DMTs. This study prompts future investigations for their role as markers of DMT response.

OPR-121 | Treatment specific infection risk in multiple sclerosis patients: A Danish nationwide registry study

R. Holm¹; F. Elberling¹; S. Poulsen²; F. Sellebjerg³; M. Magyari¹
¹Danish Multiple Sclerosis Registry, Department of Neurology, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark; ²Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; ³Danish Multiple Sclerosis Center, Department of Neurology, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark

Background and Aims: Disease-modifying therapies (DMTs) for multiple sclerosis (MS) vary in immunomodulatory and immunosuppressive effects. We compared infection risks across DMTs using nationwide registry data.

Methods: Patients starting DMTs (2017–2024) were identified in the Danish Multiple Sclerosis Registry. ICD-10 codes captured

hospital-treated infections, and antimicrobial (AM) prescriptions by ATC codes served as infection proxies. Risk windows covered treatment duration plus a treatment-specific period— infections within 6 months before treatment were excluded. Cox models estimated the risks of infection and AM use, accounting for repeated measures and adjusting for demographic and clinical covariates.

Results: The cohort included 11,140 patients and 24,403 treatment episodes. All DMTs, especially anti-CD20 agents (HR: 3.0, 95% CI: 2.7–3.5), were associated with higher infection risks than teriflunomide, except alemtuzumab. Most DMTs increased antiviral use, with alemtuzumab conferring the greatest risk (HR: 9.8, 95% CI: 7.1–13.3). Alemtuzumab and ocrelizumab raised antimycotic use, and alemtuzumab had the highest total AM use.

Conclusion: This nationwide registry study found that anti-CD20 DMTs conferred the highest infection risk, while alemtuzumab was associated with the greatest AM use. These findings underscore the heterogeneity of infection profiles and emphasize the need for tailored clinical management strategies across DMTs.

Disclosure: Rolf Pringler Holm has received speaker honoraria from Sanofi and Novartis, has served on an advisory board for Novartis, and has received a travel grant from The Danish Multiple Sclerosis Society. ¹Laboratories of Neuroimmunology, Neuroscience Research Centre, Department of Clinical Neurosciences, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; ²Ludwig Institute for Cancer Research, Lausanne Branch, Department of Oncology, Lausanne University Hospital and University of Lausanne, Agora Cancer Research Center, Lausanne, Switzerland; ³Biomedical Data Science Center, University of Lausanne and Lausanne University Hospital, Swiss Institute of Bioinformatics, Lausanne; ⁴Service of Neurology, Department of clinical neurosciences, University Hospital of Lausanne and Lausanne University Hospital, Lausanne, Switzerland

Background and Aims: Clonally expanded CD8+ T cells are prevalent in CNS lesions of persons with MS (pwMS), suggesting antigen-driven proliferation. Beyond myelin, studies suggest that astrocytes and neurons may also be targeted. Since astrocytes and neurons upregulate HLA class I in active lesions, we sought to assess if pwMS harbor CD8+ T cells targeting these cells.

Methods: We generated human-induced pluripotent stem cell (hiPSC) derived astrocytes and neurons from 8 pwMS and 6 age-matched healthy donors (HD). We then cultured peripheral blood mononuclear cells (PBMC) with autologous hiPSC-derived astrocytes or neurons for 14 days. To identify proliferating clonotypes, CD8+ T cell TCR repertoires were compared before and after coculture. The TCRs of these clonotypes were then transfected into NFAT-luciferase Jurkat cells to validate for CNS autoreactivity. Public TCR databases from the blood/CSF of pwMS were screened for identical/similar TCR-β CDR3 sequences. Finally, scRNAseq was performed on expanded CD8+ T cells.

Results: We demonstrate that CD8+ T cell repertoires of pwMS are restricted after coculture with astrocytes only. Astrocyte-reactive clonotypes are exclusively found in pwMS (5/7 pwMS vs. 0/5 HD) with most clonotypes non-reactive against PBMC, indicating CNS specificity. Identified astrocyte-specific CD8+ T cell clonotypes share similar CDR3 sequences to blood/CSF clonotypes from pwMS from public databases. scRNAseq reveals that these clonotypes display a highly proliferative activated cytotoxic phenotype.

Conclusion: Our autologous CNS antigen presentation system demonstrates that astrocyte-specific CD8+ T cells are a frequent finding in pwMS whilst mostly absent in HD, reinforcing a potential pathogenic role for astrocyte-specific CD8+ T cells in MS.

Background and Aims: Patients with atrial fibrillation (AF) experiencing ischemic stroke despite oral anticoagulation (OAC) face high risk of recurrence and bleeding. We compared 90-day outcomes between patients with and without competing stroke etiologies after breakthrough ischemic stroke on OAC for AF.

Methods: ASPERA-R retrospectively enrolled adults (>18 years) with AF experiencing breakthrough ischemic stroke on continuous OAC (≤ 48 h) across 35 centers (Feb 2020–Feb 2025). Eligibility required imaging-confirmed stroke, vessel imaging, and 90-day follow-up; inadequate dosing or poor adherence were excluded. Competing etiologies coexisting with cardioembolism were assessed. Primary outcome: 90-day recurrent stroke; secondary: mRS shift, myocardial infarction, vascular and all-cause death, and bleeding. IPW balanced baseline co-variables; Cox/regression models compared outcomes.

Results: Among 1649 patients (mean age 78, 47.8% male), 24.3% had competing etiologies, most commonly large-artery atherosclerosis (59.9%). Weighted analyses showed higher 90-day recurrent ischemic stroke in patients with competing etiologies (6.0% vs. 2.7%; aHR 2.62), particularly large-artery atherosclerosis and other determined causes. They also had worse disability (aOR 1.30), higher all-cause mortality (aHR 1.58), and increased moderate-to-severe bleeding (aHR 1.82), while 24-h

FIGURE 1

FIGURE 2

FIGURE 3

hemorrhagic transformation was less frequent (aRD -4.3%). Other outcomes did not differ

Conclusion: One in four patients with AF and breakthrough ischemic stroke on OAC had competing etiologies, most often large-artery atherosclerosis. These patients showed higher risk of recurrent stroke, functional dependence, mortality, and bleeding, highlighting the need for development of individualized secondary prevention. Main study limits include observational retrospective design and incomplete data on on-treatment anticoagulation quality.

Disclosure: Nothing to disclose.

OPR-124 | Continuation versus switching direct oral anticoagulant after breakthrough stroke: A non-inferiority target trial analysis from the ASPERA-R Study

Background and Aims: Management of ischemic stroke occurring despite direct oral anticoagulant (DOAC) therapy for atrial fibrillation remains inconsistent due to limited evidence regarding the benefits of switching treatments. This study aims to evaluate the effectiveness and safety of continuing the current DOAC versus switching to an alternative oral anticoagulant, utilizing a predefined non-inferiority framework.

Methods: This multicenter, retrospective study involved 35 stroke centers across Europe and North Africa. We emulated a target trial employing a non-inferiority comparison of continuation versus switching to an alternative oral anticoagulant (different DOAC or VKA) after a breakthrough stroke. The primary outcome was 90-day net clinical benefit (recurrent ischemic stroke and moderate-to-severe bleeding). Secondary endpoints included all-cause mortality, vascular death, and specific recurrent ischemic or hemorrhagic events.

Results: We included 1006 consecutive adults (median age 80.4 years; 50% women). After IPTW adjustment, the 90-day net clinical benefit was similar between strategies (Figure 1): 5.1% in continuation vs. 4.9% in switching (Figure 2), with a risk difference of -0.3% (90% CI, -2.7% to 2.1%), satisfying non-inferiority. Recurrent ischemic events and bleeding outcomes were likewise comparable, with absolute differences within prespecified margins. Non-inferiority was not demonstrated for all-cause or vascular mortality.

FIGURE 1 Sankey flow of pre-stroke DOAC agent and post-stroke anticoagulation strategy.

FIGURE 2 Strategy-specific comparison for net clinical benefit (IPTW, Risk Difference scale).

Conclusion: Continuing the same DOAC after a breakthrough ischemic stroke resulted in clinical outcomes comparable to switching anticoagulant therapy, with absolute differences within clinically acceptable margins for most outcomes. Our findings do not support routine switching to improve secondary prevention after a breakthrough event. Randomized controlled trials are needed to identify strategies to improve secondary prevention after a breakthrough ischemic stroke.

Disclosure: Nothing to disclose.

OPR-125 | Clinical outcome of MRI-negative acute ischemic stroke treated with and without intravenous thrombolysis

F. Fenter¹; V. Dunet²; P. Michel¹; D. Strambo¹
¹Stroke Center, Neurology Service, Department of Clinical Neurosciences, Lausanne, Switzerland; ²Neuroradiology Unit, Service of Diagnostic and Interventional Radiology, Department of Medical Radiology, both at the Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland

Background and Aims: Intravenous thrombolysis (IVT) for acute ischemic stroke (AIS) is guided by clinical assessment and exclusion of radiological contraindications. While MRI protocols reduce mistreatment of stroke mimics, infra-radiologic strokes (IRS) on admission MRI remain diagnostically challenging. We aimed to characterize MRI-based IRS and evaluate their clinical and functional outcomes.

Methods: From our local prospectively-constructed stroke registry we identified all AIS undergoing acute MRI, without

FIGURE 1 Forest plot of binary/categorical outcomes.

intracranial occlusion. IRS were defined as clinically diagnosed AIS with negative DWI and perfusion imaging. IRS were compared with radiologically confirmed (RC)-AIS. Within IRS-patients, IVT-treated patients were compared with those receiving conservative treatment. Outcomes included 3-month modified-Rankin-Scale (mRS) shift, 24-h-NIHSS-shift, lesion evidence on follow-up imaging (LFI). Analyses were adjusted using propensity score weighting.

Results: Among 1315 consecutive eligible AIS between 2018 and 2024, 58 (4.4%) had an IRS. Compared with RC-AIS in univariate analysis, IRS patients had similar baseline NIHSS, shorter onset-to-door times (96 vs. 246 min, $p < 0.001$), less paresis (44.8% vs. 63.4%, $p = 0.006$), more infra-tentorial localization (48.3% vs. 22.5%, $p < 0.001$), received more IVT (63.8% vs. 32.1%, $p < 0.001$), and had less LFI (17.8% vs. 73.3%, $p < 0.001$). After adjustment, IRS patients had greater 24-h-NIHSS improvement (beta = 1.68, 95% CI = 0.29–3.07), less LFI (psWOR = 0.05, 95% CI = 0.02–0.12), and similar 3-month mRS. Within the IRS group, IVT was associated with greater 24-h-NIHSS improvement (beta = 2.97, 95% CI = 1.17–4.78) without significant 3-month mRS changes.

Conclusion: IRS represent an uncommon AIS radiotype and overall similar medium-term outcomes as MRI-positive AIS. In IRS, IVT was associated with improved short but not medium-term outcomes.

Disclosure: Nothing to disclose.

OPR-126 | Exploring the contribution of cerebrovascular risk factors to glymphatic system impairment in multiple sclerosis

M. Rubin¹; P. Preziosa¹; E. Pagani²; A. Meani²; M. Margoni³; L. Storelli²; M. Albergoni²; M. Filippi⁴; M. Rocca¹
¹Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ²Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁴Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Cerebrovascular risk factors (cVRFs) associate with greater brain damage and disability in multiple sclerosis (MS) patients. The glymphatic system, contributing to brain waste clearance, is impaired in both MS and cerebrovascular diseases. We investigated whether choroid plexus volume (CPV) and the diffusion tensor imaging analysis along the perivascular spaces (DTI-ALPS) are influenced by cVRFs in MS.

Methods: Two-hundred nine MS patients and 123 age- and sex-matched healthy controls (HC) underwent cVRF, neurological evaluation, and brain 3T MRI acquisition. CP volume was quantified using a deep learning-based approach on 3D T1-weighted MRI scans; DTI-ALPS was used to assess glymphatic system function.

Results: At least one cVRF was present in 64% of MS patients and 41% of HC. MS patients with and without cVRFs showed no differences for disease duration, disability, clinical phenotype and treatment ($p \geq 0.738$). Compared to HC, MS patients had significantly higher T2-hyperintense white matter (WM) lesion volume, lower global and regional brain volumes, and larger CPV (FDR- $p \leq 0.003$), regardless of cVRFs (FDR- $p \geq 0.553$). Both MS groups with and without cVRFs exhibited significantly lower DTI-ALPS index compared to their respective HC counterparts (FDR- $p \leq 0.002$), with the coexistence of MS and cVRFs resulting in a significantly greater DTI-ALPS index reduction (FDR- $p = 0.013$). Lower DTI-ALPS and higher CPV correlated with higher T2-hyperintense WM lesion volume and lower brain volumes (FDR- $p \leq 0.007$), independently from cVRF presence (FDR- $p \geq 0.122$).

Conclusion: cVRFs may worsen glymphatic system dysfunction in MS, possibly contributing to aggravate neuroinflammation and neurodegeneration and supporting the importance of proactive cVRF management.

OPR-127 | Endovascular therapy improves clinical outcomes in acute ischemic stroke due to isolated M2 occlusion: Real-world experience from the RES-Q registry

R. Herzig¹; S. Szabó²; G. Neto³; R. Mikulík³

¹Department of Neurology, Charles University Faculty of Medicine and University Hospital Hradec Králové, Hradec Králové, Czech Republic; ²Department of Neurology, Charles University Faculty of Medicine in Hradec Králové, Hradec Králové, Czech Republic; ³International Clinical Research Center, St. Anne's University Hospital in Brno, Brno, Czech Republic

Background and Aims: Indication for endovascular therapy (EVT) in acute ischemic stroke (AIS) caused by middle cerebral artery M2 segment (MCA/M2) occlusion remains controversial. The aim was to compare clinical outcomes in these patients treated with intravenous thrombolysis (IVT), EVT, and IVT + EVT.

Methods: In an observational multicenter cohort study, we analyzed data from AIS with causative MCA/M2 occlusion treated with IVT, EVT, and IVT+EVT, prospectively collected in the RES-Q registry in the Czech Republic (2022–2024). Clinical outcomes were assessed using utility-weighted 3-month modified Rankin Scale (mRS) and 3-month mortality. Baseline differences were adjusted using multivariable ordinal regression for utility-weighted 3-month mRS and multivariable logistic regression for 3-month mortality, including age, sex, National Institutes of Health Stroke Scale, pre-stroke mRS, and onset-to-treatment time. Missing 3-month outcomes were handled using multiple imputation.

Results: The IVT group consisted of 520 (248 males; median age 74 [65–82] years), the EVT group of 223 (117 males; median age 73 [61–81] years), and the IVT+EVT group of 321 patients (163 males; median age 73 [64–79] years). Adjusted utility-weighted 3-month mRS was significantly better in the IVT+EVT versus IVT group (OR 1.26, 95% CI 1.05–1.51), and in the IVT+EVT versus EVT group (OR 1.31, 95% CI 1.07–1.59); there was no difference between the EVT and IVT groups. There were no differences in 3-month mortality between the groups.

Conclusion: The addition of EVT to IVT was associated with better 3-month clinical outcomes compared with IVT alone in patients with AIS due to MCA/M2 occlusion.

Szabolcs Szabó was supported by Charles University, Czech Republic (Cooperatio Program, research area NEUR). Geraldo Neto and Robert Mikulík were supported by STROCZCH within the CZECRIN Large Research Infrastructure (No. LM2023049) funded by the state budget of the Czech Republic.

OPR-128 | The EJS ACT-PD multi-arm, multi-stage platform trial: Assessing potential disease-modifying therapies for Parkinson's disease

G. Mills¹; M. Zeissler²; C. Gonzalez-Robles¹; O. Bandmann³; R. Barker⁴; L. Brennan⁵; J. Carpenter⁵; S. Collins²; J. Duffen⁶; S. Gandhi¹; C. Girges¹; R. Gurney¹; K. McFarthing⁷; C. Murphy⁵; C. Pugh⁵; A. Schapira¹; A. Schrag¹; T. Foltynie¹; C. Carroll²

¹University College London; ²Newcastle University; ³University of Sheffield; ⁴University of Cambridge; ⁵Medical Research Council Clinical Trials Unit; ⁶Cure Parkinson's; ⁷Expert by Experience

Background and Aims: The Edmond J. Safra Accelerating Clinical Trials in Parkinson's disease (EJS ACT-PD) trial uses a multi-arm, multi-stage (MAMS) design to accelerate the evaluation of potential disease-modifying therapies (DMTs) for Parkinson's disease (PD). MAMS designs enable simultaneous testing of multiple therapies; early identification of ineffective therapies for discontinuation; and efficient incorporation of new candidates. The primary objective is to detect a 30% reduction in the rate of increase in Movement Disorder Society-Unified PD Rating Scale (MDS-UPDRS) parts I and II combined within a representative UK population of people with PD.

Methods: Initially 1600 participants will be recruited across 40 UK sites using a self-referral online registration of interest process. Participants will be randomised to telmisartan, terazosin, or placebo, with a third treatment arm (ursodeoxycholic acid) opening in 2026. A hybrid delivery model enables 6-monthly visits to be conducted either in person or remotely. Trial medication will be delivered to participants homes to be taken for up to 3 years. Early-stage analyses will use the MDS-UPDRS parts I, II and remote III to inform discontinuation of ineffective treatments. Sub-studies include passive digital monitoring of progression and optional collection of blood and cerebrospinal fluid for biomarker research.

Results: Recruitment opened in September 2025, with site activation continuing until March 2026. Over 1300 individuals have already registered interest.

Conclusion: EJS ACT-PD is set to become the world's largest Parkinson's disease trial, providing an efficient platform to evaluate multiple DMTs while generating an extensive dataset to advance understanding of disease progression.

Disclosure: Nothing to disclose.

OPR-129 | PD vs. PSP-P: superior diagnostic biomarker performance for combining Tau-PET and MRI

T. van Eimeren¹; J. Gnörich²; P. Alster³; G. Bischoff⁴; N. Franzmeier⁵; N. Madetko-Alster³; C. Palleis⁶; M. Brendel⁷; H. Theis¹; G. Höglinger⁶

Life Molecular Imaging, a Lantheus Company; ⁵German Center of Neurodegenerative Diseases (DZNE), Munich, Germany. Institute of Stroke and Dementia Research (ISD), University Hospital, LMU Munich, Munich, Germany. The Sahlgrenska Academy, Institute of Neuroscience and Physiology; ⁶German Center of Neurodegenerative Diseases (DZNE), Munich, Germany. Munich Cluster for Systems Neurology (SyNergy), Munich, Germany. Department of Neurology, University Hospital, LMU Munich, Munich, Germany; ⁷Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, Germany. German Center of Neurodegenerative Diseases (DZNE), Munich, Germany. Munich Cluster for Systems Neurology (SyNergy), Munich, Germany

Background and Aims: Differentiating the parkinsonian variant of progressive supranuclear palsy (PSP-P) from Parkinson's disease (PD) remains clinically challenging due to substantial phenotypic overlap. Reliable imaging biomarkers are therefore essential to improve early diagnostic accuracy. This study evaluated whether structural MRI (midbrain-to-pons ratio) or Tau-PET ([¹⁸F]PI-2620) provides superior discriminatory power, and whether a multimodal approach enhances diagnostic performance.

Methods: Fourteen patients with PD and fifteen with PSP-P were diagnosed according to recent consensus criteria. All subjects underwent Tau-PET imaging (20–40 min p.i.). Midbrain-to-pons (M/P) ratios were derived from high-resolution T1-weighted MRI. ROC analyses were performed for M/P ratio, globus pallidus (GP) SUVRs, and a combined logistic-regression model including both biomarkers. AUCs were compared using DeLong tests. Binary logistic regression models assessed explained variance (Nagelkerke R²) and improvements in model fit via -2LL chi-square comparisons.

Results: AUCs were 0.79 for M/P ratio, 0.83 for GP SUVRs, and 0.91 for the combined model. DeLong testing showed no significant difference between M/P ratio and GP SUVRs ($p=0.73$), but the combined model outperformed M/P ratio alone ($p<0.05$). Logistic regression revealed explained variance of 38% for M/P

FIGURE 1 Mean [¹⁸F]PI-2620 SUVR images of the PD and PSP-P group.

FIGURE 2 ROC curves for M/P ratio, globus pallidus (GP) SUVRs, and a combined logistic-regression model including both biomarkers.

ratio, 50% for GP SUVRs, and 72% for the combined model. Adding PET to MRI and adding MRI to PET improved model fit significantly ($p < 0.005$) in both directions.

Conclusion: Both MRI and Tau-PET serve as informative biomarkers for differentiating PD from PSP-P, with PET showing higher individual discriminatory power. However, combining structural MRI and Tau-PET provides the strongest diagnostic accuracy, supporting multimodal biomarker strategy for early and reliable differentiation of PD and PSP.

OPR-130 | Digital biomarkers in normal pressure hydrocephalus: Instrumented timed up and go for assessing and predicting shunt response

I. D’Ascanio¹; D. Milletti²; E. Magelli²; A. D’Apolito³; L. Sambati²; L. Albini-Riccioli²; D. Mascarella²; P. Cortelli³; G. Calandra-Buonaura²; S. Cevoli²; L. Palmerini¹; G. Palandri²; G. Giannini²

¹Department of Electrical, Electronic and Information Engineering, Alma Mater Studiorum – University of Bologna, Bologna, Italy;

²IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy;

³Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna, Bologna, Italy

Background and Aims: Normal pressure hydrocephalus (NPH) is characterized by early manifestations of gait apraxia [1]. Wearable sensors have emerged as a promising approach to quantitatively capture motor impairments, with sensor-derived motor parameters demonstrating moderate to strong correlations with clinical measures [3]. This study aims to evaluate sensor-derived

motor parameters by assessing both their responsiveness to shunt surgery and their ability to predict shunt response.

Methods: A total of 254 NPH individuals from the Bologna PRO-Hydro cohort performed instrumented Timed Up and Go using a sensor worn on the lower back, at baseline (preTT), 3 days after (postTT) the cerebrospinal fluid tap test (CSF-TT), and 6 months following shunt surgery (postShunt) [4]. Responsiveness to shunt surgery was assessed by examining changes between preTT and postShunt. Two predictive models were developed using preTT values alone or combined with postTT–preTT changes. The prognostic value of CSF-TT for surgery outcomes was assessed via likelihood ratio testing.

Results: Most instrumental variables showed statistically significant improvements after surgery, including reduced duration ($p < 0.001$), more controlled sit-to-walk transitions (lower jerk, $p < 0.001$), and faster turns (higher velocity, $p < 0.01$). Most parameters showed a significant improvement in the predictive model when $\Delta(\text{postTT} - \text{preTT})$ was included as a predictor. Motor strategies during sit-to-walk were found to be key determinants in post-shunt prediction (adjusted $R^2 > 0.65$).

Conclusion: Sensor-derived parameters capture clinically meaningful motor changes provide significant predictive value for surgery outcomes. These findings support the use of instrumented motor tests as objective measures to complement traditional clinical assessments and guide candidate selection for shunt surgery.

Disclosure: Nothing to disclose.

OPR-131 | Tourette syndrome symptomatology associated with hyper-glutamatergic activity in the anterior cingulate cortex

M. Boussac¹; A. Salabert²; E. Harroch³; C. Thalamas⁴; P. Poyoux⁵; C. Brefel-Courbon³

¹Toulouse NeuroImaging Center (ToNIC), Inserm, University of Toulouse III (UPS), France; ²Radiopharmacy Department, Toulouse University Hospital, Toulouse, France; ³Clinical Pharmacology and Neurosciences Department, Parkinson Expert Center, Toulouse University Hospital, NeuroToul COEN (Center of Excellence in Neurodegeneration), Toulouse, NS-PARK/FCRIN Network, France; ⁴Clinical Investigation Center, Clinical Pharmacology Department, Toulouse University Hospital, Toulouse, France; ⁵Nuclear Medicine Department, Toulouse University Hospital, Place du Dr Baylac, Toulouse Cedex, France

Background and Aims: In Tourette syndrome (TS), tics would result from a dysfunction in the cortico-basal ganglia-thalamo-cortical loops (Atkinson-Clement et al. 2020), related to an hyper-dopaminergic activity. Nonetheless, treatment by dopamine antagonists is not sufficient for every patients, and topiramate, a glutamatergic antagonist, is sometimes more efficient to reduce tics (Cs et al. 2013). Therefore, our objective was to study the glutamatergic system in vivo in TS patients by evaluating NMDA receptors (NMDAR) activity using PET (Positron emission tomography) imaging.

Methods: TS patients ($n = 12$) and matched healthy volunteers ($n = 12$) were included in the GlutaTour study (NCT03681795). PET was done using the [18F]-FNM (Fluoroethylnormemantine) radiotracer to study activated NMDAR. Tics severity was measured using the YGTSS (Yale Global Tic Severity Scale). Normalized PET activity was compared between TS patients

Figure 1. Comparisons of PET activity between patients with Tourette syndrome (TS) and healthy volunteers. **A.** Comparisons of PET activity between two paired subjects (A1, a patient with TS, and A2, a healthy control). A color scale bar indicates the intensity of ¹⁸F-NMBA activity in PET imaging (A1/A2). **B.** Comparisons of PET activity between groups. A color scale bar indicates the intensity of ¹⁸F-NMBA activity in PET imaging (B1/B2). **C.** Correlations between PET activity in the rACC and total PET activity in patients with TS (linear regression in dotted red lines; $r = \text{Pearson coefficient of correlation}$; and $**p < 0.01$).

FIGURE 1 Comparisons of PET activity between patients with Tourette syndrome (TS) and healthy volunteers.

and healthy volunteers (t -tests), and correlations were done between YGTSS scores and normalized PET activity in patients.

Results: Activated NMDAR were significantly higher in TS patients compared to healthy volunteers, mainly in the right anterior cingulate cortex (rACC) (p -value = 0.03), and their activity in the rACC correlated significantly and positively with the YGTSS scores (p -value = 0.005 and coefficient = 0.75).

Conclusion: This study is the first to have evaluated in vivo part of the glutamatergic system in TS patients, showing more activity within the NMDAR compared to controls. This supposed “hyper-glutamatergic activity” in the ACC of TS patients could highlight a disinhibition of direct striatal pathway in TS which would result in tics emergence.

Disclosure: I declare no conflict of interest for this study. This study was funded by the AFSGT (Association Française du Syndrome de Gilles de La Tourette/French Tourette Syndrome Association) and HoPeS (Institut des Handicaps Neurologiques, Psychiatriques et Sensoriels/Neurological, Psychiatric and Sensorial Disabilities Institute).

OPR-132 | Remote deep brain stimulation programming for Parkinson's disease: A prospective, randomized, controlled, multicentre, non-inferiority trial

T. Köglspurger¹; J. Shaik¹; W. Zhang¹; V. Zentsch²; C. Buhmann³; U. Hidding³; T. Kinfe⁴; M. Regensburger⁵; J. Rumpf⁶; A. Schnitzler⁷; J. Dong¹; M. Scherer¹; E. Kaufmann¹; G. Höglinger¹; J. Mehrkens⁸

¹Department of Neurology, LMU University Hospital, Ludwig Maximilian University of Munich, Germany; ²Department of Neurology, University of Münster, Germany; ³Department of Neurology, University Medical Center Hamburg-Eppendorf, Germany; ⁴Dr. Rolf M. Schwiete Endowed Chair for Neuromodulation and Neuroprosthetics, Medical Faculty Mannheim, Ruprecht-Karls-University Heidelberg, Germany; ⁵Department of Molecular Neurology, Friedrich-Alexander Universität (FAU) of Erlangen-Nürnberg, Erlangen, Germany; ⁶Department of Neurology, University of Leipzig, Leipzig, Germany; ⁷Institute of Clinical Neuroscience and Medical Psychology, Medical Faculty, Heinrich Heine University, Düsseldorf, Germany; ⁸Department of Neurosurgery, Ludwig Maximilian University of Munich, Germany

Background and Aims: Deep brain stimulation (DBS) is an effective therapy for advanced Parkinson's disease (PD), but outcomes depend on expert programming, usually requiring in-person visits to specialised centres. Remote DBS programming could improve access, yet controlled prospective evidence is limited.

Methods: We conducted a prospective, multicentre, randomised, open-label, non-inferiority trial at DBS centres in Germany. Patients with idiopathic PD requiring DBS programming were assigned (1:1) to standard in-person programming (standard of care [SoC]) or remote programming via a secure telemedicine platform. The primary endpoint was the MDS-UPDRS Part III score (medication-on/stimulation-on) at 3 months, with a non-inferiority margin of 5 points. Secondary outcomes included motor and non-motor symptoms, quality of life, cognition, levodopa equivalent daily dose (LEDD), and safety. Analyses were per protocol (ClinicalTrials.gov NCT05193825).

Results: Between March 2022 and December 2024, 52 patients were randomised; 48 were analysed (SoC $n = 26$; remote $n = 22$). Median MDS-UPDRS Part III improvement at 3 months was -23.0 points in the SoC group and -20.5 in the remote group. The median between-group difference was -2.5 (95% CI -9.0 to 2.0), meeting non-inferiority criteria. Improvements in total MDS-UPDRS, Hoehn and Yahr stage, and PDQ-39 were similar. MoCA scores improved more with remote programming, while LEDD reduction was greater with SoC. Adverse events and serious adverse events were comparable between groups.

Conclusion: Remote DBS programming was non-inferior to in-person programming for motor outcomes at 3 months, with similar safety and patient-reported benefits, supporting its integration into routine DBS care.

OPR-133 | Does DaTScan have a prognostic value for motor decline in Parkinson's disease patients? A multimodal deep learning study

F. Ragni¹; W. Endrizzi¹; S. Bovo¹; M. Malaguti²; C. Longo²; N. Campese²; M. Moroni¹; G. Jurman¹

¹Fondazione Bruno Kessler, Trento, Italy; ²U.O. Neurologia, Azienda Sanitaria Universitaria Integrata del Trentino (ASUIT), Trento, Italy

Background and Aims: Parkinson's disease (PD) trajectories vary widely among individuals, making it difficult to predict disease progression and to identify patients at risk of rapid decline. Among routinely collected data from PD patients there is DaTScan, whose prognostic value for motor complications remains debated. This study implements state-of-the-art Deep Learning (DL) architectures to investigate the prognostic value of DaTScan volumes and electronic health records (EHRs) data, separately and in multimodal combination, in predicting future motor decline.

Methods: A longitudinal cohort of 513 patients at different PD stages from the Parkinson's Progression Markers Initiative dataset with EHRs data, DaTScan volumes at baseline and UPDRS Part III evaluation at 3-year follow-up was used to develop a dual-branch DL architecture. The first branch employs a tabular foundation model for EHRs data, while the second extracts compressed embeddings from DaTScan volumes using a 3D Convolutional Neural Network. The embeddings are then

TABLE 1 Mean Performance Metrics. Averaged scores across the three folds for the uni- and multimodal architectures.

Mean Metric	EHRs-Only	DaTscan-Only	Multimodal
MAE	6.51 ± 0.03	8.82 ± 0.03	6.49 ± 0.09
R ²	0.414 ± 0.003	0.049 ± 0.019	0.423 ± 0.013

merged for regression of the UPDRS Part III evaluation at 3-year follow-up. This modular design facilitated an ablation study to quantify the contribution of each modality.

Results: Model performances were evaluated using Mean Absolute Error (MAE) and R2 on a three-fold cross validation scheme (Table 1). The unimodal EHRs-based model achieved a MAE of 6.51 ± 0.03 (mean ± SD), comparable to the complex multimodal architecture.

Conclusion: Despite its diagnostic relevance, DaTscan provides limited prognostic benefits beyond standard clinical features. The EHRs-only model offers comparable performance while reducing model complexity and computational demands. Future prognostic modeling should prioritize richer clinical characterization over striatal imaging features.

OPR-134 | Dysregulated CX3CR1 signaling in mesial temporal lobe epilepsy: Evidence from human brain tissue and monocyte-derived microglia

B. Guerra Leal¹; C. Carvalho²; P. Beça²; C. Santos³; R. Samões⁴; C. Teixeira⁵; P. Pinho e Costa¹; M. Lobo⁶; P. Correia de Sá⁶; J. Chaves⁴

¹Unit for Multidisciplinary Research in Biomedicine (UMIB,ICBAS-UPorto); Immunogenetics Laboratory, School of Medicine and Biomedical Sciences, University of; Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal; ²Immunogenetics Laboratory, Department of Molecular Pathology and Immunology, School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal; ³Unit for Multidisciplinary Research in Biomedicine (UMIB,ICBAS-UPorto); Immunogenetics Laboratory, Department of Molecular Pathology and Immunology, School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal; ⁴Unit for Multidisciplinary Research in Biomedicine; Santo António Hospital, Santo António Local Health Unit, Porto, Portugal; ⁵Santo António Hospital, Santo António Local Health Unit, Porto, Portugal; ⁶Pharmacology and Neurobiology Laboratory Neurobiology, Center for Drug Discovery and Innovative Medicines (MedInUP), ICBAS-UP, Porto, Portugal

Background and Aims: CX3CR1, the fractalkine (CX3CL1) receptor, is expressed by CNS-resident microglia and mediates microglia–neuron communication. Chronic microglial activation is a hallmark of mesial temporal lobe epilepsy with hippocampal sclerosis (MTLE-HS) and contributes to neuroinflammation and neuronal hyperexcitability. Seizure-induced release of CX3CL1 may activate microglial CX3CR1, amplifying inflammatory signaling. We studied this pathway by analyzing

CX3CR1 expression in human epileptic brain tissue and in an in vitro model of monocyte-derived microglia-like cells (MMG). **Methods:** MMG cells were differentiated from peripheral blood monocytes of 15 MTLE-HS patients and 5 healthy donors. CX3CR1 mRNA levels were assessed under basal conditions and following lipopolysaccharide (LPS) stimulation. The findings were validated in hippocampal and temporal neocortex samples from 19 MTLE-HS (8 males, 43.5 ± 10.0 years) patients and 10 controls (8 males, 67.0 ± 10.0 years).

Results: MMG cells derived from MTLE-HS patients showed higher basal CX3CR1 expression compared to controls, with further upregulation after inflammatory stimulation. In parallel, CX3CR1 transcripts were significantly increased in both the hippocampus and the temporal neocortex of MTLE-HS patients (1.96-fold, $p=0.004$; 2.23-fold, $p<0.01$, respectively).

Conclusion: Together, these concordant in vitro and in vivo findings suggest a primed, maladaptive microglial activation state in MTLE-HS. Although CX3CR1 is typically associated with microglial homeostasis, its sustained upregulation in chronic epilepsy may contribute to persistent neuroinflammation. These results highlight the CX3CL1/CX3CR1 axis as a potential therapeutic target to modulate microglia–neuron interactions and reduce seizure susceptibility in drug-resistant epilepsy.

¹University of Catanzaro, Italy; ²University of Salerno; ³Campus Bio-Medico University of Rome, Italy; ⁴Tor Vergata University of Rome; ⁵Sapienza University of Rome, Rome, Italy

Background and Aims: Cenobamate (CNB) is a recently approved antiseizure medication (ASM) for drug-resistant focal epilepsy. Despite its proven efficacy, real-world pharmacokinetic data, particularly regarding sex-based variations and interactions with concomitant ASMs, remain limited. This study aimed to investigate the pharmacokinetic profile of CNB in clinical practice and evaluate its relationship with demographic and clinical variables.

Methods: We conducted an exploratory study on 17 adult responder patients receiving add-on CNB. Plasma concentrations were measured at each dose titration step using a validated method. Pharmacokinetic parameters, including concentration-to-dose ratio, incremental slope (delta C/delta D), and area under the dose-concentration curve (AUC), were calculated. Patients were stratified into three exposure clusters (low, medium, and high) based on AUC distribution.

Results: A significant association was observed between sex and AUC exposure clusters ($p=0.026$), with females predominating in the high-exposure group. The analysis revealed a non-linear dose-concentration relationship, characterized by steeper

incremental slopes at lower doses (12.5–50 mg) and increased variability at higher dosages (100–200 mg). Regarding drug interactions, higher CNB concentrations were observed in patients co-treated with lacosamide ($p=0.0335$), while concomitant topiramate was associated with lower exposure ($p=0.0044$).

Conclusion: The pharmacokinetics of cenobamate appear highly variable and are influenced by sex and concomitant ASMs. These findings highlight the importance of therapeutic drug monitoring and individualized titration strategies to optimize efficacy and safety in real-world clinical practice.

Disclosure: Nothing to disclose.

OPR-136 | The effect of subacute neocortical stimulation during intracranial EEG on seizure frequency

I. Stavropoulos¹; D. Jiménez-Jiménez²; S. Freigang³; J. Díaz-Díaz¹; F. Kazi¹; M. Pina⁴; B. Diehl²; R. Selway⁵; G. Alarcón¹; A. Valentin¹

¹Department of Basic and Clinical Neuroscience, Institute of Psychiatry, Psychology and Neuroscience, King's College London, UK; ²Department of Clinical and Experimental Epilepsy, UCL Queen Square Institute of Neurology, London, UK; ³Department of Neurosurgery, Medical University Graz, Austria; ⁴Department of Clinical Neurophysiology, King's College Hospital NHS Trust, London, UK; ⁵Department of Neurosurgery, King's College Hospital, NHS Trust London, UK

Background and Aims: Neurostimulation is an alternative therapy for patients with drug-resistant epilepsy (DRE) who are not candidates for resective surgery. This study evaluates the impact of Subacute Neocortical Stimulation (SNCS) during intracranial presurgical assessment on seizure frequency.

Methods: This study was approved by the HRA ethical committee (IRAS 187072). Patients undergoing intracranial EEG with subdural or depth electrodes for epilepsy surgery evaluation were recruited. SNCS was initiated after sufficient seizures were captured for clinical purposes and reinstatement of all antiseizure medications. Following a 24-h baseline, SNCS was applied for approximately 48 h using different stimulation parameters (varying electrode pairs and cortical locations), separated by periods without stimulation. Each stimulation period involved one electrode pair. Stimulation targeted electrode pairs located within MRI-visible lesions, the seizure onset zone and/or areas with high interictal epileptiform discharge rates, or delayed responses to single-pulse electrical stimulation (450 μ s pulse width, up to 2 V or 2.5 mA, 130 Hz). Seizure rate ratio per hour (SRR/h) was calculated as the seizure rate during SNCS divided by the baseline rate.

Results: Twenty-eight patients were included (11 females; mean age 25 ± 44). Median SRR/h during baseline was $0.296 (\pm 3.57)$ and decreased to $0.0947 (\pm 4.27)$ during SNCS ($p=0.0179$). Twenty-three patients showed a reduction in SRR/h (median reduction 77%), with 17 demonstrating reductions greater than 50%.

Conclusion: SNCS is safe and significantly reduces seizure frequency. It may represent a therapeutic alternative for patients unsuitable for resective surgery and could serve as an additional marker of epileptogenic tissue, warranting further investigation.

Disclosure: This study was funded by Epilepsy Research UK and by a jointly grant from both Action Medical Research and Great Ormond Street Hospital Children's Charity.

OPR-137 | Integrative approach to transient loss of consciousness: Guided protocol of differential diagnosis

G. Nadejda¹; C. Carolina²; D. Diana¹; S. Siluan¹; M. Serghei³; B. Corneliu⁴; G. Stanislav⁵

¹Epileptology Department, Institute of Emergency Medicine, Chisinau, Republic of Moldova; ²Department of Neurosciences Cliniques, Centre Hauspitaier Universitaire Vuadois (CHUV), Lausanne, Switzerland; ³Cardiology Department, "Holy Trinity" Municipal Clinical Hospital, Chisinau, Republic of Moldova; ⁴Nuffield Department of Primary Care Health Sciences, Oxford University, Oxford, UK; ⁵Department of Neurology nr. 2, State University of Medicine and Pharmacy "Nicolae Testemițanu", Chisinau, Republic of Moldova

Background and Aims: Transient loss of consciousness (TLOC) represents a spontaneous loss of consciousness with complete resolution being a common and serious presentation in the emergency department (ED). Despite the existence of evidence-based recommendations, the diagnostic process is frequently fragmented, discipline-specific and sequential. This leads to a significant proportion of cases remaining either unexplained or misclassified. The objective of this study is to develop an integrated neuro-cardiology protocol to reduce "unexplained" TLOC after initial ED assessment.

Methods: We conducted a structured review of the literature (PubMed/Embase/Cochrane) from 2000 to 2025 to identify existing diagnostic frameworks approaches for TLOC and their limitations in practice. In parallel, we performed a prospective, single-centre pilot study including adult patients, presenting with unexplained TLOC after an initial standard assessment. We applied a standardised diagnostic pathway involving the targeted use of neuroimaging, prolonged simultaneous ECG, arterial tension and EEG monitoring, echocardiography and tilt-table testing. Final diagnoses were adjudicated using ESC syncope guidelines and ILAE seizure definitions, with clinical follow-up.

Results: No fully operationalised, integrated diagnostic protocol for TLOC applicable to the neurological and cardiological settings was identified in the literature revising 1470 publications. Implementation of the structured multidisciplinary pathway in our cohort substantially reduced the proportion of unexplained TLOC cases and clarified the diagnostic yield of individual investigations when applied within a coordinated framework.

Conclusion: The evaluation of TLOC should evolve from isolated neurological or cardiological reasoning towards structured, synchronised diagnostic pathways. Translating the existing guidance in the form of a standardised protocol improves diagnostic accuracy, reduces uncertainty and enhances patient safety.

Disclosure: The authors declare no conflicts of interest.

OPR-138 | Mortality and SUDEP in developmental and epileptic encephalopathies: A bayesian meta-analysis of rcts and open-label extensions

P. Moro; M. Borioni; A. Mazzeo; C. Di Bonaventura; E. Cerulli Irelli

Department of Human Neurosciences, Sapienza Università di Roma, Rome, Italy

FIGURE 1 PRISMA 2020 flow diagram for new systematic reviews which included searches of databases and registers only.

Background and Aims: Mortality and Sudden Unexpected Death in Epilepsy (SUDEP) are major concerns in Developmental and Epileptic Encephalopathies (DEEs), particularly Lennox-Gastaut (LGS) and Dravet syndromes (DS). Accurate incidence estimates from prospectively monitored populations are limited. We aimed to estimate long-term rates of all-cause mortality and SUDEP by pooling data from RCTs and their corresponding long-term open-label extensions (OLEs) using a Bayesian framework.

Methods: We systematically reviewed pharmacological trials in DEEs and performed a Bayesian random-effects Poisson meta-analysis with informative priors derived from published literature. Sensitivity analyses were conducted using weakly informative priors and frequentist generalized linear mixed models. Results are expressed as incidence per 1000 person-years (PY) with 95% Credible Intervals (CrI).

Results: The analysis included 37 RCTs (3757 patients) and 16 OLE studies (2210 patients). In the overall population, all-cause mortality was 8.17 per 1000 PY (95% CrI 4.77–11.84), and SUDEP was 3.96 (2.24–6.12). These estimates were consistent across sensitivity analyses. In LGS, all-cause mortality was 7.77 (3.58–13.31) and SUDEP 3.73 (1.73–6.49) per 1000 PY. In DS, all-cause mortality was comparable (8.97; 3.84–16.99), whereas SUDEP incidence appeared higher at 7.29 (2.88–14.42).

Conclusion: This study provides robust long-term estimates of mortality and SUDEP in DEEs by leveraging pooled trial data. The consistency between Bayesian and frequentist approaches validates these findings, highlighting a substantial mortality burden, with SUDEP particularly elevated in DS. These results emphasize the need for proactive risk management and counseling in this vulnerable population.

Disclosure: Nothing to disclose.

OPR-139 | Cognitive impairment and cardiovascular autonomic failure as independent and combined predictors of progression and phenoconversion in iRBD

L. Baldelli¹; F. Di Lauro¹; L. Sambati²; D. Cimatti¹; P. Guaraldi²; G. Giannini¹; A. Cecere¹; G. Loddo³; G. Mainieri²; F. Mignani¹; G. Barletta¹; P. Cortelli¹; G. Calandra-Buonaura¹; F. Provini¹

¹Department of Biomedical and NeuroMotor Sciences, University of Bologna, Bologna, Italy; ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; ³Dipartimento delle Cure Primarie, Azienda AUSL di Bologna, Bologna, Italy

Background and Aims: REM sleep behaviour disorder (RBD) is a parasomnia caused by loss of physiological muscle atonia during REM, resulting in dream-enactment behaviours. Isolated RBD (iRBD) is recognized as a prodromal manifestation of α -synucleinopathies, including Parkinson's disease (PD), dementia with Lewy bodies (DLB), and multiple system atrophy (MSA). Although cardiovascular autonomic failure (cAF) and cognitive impairment (CI) are established prodromal biomarkers, their combined prognostic significance remains unclear. This study investigated the interaction between cAF and CI in iRBD at baseline and longitudinally, evaluating their individual and combined phenoconversion predictive value.

Methods: Seventy-four iRBD (73% male; age 68.61 ± 7.23 years) were prospectively enrolled and followed-up for a mean of 3.17 ± 1.88 years. Cardiovascular autonomic function was assessed using a standardized reflex testing battery alongside a comprehensive neuropsychological battery. Cross-sectional and longitudinal cognitive and autonomic changes were analyzed, conversion risk was assessed using survival analyses.

Results: At baseline, 17 patients (25.4%) had mild CI (MCI) and 12 (17.9%) had neurogenic orthostatic hypotension (nOH), with no significant association between them ($p=0.484$). Longitudinally, multidomain MCI increased significantly ($p=0.038$), driven by visuospatial ($p=0.001$) and memory decline ($p=0.050$), and nOH prevalence also rose ($p=0.026$). Fifteen patients (20.3%) converted to an α -synucleinopathy (6 DLB, 5 PD, 2 MSA, 2 parkinsonism). Both MCI (HR=3.71; 95% CI: 1.22–11.22; $p=0.020$) and nOH (HR=3.64; 95% CI: 1.20–10.98; $p=0.022$) independently predicted conversion, while their coexistence markedly increased risk (HR=12.12; 95% CI: 2.76–53.29; $p=0.001$).

Conclusion: In iRBD, CI and cAF evolve largely independently, but their coexistence strongly increases the risk of phenoconversion, supporting multidimensional biomarker-based risk stratification.

Disclosure: Nothing to disclose.

D. Hoxhaj¹; J. Maranci²; S. Leu-Semenescu²; P. Dodet²; A. Pascazio²; E. Bonanni¹; M. Maestri Tassoni¹; I. Arnulf²
¹Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Italy; ²Paris Brain Institute (ICM), DreamTeam, Paris, France

Background and Aims: Are gestures in dreams produced symmetrically or as an inverted mirror image of real-life gestures? Evidence from actigraphy and analyses of nocturnal movements in sexual parasomnia during NREM sleep suggests that motor activity during sleep may shift toward the non-dominant hand. We aimed to investigate whether a similar state-dependent inversion of motor lateralisation occurs in REM sleep behaviour disorder (RBD), a condition in which dream-enacting movements can be directly observed.

Methods: Consecutive patients with RBD underwent a structured interview to assess handedness, and their video-polysomnography recordings were visually analysed. Upper limb movements during wakefulness and REM sleep were annotated according to laterality (right, left, bilateral), movement

type (simple, complex, jerk-like), and duration. Linear mixed-effects models were used to examine the interaction between behavioural state (wakefulness vs. REM sleep) and motor lateralisation.

Results: Seventy-one patients were included: 33 with isolated RBD and 38 with RBD associated with parkinsonism (13 Parkinson's disease, 25 multiple system atrophy). Most participants were right-handed (65/71, 91.5%). A total of 22,066 movements were analysed. During wakefulness, right-handed individuals showed longer right-arm movements, consistent with normal motor dominance. In contrast, during REM sleep this pattern was reversed: right-sided movements became shorter and less frequent, while left-sided movements predominated, particularly for complex gestures. Jerks were largely symmetrical. Among right-handed patients, 72% exhibited leftward motor predominance during REM sleep. Importantly, the side affected by parkinsonism did not abolish this inversion.

Conclusion: Dream-enacting movements in RBD are preferentially expressed through the non-dominant hand, suggesting a transient reversal of motor lateralisation during REM sleep.

Background and Aims: Loss of hypocretin-1/orexin-A (Hcrt-1) immunoreactivity in cerebrospinal fluid is a biomarker for type 1 narcolepsy (NT1). However, the current radioimmunoassay (RIA) does not allow for precise quantification, which limits the assessment of disease severity and progression. Three previous mass-spectrometry studies showed mixed results. Following the identification of RIA antibody targets by immunoprecipitation (IP), this study aimed to compare the ability of two purification methods (IP and solid phase extraction (SPE)) followed by nano-liquid chromatography coupled to high-resolution mass spectrometry (nLC-HRMS) to identify patients with NT1.

Methods: IP with magnetic beads coupled to the RIA antibody (Phoenix Pharmaceuticals) was performed, and the resulting peptides were identified by MS using data-dependent acquisition. Full-length Hcrt-1 and Hcrt-1 fragment_1-16 levels were analyzed in 4 NT1 patients and 4 controls after both IP and SPE by nLC-HRMS.

FIGURE 1 Boxplot of mean simple and complex movement duration per subject(s) across wakefulness and REM sleep. (*): $p < 0.05$, (***): $p < 0.001$ Each box represents the distribution of subject-level mean durations for movements performed with the left (blue) or right (orange).

FIGURE 2 Distribution of individual complex movement durations during wakefulness and REM sleep. Each dot represents a single movement performed with the left (blue) or right (orange) arm, while boxes indicate the interquartile range (IQR) and whiskers extend to 1.

Results: The discovery experiment with IP most reliably revealed Hcrt-1 fragment_1-16. SPE generally revealed much higher concentrations than IP. Hcrt-1_1-16 levels enabled the distinction between patients and controls after both IP (controls 0.94 pg/mL [0.71–1.21] NT1 0.15 pg/mL [0.04–0.30], $p=0.029$) and SPE (controls 29.19 pg/mL [21.67–37.55], NT1 1.66 pg/mL [0.49–2.57], $p=0.029$), whereas full-length Hcrt-1 levels after IP (controls 1.48 pg/mL [0.89–2.33], NT1 2.26 pg/mL [1.86–2.89], $p=0.2$) did not.

Conclusion: Hcrt-1_1-16 appears stable and abundant in the CSF of controls and allows the identification of patients with NT1, making it a promising surrogate marker and confirming results of a recent study. SPE seems to be a more suitable method for further validation in clinical practice.

Disclosure: The authors declare no conflict of interest. The international Swiss Primary Hypersomnolence and Narcolepsy Cohort study is supported by the Swiss National Science Foundation (SNF 320030_185362; SNF 32003B_215721).

OPR-142 | Brain and heart cross-talk: Cortical topography of slow-wave–heart rhythm coupling is associated with cognition

I. Filchenko¹; M. Schmidt¹; C. Bassetti²

¹Department of Neurology, Bern University Hospital (Inselspital) and University of Bern, Bern, Switzerland; ²Medical Faculty, University of Bern, Bern, Switzerland

Background and Aims: Cognitive dysfunction is associated with both cardiac autonomic dysfunction and reduced slow-wave (SW) activity. Slow-wave–heart rhythm (SW–HR) coupling reflects the interaction between SW and autonomic activity and is largely underexplored. We investigated its association with cognition.

Methods: “Sleep and cognitive functioning” ($n=63$) included volunteers in good or excellent health condition. Demographics, medical history, cognition (11 tests), sleep architecture by polysomnography were assessed at study inclusion (Figure 1). SW–HR coupling was quantified using previously described (Fabus et al., 2024) and newly conceptualized metrics in terms of temporal coherence, SW amplitude, and SW globality (Figure 2). Associations between SW–HR coupling (dependent variables) and cognition (independent variables) were explored using multivariate linear regression, adjusted for age and arousal index at the level of individual electrodes for all parameters except globality. The significance level was set at $\alpha=0.05$.

FIGURE 1

FIGURE 2

FIGURE 3

Results: A subset of 31 participants with 256-electrode electroencephalography was analyzed. SW–HR coupling was bi-directional and mostly involved fronto-central cortical areas. Stronger temporal and amplitude coupling was associated with alertness (frontal, left-lateralized), response inhibition (frontal and occipital, left-lateralized), verbal memory (frontal and occipital), and visual memory (central regions; Figure 3). Stronger

globality coupling was associated with the same domains (e.g., significance with visuospatial memory recall: $\beta = 5.84$ SD, $p < 0.008$). No associations were found for density coupling.

Conclusion: This is the first description of the cortical topography of SW-HR coupling and its association with multiple cognitive domains. SW-HR coupling may represent a promising marker of brain health.

Disclosure: Nothing to disclose.

OPR-143 | Behind the mirror: Clinical and neuroradiological significance of mirror movements in idiopathic REM sleep behavior disorder

R. Balestrino¹; E. Sarasso²; S. Basaia³; A. Gardoni⁴; S. Sangermano⁵; S. Marelli⁵; A. Castelnuovo⁶; A. Grassi⁴; E. Canu⁴; L. Ferini Strambi⁵; M. Filippi⁷; F. Agosta⁸

Background and Aims: Idiopathic REM Sleep Behavior Disorder (iRBD) is a prodromal stage of synucleinopathies such as Parkinson's disease (PD). Mirror movements (MM) are involuntary contralateral mirroring of voluntary actions, considered para-physiological in childhood and described in stroke, multiple sclerosis, and movement disorders, including PD. Their presence and significance in iRBD remain unexplored.

Methods: We enrolled 49 polysomnography-confirmed iRBD patients, divided into MM-positive ($n = 33$) and MM-negative ($n = 16$) groups. MM were further classified as monolateral ($n = 10$) or bilateral ($n = 23$). All underwent neurological, cognitive (MMSE, FAB, Rey and Benson figures, Rey Word List, Corsi, Token Test), motor (UPDRS I–III, 9HPT, 5TSTS, 10MWT), and MRI evaluations. FLAIR, 3DT1, and 3DT2 sequences quantified juxtacortical, deep grey matter (DGM), periventricular, and infratentorial hyperintensities.

Results: MM-positive patients showed lower upper limb dexterity (9HPT, $p = 0.029$) and reduced visuospatial-executive function (Corsi, $p = 0.004$, $p = 0.01$). Monolateral MM were associated with younger age and worse visuospatial, memory, and language

performance. Bilateral MM showed higher DGM hyperintensity volume ($p = 0.049$) and number ($p = 0.029$), with a trend toward higher periventricular burden ($p = 0.071$). Periventricular lesion volume and number correlated with worse visuospatial performance (Rey copy: $r = -0.668$, $p = 0.002$), mood symptoms (BDI-II: $r = 0.572$, $p = 0.013$), and gait impairment (10MWT steps: $r = 0.555$, $p = 0.014$).

Conclusion: Mirror movements are common in iRBD and show distinct clinical and radiological patterns. Monolateral MM may indicate early neurodegenerative changes, while bilateral MM may reflect a less specific pattern. MM assessment could help stratify RBD patients.

OPR-144 | CSF proteomic alterations in spontaneous intracranial hypotension

A. El Rahal¹; K. Joseph¹; K. Wolf¹; B. Haupt²; F. Volz¹; S. Behringer¹; N. Neider¹; S. Tholen³; O. Schilling³; M. Overstijns¹; N. Lützen⁴; H. Urbach⁴; C. Zander⁴; V. Ravi¹; J. Beck¹

¹Department of Neurosurgery, Medical Center University of Freiburg, Freiburg, Germany; ²Department of Neurological Surgery, Feinberg School of Medicine, Northwestern University, Chicago, USA; ³Proteomics Platform – Core Facility (ProtCF), Medical Center – University of Freiburg/Medical Faculty – University of Freiburg, Freiburg, Germany; ⁴Department of Neuroradiology, Medical Center University of Freiburg, Freiburg, Germany

Background and Aims: Spontaneous intracranial hypotension (SIH) results from spinal CSF leaks, but there is sparse knowledge about metabolic sequelae, and no fluid biomarkers exist. We investigated the CSF proteome of SIH patients, aiming to identify disease signatures and potential biomarkers.

Methods: We analyzed CSF from 26 patients (9 with type I ventral dural leaks and 17 controls). Samples were analyzed by label-free liquid chromatography-tandem mass spectrometry after depletion and SP3-based preparation. Data were evaluated using differential expression, weighted correlation network analysis (WGCNA), gene set variation analysis (GSVA) with 50 Hallmark pathways, and protein–protein interaction network centrality. Classification performance was assessed with cross-validation and permutation testing.

Results: A total of 918 proteins were quantified, 311 were included in the final analysis, of which 31 were significantly dysregulated (FDR<0.05). A 31-protein panel discriminated leaks from controls with an AUC of 0.93 ($p<0.001$). LYVE1, a regulator of extracellular matrix and fluid balance, was the most stable biomarker, potentially implicating meningeal lymphatic dysfunction in patients with CSF leaks. Network analysis highlighted ENPP2, GOT1, CTSD, and RELN as central hubs within the disease network. Functional clustering pointed out the downregulation of extracellular matrix remodeling (e.g., FAT2, CD44) and aberrant tissue repair proteins, coupled with

FIGURE 1 CSF-leak proteomic signature showing a leak-associated proteomic fingerprint.

FIGURE 2 Protein co-expression network analysis of ventral CSF leaks reveals a specific leak-associated protein module.

FIGURE 3 Integrated stratification of leak and control samples, enabling group stratification with high accuracy.

the downregulation of metabolic and neuroprotective pathways (CYST C, ENPP2, GOT1, ALDOA).

Conclusion: CSF proteomics revealed that CSF leaks induced a distinct proteomic biological signature. Interestingly, we identified proteomic patterns commonly associated with tissue remodeling, lymphatic dysfunction, and cognitive disturbance. CSF proteomics may identify biomarkers for CSF leaks.

Disclosure: Nothing to disclose.

OPR-145 | MRI biomarker predicts headache burden in spontaneous intracranial hypotension

F. Volz¹; A. El Rahal¹; N. Lützen²; C. Zander²; M. Overstijns¹; H. Urbach²; J. Beck¹; K. Wolf¹

¹Department of Neurosurgery, Medical Center, University of Freiburg, Germany; ²Department of Neuroradiology, Medical Center, University of Freiburg, Germany

Background and Aims: Spontaneous intracranial hypotension (SIH) is caused by spinal cerebrospinal fluid (CSF) leaks and is classically characterized by orthostatic headache. Objective: To evaluate whether headache intensity is associated with clinical, anatomical, or dynamic MRI parameters.

Methods: Patients with SIH and a confirmed spinal CSF leak (12/2021–07/2024) were analyzed. Data included demographics, symptom duration, leak type, Bern score, HIT-6, and phase-contrast MRI-derived measures of CSF and spinal cord velocities at C2/C3. From these, derivatives as intradural volume

FIGURE 1 Example of cardiac dynamic phase-contrast MRI measurements of CSF and spinal cord velocities.

FIGURE 1 Data assessed per patient.

FIGURE 2 Results on demographics, leak types and headache intensity.

displacements and accelerations as compliance surrogates ($C = \Delta V / \Delta P$) were calculated.

Results: 150 patients were included (57% female; mean age 46.6 ± 12 years). Leak types were ventral (60%), lateral (17.3%), CSF–venous fistula (21.4%), and sacral (1.3%). Median symptom duration was 8 months (IQR 3–21). Substantial to severe headache burden was reported by 81%, and 75% had predominantly orthostatic headaches. Conventional MRI findings and clinical variables did not predict headache severity. However, in patients with dural tears (ventral&lateral leaks), increased cranially directed CSF acceleration was strongly associated with orthostatic headache burden within the first 12 months ($R = 0.574$, adj. $R^2 = 0.268$, $p = 0.012$), particularly in early disease (<3 months: $R = 0.909$, adj. $R^2 = 0.786$, $p < 0.001$). These associations became diffuse in chronic disease, and in CSF–venous fistulas.

Conclusion: SIH is associated with a high headache burden not explained by standard imaging or demographics. In early and intermediate disease, dynamic MRI biomarkers identify patients with greater orthostatic headache burden, whereas chronic SIH shows increasing heterogeneity, suggesting evolving pathophysiology.

Disclosure: none in relation to this study. KW is supported by the Margarete-Von-Wrangell-Fellowship, Ministry of Science, Research and Arts, Baden-Württemberg, Germany.

OPR-146 | Machine learning-based statistical interpretation of headache pattern data: Insights from the myclusters application

L. Jabbarian¹; D. Ramanagoudra²

¹Department of Psychiatry, Erasmus Medical Center Rotterdam, The Netherlands; ²MyClusters, Leiden, The Netherlands

Background and Aims: Management of cluster headache (CH) remains a challenge due to its variable presentation patterns, idiosyncratic nature of attacks and the rarity of the disease. Most patients with CH experience a diagnostic delay and effective treatment strategies are limited. The MyClusters application collects real-world global patient-reported data on, among others, attack frequency, timing and patient characteristics. The aim of the app is to aid pattern recognition, both on an individual as well as population level.

Methods: As of now, 2060 patients with (cluster) headaches have input 21,048 data points on attack timing, duration of the attack, intensity, symptoms, medications and trigger factors. An unsupervised machine learning model was trained for automated statistical analyses, to identify and classify clinically relevant headache attack patterns, predict bout periods, and identify personalised risk factors with trigger fingerprinting.

Results: The model successfully classified five distinct attack pattern subtypes with significant differences in treatment response. Personalised trigger identification showed 82% concordance with patient-reported associations, revealing temporal relationships between lifestyle factors and attack occurrence.

Conclusion: This machine learning-based tool provides objective, automated statistical analysis of MyClusters data, enabling early bout detection, pattern classification and personalised trigger identification. Integration of artificial intelligence with patient-reported outcomes offers promising applications for improving management of CH, potentially informing treatment decisions. This shows promise of further analysis by adding more data points by integrations with wearables and weather data to establish more pattern based sub-types.

Disclosure: Nothing to disclose.

OPR-147 | Beyond the aura: Is burden measurable in migraine?

Ö. Soylu; F. Bachhuber; P. Klassen; H. Tumani

Department of Neurology, Ulm University Hospital, Ulm, Germany

Background and Aims: Migraine is traditionally considered a benign disorder; however, it can be sorely disabling. Its pathogenesis includes multiple mechanisms, notably neurogenic

inflammation and neuroaxonal involvement. Therefore, a measurable biomarker to demonstrate subclinical disease burden is needed.

Methods: We included 86 patients with migraine (62 with aura [MWA]; 24 without aura [MWOA]) (classified according to ICH 3rd beta Version), and 126 (age- and sex-matched) control subjects (tension-type headache, dizziness, functional disorder [Controls]). Individuals with comorbidities associated with neuroaxonal damage, obesity, or renal insufficiency were excluded. By the selection of Controls, we aimed to strengthen the clinical relevance of the study. Serum neurofilament light chain (sNfL) and glial fibrillary acidic protein (sGFAP) were analyzed on a sensitive immunoassay platform. Age- and sex-adjusted biomarker levels were derived using linear regression residuals. Comprehensive demographic and clinical characteristics were considered.

Results: sNfL levels differed significantly between patients with migraine groups and Controls (Kruskal–Wallis, $p=0.004$). In contrast, sGFAP levels did not differ between the groups. The subgroup analysis revealed higher sNfL levels in patients with MWOA (median 0.58; IQR 4.22) compared to Controls (median -0.40 ; IQR 2.16) ($p=0.001$), whereas no statistically significant difference was found between MWA (median -0.26 ; IQR 2.00) and Controls ($p=0.307$).

Conclusion: These findings point to neuroaxonal involvement rather than astroglial injury and suggest that axonal burden is mainly dominant in MWOA. Furthermore, this study highlights the need to search for neurobiological differences between migraine phenotypes, to enable diagnostic and therapeutic stratification.

TABLE 1 Classification of thalamic nuclei according to their functional specialization

Functional Group	Abbreviation	Full Name
Sensory nuclei	VPL	Ventral posterolateral
	VPM	Ventral posteromedial
	LGN	Lateral geniculate nucleus
	MDN	Medial geniculate nucleus
	L-SS	Lateral subgenicular state
Motor nuclei	VA	Ventral anterior
	VAmc	Ventral anterior, macular nucleus
	VLa	Ventral lateral anterior
	VLD	Ventral lateral posterior
Associative nuclei	LP	Lateral posterior
	PuA	Pulvinar anterior
	PuI	Pulvinar inferior
	PuL	Pulvinar lateral
	PuM	Pulvinar medial
Limbic nuclei	AV	Anteromedial
	LD	Lateral dorsal
	MDL	Mediodorsal lateral
	MDm	Mediodorsal medial
Intralaminar nuclei	CeM	Central medial
	CL	Central lateral
	CM	Centromedian
	Pc	Paracentral
	PI	Parasagittal
	Pl	Paralateral
	MY-Ra	Reunions (medial ventral)

FIGURE 1 Scatter plots with regression lines showing inverse association between FBI total score and volume of limbic thalamic nuclei. FBI, frontal behaviour inventory.

Background and Aims: Although amyotrophic lateral sclerosis (ALS) has traditionally been regarded as a disease primarily affecting cortical structures, growing evidence highlights the significant involvement of subcortical regions in the emergence and progression of clinical symptoms. In this study, we investigated whether thalamic subnuclei, grouped according to their

FIGURE 2 Scatter plots with regression lines showing positive association between serum NFL levels and volume of associative thalamic nuclei. NFL, neurofilament light chain.

functional specialization, contribute to the motor and neuropsychological phenotype of ALS patients.

Methods: We retrospectively analyzed 289 ALS patients who underwent 3-Tesla MRI with a 3D T1-weighted acquisition. Thalamic subnuclei volumes were estimated using FreeSurfer based on the probabilistic atlas of human thalamic nuclei (Iglesias et al., 2018) and subsequently grouped according to their functional classification into sensory, motor, limbic, associative, and diffuse projection nuclei.

Results: Thalamic subnuclei volumes were not significantly associated with the motor or cognitive profiles of the cohort. In contrast, limbic nuclei volumes (specifically mediodorsal medial and lateral) were inversely associated with behavioral symptom burden ($\beta = -0.28$; $p < 0.001$) and plasma neurofilament light chain (NFL) levels ($\beta = -0.26$; $p = 0.009$). Notably, volumes of associative (specifically pulvinar and lateral posterior) thalamic nuclei were positively correlated with disease progression rate ($\beta = 0.17$; $p = 0.001$) and plasma NFL levels ($\beta = 0.31$; $p < 0.001$).

Conclusion: Findings from our work suggest that limbic thalamic nuclei may contribute to the emergence of behavioural symptoms and to the rate of neurodegeneration. In contrast, associative nuclei appeared to be relatively spared in patients with rapid disease progression, supporting a putative protective or compensatory role of the pulvinar–lateral posterior nuclei in the progression of ALS.

OPR-149 | Structural brain changes in Alzheimer's disease: Relationship with cerebrospinal fluid pTAU181 and clinical implications

C. Manco¹; D. Van Rossem²; S. De Witte²; D. Righi¹; F. Galasso¹; B. Pucci³; I. Chiarotti⁴; A. Cerase³; N. De Stefano¹; S. Engelborghs²; D. Plantone¹

¹Department of Medicine, Surgery and Neuroscience, University of Siena, Siena, Italy; ²NEUR Research Group, Center for Neurosciences (C4N), Vrije Universiteit Brussel (VUB) and Department of Neurology, UZ Brussel, Brussels, Belgium; ³Azienda Ospedaliera Universitaria Senese, Siena, Italy; ⁴Neuroradiologia, AOU Meyer, Florence, Italy

Background and Aims: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by cognitive decline and brain atrophy. Neuroimaging biomarkers reflecting underlying neuropathological processes are essential for diagnosis and prognosis. This study aims to investigate the relationship between cerebrospinal fluid (CSF) biomarkers, atrophy of relevant brain regions and cognitive decline in patients with AD.

Methods: Ninety-four patients with mild cognitive impairment and mild dementia due to AD, diagnosed according to the 2024 NIA-AA criteria, were enrolled [1]. Available data included CSF biomarkers, MRI-derived brain volumes, demographic information at diagnosis, and Mini-Mental State Examination (MMSE) scores at 1-year follow-up (56/94 patients). Patients were classified according to: pTAU181 levels above or below 78 pg/mL [2] (54/94 vs. 40/94); MMSE outcome at 1-year (stable vs. worsened). Brain volumes were adjusted for age, sex, magnetic field strength, and total intracranial volume. Analyses of covariance and binomial regression models were applied.

Results: Forty-six patients were recruited in Vrije Universiteit Brussels (mean age 72.17; 21 males/25 females; education 12.75) and forty-eight in University of Siena (mean age 74.14; 25males/23females; education 9.34). Higher pTAU181 levels were associated with lower volumes of the hippocampal head ($p = 0.005$), body ($p = 0.04$), and tail ($p = 0.03$), the CA1 hippocampal subfield ($p = 0.004$), the medial-mediodorsal thalamic nucleus ($p = 0.02$), total amygdala volume ($p = 0.003$), and basal ($p < 0.001$) and cortical ($p = 0.02$) amygdala nuclei. Only

FIGURE 1 Boxplots showing the comparison of regional brain volumes in subjects with high and low pTAU181 levels. Subjects with high pTAU181 levels exhibit significantly reduced volumes in all the brain regions shown.

hippocampal head ($p=0.02$) and CA1 volumes ($p=0.03$) predicted cognitive performance at 1-year follow-up.

Conclusion: Elevated CSF pTAU181 levels are associated with selective atrophy of hippocampal, thalamic, and amygdala regions. Hippocampal head and CA1 subfield volumes are linked to cognitive outcome.

Disclosure: Nothing to disclose.

OPR-150 | The developmental dynamics of cortical grey matter in children with self-limiting epilepsy and centrotemporal spikes

C. Ciumas¹; K. Ostrowsky-Coste²; E. Panagiotakaki²; P. Ryvlin¹

¹Department of Clinical Neurosciences, CHUV, Lausanne, Switzerland; ²ESEFNP Department – Clinical Epileptology, Sleep Disorders and Pediatric Functional Neurology, Femme Mère Enfant Hospital, Hospices Civils de Lyon (HCL), France

Background and Aims: Self-limited epilepsy with centrotemporal spikes (SeLECTS) has long been considered to be a benign condition that resolves without lasting consequences. However, evidence has emerged linking epileptiform activity in SeLECTS to impairments in language, attention, working memory and socio-emotional processing, challenging this assumption. Recurrent centrotemporal spikes may disrupt critical phases of cortical maturation. In this context, the longitudinal impact of epileptiform activity on grey matter development in SeLECTS remains insufficiently explored.

Methods: We conducted a 5-year longitudinal 1.5 T MRI study (Siemens) in children with SeLECTS and matched controls. 23 patients and 28 healthy participants (mean age: ~9–14 years) were included in the analyses. Cortical thickness trajectories were analysed using CAT12/SPM12, with vertex-wise non-parametric permutation testing of linear and quadratic effects adjusted for age, age², and sex with family-wise error correction, used for quantitation of thickness and thickness change.

Results: Vertex-wise longitudinal analyses revealed the expected progressive cortical thinning in the control group across the frontal, cingulate, parietal, occipital and insular cortices. In the SeLECTS group cortical maturation followed distinct trajectories, with delayed linear thinning observed in the fronto-central and paracentral regions alongside steeper thinning in the posterior associative cortices. Quadratic effects further distinguished between the two groups, indicating nonlinear deviations in cortical thickness trajectories over time, particularly within the medial frontal, cingulate and temporo-parietal regions.

Conclusion: SeLECTS shows subtle, region-specific alterations in cortical thinning trajectories, suggesting a

FIGURE 2 Differences in each group over time.

FIGURE 3 Statistically significant differences between groups over 5 years period.

neurodevelopmental impact that challenges its traditional characterization as a benign condition.

Disclosure: Nothing to disclose.

Background and Aims: Physiological aging involves brain structural changes. Understanding these changes is essential to distinguish normal aging from disease-related alterations in multiple sclerosis (MS). This study modeled normative age-related trajectories of brain and grey matter (GM) volumes in healthy controls (HC) and applied them to a large multicenter MS cohort to identify disease-specific atrophy patterns.

Methods: We analyzed 3D T1- and T2-weighted MRI scans from 995 HC and 2016 MS patients from the Italian Neuroimaging Network Initiative (INNI). After image pre-processing, normalized brain, cortical, and deep GM volumes were estimated using FSL-SIENAX and FSL-FIRST. Age-related volumetric trajectories were modeled in HC using regression analyses accounting for linear and non-linear age effects, sex, scanner, and interactions. These models were applied to MS patients to compute z-scores reflecting disease-related atrophy beyond normal aging, with analyses stratified by sex and age at disease onset.

Results: In HC, brain volume declined non-linearly with age, while cortical and deep GM decreased linearly. In MS patients, z-scores declined linearly with age ($p < 0.01$), indicating progressively greater MS-related brain and GM atrophy. Cortical atrophy was more pronounced in men after age 40 ($p = 0.03$), while deep GM atrophy was greater in women after age 30 ($p < 0.001$). Pediatric-onset MS showed faster brain and cortical atrophy than adult-onset MS, whereas late-onset MS exhibited greater brain and cortical atrophy than adult-onset MS with aging.

Conclusion: In conclusion, these results highlight the need to account for both physiological aging and patient-specific factors, such as sex and age at onset, when evaluating brain atrophy in individuals with MS.

Ageing and Dementia 1

EPO-0001 | Sodium channel blockers are associated with reduced dementia risk in late-onset unexplained epilepsy

C. Ferreira-Atuesta¹; K. Schubert¹; X. Tai²; T. Hedden³; J. Zelano⁴; T. Marson⁵; G. Lip⁶; G. Mbizvo⁷; M. Galovic¹
¹Department of Neurology, Clinical Neuroscience Center, University Hospital Zurich and University of Zurich, Zurich, Switzerland; ²Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK; ³Department of Neurology, Icahn School of Medicine at Mount Sinai, New York, USA; ⁴Department of Clinical Neuroscience, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; ⁵Department of Pharmacology & Therapeutics, Institute of Systems, Molecular and Integrative Biology, Faculty of Health and Life Sciences, University of Liverpool, Liverpool, UK; ⁶Liverpool Centre for Cardiovascular Science, University of Liverpool, Liverpool, UK; ⁷Liverpool Interdisciplinary Neuroscience Centre, University of Liverpool, Liverpool, UK

Background and aims: Late-onset unexplained epilepsy is associated with increased dementia risk. Network hyperexcitability, central to seizure generation, has been implicated in amyloid- β release and tau propagation, suggesting a mechanistic link. Under this model, antiseizure medications that more effectively suppress excitability may modify dementia risk, but comparative neuroprotective effects across commonly used ASMs remain unclear.

Methods: We emulated a target trial using real-world healthcare data from the TriNetX platform to compare dementia outcomes across ASM monotherapy strategies in patients with newly diagnosed LOUE. Confounding addressed with propensity-score matching. Cox proportional hazards models estimated hazard ratios (HRs) with 95% confidence intervals (CIs) for incident all-cause dementia and Alzheimer's disease. The cohort included 24,262 patients treated with SV2A ligands, sodium channel

FIGURE 1 Hazard ratios (95% CI) for dementia and mortality outcomes comparing mechanism-based antiseizure medication groups versus SV2A inhibitors. Panels show: (A) All-cause dementia, (B) Alzheimer's disease, (C) Mortality, (D) All-cause dementia + death. Diamond.

FIGURE 2 Hazard ratios (95% CI) for dementia and mortality outcomes in the Down syndrome cohort comparing mechanism groups vs SV2A inhibitors. Panels show: (A) All-cause dementia, (B) Alzheimer's disease, (C) Mortality, (D) All-cause dementia + death. Diamond mark.

blockers, multi-mechanism agents, calcium channel blockers, or GABAergic agents. Findings were externally validated in a high-risk Down syndrome cohort and the National Alzheimer's Coordinating Center (NACC) dataset.

Results: Sodium channel-blocking ASMs were associated with lower dementia risk compared with SV2A ligands, including a 27% reduction in all-cause dementia (HR 0.73, CI 0.61–0.88) and a 36% reduction in Alzheimer's disease (HR 0.66, CI 0.49–0.88). Phenytoin and carbamazepine showed the strongest inverse associations with dementia, lamotrigine was associated with lower mortality. Associations were consistent across earlier cognitive endpoints, absent for negative controls, and directionally concordant in external validation.

Conclusion: Sustained suppression of neuronal hyperexcitability by specific ASMs appears to modify downstream neurodegenerative risk. These findings nominate sodium channel blockers as candidates for repurposing in dementia prevention and support prospective randomized trials targeting early network excitability.

Disclosure: Nothing to disclose.

EPO-0002 | Hearing aid use and risk of dementia in adults with late-onset epilepsy, stroke, or diabetes and comorbid hearing loss

C. Ferreira-Atuesta¹; K. Schubert¹; H. Jung¹; T. Marson²; G. Lip³; G. Mbizvo⁴; M. Galovic¹

¹Department of Neurology, Clinical Neuroscience Center, University Hospital Zurich and University of Zurich, Zurich, Switzerland; ²Department of Pharmacology & Therapeutics, Institute of Systems, Molecular and Integrative Biology, Faculty of Health and Life Sciences, University of Liverpool, Liverpool, UK; ³Liverpool Interdisciplinary Neuroscience Centre, University of Liverpool, Liverpool, UK; ⁴Liverpool Centre for Cardiovascular Science, University of Liverpool, Liverpool John Moores University and Liverpool Heart & Chest Hospital, Liverpool, UK

Background and aims: Hearing loss is a major modifiable risk factor for dementia, yet its impact on high-risk neurological populations remains poorly characterized. We investigated whether hearing aid (HA) use reduces dementia incidence in adults with late-onset epilepsy (LOE), stroke, or diabetes with comorbid hearing loss.

Methods: Using TriNetX, a federated electronic health record network, we conducted retrospective cohort studies emulating target trials. We analyzed propensity score-matched cohorts of 1,093 LOE pairs, 2,363 stroke pairs, and 14,934 diabetes pairs (all aged ≥ 55 years). Primary outcomes included incident Alzheimer's disease (AD) and all-cause dementia over a median follow-up of 4.2–5.1 years.

Results: HA use was associated with significant reductions in AD across all cohorts: LOE (HR 0.52, 95% CI 0.38–0.71), stroke (HR 0.59, 0.37–0.95), and diabetes (HR 0.69, 0.53–0.90). All-cause dementia risk was also significantly reduced in LOE (HR 0.50, 0.32–0.79) and diabetes (HR 0.81, 0.70–0.94). Negative control outcomes (glaucoma, frailty) showed no consistent protective patterns. Sensitivity analyses in LOE patients indicated that significant protective effects for AD persisted even when HA intervention was initiated after five years of hearing loss onset.

FIGURE 1 Hazard ratios (95% CI) for outcomes across the epilepsy, stroke and diabetes cohorts.

Conclusion: Auditory intervention is a scalable, low-risk strategy for dementia prevention in neurologically vulnerable populations. The protective effects in these groups may exceed those observed in the general population, likely by reducing cognitive load and potentially interrupting shared neurodegenerative pathways.

Disclosure: Nothing to disclose.

EPO-0003 | Sleep-related experiences inflate hallucination scores across neurodegenerative disorders

D. Urso¹; V. Gnoni¹; A. Giugno¹; M. Caccamo¹; A. Nanni¹; E. Rollo¹; G. Logroscino¹; G. Foffani²

¹Center for Neurodegenerative Diseases and the Aging Brain, Department of Clinical Research in Neurology, University of Bari 'Aldo Moro', "Pia Fondazione Cardinale G. Panico", Tricase, Lecce, Italy; ²Reina Sofia Foundation Alzheimer Center, CIEN Foundation, ISCIII, Madrid, Spain

Background and aims: Hallucinations are widely used to support diagnosis, prognosis, and treatment decisions in neurodegenerative disorders. However, standard clinical scales do not distinguish hallucinations occurring during full wakefulness from perceptual experiences emerging at sleep–wake transitions (hypnagogic and hypnopompic phenomena), which are non-psychotic by definition.

Methods: We developed the Hypno/Awake Hallucination Assessment (HAHA), a two-item extension of the MDS-UPDRS hallucination item, and the Sleep-Related Experiences Questionnaire (SREQ), a 7-item scale capturing dream and sleep–wake boundary phenomena. These were administered in 73 patients with Parkinson's disease and in 177 consecutive patients from a tertiary neurodegenerative disorders clinic. Bayesian multiple regression tested whether sleep-related hallucinations contributed to standard hallucination scores independently of awake hallucinations, and whether they were specifically associated with sleep-related experiences.

Results: Across both cohorts, sleep-related hallucinations showed extreme evidence of contributing to standard hallucination scores even after accounting for awake hallucinations. Sleep-related hallucinations, but not awake hallucinations, were strongly associated with the frequency of sleep-related experiences. Sleep-related experiences differed across diseases with extreme evidence, being more frequent in Lewy-body disorders than in Alzheimer's disease and frontotemporal lobar degeneration syndromes and correlated with REM sleep behavior disorder.

Conclusion: Standard hallucination scales conflate awake hallucinations with sleep-related perceptual phenomena, leading to systematic inflation of hallucination estimates, particularly in Lewy-body disorders. Disentangling these mechanisms

is essential for accurate diagnosis, appropriate treatment, and mechanistic interpretation of hallucinations.

Disclosure: Nothing to disclose.

EPO-0004 | Volumetric analysis of hippocampal subfields and cognitive change in Alzheimer's dementia and mild cognitive impairment: A prospective cohort study

D. Jung; T. Kim
Department of Neurology, Incheon St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea

Background and aims: Hippocampal subfield atrophy demonstrates differential vulnerability in Alzheimer's disease (AD), but the clinical relevance of specific subfield volume ratios for predicting cognitive decline remains unclear. This study examined associations between hippocampal subfield volume ratios

FIGURE 1 Representative segmentation of hippocampal and amygdala subfields on high-resolution T1-weighted MRI. (A) Axial, (B) coronal, (C) sagittal, and (D) three-dimensional views with color-coded subregions.

FIGURE 2 Hippocampal subfields demonstrating associations with cognitive decline. (A-D) Multiple viewing planes showing color-filled regions with statistically significant associations (green for CA3, pink for fimbria).

TABLE 1 Multivariable associations of bilateral CA3 and fimbria volume ratios (per 1-SD) with changes in cognitive scores (MMSE and MoCA).

		Associations to cognitive ratio to total hippocampal volume			Associations to cognitive ratio to TIV		
		B	SE	P-value	B	SE	P-value
MMSE (scores)	Model 1	-1.827	0.579	0.001**	-1.558	0.589	0.010*
	Model 2	-1.828	0.580	0.001**	-1.559	0.603	0.013*
	Model 3	-1.829	0.580	0.001**	-1.560	0.612	0.017*
MoCA (scores)	Model 1	-2.081	0.648	0.001**	-1.860	0.657	0.004**
	Model 2	-2.082	0.649	0.001**	-1.861	0.668	0.006**
	Model 3	-2.083	0.650	0.001**	-1.862	0.679	0.008**
TIV (cm³)	Model 1	-0.037	0.003	0.001**	-0.039	0.004	0.002*
	Model 2	-0.038	0.004	0.001**	-0.040	0.004	0.001*
	Model 3	-0.039	0.004	0.001**	-0.041	0.005	0.001*
Ratio of fimbria	Model 1	2.178	0.528	0.000**	2.128	0.566	0.000**
	Model 2	2.182	0.529	0.000**	2.132	0.578	0.000**
	Model 3	2.183	0.530	0.000**	2.133	0.589	0.000**

and longitudinal cognitive changes in AD dementia and amnesic mild cognitive impairment (aMCI).

Methods: Fifty-four participants with AD dementia or aMCI underwent baseline cognitive assessments, high-resolution T1-weighted MRI, and follow-up cognitive evaluations at two years. Hippocampal subfield volumes were automatically segmented and normalized to total hippocampal volume and total intracranial volume (TIV). Linear regression analyses examined associations between standardized subfield ratios and changes in Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA) scores.

Results: The volume ratios of the fimbria and cornu ammonis 3 (CA3) demonstrated the strongest associations with changes in MMSE (fimbria: B = 1.95, SE = 0.51, $p < 0.001$; CA3: B = 1.75, SE = 0.52, $p = 0.002$) and MoCA (fimbria: B = 1.818, SE = 0.559, $p = 0.002$; CA3: B = 1.58, SE = 0.57, $p = 0.008$) scores. Similar patterns emerged with TIV normalization. Associations remained significant after adjusting for age, education, baseline cognition, ApoE4 genotype, and medication use.

Conclusion: Among hippocampal subfields, the fimbria and CA3 regions demonstrate stronger associations with longitudinal cognitive decline in AD and aMCI compared to other subfield structures. These in vivo findings may serve as useful biomarkers for risk assessment, though further validation studies are needed to confirm their clinical utility.

Disclosure: Nothing to disclose.

EPO-0005 | A 48-month analysis of the lecanemab clarity AD open-label extension in the ApoE ε4 non-carriers or heterozygotes early Alzheimer's disease population

L. Froelich¹; S. Dhadda²; D. Li²; M. Kanekiyo²; A. Goodwin²; M. Hodgkinson³; S. Trafford³; S. Hersch³; M. Irizarry²; L. Kramer²

¹Medical Faculty Mannheim, University of Heidelberg, Central Institute of Mental Health, Mannheim, Germany; ²Eisai Inc, Nutley, USA; ³Eisai Europe Ltd, Hatfield, UK

Background and aims: Lecanemab, an Aβeta-directed antibody, showed meaningful delay in disease progression and biological effects consistent with disease modification in Clarity AD. Herein, we present the 48-month results in ApoE ε4 non-carriers or heterozygotes population from the ongoing Clarity AD open-label extension (OLE) study.

Methods: Clarity AD is an 18-month, randomized study (Core) with a subsequent OLE phase in individuals with early AD.

Safety and clinical efficacy outcomes (CDR-SB, ADAS-Cog14, and ADCS-MCI-ADL) were assessed from OLE data out to 48 months. Continued lecanemab treatment in the OLE beyond the 18 months from the Core study was compared to matched historical placebo controls from Alzheimer's Disease Neuroimaging Initiative (ADNI) data and the Swedish BioFINDER1 study. Subgroup analyses were conducted for participants with no/low baseline tau.

Results: In the ApoE ϵ 4 non-carriers or heterozygotes population, 1521 participants were treated with lecanemab across the Clarity AD Core and OLE. No new safety signals were observed. ARIA rates were low and similar on placebo after 6 months. Lecanemab-treated participants continued to accrue benefit in CDR-SB through 48 months, with continued separation through 36 months relative to the historical controls. Results were similar for ADAS-Cog14 and ADCS-MCI-ADL. Consistent rates of clinical stability or improvements were observed across assessments regardless of baseline tau levels. Lecanemab reduced relative risk of progression to next dementia stage by 55% and 62% vs ADNI and BioFINDER, respectively.

Conclusion: In the ApoE ϵ 4 heterozygotes or non-carrier subgroup of Clarity AD, lecanemab slowed decline in disease progression with expanding benefit over time.

Disclosure: L reports a relationship with Anavex, Avanir/Otsuka, Biogen, BioVie, Bristol-Myers-Squibb, DerCampus, Eisai, Eli Lilly, FOMF, Araclon/Grifols, Janssen Cilag, Johnson & Johnson, Medical Tribune, Medfora, Medscape, Neurimmune, Neuroscios, Noselab, NovoNordisk, Pharmatrophix, Hoffmann-La Roche, TauRX, Schwabe, StreamUp, Vivoryon that includes: personal consulting fees. SD, DL, MK, AG, MH, ST, SH, MI, and LK are employees of Eisai.

EPO-0006 | Electric field modulation of amyloid- β fibril propagation: Molecular insights supporting neuromodulation approaches in Alzheimer's disease

F. Toplek¹; M. Guidetti²; N. Maiorana²; S. Marceglia²; R. Capelli¹; A. Priori³; C. Camilloni¹

¹Department of Biosciences, University of Milano, Milan, Italy;

²"Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, University of Milano, Milan, Italy; ³"Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, University of Milano, Milan, Italy; Clinical Neurology Unit, "Azienda Socio-Sanitaria Territoriale Santi Paolo E, Milan, Italy

Background and aims: Amyloid- β 42 (A β 42) fibril accumulation is a central pathological hallmark of Alzheimer's disease and a primary target of disease-modifying therapies. Non-invasive brain stimulation techniques, such as transcranial direct current stimulation (tDCS), are increasingly explored as complementary interventions, but their direct biological targets remain unclear. This study aimed to investigate whether electric fields, conceptually analogous to those induced by tDCS, can modulate A β 42 fibril structure and propagation at the molecular level.

Methods: We performed molecular simulations on a brain-derived A β 42 fibril model composed of 66 monomers arranged in 33 layers, reconstructed from cryo-EM data and including

disordered N-terminal regions. Static electric fields ranging from 0 to 0.2 V/nm were applied under different structural restraint conditions to separately assess effects on fibril surface properties and fibril elongation. Simulations were run for 1–2 μ s in triplicate.

Results: Electric fields induced a displacement of the disordered N-terminal regions that saturated at $\sim$ 0.08 V/nm, reducing their interactions with the fibril core and modifying surface properties associated with amyloid proliferation. In addition, increased structural fluctuations were observed at fibril ends, particularly in residues involved in elongation, indicating a destabilizing effect on fibril growth. These effects were systematic and increased with field strength.

Conclusion: These findings provide mechanistic evidence that electric fields can influence molecular processes underlying amyloid fibril propagation. Although the applied field strengths exceed those generated by clinical tDCS, the results support the biological plausibility of neuromodulation approaches as potential modifiers of amyloid pathology and encourage further experimental and clinical investigation.

Disclosure: Nothing to disclose.

EPO-0007 | OCTARIA-AD: Optical coherence tomography angiography as a non-invasive biomarker for ARIA in early Alzheimer's disease

N. Krajnc¹; H. Untersteiner¹; T. Parvizi¹; M. Bertich²; S. Silveira¹; E. Berger-Sieczkowski¹; R. Wurm¹; B. Pemp²; E. Stögmüller¹; G. Bsteh¹

¹Department of Neurology, Medical University of Vienna, Vienna, Austria; ²Department of Ophthalmology, Medical University of Vienna, Vienna, Austria

Background and aims: Alzheimer's disease (AD), the leading cause of dementia worldwide, is characterized by progressive cognitive decline driven by amyloid- β and tau pathology. Anti-amyloid monoclonal antibodies show clinical benefit in early AD but are limited by amyloid-related imaging abnormalities (ARIA). Current monitoring relies on resource-intensive MRI, which may miss early microvascular changes. Optical coherence tomography (OCT) and OCT angiography (OCT-A) offer non-invasive assessment of retinal neuroaxonal and microvascular integrity and may reflect cerebral small-vessel pathology.

Methods: OCTARIA-AD is a monocentric, prospective observational study enrolling 60 participants aged 50–90 years: 30 patients initiating anti-amyloid therapy and 30 age- and sex-matched controls with mild cognitive impairment or mild AD. OCT and OCT-A are performed at baseline and four follow-ups up to 52 weeks. Outcomes include peripapillary retinal nerve fiber layer (pRNFL) and ganglion cell-inner plexiform layer (GCIPL) thickness, vessel density and foveal avascular zone area. ARIA is assessed using routine MRI.

Results: As of January 25, 2026, 8 and 7 patients receiving lecanemab and donanemab have been enrolled, respectively; two were excluded due to insufficient baseline OCT image quality. The preliminary cohort comprises 13 patients (mean age 71 years [4.7], 83.3% female, 66.7% APOE heterozygotes, median MMSE 27 [range 23–30]). Mean baseline pRNFL and GCIPL thickness were 98.8 μ m (8.3) and 67.2 μ m (7.1), respectively. After a

median follow-up of 33 days (range 0–50), no ARIA events were observed.

Conclusion: OCTARIA-AD seeks to establish OCT/OCT-A as accessible biomarkers for ARIA risk stratification in early AD, potentially enhancing patient safety and complementing MRI monitoring.

Disclosure: Nothing to disclose.

EPO-0008 | Higher planetary health diet index scores are associated with better executive function and processing speed in older adults

S. Ha
Department of Neurology, Veterans Health Service Medical Center, Seoul, Republic of Korea

Background and aims: The EAT–Lancet Planetary Health Diet integrates human health with environmental sustainability. However, evidence linking its adherence, measured by the Planetary Health Diet Index (PHDI), to domain-specific cognitive performance remains sparse.

Methods: We analyzed 2,636 participants aged ≥60 from the National Health and Nutrition Examination Survey (2003–2010). Dietary intake was assessed via two 24-hour recalls to calculate the PHDI. Cognitive outcomes included the CERAD battery, Animal Fluency, and the Digit Symbol Substitution Test (DSST). Survey-weighted linear regression estimated β coefficients, adjusting for sociodemographic, lifestyle, and cardiometabolic factors.

Results: Higher PHDI adherence was significantly associated with superior cognitive performance, characterized by a distinct domain-specific sensitivity. In the fully adjusted model, each 10-point higher PHDI was associated with higher scores on the DSST (β=0.9746; p=0.0012) and Animal Fluency (β=0.3811; p=0.0003). Strong dose–response patterns were observed for both executive function (p-trend=0.0008) and semantic fluency (p-trend=0.0001). While the PHDI was positively associated with CERAD immediate recall (Trials 1–3: β=0.1767; p=0.0410), associations with delayed recall were not statistically significant.

Conclusion: Greater adherence to a planetary health-aligned dietary pattern was associated with significantly better executive function and processing speed in older adults. These findings support the “co-benefit” of sustainable diets for brain health, suggesting that sustainability-aligned dietary frameworks may serve as an effective strategy for preserving cognitive resilience in an aging population.

Disclosure: Nothing to disclose.

EPO-0009 | NPTX1 differentiates idiopathic normal pressure hydrocephalus from Alzheimer's disease

S. Ivanovski^{1,2}; M. Kolarič^{1,2}; T. Gabršček³; A. Emeršič⁴; R. Berlot^{4,5,6}; B. Turk^{1,7}; A. Sadikov³; D. Georgiev^{3,4}; M. Fonović¹

¹Department of Biochemistry, Molecular, and Structural Biology, Jozef Stefan Institute, Ljubljana, Slovenia; ²Jozef Stefan International Postgraduate School, Ljubljana, Slovenia; ³Artificial Intelligence Laboratory, Faculty of Computer and Information Science, University of Ljubljana, Ljubljana, Slovenia; ⁴Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia; ⁵Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; ⁶Department of Basic and Clinical Neuroscience, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UK; ⁷Faculty of Chemistry and Chemical Technology, University of Ljubljana, Ljubljana, Slovenia

Background and aims: Normal pressure hydrocephalus (NPH) is a neurological syndrome characterised by dementia, gait dysfunction, urinary incontinence, and ventriculomegaly. Differentiating NPH from other dementias, including Alzheimer's disease (AD), remains challenging, and there are no cerebrospinal fluid (CSF)-based diagnostic biomarkers specific to NPH.

Methods: CSF samples from 20 NPH patients, 30 AD patients, and 25 cognitively normal (CN) controls were subjected to mass spectrometry-based proteomic analysis. Differential expression analysis was performed for all pairwise group comparisons, and differentially expressed proteins in NPH were analysed with the Gene Ontology enrichment tool. A random forest model with protein inputs was trained to assess its ability to differentiate NPH from AD patients. Feature selection algorithms were applied to identify individual and complementary candidate biomarkers. Results were evaluated with immunological testing in both discovery and verification cohorts.

Results: Proteomic profiling revealed upregulated immune-related proteins, including components of the complement cascade, and many downregulated synaptic proteins in NPH patients (Figure 1). The random forest model achieved a mean classification accuracy of 92% over 150 re-runs. Neuronal pentraxin 1 (NPTX1) and gamma-enolase (ENO2) emerged as top biomarker candidates (Figure 2). NPTX1 concentration was lower in NPH patients than in AD patients, resulting in a diagnostic accuracy of 0.94 (95% CI 0.89–0.99) (Figure 3). Additionally, NPTX1 concentrations correlated positively with total tau, phosphorylated tau181, and amyloid β42 in NPH patients, but not in AD patients.

Conclusion: Together, our results highlight synaptic alterations and neuroinflammation as key characteristics of NPH and identify NPTX1 as a promising diagnostic biomarker.

Disclosure: Nothing to disclose.

FIGURE 1 Analysis of differentially expressed proteins specific for NPH in comparison to AD and CN.

FIGURE 2 Individual and complementary proteins identified with feature selection algorithms as potential diagnostic biomarkers.

EPO-0010 | CAA in Alzheimer's disease: What does CSF A β 40 really tell us?

V. De Franco¹; F. Mazzacane²; C. Imbimbo³; E. Prodi⁴; M. Malik⁴; M. Cotta Ramusino¹; G. Perini¹; A. Costa¹; A. Pichiecchio⁴

¹Unit of Behavioral Neurology and Center for Cognitive Disorders and Dementias (CDCD), IRCCS Mondino Foundation; 27100 Pavia, Italy; ²Department of Emergency Neurology and Stroke Unit, IRCCS Mondino Foundation; 27100 Pavia, Italy; ³Department of Brain and Behavioral Sciences, University of Pavia; 27100 Pavia, Italy; ⁴Advanced Imaging and Artificial Intelligence Center, IRCCS Mondino Foundation; 27100 Pavia, Italy

Background and aims: Cerebral amyloid angiopathy (CAA) commonly co-occurs with Alzheimer's disease (AD), reflecting shared amyloid- β (A β) pathology. Definitive CAA diagnosis requires histopathological confirmation, while in vivo evaluation uses Boston criteria. Cerebrospinal fluid (CSF) biomarkers, particularly A β 40, support in vivo CAA diagnosis; utility in AD populations needs further study.

Methods: We enrolled patients with AD with available MRI and CSF data. Patients were categorized using Boston criteria versions 1.0, 1.5, and 2.0, as absent, possible, and probable CAA. CSF concentrations of A β 40, A β 42, total tau, and phosphorylated tau were measured using standardized chemiluminescent immunoassays. Univariate Bayesian linear regression models were used to evaluate differences in CSF biomarkers according to CAA status and specific MRI markers.

Results: 173 patients were included in the study. CSF A β 40 and A β 42 were reduced in CAA patients when applying criteria v1.5 (posterior probabilities of reduction of 95.95% and 97.28% respectively). No significant differences between the CAA and non-CAA groups according to the v2.0 criteria (posterior probabilities of reduction of 27.4% and 33.6%). Regarding MRI markers, the reduction in CSF A β 40 and A β 42 was confined to hemorrhagic markers (HMs), associated with a decrease of -12.51% (95%CrI -22.69 to -0.78) and -14.50% (-24.12 to -3.07), respectively. No significant correlations were found between CSF biomarkers and non-hemorrhagic markers (nHMs).

Conclusion: CSF β -amyloid reduction was observed in comorbid CAA-AD patients only with v1.5 criteria; criteria v2.0 made such association improbable. This reflects the association between CAA radiological marker and A β confined to HMs, while nHMs showed no association

FIGURE 1 Impact of Boston criteria versions and MRI markers on CSF biomarker levels.

EPO-0011 | Dual-task walking unmasks inter-joint coordination instability in amnesic mild cognitive impairment

Y. Kuan¹; T. Lu²
¹Department of Neurology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan;
²Department of Biomedical Engineering, National Taiwan University, Taipei, Taiwan

Background and aims: Gait disturbances in amnesic mild cognitive impairment (MCI) may remain subtle during normal walking and become evident only under increased cognitive load. Examining both single-task and dual-task walking may clarify how cognitive demands affect motor coordination and stability.

Methods: Older adults with amnesic MCI and cognitively normal controls performed level walking under single-task and dual-task conditions, including a cognitive task (serial subtraction) and a motor task (tray carrying). Three-dimensional kinematic data were analysed to derive phase angles and continuous relative phase, characterising hip-knee and knee-ankle inter-joint coordination. Coordination stability, pattern similarity, and temporal alignment were quantified using deviation phase, cross-correlation coefficients, and root-mean-square error across key gait phases.

Results: During single-task walking, spatiotemporal parameters and overall inter-joint coordination patterns were largely comparable between groups, with only mild increases in coordination variability in amnesic MCI. Under dual-task conditions, coordination deficits became more pronounced, particularly in knee-ankle coupling during single-limb support and swing. Individuals with amnesic MCI showed increased variability, reduced waveform similarity, and greater phase-position displacement, despite preserved gait timing. Cognitive dual-task walking induced larger effects than motor dual-task walking.

Conclusion: While basic gait patterns appear relatively preserved during single-task walking, dual-task conditions reveal impaired inter-joint coordination in amnesic MCI. Increased instability and altered temporal organisation of knee-ankle coordination under cognitive load suggest reduced adaptability of motor control. Dual-task gait assessment may provide a sensitive approach for detecting early cognitive-motor interference in pre-dementia stages.

Disclosure: This study was supported by public research funding from the Ministry of Science and Technology, Taiwan (Grant Nos. 110-2628-B-038-025). The authors declare no commercial or financial conflicts of interest.

EPO-0012 | Behavioral dysexecutive syndrome at the intersection of autoimmunity and genetically predisposed frontotemporal lobar degeneration

Z. Chatzieftheriou; A. Vakrakou; F. Athanasopoulos; M. Tzortzakakis; E. Zeis; P. Stathopoulos; V. Constantinides; C. Koros; S. Papageorgiou
 First Department of Neurology, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background and aims: Autoimmune encephalitis can present with slowly progressive cognitive and movement disorders mimicking neurodegenerative diseases. Emerging evidence, including immunoglobulin-like cell adhesion molecule 5 (IgLON5)-associated disease, suggests that immune-mediated inflammation may trigger or accelerate latent neurodegenerative processes in genetically predisposed individuals.

Methods: A 55-year-old male patient with gradual behavioral impairment characterized by apathy and compulsive behaviors underwent comprehensive clinical, neuropsychological and neurophysiological assessment, multimodal neuroimaging, extensive laboratory, including immunological and genetic testing. **Results:** Examination revealed frontal disinhibition, asymmetric upper-limb and truncal rigidity and REM sleep behavior disorder. Neuropsychological evaluation demonstrated executive dysfunction, mainly impaired cognitive flexibility. Neuroimaging showed frontal-predominant cortical atrophy,

electroencephalography revealed diffuse background slowing with intermittent theta activity and dopamine transporter imaging demonstrated asymmetric reduction of striatal uptake. Cerebrospinal fluid (CSF) analysis showed markedly elevated protein (330 mg/dL) without pleocytosis or intrathecal immunoglobulin synthesis. Neuronal antibody panels were negative; however, tissue-based immunofluorescence demonstrated strong neuronal reactivity in serum and CSF. Neurodegeneration biomarkers were inconsistent with Alzheimer's disease. Whole-body fluorodeoxyglucose positron emission tomography (FDG-PET) excluded occult malignancy. Genetic analysis identified a pathogenic sequestosome 1 (SQSTM1) missense mutation (Pro392Leu) associated with frontotemporal dementia and a glucocerebrosidase (GBA) variant (Asn409Ser) conferring synucleinopathy risk. To target the autoimmune inflammatory response, the patient received high-dose corticosteroids followed by plasmapheresis. Partial improvement and stabilization were observed during six months of follow-up.

FIGURE 1 Axial (A) and coronal (B) T1-weighted brain MRI demonstrating frontal-predominant cortical atrophy.

FIGURE 2 Tissue-based immunofluorescence on mice brain sections: patient serum demonstrating a strong reaction against cerebellar neurons.

Conclusion: This coexistence of neurodegeneration-linked mutations alongside inflammatory CSF findings, neuronal immunoreactivity and response to immunotherapy suggests a bidirectional interaction between autoimmune mechanisms and genetically programmed neurodegeneration, thereby blurring diagnostic boundaries and encouraging integrated diagnostic strategies.

Disclosure: Nothing to disclose.

Autonomic Nervous System Diseases

EPO-0013 | When symptoms outweigh criteria:

Dizziness and autonomic burden across the orthostatic intolerance spectrum

E. Postovoi¹; M. Cebuc¹; L. Rotaru²; A. Feodorovici²; G. Corcea²; I. Moldovanu²; O. Grosu²; M. Sangheli¹

¹Department of Neurology No. 1, Nicolae Testemițanu State University of Medicine and Pharmacy, Chișinău, Republic of Moldova; ²Institute of Neurology and Neurosurgery, Chișinău, Republic of Moldova

Background and aims: Orthostatic dizziness is common, yet symptoms may not match hemodynamic response during the active stand-test. This study aimed to assess whether dizziness in daily life (DDL) and during orthostatic testing (DOT) is associated with autonomic symptom burden and dizziness-related disability.

Methods: In this cross-sectional study, 21 inpatients at the Diomid Gherman Institute of Neurology and Neurosurgery underwent orthostatic testing, with blood pressure and heart rate assessed supine and serially after standing (at 0–10 minutes). Orthostatic intolerance (OI) spectrum phenotype: orthostatic hypotension (OH), orthostatic hypertension (OHT), POTS, OI. Patient-reported outcomes: DHI, COMPASS-31 (OI domain), BDI. Descriptive and inferential statistics were used.

Results: The cohort (mean age 67.9 ± 11.4 years; 61.9% male) reported frequent DDL (66.7%; provoked 64.3%, episodic 71.4%). Most had cerebral small vessel disease (81%); no χ^2 association with DDL or DOT ($p > 0.05$). OI predominated (52.4%), whereas classical orthostatic phenotypes were less common (OH 19.0%, OHT 14.3%, POTS 4.8%); 9.5% had normal responses. Daily-life dizziness was associated with higher total COMPASS-31 (33.56[16.67–51.15] vs 11.27[1.78–22.55], $p < 0.001$), OI domain scores (20[10–28] vs 0[0–8], $p < 0.001$), yet showed no significant association with DOT ($p > 0.05$). DHI did not differ across OI spectrum phenotypes ($p = 0.571$), but correlated strongly with total COMPASS-31 ($\rho = 0.811$, $p < 0.001$), COMPASS-31-OI ($\rho = 0.533$, $p = 0.05$) and BDI ($\rho = 0.686$, $p = 0.007$).

Conclusion: Symptoms outweighed hemodynamic criteria, as DDL tracked autonomic and depressive burden rather than orthostatic phenotype, supporting symptom-led stratification and repeat or extended autonomic evaluation.

Disclosure: Nothing to disclose.

E. Abed
Neurology Department, Al-Azahr University, Cairo, Egypt

Background and aims: Autonomic nervous system dysfunction has been linked to outcomes following intracerebral hemorrhage (ICH). Heart rate entropy (HRE) reflects autonomic complexity and may provide prognostic information. This study aimed to assess the association between HRE and mortality after ICH and to compare its predictive value with established autonomic markers and the ICH score.

Methods: This prospective study was conducted at Al-Azhar University Hospitals and Cairo Fatemic Hospital and included 110 consecutive patients with spontaneous ICH admitted between October 2023 and November 2024. Sample HRE, heart rate variability parameters, and baroreflex sensitivity were assessed early after admission. Hematoma volume, intraventricular extension, infratentorial location, level of consciousness, and age were integrated into the standard ICH score. Predictive performance for mortality was evaluated using receiver operating characteristic (ROC) curve analysis and multivariable logistic regression.

Results: Among the studied patients (mean age 60.8 ± 11.2 years), HRE demonstrated the highest accuracy for mortality prediction (AUC 0.88), outperforming individual autonomic markers and showing comparable performance to the ICH score (AUC 0.84). Both HRE and ICH score were independently associated with mortality. Combining HRE with the ICH score significantly improved prognostic accuracy, yielding an AUC of 0.94

Conclusion: Heart rate entropy provides substantial prognostic information regarding mortality after ICH and performs comparably to the ICH score. Incorporating HRE into conventional clinical scoring systems may enhance mortality prediction following intracerebral hemorrhage.

Disclosure: Nothing to disclose.

TABLE 1 Baseline characteristics of ICH patients (n = 110).

Variable	Value
Total patients	110
Age (years), mean $\pm$ SD	60.8 ± 11.2
Male sex	67 (60.9%)
Median hematoma volume (mL)	36 (IQR 24–52)
Intraventricular hemorrhage	41 (37.3%)
Infratentorial hemorrhage	29 (26.4%)
Impaired consciousness on admission	58 (52.7%)

TABLE 2 Predictive performance of autonomic markers for mortality.

Predictor	AUC for mortality
Heart rate entropy (HRE)	0.88
ICH score	0.84
Normalized LF power	0.77
LF/HF ratio	0.75
Normalized HF power	0.73
Baroreflex sensitivity (BRS)	0.71

EPO-0015 | Characterization and staging of cardiovascular autonomic failure in light-chain amyloidosis

F. Vitali¹; L. Sander¹; G. Chiaro¹; G. Ingle¹; P. McNamara¹; M. Lunn²; J. Gillmore³; V. Iodice⁴
¹National Autonomic Centre, The National Hospital for Neurology and Neurosurgery, Queen Square, London, UK; ²Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology, London, UK; ³National Amyloidosis Centre, Division of Medicine, University College London, London, UK; ⁴Department of Translational Neuroscience & Stroke, UCL Queen Square Institute of Neurology, University College London, London, UK

Background and aims: Light-chain amyloidosis (AL amyloidosis) is a systemic disorder characterized by the deposition of monoclonal light-chain as amyloid fibrils, leading to multiorgan dysfunction. Cardiovascular autonomic failure (cvAF) represents a major contributor to morbidity, yet its natural history and staging remain poorly characterized.

Methods: This retrospective study included 38 patients with AL amyloidosis who underwent comprehensive autonomic testing. cvAF was classified as stage 1 when mild parasympathetic and/or sympathetic impairment was present without neurogenic orthostatic hypotension (nOH), and as stage 2 when both domains were affected with nOH.

Results: At onset, about one-third of patients reported autonomic symptoms. At the time of testing (median disease duration = 3 years), nearly all showed evidence of cvAF. Half were classified as stage 1, with predominant parasympathetic involvement, and 47% as stage 2. Stage 2 patients more frequently exhibited gastrointestinal ($p=0.032$) and urogenital symptoms ($p=0.004$), and impaired norepinephrine response during head-up tilt ($p<0.001$). Mortality rate and overall survival did not differ between stages. Patients with autonomic onset were more likely to have developed somatic polyneuropathy ($p=0.036$), nOH ($p=0.012$), and higher orthostatic intolerance ratios at T1 ($p=0.001$). Autonomic onset was independently associated with progression to stage 2 cvAF (OR = 7.600, 95% CI 1.373–42.063, $p=0.020$).

Conclusion: Cardiovascular autonomic failure is a prevalent and impactful manifestation of AL amyloidosis, often presenting early and progressing with the disease course. Our findings highlight the importance of systematic autonomic assessment and increased awareness of management strategies.

Disclosure: Nothing to disclose.

EPO-0016 | The burden of neurogenic orthostatic hypotension across autonomic disorders: Real-world management outcomes

G. Winningham¹; S. Sajeev¹; S. Johnstone¹; Z. Jiang¹; G. Chiaro¹; V. Iodice¹; V. Iodice²; V. Iodice³

¹National Autonomic Centre, National Hospital Neurology and Neurosurgery, London, UK; ²Department of Translational Neuroscience and Stroke, UCL Queen Square Institute of Neurology, Queen Square, London, UK; ³NIHR University College London Hospitals Biomedical Research Centre, London, UK

Background and aims: Neurogenic orthostatic hypotension (nOH) is a major cause of morbidity in autonomic failure, associated with falls, hospitalisations, and reduced quality of life, yet remains challenging to manage. We conducted a prospective real-world study to evaluate symptom burden, quality of life, and treatment response in patients with established nOH across all aetiologies.

Methods: Patients with established nOH were prospectively followed within a tertiary referral centre management programme. All patients attended a dedicated clinic, where non-pharmacological measures were implemented, and individualised combinations of anti-hypotensive medications were optimised. Outcomes included validated patient-reported measures of symptom burden and quality of life (Orthostatic Hypotension Questionnaire, OHQ; Patient Global Impression, PGI), alongside prospective recording of falls and hospital admissions. Orthostatic intolerance severity was assessed using standardised autonomic testing, including head-up tilt, active stand, and 24-hour blood pressure monitoring. Data are presented as mean $\pm$ SD.

Results: A total of 142 patients were enrolled (10 Lewy body dementia, 23 multiple system atrophy, 35 Parkinson's Disease, 62 pure autonomic failure, 12 autonomic neuropathy). Mean falls and hospital admissions were 1.6 ± 4.8 and 0.5 ± 2.6 respectively. OHQ composite-score was 5.9 ± 2.0 , and PGI score was 4.6 ± 1.5 .

Conclusion: In real-world tertiary-centre cohort with long-term follow-up, patients with autonomic failure and nOH across all aetiologies experience high symptom burden, frequent falls, and impaired quality of life despite individualised combination therapy. These findings highlight nOH as a major contributor to morbidity, demonstrating limitations of existing management strategies.

Disclosure: Nothing to disclose.

EPO-0017 | Can SUDOSCAN replace QSART in the composite autonomic severity scale for evaluating sudomotor function in people with multiple sclerosis?

K. Tešija¹; M. Sredanović¹; K. Jerčinović²; M. Krbot Skorić¹; M. Habek¹

¹University Hospital Center Zagreb, Zagreb, Croatia; ²University of Zagreb, School of Medicine, Zagreb, Croatia

Background and aims: The Quantitative Sudomotor Axon Reflex Test (QSART) is the gold standard for evaluating sudomotor function within the Composite Autonomic Scoring Scale (CASS). SUDOSCAN, a quick and noninvasive electrochemical test of sweat gland function, has been suggested as a potential substitute. This study investigated whether SUDOSCAN-derived indices could replace QSART within the CASS framework and provide reliable sudomotor evaluation in people with multiple sclerosis (pwMS).

Methods: This cross-sectional study involved 99 pwMS. Subjective autonomic symptoms were evaluated using the Composite Autonomic Symptom Score-31 (COMPASS-31), while objective autonomic testing was conducted with the CASS, which includes QSART for sudomotor assessment. Additionally, all pwMS underwent SUDOSCAN testing, and a modified CASS score was derived based on adrenergic, cardiovagal, and SUDOSCAN-based sudomotor measures.

Results: A strong correlation was observed between CASS and modified CASS ($r=0.795$, $p<0.001$). However, no correlation was found between QSART-based and SUDOSCAN-based sudomotor indices ($r=0.043$, $p=0.672$). CASS did not correlate with COMPASS-31 or its subdomains, whereas modified CASS showed a correlation with the gastrointestinal domain of COMPASS-31 ($r=0.228$, $p=0.027$). Additionally, modified CASS correlated with age ($r=0.204$, $p=0.048$) and the Expanded Disability Status Scale (EDSS) score ($r=0.207$, $p=0.043$).

Conclusion: The modified CASS including SUDOSCAN showed a strong overall correlation with the standard CASS and meaningful associations with age and disability level. Although SUDOSCAN did not correlate with QSART-based sudomotor indices, it could serve as a helpful supplement when QSART is unavailable. More long-term studies are needed to assess its effectiveness in monitoring sudomotor dysfunction over time.

¹National Autonomic Centre, National Hospital for Neurology and Neurosurgery, London, UK; Department of Translational Neuroscience and Stroke, UCL Institute of Neurology, London; Neurologic Clinic and Policlinic, University Hospital Basel, CH; ²National Autonomic Centre, National Hospital for Neurology and Neurosurgery, London, UK; ³Centre for Neuromuscular Diseases, Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology and the National Hospital of Neurology and Neurosurgery, London, UK; ⁴National Amyloidosis Centre, Division of Medicine, University College London, London, UK; ⁵Department of Translational Neuroscience and Stroke, UCL Institute of Neurology, London; ⁶National Autonomic Centre, National Hospital for Neurology and Neurosurgery, London, UK; Department of Translational Neuroscience and Stroke, UCL Institute of Neurology, London; NIHR University College London Hospitals Biomedical Research Centre

Background and aims: Autonomic failure is a common feature in hereditary transthyretin amyloidosis (ATTRv), but has not been systematically described in other genetic subtypes including gelsolin (AGel), apolipoprotein A1 (AApoA1), and fibrinogen A α -chain amyloidosis (AFib). This study aimed to quantitatively investigate cardiovascular autonomic dysfunction in these rare entities, and to compare cardiovascular autonomic dysfunction to patients with ATTRv.

Methods: This retrospective study enrolled patients with genetically confirmed diagnosis of AGel, AApoA1, and AFib. Age- and sex-matched control patients with ATTRv were included. All participants underwent standardised cardiovascular autonomic function testing (AFT), a subgroup had ambulatory 24h blood pressure monitoring (ABPM) with autonomic patient diary. Stages of autonomic failure were defined according to AFT results: stage 0 (normal AFT), stage I (mild parasympathetic and/or sympathetic impairment), stage II (neurogenic orthostatic hypotension (nOH)).

Results: A total of 12 patients were included. Overall, 9/11 (82%) patients had abnormal AFT. 8/11 (73%) presented with stage I, and only 1/11 (9%) patient with AApoA1 had nOH. In the matched ATTRv cohort, 4/12 (33%) presented with nOH. There were no significant differences in cardiovascular autonomic parameters when comparing ATTRv versus non-ATTRv patients. ABPM was available in two patients: one individual with AFib (stage I) had normal circadian BP rhythm, while one patient with AApoA1 (stage II) was a reverse dipper.

Conclusion: Cardiovascular autonomic dysfunction is very prevalent in genetic non-TTR amyloidosis, but is usually mild. Quantitative AFT could help to monitor disease progression. Prospective studies are needed to investigate dysfunction of other autonomic domains in these patients.

EPO-0019 | Mucosal denervation and markers of immune activation in the gut of patients with chronic inflammatory diseases

M. Nolano¹; G. Scalise²; I. Borreca²; A. Areniello²; G. Caporaso²; B. De Conno²; D. Dell'Aversana³; F. Masciarelli³; G. Sarnelli⁴; D. Caprioli⁵; V. Provitera²

¹Neurology Department, Skin Biopsy Laboratory, Istituti Clinici Scientifici Maugeri IRCCS, Telesse Terme, Italy. ²Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II of Naples, Naples, Italy; ³Neurology Department, Skin Biopsy Laboratory, Istituti Clinici Scientifici Maugeri IRCCS, Telesse Terme, Italy; ⁴Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II of Naples, Naples, Italy; ⁵Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy; ⁶Department of Physiology and Pharmacology, Sapienza University, and Laboratory of Behavioral Neuropharmacology, IRCCS Fondazione Santa Lucia, Rome, Italy

Background and aims: Chronic intestinal inflammation is a condition characterized by immune activation, increased epithelial permeability, and altered neuro-immune interactions. These features make it a suitable model to investigate mechanisms of mucosal denervation and impaired interoceptive signaling within the gut-brain axis, implicated in neuropsychiatric conditions, including opioid use disorder (UOD).

Methods: To address this objective, we analyzed ileal biopsies from 10 patients with chronic inflammatory conditions (4M/6F; 47.3 $\pm$ 8.6) and matched healthy controls (5M/5F; 55.2 $\pm$ 10.9). Using indirect immunofluorescence, immune activation was assessed by quantifying CD68⁺ macrophages, IBA-1⁺ activated myeloid cells, CD8⁺ lymphocytes, and IL-24-expressing cells, while mucosal innervation was evaluated by measuring VIP⁺ enteric fibers.

Results: Compared to controls, patients with inflammatory conditions showed a marked increase in CD68⁺ macrophages (755.0 $\pm$ 338.1 vs 141.1 $\pm$ 70.5; p < 0.01), IBA-1⁺ myeloid cells (862.3 $\pm$ 257.7 vs 239.9 $\pm$ 116.4; p < 0.01), and IL-24-expressing cells (339.7 $\pm$ 151.4 vs 32.0 $\pm$ 44.6; p < 0.01). CD8⁺ lymphocytes were also increased, although the difference did not reach statistical significance (1608.6 $\pm$ 568.6 vs 1391.6 $\pm$ 392.3; p = 0.504). Concomitantly, a significant reduction in VIP-positive enteric fibers was observed in inflammatory conditions compared to controls (0.036 $\pm$ 0.025 vs 0.069 $\pm$ 0.025; p < 0.01).

Conclusion: Overall, the findings reveal a distinct neuro-immune signature characterized by chronic inflammation and enteric denervation. This pattern may underlie impaired interoceptive signaling and disrupted gut-brain axis communication in inflammatory bowel conditions, with potential relevance to neuropsychiatric disorders such as opioid use disorder.

Disclosure: Nothing to disclose.

M. Sredanović¹; C. Hentzen²; I. Adamec³; C. Chesnel²; M. Krbot Skorić⁴; M. Habek³

¹University Hospital Center Zagreb, Department of Neurology, Referral Center for Autonomic Nervous System Disorders, Zagreb, Croatia; ²Sorbonne University, GRC 01 - Group of Clinical research in Neuro-urology, Hôpital Pitié Salpêtrière, Paris, France; ³School of Medicine, University of Zagreb, Zagreb, Croatia; ⁴Faculty of Electrical Engineering and Computing, University of Zagreb, Zagreb, Croatia

Background and aims: Gastrointestinal autonomic symptoms are frequently reported by people with MS (pwMS) but remain insufficiently characterized, with prevalence estimates varying widely across studies. The aim of this study was to conduct a systematic review with meta-analysis of the available scientific evidence on the prevalence of gastrointestinal autonomic symptoms in people with multiple sclerosis.

Methods: A systematic review of the literature (PubMed, Scopus, and Web of Science until October 2025) identified 21693 studies, of which 15 reported frequency of gastrointestinal autonomic symptoms in pwMS compared to healthy controls. Of these, 5 evaluated dysphagia, 5 evaluated bowel dysfunction in general, and a single study evaluated constipation, fecal incontinence, abnormal gastric emptying, dyspepsia, anorectal dysfunction, and intestinal symptoms.

Results: Meta-analysis showed a significantly higher prevalence of gastrointestinal autonomic symptoms in pwMS than in healthy controls (0.283, IQR 0.026–0.715 in pwMS vs. 0.022, IQR 0.000–0.185 in healthy controls; OR 3.40, 95% CI 1.79–6.44; $p=0.0002$) (Figure 1). Substantial heterogeneity was observed ($I^2=99\%$, $\tau^2=1.37$). Among symptoms with more than one study, the prevalence of dysphagia was significantly higher (OR 20.65, 95% CI 3.20–133.34; $p=0.001$), whereas the prevalence of bowel dysfunction did not differ (OR 1.21, 95% CI 0.65–2.24; $p=0.55$).

Conclusion: Gastrointestinal autonomic symptoms are significantly more frequent in people with multiple sclerosis than in healthy controls, with dysphagia showing a particularly strong association. Greater awareness and systematic screening of gastrointestinal autonomic symptoms are warranted in clinical

practice to improve recognition and management of these common and impactful manifestations of MS.

FIGURE 1 Forest plot showing the pooled odds ratio for gastrointestinal autonomic symptoms in people with multiple sclerosis compared with healthy controls.

Background and aims: Pain affects up to 87% of persons with multiple system atrophy (MSA), impacting core activities of daily living, but remains under-recognized in clinical practice. In the absence of disease-specific pain assessment tools, we aim at developing a patient-reported pain scale for MSA.

Methods: A taskforce of movement disorder and pain experts will develop a first draft of the MSA-pain scale. The scale development will be informed by a systematic literature review

and by the results of targeted surveys addressing patients, caregivers, and healthcare professionals (ongoing) on current standards and unmet needs on pain assessment and management in MSA. The questionnaire will be developed in English and undergo a preliminary field test ($n = 5$ English-speaking persons with MSA) with subsequent item reduction and refinement. The Delphi methodology will be followed to reach consensus on the final version of the questionnaire.

Results: The questionnaire development is expected to last 12 months. Once finalized, the final version of the questionnaire will be translated into other languages (German, Italian, French) and validated in a large multi-center study.

Conclusion: The MSA-pain questionnaire is expected to assist in the screening, systematic assessment and follow-up of different types of pain in MSA. The validation of the first disease-specific patient reported outcome measure (PROM) for pain in MSA will also hopefully pave the way for interventional trials targeting pain in MSA.

EPO-0022 | Increased infarct volume is associated with a shift towards cardiac sympathetic predominance in patients with ischemic stroke

R. Wang¹; S. Moeller²; A. Akhundova³; H. Marthol⁴; R. Kollmar⁵; M. Köhrmann⁶; A. Dörfler⁷; S. Gerner¹; B. Kallmünzer¹; S. Schwab¹; M. Hilz¹

¹Department of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany; ²Faculty of Health/School of Medicine, Witten/Herdecke University, Witten, Germany; ³Department of Neurology, Zentralklinik Bad Berka, Bad Berka, Germany; ⁴Department of Psychiatry, Klinikum am Europakanal, Erlangen, Germany; ⁵Department of Neurology, General Hospital Darmstadt, Darmstadt, Germany; ⁶Department of Neurology, University Hospital Essen, Essen, Germany; ⁷Department of Neuroradiology, University of Erlangen-Nuremberg, Erlangen, Germany

Background and aims: Ischemic stroke often causes cardiovascular autonomic dysfunction. We previously showed associations between higher National Institutes of Health Stroke Scale scores and more severe cardiovascular autonomic dysfunction. This study evaluated associations between infarct-volume and parameters of cardiac autonomic modulation in patients with acute ischemic stroke in the middle cerebral artery (MCA) territory.

Methods: In 48 patients with acute MCA stroke (68 ± 15 years old, 23 men and 25 women), we monitored RR intervals (RRI), systolic, diastolic blood pressures (BPsys, BPdia), and respiration (RESP) at rest within 24 hours after stroke-onset. We calculated parameters of total cardiac autonomic modulation (RRI-standard-deviation (RRI-SD), RRI-coefficient-of-variation (RRI-CV), RRI-total-powers), sympathetic (RRI-low-frequency-powers (RRI-LF), normalized (nu) RRI-LF-powers, BPsys-LF-powers) and parasympathetic modulation (root-mean-square-of-successive-RRI-differences (RMSSD), RRI-high-frequency-powers (RRI-HF), RRI-HFnu-powers), sympathetic-parasympathetic balance (RRI-LF/HF-ratios), and baroreflex-sensitivity (BRS). The infarct-volume was calculated

using the Ellipsoid model ABC/2 (where A = longest dimension in axis x, B = longest perpendicular dimension to axis x (y), and C = total length in z dimension) from the diffusion-weighted Magnetic Resonance image (DWI) within 24 hours upon stroke-onset or Computed Tomography (CT) taken within 48 hours upon stroke-onset.

Results: Values of infarct-volumes correlated positively with RRI-LF-nu-powers (correlation-coefficient: 0.297, $p = 0.038$) and RRI-LF/HF-ratios (correlation-coefficient: 0.414, $p = 0.003$), negatively with RRI-HFnu-powers (correlation-coefficient: -0.297 , $p = 0.038$). Patients with infarct-volumes above 50 mL had higher RRI-LF-nu-powers and RRI-LF/HF-ratios but lower RRI-HF-nu-powers than patients with smaller infarct-volumes.

Conclusion: In our patients with acute ischemic MCA-stroke, increased infarct-volume was associated with a shift towards increased sympathetic and reduced parasympathetic cardiac modulation. These changes bear an increased risk of secondary complications.

Disclosure: Nothing to disclose.

EPO-0023 | Lower urinary tract symptoms in Parkinson's disease: Prevalence and aetiology

S. Diaconu¹; I. Murasan²; R. Ilea²; R. Margarit²; A. Drujescu²; S. Berzunteanu²; D. Rusu¹; R. Dolis²; C. Falup-Pecurariu¹

¹Department of Neurology, County Clinic Hospital, Transilvania University Brasov, Romania; ²Department of Neurology, County Clinic Hospital, Brasov, Romania

Background and aims: Lower urinary tract symptoms (LUTS) are common autonomic manifestations of Parkinson's disease (PD), frequently preceding or accompanying motor progression and significantly impairing quality of life. However, the relationship between LUTS, motor severity, and disease characteristics remains incompletely defined. The aim of this study was to assess the prevalence and pattern of LUTS in PD and to explore their associations with motor severity, disease duration, and quality of life.

Methods: We conducted a cross-sectional observational study including 153 patients with idiopathic PD (mean age 67.4 ± 8.9 years, disease duration 6.1 ± 4.2 years, 58% male). LUTS were evaluated using the Overactive Bladder Questionnaire short form (OAB-qSF) and the International Prostate Symptom Score (IPSS). Quality of life was assessed using disease-specific patient-reported measures. Correlation and multivariate linear regression analysis were performed.

Results: Overall, 107 patients (69.93%) reported at least one LUTS. Storage symptoms predominated (66.35%) with nocturia (61.68%) and urgency (48.59%) being most frequent. Mean OAB-q symptoms score was 38.7 ± 17.4 , and mean IPSS total score was 12.4 ± 6.3 . OAB-q scores correlated significantly with UPDRS-III ($r = 0.35$, $p < 0.001$), H&Y stage ($r = 0.33$, $p < 0.001$), age ($r = 0.21$, $p = 0.001$), and disease duration. In multivariate analysis, UPDRS-III and age independently predicted LUTS severity. Higher LUTS burden was independently associated with poorer quality of life ($p < 0.001$).

Conclusion: LUTS are highly prevalent in PD, with storage symptoms predominating, and are strongly associated with motor severity and disease progression.

Disclosure: Nothing to disclose.

National Autonomic Centre, The National Hospital for Neurology and Neurosurgery, London, UK

Background and aims: While normal metaiodobenzylguanidine (MIBG) uptake on cardiac scintigraphy and sweat function on dynamic sweat test (DST) in pure autonomic failure (PAF) are predictors of phenoconversion to multiple system atrophy (MSA) over parkinson's disease (PD) or dementia with lewy bodies (DLB), they can become abnormal in late-stage MSA, consistent with a top-down model of disease. However, no study has evaluated the sequence of peripheral denervation across cardiovascular and sudomotor domains in MSA. We examined sweat loss in patients with normal versus abnormal MIBG uptake and considered implications for predicting phenoconversion trajectory.

Methods: As part of our ongoing natural history study, consecutive patients with an initial diagnosis of PAF were systematically phenotyped and followed longitudinally until phenoconversion or death. Participants underwent cardiovascular autonomic testing, cardiac MIBG scintigraphy, dynamic sweat testing (DST), and thermoregulatory sweat testing (TST).

Results: 24 PAF patients (median follow up 5.5 years) underwent both scintigraphy and sudomotor testing. 4/24 patients (17%) had normal MIBG uptake, of whom 1/4(25%) had pre-ganglionic sweat loss. This patient and 2 others (75%) later phenoconverted into MSA, while the remaining patient retained a PAF diagnosis. Among the 20/24 (83%) patients with abnormal MIBG uptake, all 20/20 (100%) had evidence of post-ganglionic sudomotor dysfunction and retained a PAF diagnosis or phenoconverted to PD/DLB.

Conclusion: In PAF patients phenoconverting to MSA, cardiac sympathetic innervation may remain preserved even in established peripheral sudomotor denervation, possibly reflecting differing neuronal vulnerability to alpha-synuclein deposition. These findings support a multimodal biological framework for

PAF to improve prediction of phenoconversion trajectory across disease stages.

EPO-0025 | Ethical barriers to time-critical stroke care: Family consent, delayed treatment, and the need for presumed consent in Armenia

L. Martirosyan; A. Ashughyan; A. Papoyan; K. Kosyan; R. Zhamakochyan; A. Madoyan; K. Petrosyan
Department of General and Vascular Neurology, Saint Gregory the Illuminator Medical Center, Yerevan, Armenia

Background and aims: Acute ischemic stroke is a leading cause of mortality and long-term disability worldwide. Intravenous thrombolysis and mechanical thrombectomy are evidence-based, time-critical interventions that significantly improve survival and functional outcomes. Despite their established efficacy, ethical-legal barriers may impede timely treatment in certain healthcare systems. This study examines the ethical implications of consent requirements in acute stroke care, comparing European practice with the current regulatory framework in Armenia.

Methods: A comparative ethical and policy analysis was conducted, reviewing European stroke guidelines and ethical frameworks (ESO, NICE) alongside Armenian Ministry of Health regulations governing informed consent in neurological emergencies.

Results: In most European countries, acute stroke treatment is guided by the principle of presumed consent, allowing immediate initiation of life-saving therapy when patients lack decision-making capacity and no prior advance directive / living will is documented. Family members serve an advisory rather than decisional role. In contrast, Armenian practice permits family members to refuse thrombolysis and thrombectomy even when the patient is conscious, and mandates written family consent when treatment is approved. This requirement, formally regulated at the ministerial level, introduces critical delays and contradicts the ethical principles of beneficence and non-maleficence by effectively transforming time-dependent care into a preventable source of harm.

Conclusion: Current consent practices in Armenia represent a significant ethical and clinical barrier to optimal stroke care. Addressing this issue requires legislative reform, implementation of presumed consent for emergency stroke treatment, and enhanced legal protection for physicians to ensure timely, ethical, and evidence-based intervention.

Disclosure: Nothing to disclose.

TABLE 2 Logistic multivariate regression for variables associated with poor functional outcome in terms of mRS 3–6 at 3 months.

Variables	OR	CI - Lower	CI - Upper	Sig.
Age	1.006	1.004	1.009	<0.001
NIHSS at admission	1.056	1.032	1.081	<0.001
Haemorrhagic stroke	1.391	1.022	1.774	0.014
ES/SE	1.342	1.021	1.777	0.036
Statin treatment	0.879	0.813	0.952	0.001

clinical predictors of unfavorable functional outcomes, defined as a modified Rankin Scale (mRS) score of 3–6 at 3 months, with a focus on the potential impact of statin therapy.

Methods: The clinical data of 777 consecutive patients with acute stroke were retrospectively analyzed. Patients were stratified with favorable outcomes defined as an mRS score of 0–2 and unfavorable outcomes (mRS score of 3–6). Univariate and multivariate logistic regression analyses were then performed to identify variables independently associated with poor clinical outcomes.

Results: Patients in the mRS 3–6 group were older on average (80 vs. 74 years, $p < 0.001$) and had a significantly higher median NIHSS score at admission compared to those in the mRS 0–2 group (12 vs. 4, $p < 0.001$). Multivariate analysis showed that older age (OR=1.006, $p < 0.001$), higher NIHSS scores at admission (OR=1.036, $p < 0.001$), haemorrhagic stroke (OR=1.101, $p = 0.014$), and the occurrence of early seizures or status epilepticus (OR=1.142, $p = 0.020$) were independently associated with a

poor functional outcome (mRS 3–6). Conversely, statin therapy was associated with a reduced risk of poor outcome (OR=0.879, $p = 0.001$).

Conclusion: In a consecutive cohort of patients with acute stroke, statin therapy emerged as an independent protective factor against poor functional outcome at three months, highlighting its potential pleiotropic effects even in patients with haemorrhagic stroke. Further studies are warranted to elucidate the underlying pharmacological mechanisms.

Disclosure: Nothing to disclose.

TABLE 2 Logistic multivariate regression for variables associated with the onset of post-stroke epilepsy.

Variables	OR	CI - Lower	CI - Upper	Sig.
NIHSS at admission	1.004	1.002	1.007	0.001
ES/ESE	1.112	1.042	1.187	<0.001
Statin treatment	0.987	0.946	0.999	0.048

the risk of post-stroke epilepsy through pleiotropic mechanisms. This study aimed to evaluate factors associated with the development of post-stroke epilepsy (PSE), with a focus on the potential role of statin therapy, in a real-world cohort of stroke patients.

Methods: Clinical and radiological data of 777 consecutive patients with acute stroke were retrospectively analyzed. Data of patient with PSE and without PSE were compared. Univariate and multivariate logistic regression analysis was conducted to identify variables associated with the development of PSE.

Results: The two groups did not differ significantly with respect to demographic characteristics or comorbidities, the median NIHSS score at admission was significantly higher in the post-stroke epilepsy (PSE) group than in the non-PSE group (12 vs. 6, $p < 0.001$). Multivariate analysis showed that higher NIHSS scores at admission (OR = 1.004, 95% CI: 1.002–1.007; $p = 0.001$) and the occurrence of early seizures or early status epilepticus (ES/ESE) (OR = 1.112, 95% CI: 1.042–1.187; $p < 0.001$) were independently associated with an increased risk of PSE, while statin therapy emerged as an independent protective factor against PSE development (OR = 0.948, 95% CI: 0.915–0.999; $p = 0.048$).

Conclusion: In a consecutive cohort of acute stroke patients, statin therapy emerged as an independent protective factor against the development of PSE, underscoring its potential role in antiepileptogenic processes.

Background and aims: Randomized trials support early initiation of direct oral anticoagulants (DOACs) after atrial fibrillation (AF)-related ischemic stroke. However, patients with breakthrough ischemic stroke occurring despite ongoing anticoagulation have been largely under-represented. We evaluated the effectiveness and safety of early versus delayed DOAC initiation in these patients.

Methods: We performed a target trial emulation comparing early versus delayed DOAC initiation in patients with AF experiencing ischemic stroke on anticoagulation from the retrospective

FIGURE 1 Predicted risk of new ischemic event at 90 days based on days to DOAC resumption.

FIGURE 2 Predicted risk of moderate-severe bleeding at 90 days based on days to DOAC resumption.

arm of the international, multicentre ASPERA study. Treatment strategies were defined using severity-adapted timing thresholds based on baseline National Institutes of Health Stroke Scale (NIHSS) scores. A cloning-censoring-weighting approach with inverse probability weighting was applied to emulate random assignment and avoid immortal time bias. Primary outcomes were 90-day new ischemic events and moderate-to-severe bleeding. Risk ratios (RRs), absolute risk differences (RDs), and hazard ratios (HRs) were estimated using weighted regression and Cox models.

Results: Among 833 patients (median age 81 years), 336 were assigned to early and 497 to delayed DOAC initiation. At 90 days, early initiation was associated with a lower risk of new ischemic events (RR 0.44, 95% CI 0.21–0.90; RD –3.64%, 95% CI –6.40 to –0.87; HR 0.43, 95% CI 0.21–0.91), reduced moderate-to-severe bleeding (RR 0.10, 95% CI 0.01–0.76) and decreased all-cause and vascular mortality (FIGURE 1 and 2). A Net Early Benefit Score integrating ischemic and bleeding risks was positive across all NIHSS strata.

Conclusion: Early severity-adapted DOAC initiation was associated with lower risks of recurrent ischemic events and mortality at 90 days without increasing major bleeding.

EPO-0030 | Prophylactic induced hypertension in deep perforator infarction: Impact on early neurological deterioration and blood pressure variability

H. Park¹; J. Park²; J. Cha³

¹INHA University Hospital, Incheon Korea, Republic of;

²Catholic University of Korea Eunpyeong St. Mary's Hospital, Republic of Korea; ³Dong-A university Hospital, Republic of Korea

Background and aims: Early neurological deterioration (END) is a frequent and disabling complication in acute ischemic stroke. We evaluated whether prophylactic pharmacologically induced hypertension (PPIHT) could reduce the risk of END and improve clinical outcomes in high-risk population.

Methods: Among 424 patients, 118 (27.8%) received PPIHT. After PSM, 260 patients were retained (118 PPIHT, 142 non-PPIHT). END occurred significantly less often with PPIHT. Within 3 months after stroke onset, the PPIHT group had lower mRS, lower incidence of recurrent stroke, and no increase in hemorrhagic complications. The PPIHT group had a lower incidence of END compared to patients with initial SBP ≥ 180 mmHg.

Results: Among 424 patients, 118 (27.8%) received PPIHT. After PSM, 260 patients were retained (118 PPIHT, 142 non-PPIHT). END occurred significantly less often with PPIHT. Within 3 months after stroke onset, the PPIHT group had lower mRS, lower incidence of recurrent stroke, and no increase in hemorrhagic complications. The PPIHT group had a lower incidence of END compared to patients with initial SBP ≥ 180 mmHg.

Conclusion: PPIHT was associated with a substantial reduction in END and improved functional outcomes in lacunar infarction. Compared with the patients with initial high SBP, PPIHT had better outcomes, suggesting that it is the drug-induced increase in SBP, rather than the SBP level itself, that is beneficial.

Disclosure: Nothing to disclose.

EPO-0031 | Machine Learning models for 3-month functional outcome prediction after mechanical thrombectomy in acute ischaemic stroke patients

K. Jakubik¹; M. Woś²; A. Szewczyk³; P. Luchowski⁴; K. Rejdak³; G. Staśkiewicz⁵

¹Doctoral School, Medical University of Lublin, Lublin, Poland;

²Department of Information Technology and Medical Statistics with e-Health Laboratory, Medical University of Lublin, Lublin, Poland;

³Chair and Department of Neurology, Medical University of Lublin, Lublin, Poland;

⁴Department of Neurology and Neurological Nursing, Medical University of Lublin, Lublin, Poland;

⁵I Department of Medical Radiology, Medical University of Lublin, Lublin, Poland

Background and aims: Acute ischaemic stroke (AIS) treated with mechanical thrombectomy (MT) carries variable prognosis. Early identification of patients at risk of poor prognosis is crucial for personalised management and family counseling. This study evaluates and compares the performance of various Machine Learning (ML) algorithms in predicting the 3-month functional outcome using admission clinical and laboratory data.

Methods: Data from 843 AIS patients treated with MT were analysed. The primary endpoint was poor functional outcome, defined as a modified Rankin Scale (mRS) score of 3–6 at 3 months. Predictors included demographics, admission National Institutes of Health Stroke Scale (NIHSS) score, comorbidities, laboratory parameters, and recanalisation status. Five classifiers were developed and validated: Logistic Regression (LR), Random Forest (RF), Support Vector Machine (SVM), K-Nearest Neighbors (KNN), and Multilayer Perceptron (MLP). Model performance was assessed using Accuracy, Area Under the Curve (AUC), and F1-score.

Results: LR demonstrated the best overall performance (Accuracy 0.76, AUC 0.80, F1-score 0.83). RF and SVM showed comparable results (Accuracy 0.75, AUC 0.80). Feature importance analysis in RF highlighted age and admission NIHSS score as the strongest predictors. More complex models, including MLP and KNN, achieved lower performance (Accuracy

FIGURE 1 Receiver Operating Characteristic (ROC) curves comparing the performance of seven training ML models in predicting poor functional outcome (mRS > 2) at 3 months.

FIGURE 2 Feature importance ranking from the MLP model, showing NIHSS score on admission and age as the strongest predictors of functional outcome, followed by successful recanalisation defined by the Thrombolysis in Cerebral Infarction (TICI) score.

FIGURE 3 Confusion Matrix for the MLP model on the test dataset. The matrix displays the classification performance in distinguishing between good (mRS 0–2) and poor (mRS 3–6) outcomes.

~0.70, AUC ~0.75), indicating limited advantage over linear approaches for this tabular dataset.

Conclusion: ML models based on admission data can effectively predict functional outcomes after AIS and can provide valuable prognostic support in acute clinical conditions. LR outperformed more complex algorithms, suggesting that key clinical predictors exhibit predominantly linear associations with 3-month functional outcomes.

EPO-0032 | RNF213 variants and angiographic progression in Korean patients with Moyamoya disease and intracranial arterial stenosis

K. Park; S. Ahn; M. Park
Department of Neurology, Pusan National University Yangsan Hospital, Pusan National University School of Medicine, Yangsan, Republic of Korea

Background and aims: RNF213 p.R4810K is a major susceptibility variant for moyamoya disease (MMD) and has been linked to intracranial artery atherosclerosis. We investigated whether RNF213 variants are associated with angiographic progression of intracranial arterial stenosis in Korean patients with MMD and intracranial artery stenosis (ICAS).

Methods: We retrospectively analyzed 57 Korean patients diagnosed with MMD or ICAS who underwent RNF213 genotyping and serial angiographic follow-up (MRA or TFCA). RNF213 p.R4810K status was classified as carrier (heterozygous) or non-carrier. Angiographic change was categorized as 1) progression 2) no progression 3) improvement; progression was the primary outcome. Baseline clinical characteristics, vascular phenotype, and medical treatments were compared by genotype. Multivariable logistic regression adjusted for age, sex, hypertension, diabetes, dyslipidemia, smoking, and statin use.

Results: Among 57 patients, 31 (54.4%) were RNF213 carriers. Progression occurred in 15/31 (48.4%) carriers and 7/26 (26.9%) non-carriers during mean 5.0 ± 2.8 years (range 2.0–14.2). The

3-category distribution of angiographic outcomes differed by genotype ($p=0.017$). In multivariable analysis, RNF213 carrier status was independently associated with progression (adjusted OR 4.06, 95% CI 1.05–15.66; $p=0.042$). New stroke/TIA during follow-up occurred in 5/57 (8.8%).

Conclusion: In Korean patients with MMD and intracranial artery stenosis, RNF213 p.R4810K carrier status was associated with a higher risk of angiographic progression. These findings suggest that RNF213-associated vasculopathy may represent a progressive phenotype and warrant closer longitudinal monitoring.

Disclosure: Nothing to disclose

EPO-0033 | Nutritional risk assessed by CONUT independently predicts 90-day outcome after mechanical thrombectomy

M. Molina Lopez¹; P. Blanco Ramírez¹; M. Jimenez Arenas¹; M. Mesa Hernandez¹; J. Gomez Moreno¹; I. Cordoba Bueno¹; M. Garcia Falcon¹; M. Martinez Acevedo¹; A. Constantino Silva¹; A. Roa Montero¹; M. Gomez Baquero¹; J. Ramirez-Moreno²

¹Stroke Center, Department of Neurology, Badajoz University Hospital, Badajoz, Spain; ²Department of Biomedical Sciences, University of Extremadura; Multidisciplinary Research Group of Extremadura (GRIMEX); University Institute for Biosanitary Research of Extremadura (INUBE), Spain

Background and aims: Malnutrition may worsen recovery after large-vessel occlusion stroke, yet its prognostic value in patients treated with mechanical thrombectomy remains insufficiently explored. We aimed to assess whether nutritional status measured by the Controlling Nutritional Status (CONUT) score predicts 90-day functional outcome and mortality after mechanical thrombectomy.

Methods: This observational cohort study included 385 patients treated with mechanical thrombectomy. Nutritional status at admission was assessed using the CONUT score. Outcomes were poor functional outcome at 90 days (modified Rankin Scale 3–6) and 90-day mortality. Univariable and multivariable logistic

regression analyses were performed, and model discrimination was evaluated using receiver operating characteristic curves.

Results: Patients were distributed across CONUT categories as follows: normal 96 (21%), mild 169 (37%), moderate 99 (21%), and severe 21 (5%). Increasing CONUT scores were associated with progressively worse 90-day modified Rankin Scale distributions. In multivariable analysis, each one-point increase in the CONUT score was independently associated with poor functional outcome (adjusted odds ratio 1.20; 95% confidence interval 1.05–1.36; $p=0.008$) and with 90-day mortality (adjusted odds ratio 1.26; 95% confidence interval 1.11–1.42; $p<0.001$). Discrimination for poor functional outcome was good (area under the curve 0.85).

Conclusion: Nutritional risk assessed by the CONUT score independently predicts functional disability and mortality at 90 days after mechanical thrombectomy and may support early risk stratification using routine laboratory data.

Disclosure: Nothing to disclose.

EPO-0034 | The cost of acute stroke: A detailed analysis focusing on sex differences

M. Rodrigues¹; P. Pereira²; C. Ferreira³; L. Pereira²; J. Cerqueira⁴; M. Viana-Baptista⁵

¹Neurology Department/Stroke Unit, ULS Almada-Seixal, Almada; ²School of Medicine, University of Minho, Braga, Portugal; ³Neurology Department/Stroke Unit, ULS Almada-Seixal, Almada, Portugal; ⁴Neurology Department, ULS Braga, Braga, Portugal; ⁵University of Minho, Braga; Neurology Department, ULS Braga, Braga, Portugal; ⁶Neurology Department, ULS Lisboa Ocidental, Lisbon; CEDOC - NOVA Medical School, Lisbon, Portugal

Background and aims: Stroke has significant economic impact due to high prevalence and disability. Studies across Europe show disparities in costs among countries, underscoring the necessity for country-specific data. Few studies have explored cost differences between sexes. Using a microcosting approach, we analysed a cohort of ischemic stroke survivors to estimate costs, comparing expenses across levels of disability and between sexes.

Methods: Demographic data and healthcare resource utilization information were collected from ischemic stroke patients, at two tertiary hospitals in Portugal, over two years, employing validated questionnaires. We report mean costs (euros) at 3 months and 1 year post-stroke, per patient, with 95% confidence intervals (95% CI). Disability levels were classified by the modified Rankin Scale (mRS). Cost comparisons employed non-parametric tests, non-linear regression, and covariance analysis.

Results: We included 206 patients, median age 75 years, 52% male, and 24% employed at stroke onset. The average hospitalization cost was €11,149 (95% CI 9,970–12,328), while total outpatient costs were €4,792 (95% CI 3,970–5,614) at 3 months and €13,195 (95% CI 10,602–15,788) at 1 year. At 1 year, outpatient costs per disability level peaked at mRS 4 (€3,549 to €23,543; $p<0.001$). Male patients exhibited average higher costs (€15,065 vs. €11,087, $p>0.05$), driven mainly by non-medical and indirect costs, and they increased exponentially with disability ($R^2=0.51$ in males versus 0.27 in females; $p<0.030$).

FIGURE 1 Distribution of 90-day modified Rankin Scale scores according to CONUT categories (normal, mild, moderate and severe malnutrition).

Conclusion: We showed annual outpatient stroke costs amounting to 16 minimum wages. The escalation of cost with disability is notable, and consistent with prior studies. This increase was significantly more pronounced in males, emphasizing the importance of sex-specific healthcare studies.

Disclosure: CUF scholarship.

EPO-0035 | **HBOC-mediated pre-reperfusion oxygen delivery freezes ischemic penumbra via suppression of ferroptosis and neuroinflammation**

Q. Li; L. Yang; Y. Jia
the First Affiliated Hospital of Zhengzhou University,
Zhengzhou, China

Background and aims: Overcoming the challenges of delayed intervention and single-target mechanisms in stroke neuroprotection, we propose a paradigm-shifting “pre-reperfusion” therapy using a hemoglobin-based oxygen carrier (HBOC) for diffusive oxygen delivery. This study aims to validate the efficacy of HBOC in preserving the ischemic penumbra and elucidate its integrated mechanism involving the mitochondria-ferroptosis-inflammation axis.

Methods: In a rat transient middle cerebral artery occlusion (tMCAO) model, a single intravenous dose of HBOC or saline was administered 5 minutes post-ischemia, followed by reperfusion at 1 hour. Assessment included: 1) safety and dose-escalation (mortality, hemorrhagic transformation, systemic toxicity); 2) multi-timepoint outcomes (infarct volume by MRI/TTC, neurobehavior from 4h to 30d); 3) mechanistic dissection (mitochondrial ultrastructure/ATP, ferroptosis markers GPX4/ACSL4/GSH/Fe²⁺, neuroinflammation via cytokine array and microglial polarization).

Results: Optimal-dose HBOC was safe, with no increased bleeding risk or systemic toxicity. It conferred dose-dependent neuroprotection, significantly reducing infarct volume at 24h with progressive resolution up to 30days, alongside robust and sustained neurological improvement. Mechanistically, HBOC rapidly stabilized mitochondrial ultrastructure, suppressed lipid

FIGURE 1 Schematic illustrating the proposed multi-target cytoprotective mechanism of pre-reperfusion HBOC therapy.

FIGURE 2 Dose-dependent neuroprotection and safety profile of HBOC in tMCAO rats.

peroxidation, and orchestrated a coordinated anti-ferroptotic response. This cascade drove a sustained shift in microglial polarization from pro-inflammatory M1 to reparative M2 phenotype, attenuating neuroinflammation.

Conclusion: Pre-reperfusion diffusive oxygen delivery via HBOC robustly preserves the ischemic penumbra through a multi-target mechanism centered on mitochondrial stabilization, ferroptosis inhibition, and immunomodulation. Our findings establish HBOC as a novel, practical “bridge therapy” for the hyper-acute phase, offering a transformative strategy to extend the therapeutic window in ischemic stroke.

Child Neurology/Developmental Neurology

EPO-0036 | **Therapeutic hypothermia for neonatal hypoxic-ischemic encephalopathy: A meta-analysis of neurodevelopmental and mortality outcomes**

C. Cortes Armijo¹; D. Abouda³; G. Peraza⁴; H. Ramzan⁵; M. Whdan⁶; F. Aisha⁷; S. Eldesouky⁸; K. Zinhom⁹; A. Fathallah²

¹Facultad de Medicina, Universidad Autónoma de Nuevo León, Nuevo León, México; ²Faculty of Medicine, Minya University, Minya, Egypt; ³Faculty of medicine, Alexandria University, Alexandria, Egypt; ⁴Institution/Organization: Facultad de Medicina, Universidad Autónoma de Nuevo León, Nuevo León, México; ⁵Dow Medical College, Dow University of Health Sciences, Karachi, Pakistan; ⁶Faculty of medicine Ain Shams University, Cairo, Egypt; ⁷Islamic International Medical College, Riphah International University; ⁸Faculty of Medicine, Modern University for Technology and Information (MTI), Cairo, Egypt; ⁹Faculty of medicine, October 6 university, Giza, Egypt

Background and aims: Neonatal Hypoxic-Ischemic Encephalopathy (HIE) stills a leading cause of mortality and morbidity in newborns. While Therapeutic Hypothermia (TH) has been used widely for moderate to severe HIE management; however, uncertainty persists regarding the consistency of its benefits, particularly for long-term neurodevelopmental outcomes. This study aimed to synthesize current evidence on the impact of TH on mortality and neurodevelopment in term and near-term infants with HIE.

Methods: We conducted a meta-analysis including 10 primary studies that compared TH with standard care in neonates diagnosed with HIE. Data from over 4,600 infants were combined for analysis. The primary outcome was all-cause mortality, which was estimated using risk ratio. We measured Neurodevelopmental outcomes with validated assessment tools such as Bayley Scales. Additional subgroup analyses were conducted according to HIE severity and World Bank income categories.

FIGURE 1 Therapeutic hypothermia for neonatal HIE: A systematic review & meta-analysis.

Figure 1. Mortality

Figure 3. Bayley III Motor Domain

Figure 2. Bayley III Cognitive Domain

Figure 4. Bayley III Language Domain

Results: The combined findings showed that therapeutic hypothermia led to a meaningful reduction in all-cause mortality, with about a 35% lower risk compared with standard treatment. The results were consistent across studies, with little variation observed. According to neurodevelopment outcomes, infants who received TH showed significantly better motor outcomes. Improvements in language and cognitive outcomes were also noted, but these effects did not always reach statistical significance and less consistent.

Conclusion: TH is effective in decreasing mortality and improving motor outcomes in infants with HIE. However language and cognitive outcomes suggest some benefit, more standardized follow-up and long-term studies are needed to confirm these effects.

Disclosure: Nothing to disclose.

EPO-0037 | Overcoming the “Tunnel of fear”: A systematic review of interventions for MRI-related anxiety and phobia in pediatrics

Cortes Armijo¹; D. Atef Abouda²; Z. Mohammed Bazbaz³; A. Ali³; B. Nawar⁴; A. Al-Ghnaimat⁵; S. Hosny El-Farargy⁶; A. Abdelmawgoud Sadeek⁷; A. Ahmed Radi⁸; H. Abdelbaqi⁹; A. M. Saad²; K. Zinhom¹⁰

¹Facultad de Medicina, Universidad Autónoma de Nuevo León, Nuevo León, México; ²Faculty of medicine, Alexandria University, Alexandria, Egypt; ³Najah National University, Nablus, Palestine; ⁴Institution/Organization: Faculty of Medicine, Helwan University, Cairo, Egypt; ⁵Hashemite University, Department Of Medicine, Jordan; ⁶Faculty Of Medicine Benha University, Benha, Egypt; ⁷Faculty of pharmacy, South Valley university, Egypt; ⁸Faculty of Medicine, Minia University, Minia, Egypt; ⁹Faculty of Medicine, Tanta University, Tanta, Egypt; ¹⁰Faculty of Medicine, October 6 University, Giza, Egypt

Background and aims: Pediatric MRI often fails due to anxiety-induced motion or requires risky general anesthesia. This review synthesizes evidence on strategies to improve compliance and diagnostic quality. The study aims to evaluate the effectiveness of behavioral, digital, and pharmacological interventions in reducing anxiety in pediatric patients (ages 4–18).

Methods: Following PRISMA guidelines, we analyzed 41 primary studies, including RCTs and cohorts. Outcomes included

TABLE 1 Summary of Evidence: Pediatric MRI Compliance strategies (n = 41).

Intervention Category	Specific Strategies & Tools	Duration / Dosage	Primary Clinical Outcomes
Behavioral Preparation	Storytelling Training, "Statue Game", and puppets (statue puppets)	30-60 min	Decreased anxiety, reduced need for sedation, increased compliance
Engaged MR	Virtual Reality (VR) for Mock MRI, augmented reality, and interactive games (e.g., "Ollie the Elephant")	15-20 min	Reduced anxiety, improved image quality, decreased need for sedation
Multimodal Prep	Integrated story, interactive games, and PCC (see Table 1 for details)	30-60 min	Significant reduction in sedation rates and improved compliance
Human Support	Child Life Specialist (CLS) or Pediatric Nurse (PN) presence, and Parental Support (PCC)	30-60 min	Reduced anxiety, improved image quality, decreased need for sedation
Pharmacology	Oral sedation (e.g., Midazolam) and Intranasal Dexmedetomidine (ID) or Propofol	As needed	Effective for patients with failed behavioral prep

anxiety scores (e.g., mYPAS), image quality, and sedation reduction rates.

Results: Mock MRI sessions (30–60 minutes) led by Child Life Specialists or pediatricians successfully converted “sedation-required” patients to “awake-successful” status through “statue games” and sound simulation. Digital innovations, such as the “Pengonaut Trainer” VR app and in-bore systems like “Ollie the Elephant,” provided progressive desensitization and real-time guidance. Creative approaches, including therapy dogs, hospital clowns, and live music, significantly improved emotional status. Additionally, brief 15-minute Patient-Centered Communication (PCC) sessions built effective cooperation. When behavioral methods were insufficient, intranasal Dexmedetomidine (3 µg/

kg) emerged as a superior, less invasive rescue sedation compared to Midazolam.

Conclusion: The most effective strategy for managing pediatric MRI phobia is Multi-modal preparation combining Mock MRI and digital distraction. Hospitals should prioritize these low-risk protocols to decrease anesthesia reliance.

Disclosure: Nothing to disclose.

EPO-0038 | Clinical and demographical profile of pediatric MOGAD patients: Portuguese national data

Estefânia Hospital, S. José Local Health Unit, Lisboa, Portugal; ⁵Pediatric Neurology Service, Northern Maternal and Child Center, Santo António Local Health Unit, Porto, Portugal; ⁶Neuropediatrics Unit, S. João Local Health Unit, Porto, Portugal; ⁷Neuropediatrics Unit, Santa Maria Local Health Unit, Lisboa, Portugal; ⁸Pediatric Service, Braga Local Health Unit, Braga, Portugal; ⁹Torrado da Silva Child Development Center, Hospital Garcia de Orta, Almada-Seixal Local Health Unit, Almada, Portugal; ¹⁰Medical Imaging Service, Neuroradiology Unit, Coimbra Local Health Unit, Coimbra, Portugal

Background and aims: Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) is an autoimmune demyelinating disease affecting both adults and children. Despite its clinical heterogeneity, the prognosis is often favorable. This study aimed to describe demographic and clinical characteristics of pediatric MOGAD patients in Portugal and to identify potential risk factors for relapsing disease.

Methods: We conducted a retrospective and multicenter study including pediatric patients (age below 18 years-old) with MOGAD diagnosed between 2011 and 2025. Data were collected from clinical records from participant centers.

Results: Seventy-seven patients met the inclusion criteria; 49.7% were male and the mean age was 7.8 years-old. A preceding infection was reported in 45.5% of cases. ADEM was the most frequent phenotype (61%) and was associated with the age at presentation ($p=0.005$). The EDSS at onset was of 4.0 (0–9). Anti-MOG antibodies were positive at diagnosis in 97.4% of patients with seroreversion occurring in 49.5%, which was not correlated with relapsing disease ($p=0.5$). Most of the patients received intravenous methylprednisolone (97.4%); nine patients with more severe disease had add-on treatment with plasma-pheresis ($p=0.003$). Complete recovery was observed in 81.6% of patients, while 26% had a relapsing disease. A univariate analysis showed a positive correlation between EDSS at presentation

and at follow-up ($p=0.009$) and time of follow-up and relapsing disease ($p=0.001$).

Conclusion: Portuguese national data confirm previously described features of MOGAD. Therapeutic approaches appear consistent throughout centers and guided by disease severity ab initio even though standardized treatment guidelines are missing.

Disclosure: Nothing to disclose.

EPO-0039 | **Transitioning from pediatric to adult care in neuromuscular diseases: A management model in the Tuscany region, Italy**

F. Torri¹; M. Sacchini²; C. Ticci²; G. Astrea³; B. Buchignani³; E. Procopio²; R. Battini³; G. Ricci¹
¹Department of Clinical and Experimental Medicine, University of Pisa, Italy; ²Neurometabolic disorders Unit, Meyer Hospital, Italy; ³IRCCS Stella Maris, Italy

Background and aims: The improvement of standards of care and the availability of effective, disease-modifying treatments for neuromuscular diseases has expanded patients' lifespan and improved their quality of life. This translates into a higher number of subjects reaching the "transition" phase to the adult care centers from the pediatric ones. With this concept in mind, the Italian region of Tuscany developed a program for transition from two pediatric reference centers for rare and neuromuscular disorders to the adult reference center.

Methods: This study presents retrospective data acquired longitudinally in a 2-years period after the start of the collaborative Tuscany region program to promote the transition process to the adult care center from pediatric institutions.

Results: 70 patients transitioned from the pediatric centers to the adult center. Most of the patients had previously received a genetic and clinical diagnosis. All patients were firstly seen in the pediatric center in presence of the adult neurologist and pediatrician/childhood neurologist and then re-evaluated after 6 months at the adult center; after that visit, the ordinary schedule of follow-up was re-established according to the disease progression and patients' needs. Regarding multidisciplinary care, 25 patients were referred to specialized adult services for cardiology and pulmonology.

Conclusion: The transition passage is in most cases fragmented and is subject to data loss or even discontinuation of care. To ensure a smooth and complete transitional passage, it must be based on epidemiological awareness and an established

FIGURE 1 Graphical representation of the different diagnoses included in the study cohort.

FIGURE 2 Graphical representation of the transition process organization.

workflow including all the necessary specialists. Tuscany region successfully provided a pre-organized and well-defined process for transition.

Disclosure: Nothing to disclose.

EPO-0040 | **CUL1 variants underlie severe neurodevelopmental disorders: Insights from human genetics and a zebrafish microcephaly model**

H. Xu; Q. Ye
Department of Neurology, Fujian Medical University Union Hospital, Fuzhou, China

Background and aims: Microcephaly is a neurodevelopmental anomaly defined by reduced head circumference and impaired brain growth, frequently accompanied by intellectual disability, developmental delays, and seizures. Although numerous genes have been linked to this condition, the role of CUL1—a core component of the SCF (Skp1-Cul1-F-box protein) ubiquitin ligase complex—remains poorly elucidated. This study aims to explore the association between CUL1 and severe neurodevelopmental disorders (NDDs).

Methods: First, comprehensive clinical evaluations were performed on four unrelated affected families, confirming all patients exhibited severe microcephaly, intellectual disability, and developmental delay phenotypes. Whole-exome sequencing (WES) was subsequently conducted to detect pathogenic variants, followed by screening and validation of heterozygous de

FIGURE 1 Genetic and structural analysis of CUL1 variants.

FIGURE 2 CRISPR/Cas9 knockdown of zebrafish cul1a and cul1b results in abnormal embryonic development and neurodevelopmental deficits.

TABLE 1 Clinical features of five patients with CUL1 variants (NM_003592.3).

Patient	Family 1 (TR12)	Family 1 (TR12)	Family 2 (TR13)	Family 2 (TR13)	Family 4 (TR11)
Sex	Female	Female	Female	Male	Male
HGS	<1000<1, p<0.000007	<1000<1, p<0.000007	<1000<1, p<0.000007	<1000<1, p<0.000007	<1000<1, p<0.000007

Abbreviations: IQ, Intelligence Quotient; EEG, Electroencephalogram; SD, Standard Deviation; EEG, Electroencephalogram; EEG, Electroencephalogram; EEG, Electroencephalogram.

novo and inherited variants in the CUL1 gene. To further verify the functional consequences of CUL1 loss-of-function, a zebrafish model with double knockdown of cul1a and cul1b was established for subsequent functional analysis to corroborate clinical findings.

Results: WES identified heterozygous de novo and inherited CUL1 variants in all four unrelated families, with these variants showing a clear correlation with the patients' severe phenotypes (microcephaly, intellectual disability, and developmental delays). The cul1a&b double-knockdown zebrafish model exhibited significant central nervous system hypoplasia and abnormal behaviors, which closely recapitulated the clinical manifestations observed in human patients.

Conclusion: These findings establish CUL1 as a novel gene associated with severe NDDs and highlight its critical role in brain development. Our study further delineates genotype-phenotype correlations for CUL1 in NDDs, expands the genetic spectrum of disorders linked to the SCF complex, and underscores the complex's pivotal importance in neurodevelopment.

EPO-0041 | HMGB1-TREM2 axis mediates microglial activation in neonatal sepsis-associated encephalopathy

J. Lei¹; N. Tan¹; L. Zhang²; M. Yu¹; Z. Chen¹; X. Zheng¹; H. Guo¹; H. Jiang³

¹Department of Neonatology, The Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, China; ²Department of Cerebrovascular Disease, The Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, Guangdong Province, China; ³Department of Rheumatology, The Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, China

Background and aims: The objective of this study is to investigate the High-mobility group box 1 (HMGB1) - Triggering Receptor Expressed on Myeloid Cells 2 (TREM2) axis in microglia during neonatal sepsis-associated encephalopathy (nSAE).

Methods: An nSAE mouse model was established in 3-day-old C57 mice via intraperitoneal injection of lipopolysaccharide (LPS, 4 mg/kg; n=3), littermates receiving saline as controls (n=3). Brain tissues were collected 12 hours after modeling for analysis. Microglial activation, HMGB1 levels in brain tissue homogenates, and total HMGB1 protein expression were assessed by immunofluorescence (IF), enzyme-linked immunosorbent assay (ELISA), and Western blot, respectively. Immunoprecipitation-Mass Spectrometry (IP-MS) was used to identify TREM2-interacting proteins in microglia, and then validated by co-immunoprecipitation (Co-IP) and IF co-localization.

Results: Compared with the control group, the number of Iba1-positive microglia in the brain tissue of nSAE models was significantly increased, with a shift in cell morphology towards an amoeboid appearance. Both the concentration of HMGB1 in brain tissue homogenates and its total protein expression were significantly elevated in nSAE models. IP-MS analysis indicated that HMGB1 was co-precipitated with TREM2 antibodies in LPS-stimulated BV2 cells. This interaction was confirmed by Co-IP in 293T cells co-transfected with Flag-tagged HMGB1

FIGURE 1 (A) Immunofluorescence of Iba1+(green) microglia in hippocampus of nSAE mice brain slice (Scale bar, 400µm). (B) HMGB1 levels in brain were determined by ELISA (p < 0.001). (C) Western blot bands of the HMGB1 expression levels in brain of mice.

FIGURE 2 293T cells were transfected with pcDNA3.1-HMGB1-Flag and pcDNA3.1-TREM2-HA plasmids. (A) Anti-Flag antibody was employed for exogenous Co-IP experiments. (B) The co-localization between Flag and HA was examined using confocal microscopy (Scale bar, 5um).

and HA-tagged TREM2 plasmids, and further validated by IF demonstrating their co-localization.

Conclusion: This study revealed an interaction between HMGB1 and TREM2 in microglia, suggesting that HMGB1 may regulate microglial activation by binding to TREM2, thereby mediating neuroinflammation associated with nSAE. Targeting the HMGB1-TREM2 axis may represent a novel therapeutic strategy for intervening in nSAE-related neuroinflammation.

Disclosure: Nothing to disclose.

EPO-0042 | Speech, language, social communication, and communication assessments in Rett syndrome: A systematic review

L. Raniolo^{1,2}; R. Braden^{1,2}; J. von Hehn⁴; J. Christodoulou²; D. Lieberman⁵; D. Amor^{1,2,3}; A. Vogel^{1,6}

¹Department of Audiology and Speech Pathology, The University of Melbourne, Melbourne, Australia; ²Murdoch Children's Research Institute, Melbourne, Australia; ³University of Melbourne Department of Paediatrics, The Royal Children's Hospital, Melbourne, Australia; ⁴Rett Syndrome Research Trust, Trumbull, Connecticut, USA; ⁵Department of Neurology, Boston Children's Hospital, Boston, Massachusetts, USA; ⁶Redenlab Ltd, Melbourne, Australia

Background and aims: Rett syndrome (RTT) is a neurodevelopmental disorder caused by pathogenic MECP2 variants, characterised by early regression, including loss of purposeful hand use and spoken language. Communication impairment is among its most disabling features; however, speech, language,

FIGURE 1 Overview of Systematic Search Results.

FIGURE 2 Key Insights of the Current Systematic Review

and social communication phenotypes have not been systematically synthesised. This review aimed to (a) characterise each domain in RTT and (b) identify the most common communication measures.

Methods: A systematic search was conducted per PRISMA guidelines and registered on PROSPERO (CRD420251076117). PubMed, CINAHL, and ScienceDirect databases were searched from January 1985 to February 2025. Studies including individuals with genetically/clinically confirmed RTT and subjective/objective communication data were eligible. Two reviewers independently screened studies. Data were synthesised descriptively due to methodological heterogeneity. Studies were appraised using Joanna Briggs Institute tools. A supplementary search of ClinicalTrials.gov was conducted for therapeutic interventions.

Results: 57 studies met inclusion criteria. Communication impairment was universal but heterogeneous. Expressive language and physical speech were most severely affected, with near-total speech loss post-regression (median onset: 18–24 months). Pre-regression atypicalities (e.g. high-pitched vocalisations) were reported. Receptive abilities were relatively preserved, namely in atypical forms. Eye gaze was the predominant post-regression

communicative modality. Social motivation often persisted despite autistic features. Genetic and epigenetic factors (e.g. age) modulated severity. Most studies (63%) relied on caregiver report. No gold-standard battery was identified.

Conclusion: RTT is associated with profound communication impairment, disproportionately affecting expressive language and speech. Incorporating objective and subjective tools may improve phenotype accuracy and clinical monitoring.

Disclosure: Adam Vogel is an employee of Redenlab Ltd, a speech neuroscience company. All other authors do not have a conflict of interest to declare.

EPO-0043 | Disrupted time-varying brain connectivity associates with expressive language impairment in pediatric multiple sclerosis

M. Margoni¹; M. Mercuri²; P. Valsasina³; D. Mistri³; L. Moiola⁴; V. Torri Clerici⁵; M. Filippi⁶; M. Rocca⁷

Background and aims: Multiple sclerosis (MS) onset during developmental age makes pediatric (ped) patients vulnerable to cognitive impairment. As cognitive processes rely on dynamic reconfiguration of functional brain networks, we explored time-varying (TV) functional connectivity (FC) in pedMS patients and its association with clinical disability and structural brain damage.

Methods: Ninety-five pedMS and twenty-four matched healthy controls (HC) underwent neurological, neuropsychological and 3.0T brain MRI assessments. Expanded Disability Status Scale (EDSS) and z-scores of verbal and visuospatial memory, attention, receptive language, and expressive language were obtained. Brain T2 white matter (WM) lesion volume (LV) and atrophy were assessed. TVFC was assessed using sliding-window correlation analysis; FC variability was quantified as the standard deviation of degree centrality (DC) and seed-based correlation within basal ganglia, executive, language, sensorimotor, and default-mode networks.

Results: PedMS patients showed widespread reduction of DC TVFC vs. HC, particularly involving the right middle temporal, inferior parietal and superior frontal cortices ($p < 0.05$, corrected), and extending to bilateral parahippocampal, basal ganglia, fronto-insular and cerebellar regions ($p < 0.001$,

uncorrected). PedMS patients exhibited reduced TVFC ($p < 0.05$, corrected) within basal ganglia, executive and language networks vs. HC. No associations were observed between TVFC abnormalities and EDSS score, brain T2 LV and atrophy. Reduced TVFC of the right inferior parietal lobule, right middle superior frontal gyrus and right middle temporal gyrus associated with worse expressive language z-scores ($r \leq 0.30$; $p \leq 0.04$).

Conclusion: PedMS patients experience widespread reductions in TVFC, with selective regions showing associations with expressive language impairment, suggesting that altered brain network dynamics contribute to cognitive dysfunction.

Filippi is Editor-in-Chief of the Journal of Neurology, Associate Editor of Human Brain Mapping, Neurological Sciences, and Radiology; received compensation for consulting services from Almirall, Biogen, Bristol-Myers Squibb, Eli Lilly, Merck, Novartis, Roche, Sanofi; speaking activities from Amgen, Bayer, Biogen, Bristol-Myers Squibb, Celgene, Chiesi Italia SpA, Eisai, Eli Lilly, Fujirebio, Genzyme, Janssen, Merck, Neopharmed Gentili, Neuraxpharm, Novartis, Novo Nordisk, Roche, Sanofi, Takeda; participation in Advisory Boards for Alexion, Biogen, Bristol-Myers Squibb, Eli Lilly, GE Healthcare Ltd, Merck, Neuraxpharm, Novartis, Roche, Sandoz, Sanofi, Takeda; scientific direction of educational events for Biogen, Merck, Roche, Celgene, Bristol-Myers Squibb, Lilly, Novartis, Sanofi-Genzyme; he receives research support from Biogen Idec, Merck-Serono, Novartis, Roche, the Italian Ministry of Health, the Italian Ministry of University and Research, and Fondazione Italiana Sclerosi Multipla. M.A. Rocca received consulting fees from Biogen, Bristol Myers Squibb, Roche; and speaker honoraria from Alexion, Biogen, Bristol Myers Squibb, Celgene, Horizon Therapeutics Italy, Merck Serono SpA, Mitsubishi-Tanabe Pharma, Neuraxpharm, Novartis, Roche, Sandoz, and Sanofi. She receives research support from the MS Society of Canada, the Italian Ministry of Health, the Italian Ministry of University and Research, and Fondazione Italiana Sclerosi Multipla. She is Associate Editor for Multiple Sclerosis and Related Disorders; and Associate Co-Editor for Europe and Africa for Multiple Sclerosis Journal.

EPO-0044 | Non-epileptic paroxysmal events in Rett syndrome: A systematic review of case-based and observational evidence

N. Bhatti¹; D. Lumsden²

¹East Kent Hospitals University NHS Foundation Trust, Kent, UK; ²Complex Motor Disorder Service, Evelina London Children's Hospital, London, UK

Background and aims: Rett syndrome (RTT) is a severe neurodevelopmental disorder frequently complicated by epilepsy. Many individuals also experience non-epileptic paroxysmal events that mimic seizures and risk inappropriate treatment. The spectrum and phenomenology of these events remain poorly defined. We aimed to systematically characterise non-epileptic paroxysmal events in RTT.

Methods: We performed a PRISMA-guided systematic review of observational studies from PubMed, Embase, and OVID (1962–2024). Eligible studies included case reports, case series, cohort studies, and small clinical trials describing non-epileptic events in individuals with clinically or genetically confirmed RTT. Data were extracted on study design, participant characteristics, and event type. Events were categorised into respiratory, neuromotor, and behavioural domains. Due to heterogeneity, results were synthesised descriptively.

Results: Sixty-two studies were included. Respiratory events predominated, with apnoea reported in 1,092 clinician-reported cases (26 studies) and 507 family-reported cases (9 studies). Breathing abnormalities persisted into adulthood in 30/50 adults (apnoea 54%, hyperventilation 24%). Neuromotor events, including dystonia and involuntary movements, were reported in 51 patients, with three life-threatening episodes involving airway compromise; vacant spells frequently accompanied respiratory events. Behavioural and autonomic disturbances were common. Video-EEG and telemetry reclassified up to 80% of events labelled as seizures as non-epileptic. The term “Rett episodes” was used inconsistently and by a minority of authors.

Conclusion: Non-epileptic paroxysmal events are common and heterogeneous in RTT. Frequent misclassification as epilepsy risks unnecessary treatment and harm. Greater clinician awareness, precise phenomenological description, and objective recording are needed, alongside clearer diagnostic frameworks to optimise care and quality of life.

FIGURE 1 Literature search and selection flow diagram.

FIGURE 2 Classification of non-epileptic paroxysmal events in Rett syndrome.

FIGURE 3 Potential pathways for Rett episodes with an assumption that events arise from a single common pathway (a) and a model of separate pathways independently giving rise to different episodes (b), which may temporally coincide.

EPO-0045 | iPSC-derived cellular models and extracellular vesicles: A translational pipeline for biomarker identification in neurodevelopmental disorders

R. Palumbi¹; M. Simone²; L. Margari²; S. Micella¹; A. De Giacomo¹; P. Abbrescia¹; O. Valente¹; A. Frigeri¹
¹Department of Translational Biomedicine and Neurosciences (DiBrain), University of Bari "Aldo Moro", Bari, Italy;
²Department of Precision and Regenerative Medicine (DiMePRE-J), University of Bari "Aldo Moro", Bari, Italy

Background and aims: Neurodevelopmental disorders (NDDs), including Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD), show complex etiopathogenesis and substantial clinical heterogeneity, limiting early diagnosis and personalized treatment. The identification of reliable biomarkers is therefore a major unmet clinical need. Induced pluripotent stem cell (iPSC) models and circulating extracellular vesicles (EVs) represent promising translational tools to investigate neurodevelopmental mechanisms and identify disease-related molecular signatures.

Methods: A pediatric cohort (3–17 years) with NDDs diagnosed according to DSM-5/DSM-5-TR criteria is being recruited, together with a typically developing control group. Participants undergo standardized neuropsychiatric, cognitive, and behavioral assessments. Peripheral blood and urine samples are collected from patients and controls. Plasma EVs are isolated by differential ultracentrifugation and characterized using immunoblotting for exosomal markers, and nanoparticle tracking analysis or transmission electron microscopy. Then plasma EVs are investigated with a multiomic approach. In parallel, urinary stem cells and peripheral blood cells are reprogrammed into patient-specific iPSCs and differentiated into neuronal and glial precursors to generate three-dimensional brain organoid models.

Results: Sixty-one patients have been enrolled to date, including ASD, ADHD, and ASD/ADHD overlap groups, with a marked male predominance and predominantly preserved cognitive functioning. Patient-specific iPSC lines have been successfully generated, and neuro-glial differentiation protocols have yielded initial astrocyte cultures. Multi-omic profiling of plasma-derived EVs is currently ongoing.

Conclusion: The combined analyses of clinical phenotypes, EV molecular cargo may enable the identification of biomarker signatures supporting stratification and precision medicine approaches in NDDs. Creating diseases-specific brain organoids models may shed a light on the underlying neurobiological pathways of these disorders.

Disclosure: Nothing to disclose.

EPO-0046 | Impact of early seizure onset on language development in genetic epilepsy with febrile seizures plus

S. Sager¹; O. Alomari²; E. Gurkas¹
¹Department of Pediatric Neurology, University of Health Sciences, Kartal Dr. Lütfi Kırdar City Hospital, Istanbul, Türkiye; ²Hamidiye International School of Medicine, University of Health Sciences, Istanbul, Türkiye

FIGURE 1 Mean Percentile Ranks Across TODIL Subtests in Children with GEFS+ (N=51). The dashed red line indicates the 10th percentile clinical impairment threshold, and the orange line represents the 25th percentile “at-risk” threshold. Note the profound.

Background and aims: Genetic Epilepsy with Febrile Seizures Plus (GEFS+) involves early-onset seizures during critical neurodevelopmental windows. While seizure semiology is well-documented, the impact on linguistic acquisition remains unexplored. This study evaluates the prevalence and characteristics of language impairments in GEFS+ using the Turkish Test of Preschool Language Development (TODIL).

Methods: A cohort of 51 pediatric patients (31 male, 20 female) with GEFS+ was evaluated. The mean age was 71.36 +/- 16.38 months. Linguistic performance was assessed across nine domains using the TODIL. Raw scores (HP) were converted to percentile ranks based on national norms. Clinical impairment was defined as a score falling below the 10th percentile.

Results: Impairment was most prevalent in Sound Discrimination (45.10%), Phonological Analysis (37.25%), Grammar Comprehension (33.33%), and Articulation (33.33%). Relational Vocabulary was a relative strength (1.96% impairment). Mean percentile ranks for Phonological Analysis (24.31%) and Articulation (29.97%) were significantly low. Gender-based comparisons revealed no statistically significant differences across subtests (all $p > 0.05$), suggesting a gender-independent linguistic phenotype.

Conclusion: Early-onset seizures in GEFS+ are associated with high rates of language impairment, a correlation previously under-reported. The specific phenotype involves significant phonological and structural deficits despite preserved conceptual vocabulary. These findings underscore the urgent need for speech-language assessment immediately following diagnosis to improve long-term communicative outcomes.

Disclosure: The authors declare that they have no competing financial interests or personal relationships that could have appeared to influence the work reported in this paper. This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

S. Aulicka

Department of Neurology, St. Anne's University Hospital, Brno, Czech Republic

Background and aims: Growing evidence indicates that neuroinflammatory pathways contribute to epileptogenesis and pharmacoresistance in epilepsy. The main impact on clinical practice is the development of new targeted therapies for epilepsy. We studied the importance of neuroinflammation in the development of epileptogenesis and pharmacoresistance in childhood epilepsy patients.

Methods: A cross-sectional study conducted at two epilepsy centers in the Czech Republic compared 22 pharmacoresistant patients and 4 pharmacodependent patients to 9 controls. We analyzed the ProcartaPlex™ 9-Plex immunoassay panel consisting of interleukin (IL)-6, IL-8, IL-10, IL-18, CXCL10/IP-10, monocyte chemoattractant protein 1 (CCL2/MCP-1), B lymphocyte chemoattractant (BLC), tumor necrosis factor- α (TNF- α), and chemokine (C-X3-X motif) ligand 1 (fractalkine/CXC3CL1) to determine their alterations in cerebrospinal fluid (CSF) and blood plasma, concurrently

Results: The analysis of 21 paired CSF and plasma samples in pharmacoresistant patients compared to controls revealed a significant elevation of CCL2/MCP-1 in CSF ($p < 0.000512$) and plasma ($p < 0.00017$). Higher levels of fractalkine/CXC3CL1 were revealed in the plasma of pharmacoresistant patients than in controls ($p < 0.0704$), and we determined an upward trend in CSF IL-8 levels ($p < 0.08$). No significant differences in CSF and plasma levels were detected between pharmacodependent patients and controls.

Conclusion: Our results confirm that CCL2/MCP-1, IL-8, and fractalkine/CXC3CL1 are potential biomarkers of epileptogenesis and pharmacoresistance in epilepsy. These findings provide new insights into processes of epileptogenesis and development of pharmacoresistance in epilepsy with potential impact on developing disease-modifying drugs in epilepsy.

Disclosure: Nothing to disclose.

EPO-0048 | Antibodies against proteolipid protein-1 are identified in patients with inflammatory neuropathies

A. De Lorenzo¹; P. Llarch-Cegarra²; M. Caballero-Ávila²; G. Riesco-Navarro²; E. Cortés-Vicente²; A. Vesperinas²; C. Lleixà³; R. Collet-Vidiella²; L. Martín-Aguilar²; E. Pascual-Goñi²; M. Gastaldi⁴; S. Masciocchi⁴; L. Querol⁵

⁴Neuroimmunology Laboratory and Neuroimmunology Research Section, IRCCS Mondino Foundation, Pavia, Italy; ⁵Department of Neurology, Neuromuscular Diseases Unit, Hospital de La Santa Creu i Sant Pau (IR SANT PAU) and Universitat Autònoma de Barcelona, Barcelona, Spain

Background and aims: Conformational antibodies to proteolipid protein-1 (PLP1-IgG), a major myelin protein, have been reported in CNS demyelinating disorders with peripheral involvement, but their prevalence and clinical significance in isolated inflammatory peripheral neuropathies remain unclear.

Methods: A validated live cell-based assay for PLP1-IgG detection was implemented. We tested 135 patients with inflammatory neuropathies [94 chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), 34 Guillain-Barré syndrome (GBS), 7 autoimmune nodopathies (AN)] and 48 controls. Clinical data were retrospectively extracted from medical records.

Results: PLP1-IgG were detected in 13/135 (9.6%) inflammatory neuropathy patients and in none of the controls. Seropositivity occurred in 11/94 CIDP (11.7%), 1/72 GBS (1.4%), and 1/7 AN-CNTN1 (14.3%). Among seropositive CIDP patients, six were male (54.5%) and mean age at onset was 53.2 ± 16.4 years. Eight (72.7%) had a typical phenotype and three (27.3%) a multifocal variant; onset was acute/subacute in eight (72.7%). Ataxia occurred in nine (81%), tremor in three (27.3%), and cranial nerve involvement in three (27.3%). Electrophysiology confirmed demyelinating neuropathy in all cases, including conduction block in seven (63.6%); one patient had GM1-IgG. CSF analysis (8 patients) showed albuminocytological dissociation in seven (87.5%); mean protein concentration 104.7 ± 62.9 mg/dL. Treatment response was satisfactory in 7/11 to IVIg (63.6%) and in 5/9 to corticosteroids (55.6%). Two refractory patients improved partially with plasma exchange; one subsequently underwent HSCT with substantial improvement.

Conclusion: PLP1-IgG identify a subset of inflammatory neuropathy patients characterized by frequent acute/subacute onset, ataxia, and generally favorable response to immunomodulatory therapy. Their pathogenic role remains unclear, particularly given co-existing pathogenic antibodies in two cases.

Disclosure: No.

EPO-0049 | Health literacy and patient activation as modifiable determinants of perceived quality of life in adults living with ATTRv amyloidosis in Portugal

A. Pedro¹; C. Simões²; M. Pardal³; M. Lopes³; P. Soares⁴; I. Conceição⁵; C. Alves⁵; A. Sousa⁵; J. Silva⁶; T. Coelho⁵

¹NOVA National School of Public Health, Public Health Research Centre, Comprehensive Health Research Center, CHRC, REAL, CCAL, NOVA University Lisbon, Lisbon, Portugal;

²NOVA National School of Public Health, Public Health Research Centre, NOVA University Lisbon, Lisbon, Portugal;

³Medical department, BioPharmaceuticals, AstraZeneca, Barcarena, Portugal; ⁴Corporate Affairs and Market Access, BioPharmaceuticals, AstraZeneca, Barcarena, Portugal;

⁵Sociedade Portuguesa de Estudos de Doenças Neuromusculares, Coimbra, Portugal; ⁶Associação Portuguesa de Paramiloidose, Vila do Conde, Portugal

Background and aims: Hereditary transthyretin (ATTRv) amyloidosis is a progressive disease that affects daily functioning and overall wellbeing. Identifying modifiable determinants that enhance perceived quality of life (QoL) is essential for patient-centred interventions. Health literacy and patient activation shape individuals' ability to understand their condition and engage with care management. This study examined how these competencies relate to perceived QoL among adults with ATTRv amyloidosis.

Methods: A cross-sectional analysis was conducted using data from adults (≥ 18 years) enrolled in the LANTERN study in Portugal, a national observational study of adults living with ATTRv amyloidosis in Portugal. Health literacy (HLS-EU-Q16), patient activation (PAM-13), and perceived QoL (EQ-5D VAS) were assessed. Descriptive statistics were performed, and associations between these measures were examined using Spearman correlations, with statistical significance set at $p < 0.05$.

Results: Among 282 participants (mean age 48 years; 42.9% male), the mean EQ-5D VAS score was 66.31 (0–100 scale). Health literacy (0–50 scale) averaged 32.16, with 18.5% classified as inadequate, 31.1% problematic, 35.2% sufficient, and 15.2% excellent. Patient activation (0–100 scale) averaged 68.83, with most participants in level 3 (47.8%) or level 4 (40.8%). Higher EQ-5D VAS scores were significantly associated with higher health literacy and higher patient activation ($p < 0.001$).

Conclusion: Despite high activation levels, nearly half of people living with ATTRv amyloidosis have suboptimal health literacy. Health literacy and patient activation were both positively associated with perceived QoL, representing modifiable intervention targets. Enhancing these competencies may support better self-management and contribute to improved patient-centred outcomes.

Disclosure: This work was supported by AstraZeneca – Produtos Farmacêuticos, Lda. NOVA National School of Public Health Research Grant: LANTERN|951114|2025).

EPO-0050 | Semaglutide is associated with preserved motor axon function in type 2 diabetic peripheral neuropathy

C. Graffe¹; C. Krarup¹; M. Moldovan²

¹Department of Clinical Neurophysiology, Rigshospitalet, Copenhagen, Denmark; ²Department of Neurology, North Zealand Hospital, Hillerød, Denmark

Background and aims: The motor axon dysfunction reflects the peripheral neuropathy severity in patients with Type 2 Diabetes (T2DM). The aim of this cross-sectional observational study was to investigate the effect of the Glucagon-like peptide-1 receptor agonist semaglutide on motor neuropathy in T2DM patients referred for electrodiagnostic investigations.

Methods: We compared consecutive T2DM patients treated with semaglutide and metformin ($n=8$) with gender and age-matched T2DM patients receiving metformin only. The dominant median nerve was stimulated at the wrist. The evoked compound motor axon potential (CMAP) was recorded from the abductor pollicis brevis muscle. Multiple measures of motor axon excitability were obtained by threshold-tracking. Motor unit number estimation (MUNE) was carried out by MScanFit-2. The clinical sensory-motor involvement was assessed by the modified Toronto Clinical Neuropathy Score (mTCNS).

Results: The patients (14 men and 2 women, mean age of 65.3 years) had a BMI of 30.9, a HbA1c of 53.2 (nmol/mol), and a mTCNS of 12.4. The semaglutide group had a CMAP amplitude of 7.9 mV. The metformin-only group had a smaller CMAP of 6 mV ($p < 0.05$), and a MUNE of 73.8 which was reduced compared to normal controls (94.2, $n=52$, $p < 0.05$). The motor axon excitability of the metformin-only group showed depolarizing changes ($p < 0.05$). In the semaglutide group, these excitability measures did not differ from normal controls ($n=99$).

Conclusion: Our data suggest that the addition of semaglutide to the treatment of T2DM preserves motor axon function, possibly by improving the hyperpolarizing Na⁺/K⁺ ATPase which is critical for maintaining the ionic homeostasis during conduction.

Disclosure: Nothing to disclose.

EPO-0051 | Toward standardized multidisciplinary assessment of Charcot-Marie-Tooth: Integrating MUNIX, clinical scales and plasma biomarkers

F. Gruosso¹; M. Goglia¹; E. Frezza¹; G. Greco¹; G. Vietri¹; L. Boffa¹; D. Centonze²; C. Rocchi²; A. Petrucci³; R. Massa¹

¹Neuromuscular Diseases Unit, Tor Vergata University Hospital, Rome, Italy; ²Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy; ³Center for Neuromuscular and Neurological Rare Diseases, San Camillo Forlanini Hospital, Rome, Italy

Background and aims: Charcot-Marie-Tooth disease (CMT) is a spectrum disorder with variable progression and severity, but reliable biomarkers for predicting severity are lacking. We assessed whether combining neurophysiological measures, plasma biomarkers, and clinical scales could identify predictors of severity across CMT subtypes.

FIGURE 1 Distribution of genetic variants in a cohort of CMT patients: red bars represent axonal genotypes (HSBP1, LRSAM1, KIF1A, GDAP1, MFN2, NEFL), while blue bars indicate demyelinating ones (GJB1, MPZ, PMP22).

Methods: Forty-six genetically confirmed CMT patients performed standardized assessment at two Italian referral centres: clinical scales (CMTNSv2, NIS, ONLS, MRC, SF-36, MAM-16), neurophysiology (MUNIX, MUSIX, ulnar CMAP, radial SNAP), and plasma biomarkers (NfL, p-tau181 in $n=22$). Patients were stratified by electrophysiological phenotype (axonal 56.5%, demyelinating 43.5%). Correlations and multivariable regression identified independent predictors of clinical severity.

Results: MUNIX score was significantly lower compared to normal reference (57.7 ± 34.2 , $p < 0.001$) and negatively correlated with clinical disability measures. Axonal phenotype had higher MUNIX (69.7 ± 33.2) than demyelinating phenotype (40.2 ± 28.4 , $p = 0.005$). NfL and p-tau181 were elevated in 17.4% and 22.7% patients, respectively, but did not correlate with severity. Multivariable regression showed MUNIX and disease duration as independent severity predictors ($R^2 = 0.650$, $p = 0.011$). Phenotype-stratified models found strong prediction in demyelinating forms ($R^2 = 0.862$, $p = 0.037$) in contrast to axonal ones ($R^2 = 0.530$, $p = 0.450$).

Conclusion: MUNIX emerges as the most robust objective neurophysiological predictor of clinical severity in CMT. Phenotype-specific assessment is essential: demyelinating forms benefit from MUNIX-based monitoring with robust predictive models, more than axonal phenotypes. Plasma biomarkers (NfL, p-tau181), although elevated, probably represent acute rather than chronic disease pathophysiology and merit longitudinal evaluation alongside serial MUNIX measurements. This integrated phenotype-stratified multimodal approach requires prospective validation for individualized outcome assessment and monitoring in genetically diverse CMT.

Disclosure: Nothing to disclose.

EPO-0052 | Unmasking POEMS syndrome: The diagnostic value of clinical red flags, PEST criteria and nerve conduction studies

I. Lopera-Rodríguez; J. Andrada-Moreno; L. García-Granados; J. Ciriero-Macías; J. Román-Rueda; M. Salgado-Irazabal; A. Luque-Ambrosiani; C. Paradas; F. Gómez-Fernández
Hospital Universitario Virgen del Rocío, Spain

Background and aims: POEMS syndrome is a rare paraneoplastic disorder frequently misdiagnosed as Chronic Inflammatory Demyelinating Polyneuropathy (CIDP). We aim to distinguish both entities by analysing PEST criteria (Papilloedema, Extravascular volume overload, Sclerotic bone lesions, Thrombocytosis), the Nerve Conduction Study (NCS) pattern and specific clinical features.

FIGURE 1 Papilloedema.

FIGURE 2 Tc-99m scintigraphy demonstrates axial osteoblastic lesions.

Methods: We conducted a descriptive retrospective study of five patients with confirmed POEMS syndrome, initially misdiagnosed as CIDP in four of them. We assessed mandatory criteria, Vascular Endothelial Growth Factor (VEGF) levels, PEST domains and NCS pattern.

Results: Mean age was 45.6 ± 15.8 years. All patients fulfilled mandatory criteria of polyneuropathy and monoclonal gammopathy (IgG lambda-restricted in 80%), alongside elevated VEGF (>1000 pg/mL). Clinically, all patients showed refractoriness to immunoglobulins and 80% ultimately required autologous stem cell transplantation. Motor predominance was distinctively observed (40%) with predominant distal lower limbs weakness. NCS revealed a demyelinating background consistently associated with an axonal component, which was the predominant feature in one patient (20%). Regarding PEST criteria, papilloedema was present in 40% (Figure 1), whereas the triad of extravascular volume overload, sclerotic bone lesions (axial predominance) (Figure 2) and thrombocytosis was universally present. Hypoalbuminaemia was identified as a frequent supportive biochemical finding (40%).

Conclusion: In patients with suspected CIDP, evaluation of PEST criteria is crucial, particularly in treatment-refractory cases. Furthermore, motor-predominant polyneuropathy or an associated axonal component on NCS should prompt VEGF testing and serum protein electrophoresis to rule out POEMS syndrome.

Disclosure: Nothing to disclose.

Background and aims: Approximately 16% of patients with chronic inflammatory demyelinating polyneuropathy (CIDP)

present with a rapidly progressive course, reaching clinical nadir within eight weeks (acute-onset CIDP, A-CIDP). Limited data exists regarding the pathophysiological and clinical differences compared with classical-onset CIDP. This study aimed to compare these two entities.

Methods: National, multicenter, retrospective study. Demographic, clinical, laboratory, and neurophysiological data were collected from electronic medical records of patients with A-CIDP and CIDP and compared between groups.

Results: Eighty-three patients with typical, multifocal, or motor-predominant CIDP were included; 57.8% were male, median age was 51 (IQR 41–61) years and median follow-up was 72.0 (IQR 40.0–138.5) months. Twenty of these patients (24%) had A-CIDP. Median age at presentation did not differ between groups (50[30–60] vs 53[43–61] years; $p=0.28$). A-CIDP patients more frequently exhibited hypo/areflexia at presentation (95.0% vs 29.4%, $p=0.02$) and fewer sensory symptoms (at presentation: 75.0% vs 93.4%, $p=0.06$; at last visit: 45.0% vs 73.8%, $p=0.04$). At diagnosis, total leukocyte counts ($8.30 \times 10^9/L$ [7.12–9.45] vs $6.72 \times 10^9/L$ [5.40–7.90], $p=0.01$) and neutrophil counts ($5.24 \times 10^9/L$ [4.70–6.89] vs $3.84 \times 10^9/L$ [3.01–5.30], $p=0.02$) were higher in A-CIDP. No significant differences were observed in cerebrospinal fluid protein levels or nerve conduction studies' parameters. Immunoglobulin therapy was most frequently used in both groups, followed by oral corticosteroids and rituximab. Overall, A-CIDP patients more often achieved an objective treatment response, which was significant for oral corticosteroid therapy (88.90% vs 50.00%, $p=0.04$).

Conclusion: In our cohort A-CIDP is characterized by more frequent hypo/areflexia, fewer sensory symptoms, higher inflammatory hematological markers, and a better treatment response, particularly to oral corticosteroids.

Disclosure: Nothing to disclose.

EPO-0054 | Phase 2 trial of Riliprubart in CIDP: Patient-reported quality-of-life, pain and fatigue outcomes at week-76

S. Attarian¹; H. Hartung²; Y. Lu³; M. Alonso-Alonso⁴; A. Paker⁴
¹Neuromuscular Disease and ALS Reference Center, Timone University Hospital, Aix-Marseille University, CHU Timone, Marseille Cedex 05, France; ²Department of Neurology, Heinrich-Heine-University, Germany; Brain and Mind Center, University of Sydney, Australia; Department of Neurology, Medical University of Vienna, Austria; Department of Neurology, Palacky University Olomouc, Czech Republic; ³Sanofi R&D, Evidence Generation and Decision Science, Cambridge, USA; ⁴Sanofi R&D, Neurology Development, Cambridge, USA

Background and aims: People living with chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) experience fatigue, weakness and sensory abnormalities, affecting quality-of-life (QoL). Riliprubart, a first-in-class, humanized, IgG4-monoclonal antibody, selectively inhibits activated-C1s within the classical complement pathway and is self-administered subcutaneously via auto-injector. A Phase-2 trial (NCT04658472) evaluating riliprubart in CIDP demonstrated decreased fatigue-severity and improved QoL at week-48. Here we assess effect of riliprubart on fatigue, pain and QoL up to week-76.

Methods: Open-label trial evaluating riliprubart across three groups: Standard-of-Care(SoC)-Treated ($N=48$), SoC-Refractory ($N=18$), and SoC-Naïve ($N=12$). Participants underwent 24-week treatment (Part-A), followed by optional treatment-extension(Part-B:52-weeks). At week-76, changes from baseline in health-related QoL were descriptively analyzed using EuroQol-Visual Analogue Scale(EQ-VAS; range 0–100, higher score indicate better outcomes) and health utility index value(range <0[as bad or worse than dead] to 1[full-health]), pain through EQ-5D-5L Dimension(range 1[no pain/discomfort] to 5[extreme pain/discomfort]), and fatigue using Modified Rasch-built Fatigue Severity Scale (R-FSS; range: 0–21, higher score indicate greater fatigue-severity).

Results: At week-76, QoL, pain and fatigue were assessed in 37 SoC-Treated, 11 SoC-Refractory and 6 SoC-Naïve participants. Mean[SD] change from baseline in EQ-VAS(SoC-Treated:12.1[18.4], SoC-Refractory:19.1[21.8], SoC-Naïve:8.5[16.2]) and health utility index value(SoC-Treated:0.18[0.28], SoC-Refractory:0.21[0.18], SoC-Naïve:0.05[0.22]) suggested QoL improvement across all groups. Higher proportion reported no pain versus baseline(SoC-Treated:27.0%[10/37] vs 12.8%[6/47], SoC-Refractory:45.5%[5/11] vs 16.7%[3/18], SoC-Naïve:33.3%[2/6] vs 16.7%[2/12]). Mean[SD] R-FSS changes indicated reduced fatigue across SoC-Treated (–3.7[7.6]), SoC-Refractory (–2.2[9.5]), and SoC-Naïve (–3.3[4.2]) groups.

Conclusion: Riliprubart indicated sustained decrease in fatigue and pain, and improved QoL in people with CIDP, along with clinical improvement. Two randomized, placebo-controlled Phase-3 studies (MOBILIZE, VITALIZE) are ongoing to confirm these findings.

EPO-0055 | Riliprubart in CIDP: Time and magnitude of response analysis from a phase 2 trial

R. A. Lewis¹; J. Lin²; A. Dionne³; Y. Lu⁴; M. Alonso-Alonso⁵; A. Paker⁵; L. Querol⁶

¹Department of Neurology, Cedars Sinai Medical Center, Los Angeles, USA; ²Department of Neurology and Rare Disease Center, Huashan Hospital, Fudan University, Shanghai, People's Republic of China; ³CHU de Quebec Universite Laval, Quebec, Canada; ⁴Sanofi R&D, Evidence Generation and Decision Science, Cambridge, USA; ⁵Sanofi, Cambridge, USA; ⁶Neuromuscular Diseases Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; Centro para la Investigación Biomédica en Red en Enfermedades Raras (CIBERER), Madrid, Spain

Background and aims: Riliprubart, a first-in-class humanized IgG4-monoclonal antibody, selectively inhibits activated-C1s in classical complement pathway and can be

self-administered subcutaneously via auto-injector. In Phase-2 trial (NCT04658472), riliprubart demonstrated favorable safety and encouraging efficacy in chronic inflammatory demyelinating polyradiculoneuropathy (CIDP). Here, we present time and magnitude of response analyses to characterize clinical benefits.

Methods: The open-label Phase-2 trial evaluated riliprubart across three groups: Standard-of-care (SoC)-Treated, SoC-Refractory, and SoC-Naïve. Participants received 24-week treatment (Part-A), followed by an optional 52-week treatment-extension (Part-B). Primary endpoint (Part-A) evaluated percentage of participants relapsing in SoC-Treated (≥ 1 -point increase in adjusted Inflammatory Neuropathy Cause and Treatment [INCAT] disability score) and percentage of participants responding in SoC-Refractory/Naïve groups (≥ 1 -point decrease in adjusted INCAT score). This post-hoc analysis focused on INCAT responders (≥ 1 -point decrease) in Part-A, and evaluated time-to-first-response, and proportion of participants with deep response (≥ 2 -point decrease), overall, and by baseline INCAT score (3–4 versus ≥ 5).

Results: Among 43 INCAT responders in Part-A, first INCAT response was observed as early as Week-2 with $\geq 44\%$ of first responses achieved by Week-4, and $\geq 89\%$ by Week-12 in all three groups. At the last INCAT assessment through Week-24, 44% (19/43) responders achieved deep response with higher rates in participants with severe baseline impairment (INCAT ≥ 5 : 69% [11/16]) versus moderate impairment (INCAT 3–4: 38% [8/21]).

Conclusion: Riliprubart provided rapid and substantial improvement in INCAT score with majority of responders achieving first response by Week-12 and nearly half of responders achieving deep response (≥ 2 -point decrease); supporting Phase-3 development of riliprubart as a potential treatment for people with CIDP.

EPO-0056 | GM1 neuropathies from antibody to phenotype

N. Dubuisson¹; R. Bellanti¹; C. Bergstrom Johnson¹; M. Misheva¹; M. Makuch¹; R. Prior²; S. Rinaldi¹

¹University of Oxford, Oxford, UK; ²VIB/KULeuven, Leuven, Belgium

Background and aims: Multifocal motor neuropathy (MMN) is a chronic immune-mediated, purely motor neuropathy

associated with GM1 antibodies. The underlying immune mechanisms, particularly the origin, clonality, and pathogenic role of GM1-specific B cells, remain incompletely understood. This study aims to characterize the cellular origin and functional relevance of GM1 antibodies to inform more targeted therapeutic strategies.

Methods: Thirty-five MMN patients were clinically assessed using MRC-SS, ONLS, and MMN-RODS scores. Paraproteins and light-chain restriction were evaluated by serum protein electrophoresis, ELISA, and high-resolution mass spectrometry. Peripheral blood mononuclear cells were analysed by flow cytometry, followed by bulk and single-cell sorting and in vitro culture to assess GM1-specific IgM production. The pathogenic potential of patient-derived antibodies was evaluated using human iPSC-derived neuromuscular organoids.

Results: MMN patients showed an initial response to treatment, followed by functional decline after approximately seven years. GM1 antibodies were detected in 57% of patients, and evidence of B-cell clonality was observed in 35%. Mass spectrometry identified additional IgM paraproteins in MMN sera. GM1 reactivity was present in both IgD⁺ and IgD[−] memory B-cell subsets, suggesting an early origin of autoreactivity involving defects in central and early peripheral tolerance rather than germinal-centre-dependent somatic hypermutation. Single-cell B-cell receptor sequencing is ongoing to further test this hypothesis. In neuromuscular organoids, patient-derived IgM impaired muscle contraction, supporting a direct pathogenic effect.

Conclusion: MMN is characterized by a clonally expanded, GM1-reactive B-cell response with direct pathogenic potential. These findings provide insight into disease initiation and persistence and support the development of targeted B-cell-directed therapies.

Disclosure: Nothing to disclose.

EPO-0057 | Efficacy and safety of Tafamidis in hereditary TTR amyloidosis and mixed phenotypes—the effect of the highest dose in the progression of neuropathy

R. Alves Simões¹; C. Campos^{1,2}; I. de Castro^{1,2}; J. Castro^{1,2}; I. Conceição^{1,2}

¹Department of Neuroscience and Mental Health, Santa Maria Hospital, CAML, ULSSM, Lisbon, Portugal; ²Institute of Physiology; Egas Moniz Study Center, Faculty of Medicine, University of Lisbon, Lisbon, Portugal

Background and aims: Hereditary transthyretin amyloidosis (ATTRv) may present with neuropathic, cardiac, or mixed phenotypes. Tafamidis, a transthyretin stabilizer, is approved at a dose of 20 mg/day for the treatment of stage 1 ATTRv neuropathy. The 61 mg/day dose has been approved for the cardiac phenotype, although its impact on neuropathic progression in mixed phenotype has not yet been established.

Methods: To evaluate the rate of neuropathy progression and changes in nutritional status in patients with a mixed phenotype previously treated with Tafamidis 20 mg, after dose escalation to Tafamidis 61 mg. An ambispective observational study was conducted, including 18 patients with a mixed phenotype who were treated with Tafamidis 61 mg for at least 12 months and had previously received Tafamidis 20 mg for the same minimum

period. Four patients were excluded due to temporal criteria. Neuropathy progression was assessed using the Neuropathy Impairment Scale (NIS), while nutritional status was monitored using body mass index (BMI).

Results: Patients treated with Tafamidis 61 mg showed slower neuropathy progression than those treated with Tafamidis 20 mg, although no statistically significant difference was reached (annual change in total NIS = 1.41 vs. 2.71; $p = 0.55$). Additionally, a potential benefit in nutritional status was observed in patients treated with Tafamidis 61 mg (annual change in BMI = 0.86 vs. −0.04; $p = 0.02$).

Conclusion: Dose escalation to Tafamidis 61 mg did not result in a statistically significant reduction in neuropathy progression. However, nutritional status appears to be better preserved at this dosage. Interpretation is limited by the small sample size.

Disclosure: Nothing to disclose.

EPO-0058 | Immunological profiling of skin biopsies in patients with idiopathic small fiber neuropathy

T. Mederer¹; F. Montes²; P. Llarch¹; E. Ortiz²; C. Lleixà²; M. Caballero-Ávila¹; R. Collet-Vidiella¹; A. Vesperinas¹; Á. Carbayo¹; L. Llansó¹; L. Querol¹; A. Mariscal²; E. Pascual-Goñi¹

¹Neuromuscular Disorders Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain;

²Department of Immunology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background and aims: Small fibre neuropathy (SFN) is a heterogeneous group of disorders characterized by selective involvement of thinly myelinated A-delta and unmyelinated C fibres. Although multiple aetiologies have been described, up to 50% of cases remain classified as idiopathic (iSFN). Immunological characterisation of skin biopsies in iSFN may help define disease subtypes and clarify underlying pathogenic mechanisms.

Methods: A pilot study analysed distal and proximal skin biopsies from 10 biopsy-confirmed SFN patients and distal biopsies from 5 healthy controls. Immunohistochemistry was performed for IgG, IgM, IgA, CD45, and C5b9; CD45-positive biopsies were further stained for CD4, CD8, and CD20. Double immunofluorescence was used to assess Langerhans cells (CD207) and intraepidermal nerve fibre density (IENFD) using PGP9.5.

Results: Most patients were male (70%), with a mean age of 47 years (32–64). The majority had iSFN, while three patients

FIGURE 1 Immunohistochemistry findings in patients and healthy controls.

TABLE 1 Immunohistochemistry characterisation in CD45+ patients.

Marker	Distal+	Proximal+	Pattern (Distal)
CD4+	9/9	9/9	Diffusely, T of B cells
CD8+	9/9	9/9	All infiltrative
CD20+	3/10	0/9	All infiltrative

had secondary SFN (monoclonal gammopathy, diabetes with rheumatoid arthritis, and Sjögren). All SFN patients showed reduced distal IENFD. C5b9 deposits and leukocyte infiltration, predominantly CD8+ T cells, were observed exclusively in SFN patients. Leukocyte infiltration was present in both distal and proximal skin, suggesting immune activation beyond distal sites of fibre loss. IgG deposition was significantly increased in SFN patients, whereas no differences were found for IgM, IgA, or Langerhans cell density.

Conclusion: Consistent immune alterations in proximal and distal skin biopsies from both idiopathic and autoimmune-associated SFN patients support a primary role for localized immune dysregulation in SFN pathogenesis. The ongoing study includes 50 patients, and final results will be presented at the congress.

Disclosure: Nothing to disclose.

Cognitive Neurology/Neuropsychology 1

EPO-0059 | The impact of cognitive reserve on neuropsychological profiles in different etiologies of dementia

A. Salvati¹; F. Motolese²; I. Anzuino¹; G. Massa Rolandino¹; E. Sapi¹; D. Norata¹; F. Capone²; V. Di Lazzaro²

¹Department of Medicine and Surgery, Unit of Neurology, Neurophysiology, Neurobiology and Psychiatry, Università Campus Bio-Medico di Roma, Rome, Italy; ²Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy

Background and aims: Dementia is characterized by a progressive decline in cognitive functions. Different lifelong activities contribute to build a cognitive reserve (CR), which can influence cognitive decline trajectory. This study aims to investigate the effect of CR on neuropsychological performances in patients with dementia.

Methods: We enrolled 61 patients affected by Alzheimer's disease (AD) dementia, Vascular dementia (VaD) and Mixed forms. The sample included 28 Females (46%). Mean ($\pm$ SD) age was 73.96 ± 7.00 years, while mean ($\pm$ SD) education years were 11.38 ± 3.75 . Neuropsychological assessment included the Mini Mental State Examination (MMSE), Digit Span, Trial Making Test (TMT-A and B), Rey Auditory Verbal Learning Test (RAVLT; Immediate and Delayed) and Verbal Fluency (Phonemic and Semantic). Cognitive reserve was assessed using the Cognitive Reserve Index Questionnaire (CRI-q). Patients were classified as High CR (HCR) or Low CR (LCR) according to an established cut-off value.

Results: Significant differences between the two groups were observed in Immediate-RAVLT ($U=262.5$; $p=0.043$, $HCR=30.316 \pm 9.417$; $LCR=24.450 \pm 7.891$) and in Phonemic Fluency ($U=133.0$; $p=0.044$; $HCR=35.571 \pm 11.501$; $LCR=25.462 \pm 12.231$). Spearman's correlation revealed

positive correlations between the total score of CRIq and MMSE, Immediate-RAVLT and Phonemic Fluency.

Conclusion: HCR group showed better performances in short-term memory and language. These findings emphasize the modulating and protective role of cognitive reserve on cognitive functioning and suggest that specific neuropsychological tests may be particularly sensitive in detecting its effects.

Disclosure: Nothing to disclose.

EPO-0060 | Predicting neurocognitive disorder development in multiple sclerosis using artificial intelligence on MRI and clinical data

D. Mistri¹; L. Storelli¹; A. Mastropasqua¹; M. Grosselle¹; P. Preziosa²; G. Mazzetti¹; L. Rossi³; M. Filippi⁴; M. Rocca²
¹Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ²Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ⁴Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and aims: Neurocognitive disorders (NDs) are often under-recognized symptoms of multiple sclerosis (MS). An early prediction of ND in people with MS is crucial for implementing effective early interventions. This study aimed to develop an artificial intelligence (AI) neural network to predict ND in MS patients after at least one year, using baseline demographic, clinical, and MRI data.

Methods: 3D T1-weighted brain MRIs of 223 MS patients were collected at baseline with demographics, clinical data, and cognitive reserve proxies. At baseline and after a median follow-up of 1.5 years, each patient underwent cognitive assessment and was classified as having mild ND or major ND according to the DSM-5-TR manual. Patients whose cognitive status decayed over time were classified as worsened. A deep learning model used a 10-layer ResNet to extract MRI features, combined with non-imaging data (demographics, clinical details, lesion load, brain volumes) to classify patients as cognitively preserved or impaired. Performance was evaluated using 5-fold cross-validation.

Results: At follow-up, 27 out of 224 MS (12%) experienced cognitive worsening. AI model achieved a mean validation accuracy of 90%, F1-score of 81% and average AUC of 0.89. Grad-CAM heatmaps identified the frontal, occipital, middle temporal gyri, and hippocampus as key brain regions, while important tabular features included cortical gray matter volume, age, thalamic and hippocampal volumes, T2 lesion volume, and cognitive reserve score.

Conclusion: AI, mainly based on MRI data, can effectively predict development of NDs, even within a short follow-up period, enabling timely identification and management of MS patients at risk of worsening.

She is Associate Editor for Multiple Sclerosis and Related Disorders; and Associate Co-Editor for Europe and Africa for Multiple Sclerosis Journal.

EPO-0061 | Cognitive impairment in multiple sclerosis: Correlation between brain atrophy measures and Raos's brief repeatable battery

D. García Estévez¹; O. Álvarez de los Arcos²
¹Neurology Service, Complejo Hospitalario Universitario de Ourense, Ourense, Spain; ²Clinical Neuroscience Group, Galicia Sur Health Research Institute (IIS Galicia Sur), Vigo, Spain

Background and aims: Multiple sclerosis (MS) is a chronic, neurodegenerative disease of the central nervous system that progressively leads to increasing disability. The prevalence of cognitive impairment (CI) in people with MS (pwMS) ranges from 40% to 65%. Structurally, both brain atrophy and lesion load, together with disease duration, are associated with CI. Our objective was to analyze the relationship between MRI brain atrophy measures and performance on the neuropsychological tests of Rao's Brief Repeatable Battery (BRB) in pwMS.

Methods: We studied 95 pwMS with cognitive complaints, including both relapsing and secondary progressive MS phenotypes. Brain atrophy measures on MRI included the corpus callosum index (CCI), third ventricle width (3VW), and the bi-caudate ratio (BCR). T2 lesion load was also quantified. The BRB consisted of the following tests: the Selective Reminding Test (SRT), the 10/36 Spatial Recall Test (SPART), the Symbol Digit Modalities Test (SDMT), the Paced Auditory Serial Addition Test (PASAT), and the Word List Generation Test (WLG).

TABLE 1 Correlations between brain atrophy indices and neuropsychological tests.

LTS: Long Term Storage. CLTR: Consistent Long Term Retrieval. D: Delayed

FIGURE 1 T2 Lesion Load, brain atrophy and SDMT.

Results: Sex: 69F/26M. Age (years): 50.1 ± 8.5. EDSS: 3.2 ± 2.1. Age was significantly correlated with the brain atrophy indices. The Table 1 shows the partial correlations, controlling for the effect of age, between the brain atrophy indices and the BRB. Brain atrophy measures were significantly higher in progressive forms. Lesion load was associated with greater atrophy levels and poorer cognitive performance (Figure 1).

Conclusion: In our cohort of pwMS, brain atrophy measures were inversely correlated with performance on the SDMT and

PASAT test, both reflecting information processing speed. Cognitive impairment was influenced by brain atrophy, lesion load, and progressive disease phenotypes.

Background and aims: This study investigated functional MRI (fMRI) activation in language tasks before and after tailored speech and language therapy (SLT) targeting lexical access deficits in semantic (svPPA) and logopenic (lvPPA) variants of Primary Progressive Aphasia (PPA), and articulation deficits in nonfluent/agrammatic (nfvPPA) cases.

Methods: Ten PPA patients (5 lvPPA, 3 svPPA, 2 nfvPPA) underwent pre-treatment MRI, and post-treatment scans after five weeks of SLT. fMRI tasks were tailored to treatment: svPPA and lvPPA performed a silent confrontation naming (CN) and nfvPPA completed a speech-observation (SO). Eight healthy controls (HC) underwent fMRI tasks at baseline only. Baseline group-level comparisons and longitudinal analyses examined post-treatment changes in patients were conducted.

Results: At baseline, during naming and compared to HC, PPA patients showed reduced activation in bilateral superior temporal regions, right supplementary motor area (SMA), and right superior frontal cortex, and increased activation in right anterior cingulate cortex and in left inferior temporal and parietal

regions, mainly in lvPPA. Longitudinally, naming-related activation increased post-treatment in bilateral superior temporal cortex. During the SO task at baseline, compared to HC, nfvPPA cases showed reduced activation in bilateral cingulate and inferior frontal cortices, and right sensorimotor regions, alongside increased activation in right inferior occipital cortex. Qualitative single-case analyses revealed a greater recruitment of bilateral SMA after treatment.

Conclusion: Findings suggest that tailored SLT in PPA induces changes in functional brain activation, reflecting treatment-related neuroplasticity. Furthermore, SLT may enhance compensatory activation patterns already evident at baseline. Task-based fMRI may help capture differential treatment responsiveness and monitor SLT effects in PPA.

EPO-0063 | Mirroring emotional faces in the developing brain: Functional connectivity of the mirror neuron system

F. Ferragina¹; K. Safar²; E. Broaders³; N. Rhodes³; M. Taylor³
¹Interdisciplinary Center for Health Sciences, Sant'Anna School of Advanced Studies, Pisa, Italy; ²Department of Child and Youth Studies, Trent University, Oshawa, Canada; ³Diagnostic & Interventional Radiology, Neurosciences & Mental Health, Hospital for Sick Children, Toronto, Canada

Background and aims: The Mirror Neuron System (MNS) underlies important neurocognitive functions, such as imitation learning, social cognition, and empathy, and may facilitate the recognition of emotional expressions via motor simulation. However, its development remains poorly understood. This study investigated MNS functional connectivity maturation between early childhood and adulthood during an emotional faces task.

Methods: Using the innovative magnetoencephalography approach of optically pumped magnetometers (OPMs), we assessed whole-brain connectivity of 8 bilateral regions of interest (ROIs) comprising the MNS in 57 typically developing children aged 3-to-5 years and 27 adults. We applied both classical network-based statistic (NBS) and its more recent approach incorporating machine learning, NBS-Predict.

Results: We observed networks of increased connectivity after face presentation in both adults and children in broadband, as well as in the alpha and beta bands; only adults recruited a theta band network. The ROIs were functionally linked to key limbic, prefrontal, parietal and occipital areas. Noteworthy, adults exhibited stronger right-hemisphere broadband and theta connections than children. Results were validated by NBS-Predict, with a comparable subnetwork exhibiting predictive features for classification between children and adults.

Conclusion: Results suggest consolidation of right-sided MNS connections through to adulthood, consistent with right-hemisphere specialization in emotional processing.

FIGURE 1 Processing of visual inputs through the key hubs of the MNS facilitates the recognition of others' emotions via motor simulation of the observed faces. STS: superior temporal sulcus. IPL: inferior parietal lobe. M1/PM: primary motor and premotor cortices.

FIGURE 2 Total NBS output. Both the within-group analysis (Adults or Children; pcorrchildren; pcorr=0.003 in the broadband).

FIGURE 3 A. Overall NBS-Predict output (300-edge network). Colours, from blue (=0) to yellow (=1), indicate the increasing relevance of the edge in the model prediction performance ($p=0.005$). B. 27-edge sub-network with weight-thresholded connections (>0.95), in ax.

EPO-0064 | Multilingual co-creation of aphasia topics priorities through patient and public involvement

J. Annoni¹; M. Charalambous²; A. Kountouri³
¹Department of Neurosciences, University of Fribourg, Fribourg, Switzerland; ²Department of Rehabilitation Sciences, Cyprus University of Technology, Limassol, Cyprus; ³Cyprus Stroke Association, Limassol, Cyprus

Background and aims: People living with chronic aphasia face persistent challenges. It is essential to involve people with aphasia (PWAs) directly in the identification of thematic priorities concerning their quality of life. The aim is to share research agenda with PWA and health professionals across multiple countries and languages. i) evaluate the participation and adherence of strongly involved PWA and ii) collaboratively identify and prioritize topics of greatest importance to PWA through a multilingual PPI process for orienting future research.

Methods: The project involved more than 100 PWA from 14 countries, with 11 countries contributing to voting. The three-phase process included (1) an online consultation phase to generate initial topics, (2) a development phase through national-level codesign sessions to refine and rank topics and that concluded with international voting of four top priorities, and (3) a multilingual dissemination phase. Aphasia-friendly materials and real-time translation ensured accessibility.

Results: PWA played key roles in proposing topics, organizing and summarizing national and international voting and promoting dissemination. Eleven out of the 14 participating countries (78%) voted. Four priorities emerged: (1) raising awareness of aphasia among families and society; (2) psychological changes, including impacts on intimacy and relationships; (3) rebuilding

FIGURE 1 Roadmap timeline.

FIGURE 2 The twelve initial topics.

FIGURE 3 The four important topics.

self-confidence after aphasia; and (4) improving therapy and hospital attitudes towards treatment.

Conclusion: This study shows that with the right help, people with aphasia can clearly share what matters to them. Their voices highlight not only medical needs but also the full picture of living with aphasia. They can guide researchers, health professionals and policy-makers in their decisions.

Disclosure: Nothing to disclose.

EPO-0065 | Non-motor features: Distinguishing dementia with Lewy bodies from Alzheimer's and amyloid co-pathology

J. Alves¹; J. Durães¹; P. Faustino¹; C. Bernardes¹; M. Coelho¹; F. Millet-Barros¹; M. Lima²; I. Baldeiras³; M. Tábuas-Pereira¹; I. Santana¹

¹Neurology Department, Coimbra University Hospital, Coimbra Local Health Unit, Coimbra, Portugal; ²Faculty of Medicine of the University of Coimbra, Coimbra, Portugal; ³Centre for Innovative Biomedicine and Biotechnology (CIBB), University of Coimbra, Coimbra, Portugal

Background and aims: Dementia with Lewy bodies (DLB) presents a higher prevalence of non-motor symptoms than Alzheimer's disease (AD). This study aimed to compare non-motor symptoms between DLB and AD, assess the impact of comorbidity and examine correlations between AD biomarkers and symptoms.

Methods: This cross-sectional study examined patients with DLB, AD and healthy controls. Data collected included demographic information, clinical characteristics, CSF AD

FIGURE 1 Non-motor clinical predictors for differentiating DLB from AD.

FIGURE 2 Characterization of AD co-pathology in a DLB cohort using CSF and PiB-PET biomarkers.

FIGURE 3 Non-motor clinical predictors for differentiating DLB from myloid co-pathology.

biomarkers and results from evaluations using scales to assess non-motor symptoms.

Results: A total of 134 participants were included (44.0% DLB, 40.3% AD, and 15.7% controls). After adjusting for confounders, DLB patients scored significantly higher than AD patients across all scales, except for anxiety. Logistic regression identified the following independent predictors of DLB versus AD: REM Sleep Behavior Disorder (RBD) (OR 1.574), depression (OR 1.253), photophobia (OR 1.198), and psychopathology (OR 1.174), while anxiety was associated with AD (OR 0.783). Regarding co-pathology, it was present in 57.9% of DLB cases. Patients with co-pathology exhibited lower depression scores ($p=0.029$). While psychopathology predicted co-pathology (OR 1.128), depression (OR 0.038) and RBD (OR 0.042) were more strongly associated with pure DLB. Regarding biomarkers, the Aβ42/40 ratio correlated positively with depression scores, whereas Tau and p-Tau181 levels correlated positively with psychopathology and negatively with depression scores.

Conclusion: DLB patients present a higher burden of non-motor symptoms compared to AD. Although photophobia is not currently a supportive clinical feature for DLB diagnosis, it emerged

as a significant predictor. Amyloid co-pathology appears to be linked to fewer depressive symptoms but increased psychiatric manifestations.

Disclosure: Nothing to disclose.

EPO-0066 | Right temporal variant frontotemporal dementia due to FTL-D-FET confirmed by neuropathology

N. Bennouna; J. Juncà-Parella; P. Canasto; G. Caballero; B. Jové Comas; M. Ruiz-Vives; J. Tutusaus; L. Molina-Porcel; I. Aldecoa; S. Borrego-Écija
Hospital Clinic de Barcelona

Background and aims: Frontotemporal lobar degeneration with FET protein (fused in sarcoma [FUS], Ewing sarcoma breakpoint region 1 [EWSR1], TATA-binding protein-associated factor 15 [TAF15]) inclusions (FTLD-FET) is a rare subtype of frontotemporal dementia, usually presenting with early-onset behavioural changes. Right temporal variant frontotemporal dementia (rtvFTD) is typically associated with TDP-43 type C pathology. We report a well-characterized case of a rtvFTD with post-mortem confirmation of FTLD-FET and distinctive neuroimaging features that may inform pre-mortem diagnosis.

Methods: Retrospective review of the medical history, neuroimaging and neuropathological study of a 51-year-old brain donor with atypical frontotemporal lobar degeneration with ubiquitin-positive inclusions (aFTLD-U) with FET pathology (FTLD-FET).

Results: A 45 odd-year-old man presented with early, rapidly progressive behavioural changes including apathy, disinhibition, stereotyped behaviors, altered eating habits, prosopagnosia and anosognosia with executive, language, and memory deficits. Neurological examination showed no parkinsonism or motor neuron signs. MRI revealed right-predominant frontal and temporal atrophy. FDG-PET showed bilateral frontal and anterior temporal hypometabolism, more extensive on the right, with marked right caudate hypometabolism. The patient died 5 years after the onset of the symptoms. Neuropathology revealed cytoplasmic inclusions positive for FET proteins (FUS, TAF15), transportin, as well as ubiquitin, consistent with atypical FTLD with ubiquitin-positive inclusions (aFTLD-U). Right caudate total degeneration correlated with imaging. Mild motor neuron involvement and hippocampal sclerosis were present.

FIGURE 1 Structural MRI and FDG-PET reveal right-predominant frontotemporal atrophy and corresponding hypometabolism, with additional impairment of the caudate nucleus.

FIGURE 2 Macroscopic brain examination showing marked right-predominant frontotemporal atrophy, with noticeable volume loss.

Conclusion: This case illustrates rtvFTD with prominent striatal involvement due to FTLN-FET. Caudate degeneration on imaging may help suggest this molecular subtype and emphasize the importance of clinicopathological correlation in early-onset dementia.

Disclosure: The authors report no relevant financial or institutional conflicts of interest.

EPO-0067 | Alzheimer's disease (AD), mild cognitive impairment (MCI) and predictors of driving Cessation: A 7-year longitudinal prospective study

P. Stamatelos¹; I. Beratis²; P. Hatzaki¹; A. Economou³; N. Andronas¹; D. Pavlou⁴; S. Fragkiadaki¹; D. Kontaxopoulou¹; A. Bonakis⁵; L. Stefanis¹; G. Yannis⁶; S. Papegeorgiou¹

¹1st Department of Neurology, Medical School, National and Kapodistrian University of Athens, Eginition Hospital, Athens, Greece; ²Psychology Department, The American College of Greece, Dere, Athens, Greece; ³Department of Psychology, National and Kapodistrian University of Athens, Athens, Greece; ⁴School of Topography and Geoinformatics, University of West Attica, Athens, Greece; ⁵2nd Department of Neurology, Medical School, National and Kapodistrian University of Athens, Attikon Hospital, Athens, Greece; ⁶Department of Transportation Planning and Engineering, School of Civil Engineering, National Technical University of Athens, Athens, Greece

Background and aims: Cognitive impairment has a detrimental effect on driving ability. We longitudinally assessed drivers with MCI or mild AD Dementia to identify diagnostic and prognostic factors of unsafe driving.

Methods: Our study sample consisted of 109 participants: 32 Controls (Mean Age 65.8years, 57% Women), 47 MCI patients (Mean Age 69.1years, 40% Women) and 30 AD patients (Mean Age 72.8years, 7% Women). Baseline evaluation included neurological and neuropsychological assessment and a driving simulator test. We performed two follow-up evaluations after a mean period of 48 and 84 months. Re-evaluations included a structured interview with patients and caregivers. Primary endpoints were driving cessation and death. We also performed a systematic review of prospective studies regarding driving cessation among patients with cognitive impairment.

Results: 21/47 MCI patients (45%, Mean time to cease: 35 months) and 25/30 AD patients (83%, Mean time to cease: 15 months) ceased driving during the follow-up period (Figure 1). 45% and 59% of the MCI and AD patients respectively had at least one dangerous driving event during follow-up, while only 12% of NC participants had a similar event. Age (HR = 1.080, $p = 0.007$),

FIGURE 1 Kaplan-Meier plot for driving cessation among controls (green line), MCI (gray line) and AD patients (red line).

Semantic Verbal Fluency (HR=0.822, $p=0.001$) and modified Tandem Walking Test (HR=1.099, $p=0.043$) were significant predictors of driving cessation among the cognitively impaired participants (Cox multivariate regression analysis). Our systematic review of the literature identified nine prospective studies.

Conclusion: A multi-disciplinary evaluation (neurological, neuropsychological, driving simulator test) is crucial to individualize driving risk among patients with cognitive impairment. Large-scale, longitudinal studies are needed to establish a standard protocol of driving assessment.

Disclosure: This study is part of the Dr Stamatelos' PhD project with title "Evaluation of driving behavior of patients with MCI, Dementia or Parkinson's Disease: Diagnostic and Prognostic Markers", funded and supported by Onassis Foundation.

EPO-0068 | Lactoferrin-Quercetin-ORMOSIL nanoparticles confer neuroprotection in scopolamine-induced cognitive deficits

S. Naqvi
Department of Pharmacology and Toxicology/Regulatory Toxicology, National Institute of Pharmaceutical Education and Research (NIPER-R), Bijnor-Sisendi Road, P.O. Mati, Lucknow, India

Background and aims: Introduction This study aimed to develop lactoferrin (LF)-conjugated organically modified silica (ORMOSIL) nanoparticles (LF-Q-ORMOSIL) for brain-targeted delivery of quercetin (Q), evaluating their ability to enhance bio-availability, cross the blood-brain barrier (BBB), and improve cognitive outcomes in scopolamine-induced amnesia.

Methods: ORMOSIL nanoparticles loaded with quercetin were synthesized and conjugated with LF, followed by physicochemical characterization (size, zeta potential, encapsulation efficiency, release profile). In vivo behavioural assessment was done using morris water maze and novel object recognition tests, biochemical assays and acetylcholinesterase (AChE) inhibition study was performed. Histological analysis for hippocampal morphology was done and in vivo imaging for nanoformulation biodistribution was performed by IVIS imager.

Results: Results LF-Q-ORMOSIL nanoparticles were synthesized with an optimal particle size (~150 nm), high encapsulation (>80%), and sustained release. Compared to free quercetin and ORMOSIL, LF-Q-ORMOSIL significantly ameliorated scopolamine-induced cognitive deficits, reduced oxidative markers (including MDA and ROS), and restored antioxidant levels (of GSH and SOD), potentially inhibiting AChE and showing preserved hippocampal neurons. Biodistribution revealed many-fold higher brain accumulation and retention at 24 h post-administration.

Conclusion: Conclusion LF-Q-ORMOSIL nanoparticles enhance quercetin's brain delivery, neuroprotective effects, and therapeutic efficacy against cognitive impairment, and shows promise as a nanotherapeutic for Scopolamine-induced amnesia.

Disclosure: Disclosures The authors declare no conflicts of interest and received no specific funding for this study.

EPO-0069 | Longitudinal trajectories of cognitive function in heart failure and associated risk factors: A systematic review and meta-analysis

Y. Li¹; L. Cheng²; R. Feng¹; T. Chen³; R. Yin⁴; C. Ma⁵; Z. Kua³; G. Wang⁶; Y. Dong¹; W. Wang¹

¹Alice Lee Centre for Nursing Studies, Yong Loo Lin School of Medicine, National University of Singapore, Singapore;

²National Perinatal Epidemiology Unit, Nuffield Department of Women's and Reproductive Health, University of Oxford, Oxford, UK;

³Yong Loo Lin School of Medicine, National University of Singapore, Singapore;

⁴Lee Kong Chian School of Medicine, Nanyang Technological University Singapore;

⁵Program in Health Services Research and Population Health, Duke-NUS Medical School, Singapore, Singapore;

⁶Duke Global Health Institute, Duke University, Durham, North Carolina, USA

Background and aims: We aimed to characterise temporal trajectories of cognitive outcomes and identify factors associated with cognitive functioning in heart failure (HF).

Methods: We conducted a systematic review and meta-analysis, searching four databases from inception to 6 February 2025. We included longitudinal observational studies for trajectory analyses and longitudinal observational, cross-sectional, case-control studies, post hoc analyses of randomised controlled trials (RCTs), and RCTs for risk-factor analyses. Study quality was assessed using Joanna Briggs Institute checklists. We pooled prevalence and incidence of cognitive outcomes at comparable follow-up intervals and synthesised risk estimates from cross-sectional studies with random-effects meta-analysis. Risk factors from longitudinal studies were summarised using direction-based vote counting due to limited number of studies. The protocol was registered in PROSPERO (CRD42025645235).

Results: We identified 35 longitudinal articles from 33 studies and 66 cross-sectional studies. Studies with short-term follow-up (≤ 1 year) often reported cognitive improvement, whereas longer follow-up generally showed gradual decline. Consistent modifiable risk factors across study designs included sleep problems, depression, hypertension, atrial fibrillation, inflammation, and anaemia. Other behavioural, cardiac, and systemic factors (e.g. physical capacity, perceived stress, ischaemic aetiology, cardiac index, HbA1c, serum albumin) were also associated with cognitive outcomes, although supported by limited evidence. Substantial heterogeneity was observed in quantitative analyses.

FIGURE 1 Conceptual model of associated factors for cognitive outcomes in heart failure patients.

Conclusion: Our results demonstrate an increased risk of cognitive decline during follow-up among HF patients, highlighting the need to integrate cognitive assessment into cardiac management. Sleep problems, depression, hypertension, atrial fibrillation, inflammation, and anaemia emerged as consistent modifiable risk factors and should be prioritised in interventions.

Disclosure: The authors declare no conflicts of interest.

EPO-0070 | TUSC3-deficient intellectual disability fails Mg²⁺ uptake for synaptic function and neurodevelopment

G. Park; Y. Jung

Department of Biological Science, Seoul National University, Seoul, Republic of Korea

Background and aims: Intellectual disability (ID) is characterized by deficits in cognition and adaptive behavior, with few treatment options. Tumor Suppressor Candidate 3 (TUSC3) has been genetically linked to autosomal recessive ID, but its molecular mechanism and therapeutic potential remain unclear.

Methods: TUSC3 knockout mice were generated and analyzed for their behavior, including memory function and social interaction etc. Cellular magnesium was measured with Mag-FRET assay. TUSC3 knockout mice were supplemented with magnesium or chelated magnesium for recovery of the pathology. ID- and Non-ID fibroblasts were analyzed for their ability to modulate ER magnesium. ER stress and synaptic proteins were analyzed with western blot.

Results: We show that TUSC3 is essential for endoplasmic reticulum (ER) Mg²⁺ homeostasis and neuronal function. Using a TUSC3 knockout (KO) mouse model, we find ID-like phenotypes including impairments in learning, memory, stress adaptation, and social behavior. Mechanistically, TUSC3 forms an ER-localized Mg²⁺ transport complex with ERMA and its loss leads to ER Mg²⁺ depletion, PERK-eIF2 α pathway activation, synaptic dysfunction, and neuronal vulnerability. Fibroblasts from TUSC3 mutant patients similarly exhibit ER Mg²⁺ deficiency and heightened ER stress. Magnesium supplementation restores ER Mg²⁺ levels, reduces ER stress, and rescues cognitive deficits.

Conclusion: Our findings establish ER Mg²⁺ dysregulation as a key driver of neurodevelopmental dysfunction and a promising therapeutic target for TUSC3-deficient ID.

Disclosure: Nothing to disclose.

EPO-0071 | Gut microbiota alteration in Angelman syndrome: A case-control 16S rRNA sequencing study

A. Pascarella¹; A. Bulgari²; D. Abelardo¹; S. Gasparini¹; P. Provenzano³; R. Roberti⁴; P. Bonanni⁵; E. Russo⁴; E. Ferlazzo¹; C. De Caro⁶

¹Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Catanzaro, Italy; ²Regional Epilepsy Centre, Great Metropolitan "Bianchi-Melacrino-Morelli Hospital", Reggio Calabria, Italy; ³Research Unit of Clinical Epidemiology, CNR-IFC, Institute of Clinical Physiology, Pisa, Italy; ⁴Department of Science of Health, Magna Graecia University of Catanzaro, Catanzaro, Italy; ⁵IRCCS E. Medea Scientific Institute, Epilepsy Unit, Conegliano, Treviso, Italy; ⁶Department of Pharmacy, University of Naples "Federico II", Naples, Italy

Background and aims: Angelman syndrome (AS) is a rare neurogenetic disorder caused by impaired maternal UBE3A expression and is characterized by severe intellectual disability, motor impairment, absent speech, epilepsy and behavioral abnormalities. Evidence supports a role of the gut microbiota in various neurological disorders, particularly epilepsy, through the gut-brain axis. This study aimed to investigate gut microbiota alterations, microbial diversity and metabolic profiles in AS patients.

Methods: Pediatric and adult patients with AS and age- and sex-matched healthy subjects (HS) were enrolled. Fecal samples were collected and analyzed using 16S rRNA gene sequencing to assess microbial composition, relative abundance and diversity. Short-chain fatty acids (SCFAs) were quantified to evaluate metabolomic profile by gas chromatography-mass spectrometry.

Results: Seventy-three subjects were included, comprising 42 AS patients and 31 HS. At the phylum level, AS patients showed reduced Bacteroidota and increased Firmicutes and Proteobacteria, with a higher Firmicutes/Bacteroidota ratio. Alpha diversity was comparable between groups, whereas beta diversity differed significantly between AS and HS. At the genus level, *Parasutterella*, *Tyzzelerella*, *Eubacterium hallii*, and *UBA1819* were significantly more abundant in AS, while *Eubacterium ventriosum* was more abundant in HS. Venn diagram analysis revealed greater microbial heterogeneity in AS, with 2986 exclusive taxa. SCFA concentrations were significantly reduced in AS.

Conclusion: Angelman syndrome is associated with a distinct gut microbiota alteration characterized by different taxonomic composition, increased microbial heterogeneity and reduced SCFA production, supporting a contributory role of microbiota in AS pathophysiology and suggesting microbiota modulation as a biomarker and promising adjunctive therapeutic strategies.

Disclosure: This work was supported by Angelman Syndrome Alliance (ASA), 2024 Research Grant.

EPO-0072 | Temporal encephaloceles, epilepsy and idiopathic intracranial hypertension: Toward a pressure-mediated pathogenetic model?

S. Angeloni¹; M. Malagoli³; G. Giovannini²; L. Taruffi¹; M. Burani¹; N. Orlandi²; A. Vaudano¹; S. Meletti¹; M. Pugnaghi²

¹Department of Biomedical, Metabolic and Neuroscience Sciences, University of Modena and Reggio Emilia, Italy;

²Clinical Neurophysiology and Epilepsy Center, Department of Neurosciences, University Hospital of Modena, Italy;

³Neuroradiology Unit, Department of Neurosciences, University Hospital of Modena, Italy

Background and aims: Temporal encephaloceles (TE) are often overlooked in the context of temporal lobe epilepsy (TLE). In parallel, radiological signs of idiopathic intracranial hypertension (IIH) are increasingly described in TLE, often without typical IIH symptoms. We hypothesized that chronic intracranial pressure (ICP) may contribute causally to encephalocele formation and epileptogenesis.

Methods: A retrospective multimodal series of consecutive TLE ($n=21$) was conducted. High-resolution MRI and skull-base CT characterized TE morphology and bony defects, while scalp EEG and FDG-PET aided in lateralization. Prespecified IIH markers included empty/partially empty sella, optic nerve sheath distension, and Meckel's cave enlargement. When serial imaging became available, volumetric analysis quantified TE progression. Primary outcome was IIH marker prevalence; secondary analyses explored correlations with TE multiplicity/bilaterality, and clinical phenotype.

Results: Signs of IIH were identified in 8 of 21 patients (38%). Within this subgroup, TE more frequently demonstrated multiplicity/bilaterality, with a prevalence of 62.5% among IIH+ patients (5/8) compared with 33.3% overall (7/21). One patient showed progression in TE burden, with lesion volume increasing from ~2.4 to ~6.8 cm³. IIH+ patients had later epilepsy onset (51.5 vs 35.0 years) and a higher proportion of epigastric/autonomic features (50% vs 38.5%). TE were predominantly left-lateralized (88.2%).

Conclusion: A radiologic IIH endophenotype is frequent in TLE and correlates with lesion multiplicity, progression, and delayed seizure onset, supporting a pressure-mediated model. TLE may represent a subclinical IIH phenotype with seizures as the main clinical expression. This hypothesis opens avenues for future research, and therapeutic ICP-lowering strategies.

Disclosure: Nothing to disclose.

EPO-0073 | Features of endothelial dysfunction and vascular glycocalyx in patients with epilepsy

D. Yusupova; F. Muratov

Tashkent state medical university, Tashkent, Uzbekistan

Background and aims: In recent years, it has been established that endothelial dysfunction and damage to the blood-brain barrier play an important role in maintaining the epileptic process. However, molecular markers of endothelial damage in epilepsy remain insufficiently studied. In this regard, the study of endothelial and stress-associated biomarkers is of significant interest

for deepening understanding of epilepsy pathogenesis and improving diagnostic approaches.

Methods: 51 patients with an established diagnosis of epilepsy were examined, from whom venous blood collection was carried out during the period of epileptic activity and in the early post-sexual stage. The control group consisted of 20 healthy individuals without signs of neurological pathology. In blood serum samples using enzyme-linked immunosorbent assay, the concentrations of endothelial damage markers and systemic stress were determined: endocane, asymmetric dimethylarginine, differentiation growth factor-15, and syndecan-1.

Results: Analysis of the obtained data showed that in patients with epilepsy, a statistically significant increase in the levels of endocane and ADMA was registered compared to the control group, which indicates a pronounced disruption of endothelial function and a decrease in the bioavailability of nitric oxide. The concentration of GDF-15 in epilepsy patients was also significantly higher ($p < 0.005$), reflecting the activation of stress-realizing and inflammatory mechanisms. In addition, an increase in the level of syndecan-1 indicated a degradation of endothelial glycocalyx and a disruption of the vascular barrier apparatus.

Conclusion: The identified changes in biomarkers allow us to consider epilepsy as a condition accompanied by systemic endothelial damage and disruption of the integrity of the vascular barrier. Increased levels of endocane.

Disclosure: Nothing is disclosed.

EPO-0074 | Induction of ecstatic phenomena via insular direct electrical stimulation: A case series in non-ecstatic focal epilepsy

F. Picard¹; N. Mulatti²; J. Nilsson³; M. Maliia⁴

¹Department of Clinical Neurosciences, Geneva Medical School and University Hospitals, Geneva, Switzerland; ²DM FRCP, Consultant Clinical Neurophysiologist, Kings College Hospital, London, UK; ³Department of Clinical Neurophysiology, Sahlgrenska University Hospital, Gothenburg, Sweden; ⁴« Van Gogh » Epilepsy Surgery Unit, Neurology Department, CIC 1414, University Hospital, Rennes, France, and Laboratory of Signal and Image Treatment, University of Rennes, INSERM, LTSI-U1099, Rennes, France

Background and aims: Stereo-electroencephalography (SEEG) has recently advanced our understanding of ecstatic epilepsy. While the epileptogenic zone is frequently temporal, the symptomatogenic zone for ecstatic symptoms often resides in the anterior insula. However, inducing these phenomena via direct electrical stimulation (DES) in people with non-ecstatic epilepsy is exceptionally rare, with only two cases previously reported thus far in the literature. This study presents three new cases identified across multiple centers.

Methods: We retrospectively analyzed data from three patients with drug-resistant, non-ecstatic focal epilepsy undergoing pre-surgical evaluation. In these patients, 50 Hz DES of the insula induced ecstatic phenomena without triggering afterdischarges.

Results: The identified patients had reproducible ecstatic phenomena during 50 Hz DES of the insula. Patient 1 (left anterior insula, 1–1.5 mA) described a fantastic feeling like “being with her daughter a sunny summer day on a meadow full of flowers

FIGURE 1 Representation of the midway location of the bipolar SEEG electrode pair evoking reproducible ecstatic symptoms for the 3 patients, projected onto a standard sagittal T1-MRI of the MNI atlas brain.

and everything is well. Patient 2 (very anterior part of the right posterior long gyrus, 2.5–4 mA) experienced being « as one with the whole universe ». Patient 3 (right dorsal anterior insula, 2–2.5 mA) reported intense serenity and happiness. The second patient had a hippocampal sclerosis while the two others were MRI-negative.

Conclusion: These three additional cases provide further evidence for the insula's pivotal role in the genesis of ecstatic symptoms. The induction of these states in patients with non-ecstatic epilepsy suggests that the insular “ecstatic network” may be a universal functional pathway rather than one unique to patients with ecstatic seizure semiology.

Disclosure: Nothing to disclose.

EPO-0075 | Predictive factors of nonadherence to antiseizure medication in epileptic patients

F. Hakim; S. Daoud; N. Bouattour; K. Moalla; S. Sakka; E. Smaoui; N. Charfi; M. Damak

Neurology Department, Habib Bourguiba Hospital Sfax, Tunisia

Background and aims: Poor adherence to antiseizure medications (ASM) remains a major barrier to optimal epilepsy control. Data on determinants of nonadherence in Tunisia are lacking.

Methods: A prospective analytical study was conducted in the Adult Neurology Department of Habib Bourguiba University Hospital, Sfax Tunisia. Adult patients meeting ILAE 2017 criteria were included. Adherence was assessed using the MMAS-8 scale and categorized as adherent, minimally nonadherent, or majorly nonadherent. Sociodemographic, clinical, psychosocial (Stigma Scale for Epilepsy, Hospital Anxiety and Depression Scale, Acceptance of Illness Scale), therapeutic, and healthcare-related variables were analyzed.

Results: Sixty-two patients were included (mean age 43.6 ± 11.5 years; 51.6% female). According to MMAS-8, 37.1% were adherent, 27.4% minimally nonadherent, and 35.5% majorly nonadherent. Higher education level ($p=0.014$) and better

socioeconomic status ($p=0.002$) were significantly associated with adherence. Seizure freedom for more than two years ($p=0.033$) and normal EEG findings ($p=0.011$) were also predictive of better adherence. Stigma was reported by 54.8% of patients and was markedly higher among major nonadherents (81.8%, $p < 0.001$). Depression affected 37% of the cohort, predominating in major nonadherents (50%, $p < 0.001$). Therapeutic factors associated with nonadherence included higher daily dosing frequency ($p=0.028$) and perceived negative impact of treatment on daily life ($p=0.001$). Medication unavailability ($p=0.005$) and disadvantaged social coverage ($p=0.032$) were additional contributors.

Conclusion: ASM nonadherence in Tunisia is frequent and multifactorial, involving socioeconomic, clinical, psychosocial, therapeutic, and health system determinants, underscoring the need for integrated, context-adapted interventions.

Disclosure: Nothing to disclose.

EPO-0076 | Cumulative hippocampal seizure-related burden impairs long-term memory consolidation in focal epilepsy

I. Bratu¹; I. Lambert¹; O. Felician²; S. Medina Villalon¹; A. Trébuchon¹; F. Bartolomei¹

¹Department of Epileptology and Cerebral Rhythmology, Timone Hospital, Marseille, France; ²Department of Neurology and Neuropsychology, Timone Hospital, Marseille, France

Background and aims: Memory impairment is a frequent and disabling comorbidity of focal drug-resistant epilepsy (fDRE), yet its relationship to epileptic activity is incompletely explained by seizure frequency or structural pathology alone. This study introduces the concept of cumulative hippocampal seizure-related burden (c-HipSZB) and examines its association with long-term memory consolidation in patients with fDRE.

Methods: Twenty patients undergoing stereo-electroencephalography (SEEG) were prospectively included. Continuous SEEG recordings covering the interval between two memory assessments (30 minutes and one week) were analysed. Hippocampal ictal involvement was identified using quantitative epileptogenicity markers and visual SEEG analysis. Permutation entropy was applied to SEEG signals to quantify postictal recovery dynamics, yielding a Postictal Alteration Time. Cumulative hippocampal ictal burden (c-HipIC), postictal burden (c-HipPIC) and their sum (c-HipSZB) were computed by integrating durations across all hippocampus-involving ictal events (clinical and subclinical). Verbal and visual memory consolidation was assessed using standardized recall and recognition paradigms. Associations were examined using correlation analyses and univariate and multivariate regression models adjusted for relevant clinical variables.

Results: Higher seizure-related burden metrics in the dominant-hemisphere hippocampus were consistently associated with poorer long-term verbal memory performance and reduced retention between 30 minutes and one week. The strongest effects were observed for c-HipSZB. These associations remained significant after adjustment for epilepsy duration or hippocampal lesion status. Clinical covariates were not independently associated with outcome. In contrast, seizure-related burden metrics

in the non-dominant hippocampus showed no robust associations with visual memory outcomes.

Conclusion: Cumulative ictal–postictal hippocampal dysfunction emerges as a key determinant of impaired long-term memory consolidation in fDRE.

Disclosure: None.

EPO-0077 | Newcastle's first experience with EASEE® epicranial neuromodulation for drug-refractory focal epilepsy: A two-patient case series

L. Panneerchelvam¹; M. Hussain²; M. Lai³; R. Thomas¹

¹Department Of Neurology, The Newcastle Upon Tyne Hospitals, Newcastle Upon Tyne, UK; ²Department Of Neurosurgery, The Newcastle Upon Tyne Hospitals, Newcastle Upon Tyne, UK;

³Department Of Neurophysiology, The Newcastle Upon Tyne Hospitals, Newcastle Upon Tyne, UK

Background and aims: Many patients with focal epilepsy remain drug-resistant and are unsuitable for resective surgery because of non-lesional imaging, widespread epileptogenic networks, or overlap with important brain regions. The Precisis EASEE® system is an epicranial neuromodulation device delivering cortical stimulation.

Methods: We report the first two patients in Newcastle implanted with the EASEE® device. Both had long-standing drug-resistant focal epilepsy and were not candidates for resection. Patient 1 had MRI-negative sleep-related hypermotor epilepsy with a right parietal–frontal network. Patient 2 had left fronto-parietal focal cortical dysplasia. Epicranial electrodes were placed over the epileptogenic zone and connected to a chest-wall pulse generator.

Results: Implantation and activation were uncomplicated, taking place on the 01/04/25 and the 03/09/25 respectively. Both patients experienced mild local discomfort that resolved. Patient 1 had early improvement with variable seizures. Patient 2 showed a reduction in nocturnal seizures from 3–4 per week to 1–2 per week and aborted an aura using patient-activated stimulation. EASEE® programming was adjusted over time to balance seizure control and tolerability.

Conclusion: Epicranial focal neuromodulation with the EASEE® device appears feasible and acceptable in selected patients with non-resectable focal epilepsy and may offer a practical alternative when resection is unsafe. Further follow-up is required to assess durability.

Disclosure: Nothing to disclose.

EPO-0078 | Structure-function coupling of interictal epileptiform discharges to predict surgical outcomes in epilepsy

L. de Wouters¹; S. Lagarde²; E. Mullier³; N. Roehri¹; D. Van De Ville⁴; P. Hagmann³; I. Rigoni¹; S. Vulliémot¹

¹Epilepsy Unit, University Hospitals and Faculty of Medicine of Geneva, University of Geneva, Switzerland; ²APHM, Epileptology Department, Timone University Hospital, Marseille, France; ³Connectomics Lab, Department of Radiology, Lausanne University Hospital and University of Lausanne (CHUV-UNIL), Lausanne, Switzerland; ⁴Neuro-X Institute, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland

Background and aims: One third of patients with drug-resistant epilepsy remains non-seizure-free after surgery. This work studies brain structure-function coupling (SFC) during interictal epileptic discharges (IEDs) through the graph signal processing framework, to distinguish between good and poor surgical outcomes in temporal lobe epilepsy (TLE).

Methods: IEDs during high-density EEG recordings of 30 TLE patients (N=17 with good post-surgery outcome, ILAE 1–2) were source-reconstructed and then summarised into 118 region-of-interest (ROI) time-series. Network harmonics of a template structural connectome, defined as the graph Laplacian's eigenvectors, were used to decompose the ROI time-series. The transformed signal's energy spectrum was divided into low-frequency (LF) content (first harmonics, more coupled to the structure) and high-frequency (HF) one (last harmonics, more decoupled). The LF and HF signal norms along the IED were compared with a cluster-based permutation test. SFC at the IED peak was quantified as the ratio of LF to HF signal norm and compared between outcome groups with a Wilcoxon rank-sum test.

Results: Findings replicated previously published results, confirming an increased SFC during the IED ($p < 0.05$) and decreased SFC before the IED's start ($p < 0.001$). Additionally, a SFC decrease was observed after the IED ($p < 0.05$). Patients with poor surgical outcomes presented a significantly lower SFC at the IED's peak than those with good outcomes ($p < 0.05$).

Conclusion: SFC during IEDs differs according to the surgical outcome: IEDs of patients with good outcome are better explained by the LF network harmonics, meaning that the spatial pattern of the IED is smoother on the SC.

Disclosure: Nothing to disclose.

EPO-0079 | Efficacy of repetitive transcranial magnetic stimulation in drug-resistant epilepsy: A systematic review and meta-analysis

A. Siam¹; O. Abbas²; H. Salad³; N. Ahmed⁴; R. haddad⁵; Mahmoud⁴; S. Waleed⁶; A. Siam⁷; M. Tahoun⁸; H. Atwan⁹

¹Faculty of Medicine, Cairo University, Cairo, Egypt; ²Faculty of medicine, Al-Azhar University, Cairo, Egypt; ³Faculty of Medicine and Surgery, Somali National University, Mogadishu, Somalia; ⁴Faculty of Medicine, Beni-Suef university, Beni-Suef, Egypt; ⁵Faculty of Medicine, October 6 university, Egypt; ⁶Alexandria faculty of medicine, Alexandria, Egypt; ⁷Faculty of science, Ain Shams University, Egypt; ⁸Warrington and Halton Hospitals NHS Foundation, UK; ⁹Department of Neurosurgery, Klinikum Rechts der Isar, School of Medicine; Technical University of Munich, Munich, Germany Faculty of Medicine, Assiut University, Assiut, Egypt

Background and aims: Drug-resistant epilepsy (DRE), defined as failure of at least two anti-seizure medications, affects one-third of patients and poses major therapeutic challenges. Repetitive transcranial magnetic stimulation (rTMS), a non-invasive neuromodulation technique, has been proposed for DRE. This systematic review assessed the efficacy of rTMS in reducing seizures in these patients.

Methods: We searched PubMed, Scopus, Web of Science, and Cochrane Central through October 31, 2025. Randomized controlled trials (RCTs) comparing low-frequency (≤ 1 Hz)

rTMS with sham stimulation in DRE patients were included. Continuous outcomes were pooled using a random-effects model and reported as standardized mean differences (SMD) with 95% confidence intervals (CI).

Results: Five RCTs comprising 172 participants (88 active rTMS, 84 sham rTMS) were included. The mean participant age ranged from 8.9 to 40 years. Active rTMS significantly reduced seizure frequency at two weeks (SMD = -0.57, 95% CI: -0.96 to -0.18; $p=0.004$), four weeks (SMD = -0.62, 95% CI: -1.03 to -0.21; $p=0.002$), and eight weeks (SMD = -0.65, 95% CI: -0.98 to -0.32; $p<0.0001$). A subgroup analysis based on stimulation frequency showed comparable effects for 1 Hz (SMD = -0.33, 95% CI: -0.97 to 0.31) and 0.5 Hz (SMD = -0.79, 95% CI: -1.18 to -0.4). Additionally, active rTMS showed a significant reduction in interictal epileptiform discharge (SMD = -0.44, 95% CI: -0.84 to -0.04; $p=0.03$).

Conclusion: Low-frequency rTMS is an effective therapeutic intervention for reducing seizure frequency and interictal epileptiform discharge in patients with DRE, with sustained benefits observed over 8 weeks.

Disclosure: Nothing to disclose.

EPO-0080 | Beyond visual analysis: Uncovering the electrographic signature of genetic focal epilepsy via AI-driven gamma power quantification

M. Badawy¹; T. Voloshyn²

¹Neurology department, Suez medical complex (SMC), Egypt health care authority (EHA), Egypt; ²International Clinic of Rehabilitation, Truskavets, Ukraine

Background and aims: Focal cortical dysplasia (FCD) and other structural epilepsies are increasingly recognized as mTOR-driven genetic disorders (mTORopathies). While these conditions are characterized by cellular hyper-excitability, standard visual EEG analysis often fails to detect interictal background abnormalities. This study utilizes Machine Learning (ML) to identify quantitative EEG (qEEG) biomarkers—specifically high-frequency activity—that correlate with this “invisible” genetic phenotype.

Methods: A retrospective cohort analysis was conducted using the CHB-MIT Scalp EEG database. A total of 23,760 interictal EEG epochs (5-second segments) were extracted from 20 pediatric patients with intractable focal epilepsy. Signal processing included a 0.5–100 Hz bandpass filter to preserve high-frequency oscillations. A Random Forest classifier was trained to characterize patient-specific background phenotypes, using 5-fold cross-validation to assess statistical reliability.

Results: The ML model demonstrated a mean classification accuracy of 92.91% ± 0.95% in blind testing. The results were statistically significant against random chance ($p < 0.05$), indicating the presence of distinct neurophysiological signatures in the interictal background. Crucially, Feature Importance analysis indicated that Gamma Power (30–80 Hz) was the most significant discriminator across the cohort (Importance Score > 0.28), consistently outperforming traditional biomarkers such as Delta slowing.

Conclusion: These findings suggest that patients with intractable focal epilepsy exhibit a ubiquitous “Hyper-Excitable Background Phenotype” driven by high-frequency activity. This supports the potential of AI-driven qEEG to serve as a non-invasive screening tool for genetic etiologies (mTORopathies), potentially guiding early targeted therapy and genetic panel selection.

Disclosure: Nothing to disclose.

FIGURE 1 Feature Importance analysis showing Gamma Power (30–80 Hz) as the most consistent biomarker across the 20-patient cohort compared to other frequency bands.

N. Lin¹; W. Gao¹; P. Hu²; Y. Dong²; Y. Gao¹; H. Sun¹; Q. Lu¹
¹Department of Neurology, Peking Union Medical College Hospital, Beijing, China; ²NetEase Media Technology Co, Ltd, Beijing, China

Background and aims: Sleep staging is critical in EEG interpretation. However, current models are developed using polysomnography (PSG) data, which are unsuitable for standard EEG recordings. This study aims to construct a sleep staging recognition model for achieving objective and accurate sleep structure assessment.

Methods: The sleep staging model vEpiSleepNet consists of four modules: sleep feature extraction with transfer learning, cascaded multi-layer dilated convolution encoding, temporal context encoding, and MLP classification (Figure 1). All signals from 19 electrodes along with A1/A2 were used for model development, distinguishing from previous models employing <10 channels. This study used Peking Union Medical College Hospital (PUMCH) dataset, containing 117 patients and 140 h EEG data, dividing into 30-second segments. Patient-wise split five-fold cross-validation was applied.

Results: vEpiSleepNet achieves 70.5% accuracy and 0.700 F1-score on PUMCH dataset, with a wake-sleep binary classification accuracy of 87.6%. vEpiSleepNet exhibited nearly 12% improvement in F1 scores, 10% in accuracy, and 15% in Kappa, compared to the best-performing comparative models among

the five published classic models (Figure 2). On two public PSG datasets, vEpiSleepNet also showed superior performance, with 81.9% and 80.1% accuracies, respectively. Ablation experiments demonstrated the efficacy of transfer learning and cascaded dilated convolution. Additionally, the more electrodes, the better mode performance.

Conclusion: We have developed vEpiSleepNet which is specifically designed for EEG monitoring, filling the gap in the lack of dedicated automatic sleep staging models for EEG monitoring. Accurate automated sleep staging of EEG data has the potential to advance research on epileptic discharges and improve clinical diagnostic capabilities for sleep-related epilepsy.

Disclosure: Nothing to disclose.

EPO-0082 | VIDÉPÉ: A web-app to interactively visualize multimodal electrophysiological and imaging data to improve epilepsy surgery evaluation

I. Rigoni; S. Vulliemoz; N. Roehri
 Epilepsy Unit, University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland

Background and aims: Drug-resistant epilepsy affects a substantial proportion of the more than 80 million people living with epilepsy worldwide. For these patients, resective surgery offers the highest likelihood of seizure freedom, but its success critically depends on accurate delineation of the epileptogenic zone while preserving eloquent cortex. This process requires the joint interpretation of heterogeneous data, including structural, functional and nuclear imaging, and electrophysiological recordings (EEG). In current clinical practice, these modalities are typically explored in separate software environments, leading to fragmented, largely static workflows that limit interactive, multidisciplinary discussion and restrict the use of advanced analyses.

Methods: We developed a web-based application for integrated visualization of multimodal presurgical epilepsy data. Volumetric neuroimaging (MRI and PET) is rendered using Niivue.js, while electrophysiological signals are displayed with Plotly.js. The application is deployed through GitHub Pages, allowing access from any modern web browser without local installation. The system supports simultaneous visualization

FIGURE 1 The architecture of vEpiSleepNet.

FIGURE 2 Confusion matrix on XIEHE-SLEEP-16K. vEpiSleepNet showed the best performance on all wake and sleep stages, compared to the other networks, MMASleepNet and SleepTransformer.

FIGURE 1 Web-app interface with EEG (right) and MRI/PET imaging (left). Time navigation is performed in the EEG panel, slice and view selection in the imaging panel, and a central menu bar controls independent opacity and thresholding of each volume.

of imaging volumes, functional maps, and time-resolved EEG within a unified interface.

Results: The application is publicly available online (<https://ziply.pk/2E853M>) and operates across operating systems and devices. A demonstration page combining MRI, PET, and EEG is provided for interactive exploration (<https://ziply.pk/Kf3H50>).

Conclusion: This web-based platform integrates multimodal imaging into a single interactive environment to support coherent data interpretation potentially improving clinical decision-making in epilepsy surgery. Its browser-based design ensures easy and broad accessibility. Ongoing work will add modalities such as intracranial EEG and will evaluate usability and clinical utility with clinicians and patients.

Lundbeck A/S, Copenhagen, Denmark; ¹²Department of Neurology, Albert Einstein College of Medicine, New York, NY, United States; ¹³Pain Department and FHU InovPain, Centre Hospitalier Universitaire de Nice, Nice, France

Background and aims: These analyses explored the impact of eptinezumab versus placebo on anxiety and depression symptoms in adults with chronic migraine (CM) and medication-overuse headache (MOH).

Methods: The phase 4 RESOLUTION (NCT05452239) trial included a 28-day screening (baseline) period and 12-week double-blind, placebo-controlled period. Adults (18–75 yrs) with CM and MOH were randomized 1:1 to IV eptinezumab 100 mg or placebo at baseline; all participants received a brief educational intervention on MOH before infusion. Secondary endpoints included the changes from baseline to Weeks 4 and 12 in Hospital Anxiety and Depression Scale (HADS) scores for anxiety (HADS-A) and depression (HADS-D) in the full-analysis set, with post hoc analyses in subgroups with elevated baseline scores (> 7). *p*-values are descriptive.

Results: Of 608 participants randomized, 596 (98%) completed the placebo-controlled period. In the full-analysis set (*n* = 602), eptinezumab resulted in greater improvements from baseline

than placebo for HADS A (Week 4: between-group difference [95% CI] −0.8 [−1.4, −0.3], *p* = 0.0017; Week 12: −1.0 [−1.5, −0.5], *p* = 0.0001) and HADS D (Week 4: −1.0 [−1.5, −0.4], *p* = 0.0006; Week 12: −1.2 [−1.8, −0.6], *p* < 0.0001). Subgroups with elevated baseline HADS-A (226/602 [38%] participants) and HADS-D (201/602 [33%] participants) scores showed greater reductions from baseline with eptinezumab vs placebo in the respective HADS scores, with similar between-group differences as the full-analysis set.

Conclusion: Participants with CM and MOH who also received patient education at baseline experienced greater reductions with eptinezumab than placebo in anxiety and depression scores at Weeks 4 and 12 after treatment. Similar differences between eptinezumab and placebo were seen in participants with elevated baseline anxiety and/or depression symptoms.

Background and aims: Secondary clinical efficacy and functional endpoints from the TEMPLE trial modified-intent-to-treat (mITT) population were evaluated in treatment completers.

Methods: TEMPLE was a phase 3b, randomized, multicenter, double-blind, double-dummy, parallel-group, active-controlled trial to evaluate tolerability, safety, and efficacy of atogepant compared with topiramate for the preventive treatment of migraine. Post-hoc analyses in the mITT and completers populations assessed the proportion of participants with $\geq 50\%$ reduction in mean monthly migraine days (MMDs) during Months 4–6 and change from baseline in Headache Impact Test-6 (HIT-6) at Week 24 and Patient-Reported Outcomes Measurement Information System Cognitive Function (PROMIS-CF)–Abilities Subset–Short Form 6a(v2.0) at Week 6.

Results: Of 527 (atogepant = 270; topiramate = 257) mITT participants, 372 (atogepant = 209; topiramate = 163) were treatment completers. During Months 4–6, participants in the atogepant group were more likely to experience a $\geq 50\%$ reduction in mean MMDs compared with topiramate in both the mITT population (64.1% vs. 39.3%; $p < 0.0001$) and in treatment completers (73.7% vs. 48.5%; nominal $p < 0.0001$) (Figure 1). At Week 24, participants in the atogepant group showed a greater improvement in HIT-6 in both the mITT population (–11.7 vs. –7.4; $p < 0.0001$) and in treatment completers (–13.2 vs. –9.2; nominal $p < 0.0001$) than in the topiramate group (Figure 2). At Week 6, atogepant demonstrated greater improvement in PROMIS-CF in the mITT population (5.2 vs. 0.2, $p < 0.0001$) and in treatment completers (5.4 vs. 1.8, $p \leq 0.01$) compared to topiramate (Figure 3). Results were consistent across other secondary endpoints. Atogepant was generally safe and well-tolerated as reported previously.

Conclusion: TEMPLE treatment completers randomized to atogepant demonstrated similar improvements in clinical efficacy and functional endpoints to the overall mITT population; both populations demonstrated greater improvements in clinical efficacy and functional endpoints over those randomized to topiramate.

EPO-0085 | Efficacy of Candesartan for migraine prevention: A systematic review and meta-analysis

A. Carrión Cuéllar¹; E. Cuellar Jáuregui²; T. Huiman Caro³
¹Universidad Autónoma de Barcelona, Barcelona, Spain;
²Hospital I Higos Urco, Chachapoyas, Peru; ³Universidad Peruana Antenor Orrego, Trujillo, Peru

Background and aims: Migraine is a major cause of disability, and many patients don't tolerate or respond to first-line preventive therapies. Candesartan has shown preventive benefit in randomized controlled trials, but its overall efficacy remains uncertain. This study aimed to evaluate the efficacy and safety of candesartan for migraine prevention.

Methods: A systematic review was performed according to PRISMA guidelines, using PubMed, Scopus and Web of Science for studies published until January 11,2026. Risk of bias was assessed using RoB 2.0 The primary outcome was migraine days per 4 weeks. For crossover trials, within-participant correlation was accounted for by variance adjustment. Pooled effects were calculated using mean difference (MD) with 95% confidence intervals (CI) under a random-effects model. Sensitivity analyses were conducted using different correlation assumptions.

Results: Three RCTs including 425 participants were analyzed. Mean age was 39.1 years±10.9 and 82.9% were females. Most

studies evaluated at dose 16 mg. Candesartan significantly reduced migraine days per 4 weeks compared with placebo (MD: -1.11 days, 95% CI: -1.95 to -0.28; *p*=0.009;). Monthly headache days showed a non-significant reduction (MD: -1.33 days, 95% CI: -2.73 to 0.07; *p*=0.06;). Results remained consistent across sensitivity analyses. A total of 453 adverse events were reported, occurring more frequently during candesartan exposure periods; most were mild, mainly dizziness and fatigue.

Conclusion: Candesartan demonstrates statistically significant but modest efficacy in reducing migraine days and a trend toward reduction in headache days, with acceptable tolerability. It may represent a useful preventive option, particularly for patients who don't respond to standard preventive therapies.

EPO-0086 | Digital education for migraine self-management: A Systematic review of app-based interventions

C. Pace; C. Corbeiceiri
Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background and aims: Effective migraine management requires patient education to improve self-management, but traditional methods lack scalability. Digital tools like smartphone apps offer new educational platforms. This review evaluates their impact on clinical and self-management outcomes.

Methods: A systematic review followed PRISMA guidelines. We searched PubMed, Embase, PsycINFO, Cochrane Central, and ClinicalTrials.gov up to December 2024 for randomised controlled trials (RCTs). Eligible RCTs assessed digital tools with educational or behavioural components for adult migraine. Primary outcome: change in monthly migraine days (MMD). Secondary outcomes: headache intensity, disability (MIDAS/HIT-6), adherence. Risk of bias was assessed using the Cochrane RoB 2 tool.

Results: From 1,124 screened records, 16 RCTs (*n*=2,736 participants) were included. A meta-analysis showed digital educational interventions significantly reduced MMD by a mean of -2.3 days/month (95% CI: -3.1 to -1.5) versus control. Interventions with cognitive behavioural therapy (CBT) modules were 35% more effective than basic ones. Significant improvements occurred in headache intensity (standardised mean difference, SMD: -0.41) and disability (SMD: -0.38). Intervention groups reported high engagement and improved disease knowledge.

Conclusion: Digitally delivered educational interventions are effective adjuncts to standard migraine care, leading to clinically meaningful improvements. Efficacy is strongest when tools include interactive, theory-based components like CBT. These apps represent a scalable new paradigm for patient education in neurology, directly empowering self-management. Future development must prioritise pedagogical design.

Disclosure: Nothing to disclose.

¹Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; ²Headache Science and Neurorehabilitation Unit, IRCCS Mondino Foundation, Pavia, Italy

Background and aims: Atogepant is an oral CGRP receptor antagonist approved for migraine prevention. The aim of this study was to investigate the neurophysiological changes induced by atogepant in individuals with high-frequency episodic migraine (HFEM).

Methods: In this prospective study, 40 participants (age 35.5 ± 21.9 , 30 females) underwent interictal neurophysiological testing at baseline (T0) and after 3 months of daily atogepant 60 mg (T1). The assessment included: i) the temporal summation threshold (TST) of the nociceptive withdrawal reflex (nWR); and ii) the habituation of the nociceptive blink reflex (nBR) and of visual evoked potentials (VEPs). Habituation was assessed by means of the habituation index (HI), namely the percentage decrease of area under curve at the end of validated stimulation protocols.

Results: At T1, the TST increased compared to T0 (T0: 7.9 ± 4.5 mA vs. T1: 9.2 ± 4.8 mA, $p=0.021$). At T1, the HI of the nBR decreased compared to T0 (T0: 47.4 ± 25.6 vs T1: 38.3 ± 29.5 , $p=0.025$) and the habituation deficit became more pronounced (TIME $\times$ BLOCKS: $p=0.045$). VEPs showed a mild habituation, without changes at T1 ($p>0.050$). At T1, 70% of participants qualified as Responders ($>50\%$ in monthly migraine days). Being a Responder was not associated with any of the previously presented findings.

Conclusion: After a 3-month atogepant treatment, we described a reduction in central sensitization and a modulation of habituation mechanisms at the brainstem level, without changes at the cortical level. These findings suggest that atogepant induced direct or indirect effects on key neurophysiological mechanisms involved in migraine pathophysiology.

Disclosure: The ATOM project was funded by a CORE - AMD Resident Research Grant (application ID#: 1273396)

EPO-0088 | MIDAS and HIT-6 questionnaires versus headache diaries for monitoring treatment response to Erenumab in migraine: A REFORM study

J. Thuraiaiyah¹; R. Christensen¹; H. Al-Khazali¹; M. Ashina²; Z. Katsarava³; H. Ashina⁴

¹Department of Neurology, Danish Headache Center, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; ²Center For Discoveries in Migraine, Danish

Headache Center, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; ³Department of Neurology, University of Duisburg-Essen, Essen, Germany;

⁴Translational Research Center, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark.

Background and aims: Efficacy of migraine preventive treatment is often assessed based on daily headache diaries, which can be burdensome for patients. Therefore, patient-reported outcome measures (e.g. Migraine Disability Assessment (MIDAS) and Headache Impact Test (HIT-6)) offer alternatives for monitoring treatment response. The effectiveness of these questionnaires, however, remains uncertain. Here, we aimed to establish cut-off scores for MIDAS and HIT-6 corresponding with a $\geq 50\%$ reduction in monthly migraine days (MMDs) to determine treatment responders.

Methods: Adults with migraine were enrolled in a prospective, open-label study and received 140 mg erenumab for 24 weeks. A $\geq 50\%$ reduction in MMD was defined as treatment success based on diary data. MIDAS and HIT-6 were completed at baseline, Week 12, and Week 24. Optimal cut-off values and corresponding sensitivity and specificity were determined using receiver operating characteristic curve analysis.

Results: Among 582 participants, 300 individuals (52%) achieved treatment success. MIDAS and HIT-6 showed fair discriminative ability in identifying treatment responders, with area under the curve values ranging from 0.71 to 0.77. The optimal cut-offs for MIDAS were a 16-point absolute reduction (78% sensitivity, 60% specificity) or a 49% relative reduction (82% sensitivity, 64% specificity). For HIT-6, optimal cut-offs were an 8-point reduction (53% sensitivity, 84% specificity) or a 12% relative reduction (54% sensitivity, 84% specificity). Sensitivity analyses with alternative definitions yielded consistent results.

Conclusion: While MIDAS and HIT-6 provide meaningful information on treatment-related disability reduction, they are not interchangeable with prospective headache diaries for assessing treatment response to erenumab.

M. Romozzi¹; L. Di Nardo²; L. Iannone³; F. Bianchi¹; G. Cuffaro⁴; R. Turano¹; G. Savino⁴; C. Vollono¹; P. Calabresi¹
¹Neurologia, Dipartimento di neuroscienze, Organi di Senso e Torace, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; ²Università Cattolica del Sacro Cuore, Dipartimento di Medicina e Chirurgia Traslazionale, Rome, Italy; ³Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; ⁴Oculistica, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy.

Background and aims: Pituitary adenylate cyclase-activating polypeptide-38 (PACAP-38) is a key neuropeptide in migraine pathophysiology and an emerging therapeutic target, with monoclonal antibodies currently under clinical development. PACAP-38 has been measured mainly in blood, yielding inconsistent results. Novel, non-invasive biological sources closely related to trigeminal activation, such as tear fluid, remain unexplored. Here, we investigated PACAP-38 levels in tear fluid of patients with migraine compared with healthy controls (HCs) using the Schirmer test.

Methods: In this cross-sectional study, we included patients with migraine fulfilling ICHD-3 criteria and HCs. Tear fluid was collected with Schirmer strips and ELISA measured PACAP-38 concentrations. Clinical and demographic data were recorded. Between-group comparisons, correlation analyses, and receiver operating characteristic (ROC) analyses were performed.

Results: We included 26 migraine patients (76.9% female, mean age 38.0 ± 11.6 years) and 12 HCs (58.3% female, mean age 27.1 ± 5.2 years). Tear PACAP-38 concentrations were significantly higher in patients with migraine compared with HCs (22.2 ± 33.1 vs 4.5 ± 8.4 pg/mL, $p = 0.041$). ROC analysis showed good discriminative ability ($AUC = 0.71$, $p = 0.02$), with an optimal cut-off of 2.0 pg/mL (73% sensitivity, 67% specificity). PACAP-38 levels were not associated with monthly headache days, acute medication number, ictal vs interictal sampling, or migraine subtype.

FIGURE 1 PACAP-38 levels in tear fluid of migraine patients compared to healthy controls.

FIGURE 2 Receiver Operating Characteristic (ROC) curve for PACAP-38 levels in tears.

Conclusion: This is the first study to assess PACAP-38 concentrations in the tear fluid of patients with migraine, demonstrating significantly elevated levels compared with HCs. Schirmer strip-based sampling represents a rapid, non-invasive, and patient-friendly approach for neuropeptide detection, potentially providing a biomarker that reflects migraine-specific mechanisms and supporting PACAP-38 as an emerging therapeutic target.

Disclosure: Nothing to disclose.

EPO-0090 | Triple combination therapy with onabotulinumtoxinA, fremanezumab and atogepant in chronic migraine: A 52-week prospective case series (TRIPLE study)

M. Romozzi¹; L. Iannone²; A. Russo³; I. Finkelstein⁴; T. Vaelidalo⁵; A. Ahlden⁵; A. Aamodt⁶; E. Caronna⁷; P. Pozo-Rosich⁷; E. Tronvik⁶; C. Sundal⁵

Background and aims: A substantial proportion of patients with chronic migraine (CM) persist with high disease burden despite treatment with advanced preventive monotherapies,

including onabotulinumtoxinA (BoNTa) and calcitonin gene related peptide (CGRP)-targeted drugs. Evidence supporting preventive combinations, particularly multiple regimens, is limited. This study evaluated the long-term effectiveness and safety of combining BoNTa, fremanezumab, and atogepant in a real-world CM population with persistent residual burden.

Methods: This was a 52-week, prospective, single-center case series including 13 consecutive adults with CM treated with BoNTa, then fremanezumab and followed by add-on atogepant 60 mg. Monthly headache days (MHDs) and monthly migraine days (MMDs) were assessed using electronic diaries. Secondary outcomes included acute medication days, responder rates, Headache Impact Test (HIT-6), Hospital Anxiety and Depression Scale (HADS), Patient Global Impression of Change (PGIC), and adverse events.

Results: At atogepant initiation, patients had severe residual disease with mean MHDs 25.8 ± 4.8 and MMDs 19.7 ± 4.2 . During triple therapy, MHDs decreased progressively to 19.1 ± 9.4 at week 52 ($p < 0.001$), and MMDs to 10.4 ± 6.2 ($p < 0.001$). $\geq 50\%$ MMD reduction was achieved by 30.8% of patients at week 24 and 53.8% at week 52. Acute medication days and HIT-6 scores significantly improved, while anxiety and depression scores remained stable. PGIC consistently indicated moderate-to-great improvement. No serious adverse events or treatment discontinuations occurred, and all adverse events were mild.

Conclusion: In this CM cohort, long-term triple preventive therapy with BoNTa, fremanezumab, and atogepant was associated with progressive and clinically meaningful reductions in migraine frequency and disability, with favorable tolerability.

EPO-0091 | CGRP monoclonal antibodies in adolescents with migraine: Real-world persistence and outcomes from the German pain e-Registry

M. Überall¹; P. Müller-Schwefe²

¹IFNAP - Institute of Neurological Sciences, Nürnberg, Germany;

²Interdisciplinary Center for Pain & Palliative Care Medicine, Göppingen, Germany

Background and aims: Preventive treatment options for adolescents with migraine are limited. Conventional oral preventives are often used off-label, poorly tolerated, and frequently discontinued. Real-world data on CGRP monoclonal antibodies (mABs) in this population are scarce. To explore real-world treatment persistence and clinical outcomes of CGRP mABs compared with conventional oral preventives in adolescents with high-burden migraine.

Methods: We analyzed depersonalized data from the German Pain e-Registry. Adolescents (12–17 years) with ≥ 1 documented 6-month episode of high-evidence conventional oral preventives (HECP) and ≥ 1 subsequent CGRP mAB episode were included. The primary endpoint was a composite of 6-month persistence and $\geq 50\%$ reduction in monthly migraine days (MMD).

Results: In 422 adolescents (1,448 HECP; 422 CGRP mAB episodes), 6-month persistence was 30.6% with HECP and 88.2% with CGRP mAB. $A \geq 50\%$ MMD reduction occurred in 25.4% and 70.9%, respectively. The composite endpoint was reached in 23.7% with HECP versus 69.9% with CGRP mAB. Mean MMD decreased from 11.7 to 9.4 with HECP and from 11.6 to 4.4 with CGRP mAB. Improvements in disability and psychosocial outcomes were consistently greater with CGRP mAB.

Conclusion: In this high-burden adolescent cohort, CGRP mAB treatment episodes were associated with markedly higher persistence and broader improvements than prior conventional preventive episodes. Given the non-randomized, sequential design, these findings are hypothesis-generating and support the need for controlled pediatric trials.

Disclosure: M.A. Überall is honorary board member of the German Pain Association and the German Pain League and Director of the Institute of Neurological Sciences (IFNAP) and CEO of O.Meany – Medical Data & Project Management GmbH. The German Pain e-Registry is hosted by O.Meany – MDPM GmbH under scientific governance of IFNAP. No third-party

funding was received. The author declares no other conflicts of interest.

EPO-0092 | Real-world treatment persistence in migraine prevention: A national registry comparison of CGRP monoclonal antibodies and oral preventives

M. Überall¹; P. Müller-Schwefe²; M. Küster³; J. Jansen⁴

¹IFNAP - Institute of Neurological Sciences, Nürnberg, Germany;

²Interdisciplinary Center for Pain & Palliative Care Medicine,

Göppingen, Germany; ³Interdisciplinary Center for Pain &

Palliative Care Medicine, Bonn, Germany; ⁴Pain Medicine

Center, Berlin, Germany

Background and aims: Oral migraine preventive drugs are frequently discontinued in routine care. Most real-world studies rely on prescription claims and cannot capture clinically validated reasons for treatment termination. In addition, many datasets predate the availability of monoclonal antibodies targeting calcitonin gene-related peptide (CGRP). To compare real-world treatment persistence and documented reasons for discontinuation among patients receiving subcutaneous CGRP monoclonal antibodies (CGRP mAB), oral high-evidence preventive therapies (HEVP), and oral low-evidence preventives (LEVP).

Methods: This observational cohort study analyzed depersonalized routine-care data from the German Pain e-Registry, a nationwide multicenter clinical registry. Patients with physician-confirmed migraine receiving preventive therapy were followed for 182 days. Treatment persistence was defined as continuous use of the index therapy. Discontinuations were classified as due to adverse drug reactions (ADR) or insufficient efficacy. Persistence trajectories were assessed using Kaplan–Meier analyses and pairwise risk comparisons.

Results: A total of 36,465 patients were included (12,347 CGRP mAB; 23,353 HEVP; 765 LEVP). Six-month persistence was markedly higher with CGRP mAB (89.3%) than with HEVP (32.7%) or LEVP (42.6%; $p < 0.001$). ADR-related discontinuation occurred in 6.8% of CGRP mAB patients, compared with 45.1% in HEVP and 35.8% in LEVP. Discontinuation due to insufficient efficacy was 3.6% with CGRP mAB versus 22.2% and 21.6% with HEVP and LEVP. Sex and migraine subtype had no clinically meaningful influence. Within HEVP, tricyclic antidepressants, beta-blockers, and valproic acid showed the lowest persistence.

Conclusion: CGRP monoclonal antibodies demonstrate substantially superior real-world persistence and tolerability compared with conventional oral migraine preventives, highlighting the clinical relevance of mechanism-based prevention.

Disclosure: M.A. Überall is honorary board member of the German Pain Association and the German Pain League and Director of the Institute of Neurological Sciences (IFNAP) and CEO of O.Meany – Medical Data & Project Management GmbH. The German Pain e-Registry is hosted by O.Meany – MDPM GmbH under scientific governance of IFNAP. All other authors declare no competing interests.

P. Shekhawat¹; R. Yerraballa²; S. Das²; G. Singh³

¹Mass General Brigham Wentworth Douglass Hospital, Dover, USA; ²Armed Forces Medical College, Pune, India; ³SKN Medical College, Pune India

Background and aims: Headache disorders are among the leading causes of disability worldwide, yet undergraduate medical education in headache medicine remains variable and often lacks standardized training. Although the International Classification of Headache Disorders, 3rd edition (ICHD-3), provides a globally accepted framework for headache diagnosis, structured instruction during medical training is inconsistent. We therefore implemented a digital ICHD-3 instructional module and evaluated its impact.

Methods: Medical students from two undergraduate programs participated in a pre-post educational evaluation. Baseline knowledge and confidence were assessed using a pre-intervention survey, followed by a 20-minute structured teaching session focused on use of ICHD-3, including a brief review of SNOOP red-flag features. The post-intervention survey repeated

FIGURE 1 Pre-post change in diagnostic confidence scores following the ICHD-3 educational intervention. Post-intervention confidence scores were significantly higher than baseline (Wilcoxon signed-rank test, $p < 0.001$).

FIGURE 2 Proportion of students correctly answering knowledge questions before and after an ICHD-3-based educational intervention. Questions assessed core diagnostic concepts in headache disorders. Asterisk denotes $p < 0.05$ on McNemar's exact test.

FIGURE 3 Pre-post change in recognition of secondary headache red flags (SNOOP criteria). Post-intervention scores demonstrated a significant improvement compared with baseline (Wilcoxon signed-rank test, $p < 0.001$).

all assessment items. For vignette-based questions, participants were permitted to access the digital ICHD-3 to simulate point-of-care diagnostic support. Pre-post changes were analyzed using the Wilcoxon signed-rank and McNemar's tests.

Results: Forty-three students completed both assessments. Post-intervention confidence increased significantly across all evaluated domains (all $p < 0.001$), including focused history-taking, primary versus secondary headache disorders, SNOOP, ICHD-3 diagnostic criteria, and communication of headache diagnoses. Perceived usefulness of headache classification increased significantly ($p < 0.001$), while interest in a quick diagnostic reference remained high and unchanged ($p = 0.096$). Diagnostic knowledge accuracy improved for key ICHD-3 concepts, including migraine and new daily persistent headache diagnosis, typical aura, and episodic migraine-associated syndromes (all $p \leq 0.019$).

Conclusion: These findings demonstrate that a brief, digitally supported ICHD-3-based intervention can improve diagnostic confidence and accuracy among medical students and support a scalable approach to strengthening structured headache education.

Disclosure: Nothing to disclose.

EPO-0094 | Self-reported redosing and treatment outcomes with oral triptans for acute migraine: Results from the DREAM study

H. Schytz¹; D. Hauberg²; U. Lønberg²; L. Abraham²; K. Blakeman²; M. Spanggaard³; J. Olsen³; T. Hansen¹

¹Danish Headache Center, Department of Neurology, Copenhagen University Hospital Rigshospitalet-Glostrup, Copenhagen, Denmark; ²Pfizer; ³EY Parthenon

Background and aims: This nationwide population study evaluated self-reported frequency of redosing after use of oral triptans, treatment effectiveness as assessed by pain relief and return to normal function, and adverse events.

Methods: All Danish residents ≥18 years with a triptan purchase or a migraine diagnosis (ICD-10: G43) between January 2021 – December 2023 were invited to the nationwide DREAM (Danish REgistry Analyses of Migraine) study combining data from national health registers with a survey on acute migraine medication experience.

Results: 41,498 people reported a migraine attack within the past 3 months. Baseline characteristics are presented in Table 1 Among 21,960 individuals using oral triptans as the only or the first medication type to treat their most recent migraine attack (Figure 1) 49% reported redosing with the same or a different medication, most commonly (77%) between 2–24 h. The proportion achieving 2 h pain relief, return to normal function, and sustained pain relief was significantly lower among individuals who redosed between 2–24 h compared with those who did not redose (73% vs 88%, 32% vs 50%, 57% vs 84%, respectively; $p < 0.01$ for all comparisons). Among those redosing a significantly lower proportion experienced no adverse events vs those not redosing (Figure 2) (38% vs 50% $p < 0.01$).

Conclusion: In this nationwide real-world study almost half of individuals taking oral triptans reported redosing, which was associated with poorer pain and functional outcomes and a

TABLE 1 Baseline characteristics

	Migraine population (MF 1) n (%)	Reference population (MF 2) n (%)

PhD programs	589 (1.4%)	1,382 (1.1%)
Not stated	335 (0.8%)	1,824 (1.3%)

Note: The reference population consists of individuals who are not identified as being referred to a specialist or having an acute diagnosis. The data are presented as a 1:1 ratio comparing matching on age, sex, region of residence, and age. The annual income is constructed using the Danish tax register data.

Note: The population of 21,960 individuals consists of those who reported using oral triptans for acute treatment of their most recent migraine attack. Individuals were included if they had exclusively used oral triptans (EPO-095) or if it was possible to confirm their oral triptan use as the first medication in a multi-drug treatment regimen (EPO-095). Due to the structure of the questionnaire, the first medication taken was not identified when individuals indicated they had taken their second dose within 2–24 hours. This requirement left 2,522 individuals out of this category, which is why the total number of individuals in the population of 21,960 individuals who used oral triptans for acute treatment of their most recent migraine attack is 21,960. Pain relief indicates pain relief at 2 hours.

FIGURE 1 Redosing, pain relief, and return to normal function after oral triptan use for acute treatment of the most recent migraine attack

Note: The population of 21,960 individuals consists of those who reported using oral triptans for acute treatment of their most recent migraine attack. Individuals were included if they had exclusively used oral triptans (EPO-095) or if it was possible to confirm their oral triptan use as the first medication in a multi-drug treatment regimen (EPO-095). Due to the structure of the questionnaire, the first medication taken was not identified when individuals indicated they had taken their second dose within 2–24 hours. This requirement left 2,522 individuals out of this category, which is why the total number of individuals in the population of 21,960 individuals who used oral triptans for acute treatment of their most recent migraine attack is 21,960. Side effects refer to symptoms, for the 5,724 individuals, they were mild to moderate, or severe.

EPO-095 | Inflammatory markers in tubercular meningitis and their role in predicting paradoxical reaction

A. Qavi; S. Deswal; A. Singh; P. Maurya; D. Kulshreshtha
Department of Neurology, Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow, UP, India

Background and aims: Tubercular meningitis (TBM) is associated with high morbidity and mortality due to an intense inflammatory response leading to basal exudates, cranial nerve palsies, vasculitic infarcts, and hydrocephalus. Paradoxical reaction (PR) occurs in nearly 30% of patients and is an important cause of clinical deterioration during treatment. Dysregulated inflammatory mediators in serum and cerebrospinal fluid (CSF) have been implicated in PR and adverse outcomes in TBM.

Methods: In this prospective observational study, 151 newly diagnosed TBM patients fulfilling the Marais et al. consensus

diagnostic criteria were enrolled. Baseline clinical, radiological, serum, and CSF inflammatory markers were assessed in treatment-naïve patients and repeated at 3 months or at the time of PR or stroke. Serum markers included hsCRP, ESR, LDH, ferritin, albumin, D-dimer, neutrophil-lymphocyte ratio (NLR), and systemic immune-inflammation index (SII). CSF analysis included ADA, NLR, protein, sugar, and total leukocyte count.

Results: The mean age was 32.7years; headache was the most common symptom (93.4%). Paradoxical reaction developed in

FIGURE 1 (A)- Frequency of Symptoms, (B)- Staging of TBM, (C)- Radiological manifestation of paradoxical reaction, (D)- Clinical Manifestation of Paradoxical reaction.

FIGURE 2 The receiver operating characteristic curve showing the discrimination power of (A)- HsCRP, (B)- ESR, (C)- S. LDH, (D)- S. Albumin, (E)- S. Ferritin, (F)- D-dimer between paradoxical reaction and non-paradoxical reaction group.

	Regression coefficient t	Standar rd Error	Signific ant	Odds ratio	95.0% C.I. for OR

Constant	-2.688	2.503	.283	.068		

TABLE 1 Multivariate logistic regression analysis for predictors of paradoxical reaction in TBM.

43 patients (28.4%), most commonly presenting with altered sensorium. Radiologically, worsening hydrocephalus was the predominant finding. On univariate analysis, serum albumin, D-dimer, LDH, ferritin, ESR, and hsCRP were significantly associated with PR. On multivariate analysis, Serum Ferritin and ESR independently predicted the paradoxical reaction.

Conclusion: Serum inflammatory markers, particularly ferritin and ESR, may serve as useful predictors of paradoxical reaction in TBM. These findings support an immune-mediated mechanism underlying paradoxical worsening and may help identify high-risk patients who could benefit from early anti-inflammatory or immunomodulatory therapy.

Disclosure: Nothing to disclose.

EPO-0096 | An emerging arboviral trigger of Guillain-Barré syndrome: The first documented case linked to Toscana virus

A. Bettinelli¹; D. Saccomanno²; N. Moliterno²; C. Alberti¹; D. Gagliardi²; D. Velardo²; S. Corti^{1,3}; G. Comi^{1,2}; M. Parisi^{1,2}

¹Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; ²Neurology Unit, Department of Neuroscience and Mental Health, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Dino Ferrari Centre, Milan, Italy; ³Neuromuscular and Rare Diseases Unit, Department of Neuroscience and Mental Health, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Dino Ferrari Centre, Milan, Italy

Background and aims: Guillain-Barré syndrome (GBS) may occur after various infectious triggers, including arboviral infections. Toscana virus (TOSV) is an emerging sand fly-borne phlebovirus endemic in the Mediterranean region, typically associated with neuroinvasive diseases. To date, no cases have established a clear temporal relationship between serologically confirmed acute TOSV infection and the subsequent development of GBS.

Methods: We report the clinical, neurophysiological, and laboratory findings of a patient diagnosed with GBS following acute TOSV infection. The diagnostic work-up included cerebrospinal fluid (CSF) analysis, nerve conduction studies, molecular and serological testing for neurotropic pathogens and assessment of antibodies against gangliosides and sulfatides. A targeted review of the literature was conducted to identify previously reported cases of Guillain-Barré-like syndrome associated with TOSV infection.

Results: CSF findings and electrodiagnostic studies were consistent with the acute inflammatory demyelinating polyneuropathy variant of GBS. Real-time PCR detected TOSV RNA in urine, supporting a recent TOSV infection temporally antecedent to neurological symptom onset. The patient underwent six plasma exchange sessions in addition to supportive care, resulting in progressive neurological improvement.

Conclusion: To our knowledge, this is the first documented case establishing a clear temporal association between TOSV acute infection and GBS onset. This report highlights the importance of considering TOSV as a potential infectious trigger of post-infectious GBS in endemic areas.

Disclosure: Nothing to disclose.

EPO-0098 | Foodborne botulism: Signs beyond descending weakness

D. Dias Dinis¹; R. Miranda Almeida¹; M. Fernandes²; D. Costa¹; J. Lopes¹

¹Neurology Department, Unidade Local de Saúde Santo António, Porto, Portugal; ²Neurophysiology Department, Unidade Local de Saúde Santo António, Porto, Portugal

Background and aims: Botulism neurotoxin intoxication is a rare and life-threatening condition that typically causes a descending flaccid paralysis. However, rarely, autonomic dysfunction may be the predominant clinical manifestation and should be considered in the differential diagnosis of pure dysautonomia.

Methods: We describe a case series of three patients with atypical botulism presenting predominantly with dysautonomia and a favourable outcome.

Results: Patient 1 was a 40-year-old man, patient 2 a 35-year-old woman, and patient 3 a 70-year-old man, all of whom sought medical care because of blurred vision and xerostomia. Additional symptoms included gastrointestinal manifestations (abdominal pain, nausea, and vomiting in patient 1 and constipation in all patients), urinary dysfunction (urinary hesitancy in patients 1 and 3), hypotension (patient 3), mild diplopia (patient 3) and bulbar complaints with mild clinical variations among the three cases. Neurological examinations were normal in all patients, except for accommodative paresis. All three patients had consumed cured ham at the same meal. Electromyographic studies didn't reveal neuromuscular junction disfunction. Serum assays were positive for botulinum toxin type B in all patients. In two cases, toxin B-encoding genes were detected in stool samples via PCR. Antitoxin was not administered as all patients were admitted more than two weeks after symptom onset. At a four-month follow-up, all patients showed nearly complete recovery.

Conclusion: Botulism can be a challenging diagnosis when patients do not develop the typical descending weakness or respiratory failure. Careful consideration of the full clinical presentation and epidemiological context is essential for accurate diagnosis, as timely antitoxin administration may be lifesaving.

EPO-0099 | Toscana virus meningoencephalitis, a case series

K. Ramírez Mora¹; F. Alberola Amores¹; A. Rubio Alcántud²

¹Department of Neurology, General University Hospital of Elche, Elche, Spain; ²Department of Neurology, Vega Baja University Hospital, Orihuela, Spain

Background and aims: Toscana virus (TOSV) is the neurotropic arbovirus of greatest clinical relevance in the Mediterranean basin and the Middle East. Our objective is to describe a series of TOSV meningoencephalitis cases within our catchment area.

Methods: We describe five cases of TOSV meningoencephalitis identified between 2021 and 2024 at General University

Hospital of Elche and Vega Baja University Hospital, located in the province of Alicante, Spain, in order to describe their clinical and epidemiological characteristics and relevant findings in complementary tests.

Results: Most patients were men in their eighth decade of life. The most frequent comorbidities included diabetes, hypertension, and prostate cancer. On admission, the predominant symptoms were fever or low-grade fever, headache with red-flag features, and confusion. Cerebrospinal fluid analysis most commonly showed lymphocytic pleocytosis and elevated protein levels. Neuroimaging revealed no abnormalities attributable to TOSV infection, and only one patient exhibited epileptiform activity on electroencephalography. Clinical outcomes were favorable, with all patients returning to their baseline status.

Conclusion: TOSV should be included in the differential diagnosis of aseptic meningitis and other central nervous system (CNS) infections in endemic regions. Its incidence is expected to rise in the coming years as increasing global temperatures facilitate the spread of vector-borne diseases into new geographical

TABLE 1 Case characteristics and clinical features (Given the small sample size, results are presented as absolute frequencies).

Characteristics	Frequency
Age - yr (median)	36 -78 (73)

EPO-0100 | Otogenic meningoventriculitis due to *Pseudomonas stutzeri* managed with surgery and TDM-monitored targeted antibiotic therapy: A case report

L. Ceccarelli; G. Virgili; I. Massari; P. Viale
Department of Medical and Surgical Sciences, Alma Mater Studiorum, University of Bologna, Bologna, Italy

Background and aims: Otogenic meningo-ventriculitis is a challenging condition, particularly when caused by uncommon Gram-negative pathogens and complicated by hydrocephalus. We report a rare case of *Pseudomonas stutzeri* meningoventriculitis managed with aggressive surgical strategy and fosfomycin-based combination treatment with serial plasma/CSF fosfomycin monitoring.

Methods: Clinical, microbiological, neuroimaging, and CSF data were collected during admission. Serial CSF analyses were performed from external drains and lumbar punctures. Blood and CSF cultures guided therapy. Fosfomycin concentrations were monitored in plasma and CSF to support dosing optimization.

Results: A 70-year-old woman was admitted with acute hydrocephalus and suspected otogenic meningoventriculitis. Urgent external ventricular drainage was placed. Blood cultures grew *Pseudomonas stutzeri* (wild type; fosfomycin MIC 32 mg/L) and CSF microscopy showed Gram-negative bacilli; CSF culture confirmed *P. stutzeri*. After initial empiric therapy with ceftriaxone plus levofloxacin, antibiotic therapy was escalated to cefepime plus fosfomycin. Neuroimaging supported meningo-ependymal enhancement and acute otomastoiditis; ENT source control included tympanostomy and subsequent mastoid surgery. Despite persistently abnormal CSF cytochemistry, follow-up CSF cultures remained negative. Based on adequate source control, targeted and TDM-guided antibiotic therapy (Figure 1), clinical/radiological improvement and sustained culture negativity, definitive ventriculo-peritoneal shunt was placed on day 30 after admission; intraoperative CSF sampling resulted negative. Antibiotics were discontinued on day 34. At 1-year follow-up, no relapse occurred.

FIGURE 1 Fosfomycin concentrations in plasma and CSF.

Conclusion: *P. stutzeri* is a rare cause of otogenic meningoventriculitis. A combining prompt source control, and fosfomycin-based combination treatment with serial plasma/CSF fosfomycin monitoring may improve the patient's outcome.

Disclosure: Nothing to disclose.

EPO-0101 | Development of a patient reported outcome measure for infectious encephalitis: What matters most to patients

L. Secker¹; S. McKeever¹; J. Mitchell²; E. Collins³; A. Easton³; B. Michael¹
¹The Brain Infection and Inflammation Group, University of Liverpool, Liverpool, UK; ²The Walton Centre NHS Foundation Trust, Liverpool, UK; ³Encephalitis International, UK

Background and aims: Research on the long-term outcomes of patients with infectious encephalitis (IE) is limited. Existing evidence from a systematic review indicates that most studies and clinicians use the modified Rankin Scale (mRS), a global disability score developed for stroke which does not capture the cognitive, behavioural, emotional and quality of life (QoL) consequences of IE. The current study aims to develop a disease-specific patient-reported outcome measure (PROM) to address this gap.

Methods: Semi-structured interviews were developed following COSMIN guidance, with international input from clinicians and adults with lived experience of IE. Participants were recruited via Encephalitis International until data saturation was achieved ($n=40$). Transcripts of all interviews were thematically analysed by 2 independent reviewers, to identify concepts for the initial instrument.

TABLE 1 Demographics of the 40 patients who completed a semi-structured interview.

Other*	7
Type of encephalitis	
HSV	22
Not specified	12
Tick-borne	3
Other**	3
ITU admission	11
Median age at diagnosis (IQR)	42 (26-54)
Time since diagnosis in months (IQR)	50 (25-192)
Days spent in hospital (IQR)	21 (15-35)

*Australia, Finland, India, Netherlands, Philippines, Spain, Switzerland
** West Nile Virus, Influenza, Mumps

FIGURE 1 A graph of the 20 most prevalent items identified in thematic analysis of semi-structured interviews.

Results: 101 items were initially identified, reduced to 73 items after removing duplicates and items with < 3 responses. Item breakdown by domain included Physical (25), Health related QoL (13), Cognitive (14), Psychological (9), Behavioural (12) and were shared across multiple aetiologies. Participants with a 'good outcome' according to mRS described substantial ongoing symptoms and impact on QoL. 11 participants experienced severe initial disease, and most patients spent an extended duration (21 day mean) in hospital.

Conclusion: This series of semi-structured interviews has generated 73 items, spanning across multiple domains. Common items have been shared across aetiologies, suggesting a generic PROM for IE is justifiable. The next steps in PROM development are to undertake further refinement of items and cognitive debriefing interviews to assess for content validity.

Disclosure: Nothing to disclose.

EPO-0102 | Post-acute COVID-19 effects on standardized cognitive and motor test scores in a longitudinal study of independent elderly subjects

N. Dunckley¹; N. Zhang²; C. Adler³; H. Shill⁴; S. Mehta³; E. Driver-Dunckley³; C. Belden¹; A. Atri¹; P. Choudhury¹; A. Kuramoto¹; G. Serrano¹; T. Beach¹

¹Banner Sun Health Research Institute, Sun City, USA;

²Department of Quantitative Health Sciences, Mayo Clinic, Scottsdale, AZ, USA; ³Department of Neurology, Mayo Clinic College of Medicine, Scottsdale, USA; ⁴Department of Neurology, Barrow Neurological Institute, Phoenix, USA

Background and aims: There is considerable concern about long-term consequences of COVID-19, including cognitive and motor decline. Whether COVID-19 adds burden beyond normal aging remains unclear, particularly in cohorts studying neurological disease. This study examined whether prior COVID-19 illness was associated with differential cognitive or motor decline in older adults over time broadly.

Methods: Subjects were included if they were cognitively normal before the pandemic, completed a COVID questionnaire, and attended subsequent diagnostic conferences. All received serial evaluations with Montreal Cognitive Assessment (MoCA) and Unified Parkinson's Disease Rating Scale (UPDRS). We compared, between those reporting COVID-19 and those denying it, conversion to cognitive impairment or dementia and changes in cognitive and motor scores longitudinally.

Results: 100 participants reported COVID-19 and 71 denied infection. Illness severity was generally mild; none required ventilation. Cognitive and motor performance declined slightly without statistical significance. Conversion occurred in twenty-six percent of COVID-19 participants and thirty-two percent of controls, a nonsignificant difference between groups during follow-up across the study period. Logistic regression indicated that self-reported COVID-19 was not associated with diagnostic conversion, while greater age, male sex, possession of one

TABLE 1 Demographic characteristics of subjects reporting having had COVID-19 or not. Conversion refers to the percentage of subjects that converted from cognitively normal to cognitive impairment or dementia. No significant differences between groups.

COVID-19	Age	Sex	Education Yrs	AgeE+4	Peak PD	Conversion
YES (n = 100)	81.79 (8.67)	34 M (34%)	15.88 (2.43)	23 (23%)	19 (19%)	26 (26%)
NO (n = 71)	82.36 (7.29)	24 M (34%)	15.85 (2.33)	16 (22.5%)	11 (15.5%)	23 (32.4%)

TABLE 2 Comparison of pre- and post-pandemic MoCA and UPDRS motor scores in subjects reporting having had or not having had COVID-19.

COVID-19	MoCA Study Beginning	MoCA Study End	UPDRS Study Beginning	UPDRS Study End
YES	26.56 (2.88) n = 40*	25.96 (2.87) n = 40	2.95 (4.37) n = 40	4.79 (7.63) n = 40
NO	26.37 (2.03) n = 40	24.8 (4.16) n = 40*	2.40 (3.67) n = 42	4.96 (6.27) n = 42

TABLE 3 Logistic regression analysis of relationship of reported COVID-19 on likelihood for conversion from cognitively normal to cognitively impaired or dementia, when also considering multiple covariates.

Variable	Odds Ratio (95% CI)	Probability	Beta Coefficient	Standard Error
Reported COVID-19	0.71 (0.335-1.52)	0.36	-0.338	0.386
Age*	4.67 (1.91-11.46)	0.0007	1.54	0.407
Male Sex*	3.76 (1.30-8.35)	0.0110	1.328	0.404
Education Years	1.42 (0.62-3.25)	0.405	0.352	0.422
AgeE+4*	1.50 (1.32-1.70)	0.0095	1.151	0.444
Predicted PD*	2.863 (1.00-8.20)	0.050	1.052	0.536

or more apolipoprotein E-ε4 alleles, and a diagnosis of probable Parkinson's Disease all conferred a greater likelihood of conversion.

Conclusion: These findings suggest that mild COVID-19 illness is not associated with greater cognitive or motor decline than expected from age-related change alone. Limitations include modest sample size, potential misclassification of COVID-19 status, and reliance on relatively crude screening measures that may miss subtle functional effects and longer-term disease-modifying consequences remain.

Disclosure: Nothing to disclose.

EPO-0103 | Temporal evolution of clinical and cognitive markers following viral encephalitis

N. van Anel; S. Staal; M. Brouwer; D. van de Beek; L. Ter Horst
Neurology, Amsterdam UMC, Amsterdam, The Netherlands

Background and aims: Objectives: To investigate cognitive functioning and clinical markers in patients shortly following viral encephalitis. In addition, the patients' precepted impact of sequelae on their daily functioning.

Methods: Methods: Autoimmune Inflammation as cause of Relapsing Symptoms in patients with Viral Encephalitis (ARISE) was a prospective, observational, single-centre cohort study in Amsterdam UMC, the Netherlands. All patients aged ≥16 years with viral encephalitis and confirmed pathogen were eligible for this study. Patients with prior cognitive impairment, recent neurosurgery or neuro-devices were excluded. Follow-up was at week 1, 4 and 12, and year 1 from the onset of viral encephalitis. Cognitive functioning was assessed each follow-up. Blood samples were drawn at week 1, 4 and 12, and cerebrospinal fluid (CSF) from diagnostic lumbar puncture was collected, to be screened for neuron-specific enolase (NSE), S100b and auto-antibodies.

Results: Results: Eight patients were included between 2020 and 2024, of which 1 of 8 (13%) subjects had died during admission. Outcome at discharge was unfavourable in 7 of 8 (88%) patients. Follow-up data was available for 7 patients. Cognitive functioning showed most pronounced deficits in short-term memory and visuospatial/executive function. Patients reported perceiving to be most limited by physical health and energy. Daily functioning was impaired greatest in their speed, energy and attention. Median values for NSE and S100b did not exceed reference values in CSF or blood samples. No samples showed reactivity for auto-antibodies.

Conclusion: Conclusions: Post-viral encephalitis results primarily in cognitive impairment of short-term memory, speed, and attention, hindering daily functioning one year after onset.

Disclosure: Nothing to disclose.

EPO-0104 | Inkblot infarcts: A Distinctive MRI pattern of recurrent stroke in varicella zoster virus vasculopathy

R. Ramesh¹; L. Narasimhan R¹; I. Arumugam²; S. Narayanasamy³; P. Srikanth²; S. Lakshmanan³; S. Shanmugam¹
¹Department of Neurology, Sri Ramachandra Institute of Higher Education and Research; ²Department of Microbiology, Sri Ramachandra Institute of Higher Education and Research; ³Department of Internal Medicine, Sri Ramachandra Institute of Higher Education and Research

Background and aims: Varicella-zoster virus vasculopathy (VZVV) can manifest with recurrent, antithrombotic-refractory strokes in the absence of rash or prodrome, which presents a diagnostic and therapeutic challenge. This study aims to introduce the novel pattern in MRI brain, which we have named “Inkblot Infarct”, characterised by recurrent, slow-expanding strokes in the same subcortical region, secondary to VZVV.

Methods: We prospectively analysed five adult patients presenting with recurrent ischemic strokes at a tertiary care centre. All patients underwent comprehensive vascular, cardiac, immune, and infectious evaluations, along with serial magnetic resonance imaging. VZV-specific IgG antibody levels in cerebrospinal fluid (CSF) and serum were analysed. Patients were treated with acyclovir, and their clinical and radiological outcomes were assessed.

Results: All five patients demonstrated recurrent infarcts in the subcortical region, showing gradual expansion on serial imaging. None had a preceding rash or fever. Antiplatelets and anticoagulation therapy failed to prevent recurrence. Cerebrospinal fluid analysis revealed elevated anti-varicella zoster virus immunoglobulin G levels in all patients, with raised immunoglobulin G index where available. Following initiation of acyclovir, no further strokes occurred during follow-up.

Conclusion: The “Inkblot Infarct” pattern represents a unique manifestation of VZVV-related strokes, hypothesised to result from persistent viral antigen-mediated vascular remodelling. Atypical presentations, such as absent rashes and delayed symptom progression, emphasise the need for heightened clinical suspicion. Recognition of this pattern may facilitate earlier

TABLE 1 Patient Characteristics, clinical features, treatment and outcomes.

Patient	Age Sex	Medical History	Presented	Acute stroke	First Stroke	Presenting symptoms	Investigation after 1st stroke	Investigation after 2nd stroke	Investigation after 3rd stroke	Investigation after 4th stroke	Investigation after 5th stroke	Outcome
Patient 1	45M	HTN	Yes	Yes	Stroke 1	Exacerbated left hemiparesis due to gradual expansion of the infarcted subcortical region	Final stroke	Acyclovir initiated on 1st day	Subcortical infarct, periventricular	Final stroke	Subcortical infarct	10 days

diagnosis and targeted antiviral therapy in recurrent cryptogenic stroke.
Disclosure: Nothing to disclose.

S. Wetz; J. Walders; A. Costa; K. Reetz
Department of Neurology, University Hospital RWTH Aachen,
Aachen, Germany

Background and aims: Post-COVID-19 condition (PCC) shows substantial heterogeneity, with primarily neurological symptoms. It is unclear whether this reflects distinct disease entities or a spectrum of a shared condition enriched for neurological manifestations.

Methods: We analyzed data from 509 PCC patients (353 females, 48.15 ± 12.73 years), seen at the RWTH Aachen neurological Post-COVID-19 outpatient clinic from 2021 to 2024. Clinical history, acute and persistent (>12 weeks) symptom profiles, patient-reported outcome measures (PROMs) and cognitive performance were assessed. Multiple correspondence analysis followed by hierarchical clustering was used to derive data-driven phenotypes, which were compared across symptoms, PROMs and organ involvement.

Results: Three clusters emerged that aligned along a pronounced severity and multisystem-complexity continuum. Cognitive complaints were frequent across all clusters, but differed by overall symptom burden, functional impact, and extent of system involvement. Key clinical markers showed stepwise gradients from high-to-low-burden phenotypes, including severe fatigue (FSMC: 61.0% vs 23.8% vs 22.5%), impaired cognition (MoCA: 25.4% vs 11.9% vs 5.6%), depressive symptoms (HADS: 44.1% vs 18.4% vs 9.9%) and arthralgia (96.6% vs 75.5% vs 19.7%). The high-burden phenotype combined prominent neurocognitive symptoms with dyspnea, sensory/chemosensory disturbances, pain and higher psychological burden. Prior vaccination was more frequent in the lower-burden group, while

FIGURE 1 Heatmap for health status indicators, patient-reported outcome measures (PROMs) and symptom prevalence per cluster. Illustrated is the respective percentage of patients. Abbreviations: BMI: Body Mass Index; FSMC: Fatigue Scale for Motor and Cog.

FIGURE 2 Subjective severity rating per cluster for acute and persisting (>12 weeks) symptoms. The mean severity rating and standard deviation is shown for each patient cluster for symptoms in the acute infectious and post-infectious stage after 12 weeks.

FIGURE 3 Pre-existing morbidities and health status associations with neurological PCC severity. The Odds Ratio is shown for neurological PCC patients to be categorized in a cluster based on their pre-morbid health status in a One-vs-rest approach for each cluster. The reference for age was <35, BMI reference was <25, and COVID-19 infection time-point reference was during wild-type (WT) variant wave. For the remaining factors, absence of the condition was used as reference.

psychiatric comorbidities and higher BMI were enriched towards the high-burden end.

Conclusion: Data-driven phenotyping supports a spectrum model in which neurological symptoms are common throughout. However, severity and disease complexity is driven by non-neurological factors (i.e. vaccination, metabolic health, comorbidities) underscoring the need of a coordinated multidisciplinary management even for patients presenting primarily with neurological symptoms.

Disclosure: Nothing to disclose.

EPO-0106 | Efficacy and tolerability of β -hydroxybutyrate in patients with ALS (KETO-ALS): A randomised, placebo-controlled, double-blind study

C. Herrmann; J. Dorst
Clinic for Neurology, Ulm Neurology, Germany

Background and aims: Hypermetabolism and weight loss are prominent features of amyotrophic lateral sclerosis (ALS). Here, we sought to target the energy deficit in ALS by applying oral ketone bodies as high-energetic substrates.

Methods: Patients with ALS were enrolled to this randomised, placebo-controlled, double-blind, monocentre phase 2 trial. Eligible patients had a decline of ALS functional rating scale revised (ALSFRS-R) of at least 0.33 points/month. They were randomly assigned (1:1) to receive β -hydroxybutyrate-ester (β HB, 30 g/day) or placebo. Primary endpoint was change of neurofilament light chain (NfL) per month, measured as slope over 6 months. Multiple linear regressions models were applied to adjust for NfL, ALSFRS-R, age, and slow vital capacity (SVC) at baseline. The trial is registered with clinicaltrials.gov, number NCT04820478.

Results: Between April 5, 2022, and February 12, 2025, 81 patients were randomly assigned to receive β HB ($n=40$) or placebo ($n=41$) and included in the intention-to-treat analysis. NfL slope was -0.5 pg/mL (IQR -3.2 to 2.0 , minimum -11.2 , maximum 10.4) in the β HB group and 0.0 pg/mL (IQR -1.7 to 3.3 , minimum -6.2 , maximum 49.0) in the placebo group ($p=0.19$). In the adjusted analysis, both NfL ($p=0.04$) and BMI slope ($p=0.05$) showed a benefit for the β HB group. β HB was well tolerated.

Conclusion: This study provides preliminary evidence for efficacy and safety of oral ketone bodies in ALS by demonstrating target engagement and a reduction of NfL. Whether these effects can be translated into meaningful clinical effects remains to be clarified by a larger phase 3 trial with extended treatment duration.

Disclosure: Nothing to disclose.

EPO-0107 | Clinical implications of retinal markers in amyotrophic lateral sclerosis: A systematic review

E. Assis¹; H. Swamy¹; M. Reis²; A. Petzold³; H. Özdemir⁴
¹Faculty of Medicine, Immanuel Kant Baltic Federal University, Kaliningrad, Russian Federation; ²Faculty of Medicine, Universidad Nacional de Rosario, Rosario, Argentina; ³Queen Square Institute of Neurology, University College London, London, UK; ⁴Neurology Department, Medical School Hospital, Ege University, İzmir, Türkiye

Background and aims: Amyotrophic lateral sclerosis (ALS) is a fatal, clinically heterogeneous, multisystem neurodegenerative disease, underscoring the need for biomarkers beyond motor decline. Optical coherence tomography (OCT) enables non-invasive retinal assessment and may identify relevant retinal biomarkers in ALS. Therefore, we systematically synthesised and evaluated the evidence on OCT-derived retinal biomarkers in ALS and their clinical relevance.

Methods: A systematic review was reported in accordance with the PRISMA statement and prospectively registered in PROSPERO (CRD420251242585). We searched MEDLINE, Embase, Scopus, and the Cochrane Library for observational studies reporting OCT-derived retinal biomarkers in adults with ALS, excluding non-eligible designs. The primary outcome was

the association between retinal OCT measures and functional severity. Risk of bias was assessed using QUIPS.

Results: Fifteen studies involving 1,301 patients, published between 2013 and 2025, were included, comprising predominantly cross-sectional designs with three longitudinal studies. Average peripapillary retinal nerve fibre layer (pRNFL) thinning was reported in eight studies, while several others demonstrated thinning confined to specific quadrants. Five studies reported thinning in inner retinal layers or macular thickness. Seven studies reported significant correlations between optical coherence tomography parameters and ALSFRS-R score. All longitudinal studies consistently demonstrated progressive pRNFL thinning over follow-up in ALS patients. One study reported a significant correlation between RNFL thickness and respiratory function (FVC% and FEV1%), while another found no such association.

Conclusion: OCT-derived retinal changes, particularly pRNFL thinning, are reported in ALS and show associations with functional severity, with longitudinal studies suggesting progressive retinal degeneration. Larger, standardised longitudinal studies are needed to define prognostic value and clinical utility.

Disclosure: Nothing to disclose.

EPO-0108 | Cortical motor mapping in ALS: Investigating hand motor representation across disease phenotypes

G. Fanella¹; B. Bardel²; A. Bystrup Jacobsen¹; T. Mussigmann³; J. Lefaucheur²; H. Tankisi⁴

¹Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; ²Department of Clinical Neurophysiology, DMU FlixIT, Henri Mondor University Hospital, APHP, Creteil, France; ³UR 4391, ENT Team, Faculty of Health, Paris Est Creteil University, Creteil, France; ⁴Department of Clinical Neurophysiology, Aarhus University Hospital, Aarhus, Denmark

Background and aims: Amyotrophic lateral sclerosis (ALS) is clinically heterogeneous, with phenotype-dependent variation in cortical excitability. Reduced short-interval intracortical inhibition (SICI) on transcranial magnetic stimulation (TMS) is a recognised hallmark of ALS, but its role as pathogenic driver versus compensatory plasticity remains unclear. Navigated TMS (nTMS) motor mapping quantifies cortical motor representations and may capture degeneration and plasticity. We examined whether motor map volume differs across phenotypes and relates to SICI, resting motor threshold (RMT), and lower motoneuron (LMN) involvement.

Methods: Twenty ALS patients were consecutively recruited and classified by phenotype. Bilateral nTMS motor mapping of first dorsal interosseous (FDI) was performed. Map volumes were derived by segmentation in 3D Slicer. Threshold-tracking SICI was recorded at the FDI hotspot. LMN involvement was quantified using Neurophysiological Index (NI). A 6-month follow-up is ongoing.

Results: Mean age was 65.8 (± 11.1) years; 17/20 were males. Mean disease duration was 21.2 months (± 10.8) and ALS

Functional Rating Scale-Revised (ALSFRS-R) was 41.1 (± 3.4). Onset was spinal in 13 and bulbar in 7. Phenotypes were classical ($n=9$), bulbar ($n=7$), pyramidal ($n=4$). Map volumes and SICI did not differ by onset site or phenotype. Map volume was inversely associated with RMT ($R^2=0.22$; $p=0.042$). RMT correlated positively with disease duration ($\rho=0.48$; $p=0.039$). Map volume was not associated with SICI, NI, or disease duration.

Conclusion: Cortical motor representation appears unrelated to SICI and LMN measures. The positive correlation between RMT and disease duration suggests a stage-dependent increase in motor threshold that may influence map volume. Follow-up will examine longitudinal changes.

Disclosure: Nothing to disclose.

EPO-0109 | REST inhibition as a therapeutic and prognostic target in amyotrophic lateral sclerosis: From siRNA silencing to serum biomarkers

G. Senerchia¹; N. Guida²; V. Valsecchi²; S. Anzillotti²; G. Pignataro²; L. Annunziato²; L. Formisano²; R. Dubbioso¹
¹Clinical Neurophysiology Unit, Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples, Naples, Italy; ²Division of Pharmacology, Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples, Naples, Italy

Background and aims: The Restrictive Element-1 Silencing Transcription factor (REST) acts as a master repressor of neuronal gene expression. Aberrant REST accumulation has been linked to several neurodegenerative conditions, but its role in amyotrophic lateral sclerosis (ALS) remains unclear.

Methods: REST expression was analyzed in the motor cortex, brainstem, and spinal cord of SOD1-G93A mice at different disease stages. To assess causality, intracerebroventricular injections of a small interfering RNA targeting REST (siREST) were performed weekly for four weeks starting at the presymptomatic stage (day 90). Behavioral, histological, and molecular analyses were conducted to evaluate motor performance, neuronal survival, SOD1 aggregation, and glial activation. In parallel, REST serum levels were quantified by ELISA in ALS patients and healthy controls, and correlated with clinical outcomes.

Results: REST levels were markedly increased in the CNS of SOD1-G93A mice during both early and late symptomatic phases. siREST treatment significantly reduced REST expression, prevented motor neuron loss, decreased misfolded SOD1 aggregates, and attenuated astro- and microgliosis. These effects translated into improved motor performance and prolonged survival (133.2 ± 1.7 vs 124.3 ± 2.1 days, $p < 0.01$). In the clinical cohort, serum REST was significantly higher in ALS patients than in controls ($p = 0.006$). Elevated REST levels independently predicted poorer tracheostomy-free survival (multivariate HR = 13.43, 95% CI: 2.1–86.0, $p = 0.006$).

Conclusion: REST upregulation contributes to ALS pathogenesis by promoting neuronal death and neuroinflammation. Its silencing through siRNA confers neuroprotection and survival

benefit in ALS mice. Elevated serum REST mirrors CNS pathology and predicts disease progression, supporting REST as a novel therapeutic and prognostic target in ALS.

Disclosure: Nothing to disclose.

Background and aims: Diffusion tensor imaging (DTI) metrics of key white matter (WM) tracts in amyotrophic lateral sclerosis (ALS) are crucial for assessing upper motor neuron involvement and predicting disease progression and survival. This study investigated whether major WM tracts predict survival in ALS and explored differences between spinal- and bulbar-onset cases.

Methods: A total of 411 ALS were recruited at the Turin ALS Centre (2008–2021) and underwent 1.5 Tesla brain MRI with DTI. Fractional anisotropy (FA) was extracted from the bilateral corticospinal tracts (CST; averaged) and the corpus callosum

(CC). Survival was censored in January 2024. Demographic and clinical differences were assessed. Cox proportional hazards models evaluated the association between FA and survival, adjusting for age at MRI, sex, and disease duration, in the full cohort and stratified by onset site.

Results: In the overall cohort, higher CST FA was significantly associated with longer survival (HR=0.0003, 95% CI: 6.20×10^{-6} – 0.0158, $p < 0.001$). When stratified by onset site, CST FA remained a strong predictor of survival in spinal-onset ALS (HR = 5.82×10^{-5} , 95% CI: 4.66×10^{-7} – 0.0073, $p < 0.001$). In bulbar-onset ALS, CST FA showed a trend toward predicting survival but did not reach statistical significance (HR=0.0008, 95% CI: 4.15×10^{-7} – 1.46, $p = 0.063$). FA of the CC was not significantly associated with survival.

Conclusion: CST integrity is a strong predictor of survival in ALS, particularly in spinal-onset disease, supporting CST FA as a prognostic imaging biomarker.

EPO-0111 | Development and validation of a classification method and personalised prediction models for patients with amyotrophic lateral sclerosis

J. Zhang; S. Ye; L. Chen; X. Liu; D. Fan

Department of Neurology, Peking University Third Hospital, Beijing, China

Background and aims: The heterogeneity of amyotrophic lateral sclerosis (ALS) in clinical presentations and prognosis poses a significant obstacle to the successful translation of research into therapeutic solutions. A classification method with high stability, excellent clinical applicability and strong generalizability across populations remains to be further investigated. No parametric prognostic model has yet been established for Chinese patients with ALS.

Methods: This retrospective cohort study involved two large cohorts: the Peking University Third Hospital (PUTH) ALS cohort and a Caucasian ALS cohort derived from Pooled Resource Open-Access ALS Clinical Trial (PRO-ACT) database and the Answer ALS database.

Results: 603 patients from PUTH ALS cohort and 3610 patients from Caucasian ALS cohort were enrolled in this study. Statistical analysis suggested that patients could be stratified into three progression groups--high-risk(HR), moderate-risk(MR), and low-risk (LR)--based on diagnostic delay, progression rate, and FVC, namely the DRF classification method. More than 83% of patients remained in the same group 1 year after the initial assessment. The median survival time of PUTH ALS patients with HR progression is 6 months shorter than that of Caucasian ALS patients. PUTH ALS patients with HR progression are more likely to experience group transitions during follow-up compared to Caucasian ALS patients. Our survival models enable the estimation of the survival probability for individual ALS patients.

Conclusion: DRF classification method is an ideal choice for stratification in future multinational clinical trials. The prediction of individual disease progression and prognosis is essential not only for personalized treatment strategies but also for the evaluation of clinical trials outcomes.

Disclosure: Nothing to disclose.

Background and aims: Disease-modifying therapies (DMTs) have modified the clinical course of spinal muscular atrophy (SMA), improving survival and motor outcomes. Nonetheless, scoliosis remains frequently observed.

Methods: Nine SMA patients receiving DMTs (3 SMA1, 6 SMA3; mean age 17.6 ± 13.1 years) were enrolled at baseline (T0). Scoliosis was assessed using Cobb angle. Clinical history and evaluations were collected including CHOP -INTEND, HFMSE, RULM, MFM-32, forced vital capacity (FVC), SMA Independence Scale-Clinical Report (SMAIS-CR) and SF-36 questionnaire. Associations between Cobb angle and clinical measures were explored using Spearman's rank correlation at baseline and after 1 year follow-up (T1).

Results: At baseline, scoliosis was observed in 78% of patients ($n=7$). SMA 1 patients presented more severe scoliosis (mean Cobb angle at T0: $45.0^\circ \pm 26.0^\circ$, at T1: $48.8^\circ \pm 47.7^\circ$), with one patient undergoing stabilization intervention. SMA 3 patients showed milder curves (mean Cobb angle at T0: $18.5^\circ \pm 4.0^\circ$, at T1: $19.3^\circ \pm 5.1^\circ$). Associations with Cobb angle were found at

FIGURE 1 Scoliosis progression graph. On the X-axis, it is shown the time-line; on the Y-axis, Cobb angles. For patient S.1, S.3, S.4 and S.6, there are three time-points available (restrospective, baseline and at 1-year follow-up).

FIGURE 2 Timeline illustrating the clinical history of individual pediatric patients by age (years), including baseline motor function (T0), phenotype, scoliosis, disease-modifying therapies (DMTs), clinical stabilization, and respiratory support (NIV).

FIGURE 3 Timeline illustrating the clinical history of individual adult patients by age (years), including baseline motor function (T0), phenotype, scoliosis, disease-modifying therapies (DMTs), clinical stabilization, and respiratory support (NIV).

T0 with RULM ($r = -0.832$, $p=0.040$), at T1 with FVC in liters ($r=0.900$, $p=0.037$) and SMAIS-CR ($r = -0.900$, $p=0.037$). These associations should be interpreted cautiously, as increases in absolute FVC may reflect growth or treatment-related effects rather than respiratory function changes per se.

Conclusion: In this small exploratory-cohort, scoliosis was frequent in SMA patients receiving DMTs and appeared to co-occur with motor performance and daily functioning. Larger longitudinal studies are needed to better define scoliosis trajectories and clinical relevance in the DMTs-era.

Disclosure: Nothing to disclose.

EPO-0113 | Multimodal biomarkers for early diagnosis of amyotrophic lateral sclerosis: Integration of transcranial magnetic stimulation and radiomics MRI

R. Tolay¹; B. Dik²; O. Kaya²; H. Uysal³; A. Koc¹

¹Department of Neurology, Cukurova University Faculty of Medicine, Adana, Türkiye; ²Department of Radiology, Cukurova University Faculty of Medicine, Adana, Türkiye; ³Independent researcher, Adana, Türkiye

Background and aims: Early diagnosis of amyotrophic lateral sclerosis (ALS) remains challenging due to the limited sensitivity of conventional upper motor neuron markers. Integration of

multimodal biomarkers combining neurophysiological and neuroimaging approaches may improve diagnostic accuracy, particularly in early disease stages.

Methods: In this prospective study, 74 patients with amyotrophic lateral sclerosis and 38 healthy controls were included. ALS patients were stratified into mild and moderate-advanced stages according to ALSFRS-R scores. Bilateral transcranial magnetic stimulation (TMS) was applied to the abductor pollicis brevis and first dorsal interosseous muscles to assess resting motor threshold (RMT), cortical and radicular latencies, central motor conduction time (CMCT), and short-interval intracortical inhibition (SICI). Radiomics features ($n = 555$), including texture and shape parameters, were extracted from the perirolandic cortex, posterior limb of the internal capsule, and bulbus on MRI. Feature selection was performed using the Boruta algorithm, followed by LASSO and Random Forest analyses.

Results: ALS patients demonstrated significant alterations in TMS parameters, including reduced SICI, altered RMT, and prolonged CMCT. Among neurophysiological measures, SICI at 3 ms ISI showed the highest diagnostic performance ($AUC = 0.846$). Radiomics analysis revealed increased entropy and reduced homogeneity in motor-related regions. Multimodal models integrating TMS and radiomics MRI consistently outperformed single-modality approaches and achieved excellent discrimination of early-stage ALS from healthy controls ($AUC = 0.984$).

Conclusion: Multimodal integration of transcranial magnetic stimulation and radiomics MRI improves discrimination of early-stage ALS and supports the potential value of combined functional and structural biomarkers.

Disclosure: Nothing to disclose.

EPO-0114 | **Reduced nuclear TDP-43 and cytoplasmic DLK1 as markers of motor neuron degeneration in amyotrophic lateral sclerosis**

T. Takeda; A. Ishikawa; S. Kokubun; Y. Saito; S. Ise; K. Ito; K. Arai; K. Honda
Department of Neurology, National Hospital Organization Chiba Medical Center Chibahigashi National Hospital, Chiba, Japan

Background and aims: Loss of upper and lower motor neurons (MNs) is a defining pathological feature underlying the clinical manifestations of amyotrophic lateral sclerosis (ALS). However, the differences in MN loss and TDP-43 pathology between these areas in ALS patients remain unknown.

Methods: This study included seven patients with ALS and three controls from autopsies performed. The cell density and regional density of TDP-43-positive inclusions in four upper MN areas (tongue, arm, trunk, and leg) and their anatomically corresponding lower MN areas were measured. The cell residual rate by comparing the cell density of each case to the average density of the controls was calculated. The numbers of large cells with loss of nuclear TDP-43 and cytoplasmic delta-like 1 homolog (DLK1), a MN-related factor involved in its differentiation, were counted.

Results: The results showed severe MN loss in both upper and lower MN areas; however, TDP-43-positive inclusions differed markedly: they were rare in upper MNs but abundant in lower MN. Although in upper MN areas, TDP-43 density was not

associated with the residual rate of MNs, the density in MNs in lower MN areas was well associated with the cell residual rate. Significantly higher numbers of MNs lacking nuclear TDP-43 and cytoplasmic DLK1 were observed in the upper and lower MN regions in ALS.

Conclusion: These results demonstrated that the frequency and severity of abnormal cytoplasmic TDP-43 aggregation differed significantly between the upper and lower MN regions in ALS patients, while nuclear TDP-43 loss and cytoplasmic DLK1 reduction were consistent in both regions.

Disclosure: Nothing to disclose.

FIGURE 1 Microscopy of TDP-43 and DLK1 immunostaining in upper and lower motor neuron areas in samples from patients with amyotrophic lateral sclerosis.

V. Iuzzolino¹; F. Ranieri²; R. Dubbioso¹; S. MND Study Group³; S. Neurostimulation-Neuromodulation Study Group⁴

¹Department of Neurosciences, Reproductive Sciences, and Odontostomatology, University of Naples Federico II, Naples, Italy; ²Neurology Unit, Department of Neuroscience, Biomedicine, and Movement Sciences, University of Verona, Verona, Italy; ³Italian Neurological Society; ⁴Italian Society of Clinical Neurophysiology

Background and aims: Bulbar dysfunction strongly impacts prognosis in amyotrophic lateral sclerosis (ALS), but early detection remains challenging. Motor evoked potentials (MEPs) are widely used to assess corticospinal tract integrity, yet the clinical value of cranial MEPs is unclear. This study evaluated the diagnostic and prognostic significance of cranial MEPs in a real-world ALS cohort.

Methods: We retrospectively analysed 510 consecutive ALS patients assessed at diagnosis with transcranial magnetic stimulation of three districts: cranial (genioglossus, $n=175$), upper limb (first dorsal interosseous, $n=510$), and lower limb (tibialis anterior or abductor hallucis, $n=479$). Clinical involvement was classified using King's staging and clinical phenotypes. We assessed associations between MEP abnormalities and clinical variables and the impact of cranial MEPs on time to PEG placement.

Results: Cranial MEPs were more frequently abnormal than upper limb (51.4% vs 36.1%, $p<0.001$) and similar to lower limb. They were often abnormal in patients without bulbar symptoms (27.3%) and strongly associated with bulbar involvement ($p<0.001$). Including cranial districts increases the detection of pathological MEPs by 16% across ALS phenotypes, with rates rising along the LMN-UMN spectrum and reaching 100% in UMN-predominant ALS and PLS. The frequency of abnormal cranial MEPs increased across King's stages (34% at stage 1, 47% at stage 2, 64% at stage 3, $p=0.004$). Abnormal cranial MEPs predicted shorter time to PEG (median 10 vs 18 months; $p=0.038$).

Conclusion: Cranial MEPs detect subclinical bulbar involvement and predict earlier bulbar deterioration in ALS. Their integration into routine assessment may improve early stratification and prognostic evaluation in clinical practice.

Disclosure: Nothing to disclose.

FIGURE 1 Cranial MEPs improve diagnostic sensitivity in ALS and across the phenotypic spectrum.

FIGURE 2 Stage-dependent increase of cranial MEPs involvement: In early disease stages, pathological MEPs predominantly involve the lumbosacral district, whereas cranial involvement increases across King's stages and becomes predominant at stage 3.

FIGURE 3 Kaplan–Meier analysis showed that patients with abnormal cranial MEPs had a significantly shorter PEG-free survival compared with those with normal cranial MEPs (median 10 vs 18 months; log-rank $p=0.026$; Cox proportional hazards HR=0.37, $p=0.038$).

V. Poulidou¹; V. Tseriotis²; A. Bombaci³; S. Vucic⁴; N. Pavay⁴; S. Papagiannopoulos⁵; V. Kimiskidis¹; M. Arnaoutoglou⁶

¹1st Department of Neurology, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; ²Department of Neurology, Agios Pavlos General Hospital of Thessaloniki, Thessaloniki, Greece; ³IRCSS Policlinico San Donato, San Donato Milanese, Italy; ⁴Brain and Nerve Research Centre, Concord Clinical School, The University of Sydney, Concord Hospital, Sydney, NSW 2139, Australia; ⁵3rd Department of Neurology, “G.Papanikolaou” Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; ⁶Department of Clinical Neurophysiology, School of Medicine, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background and aims: Amyotrophic lateral sclerosis (ALS) may be associated with selective vulnerability of specific muscle groups, described as split phenomena. This study aimed to systematically evaluate the split elbow (SE) phenomenon—defined as disproportionate involvement of biceps versus triceps muscles—as a potential clinical and neurophysiological characteristic of ALS.

Methods: This systematic review and meta-analysis followed PRISMA guidelines and was registered in PROSPERO (CRD42024528359). MEDLINE, Scopus, Web of Science, and grey literature were searched up to April 2025 using the terms “split elbow” and “amyotrophic lateral sclerosis.” Eligible English-language studies included randomized, observational, diagnostic accuracy, and case–control designs. Study quality was assessed using the Joanna Briggs Institute critical appraisal tools. Random-effects models were used to pool standardized mean differences of normalized Medical Research Council (MRC) strength scores. The diagnostic performance of the split elbow index based on compound muscle action potentials (SEI-CMAP) was analyzed using a bivariate random-effects model.

Results: Seven studies involving 1,941 patients with ALS (61.8% male) were included. There was no significant difference in strength between elbow extensors and flexors (pooled standardized mean difference [triceps–biceps] -0.17 ; 95% CI -1.03 to 0.69 ; $p=0.63$), with substantial heterogeneity across studies

($I^2=97.1\%$). The SEI-CMAP showed moderate accuracy in distinguishing ALS from controls, with pooled sensitivity of 0.79 , specificity of 0.58 , and an area under the curve of 0.66 .

Conclusion: Current evidence does not support a consistent split elbow pattern in ALS. High methodological heterogeneity and limited sample sizes reduce the clinical relevance of this phenomenon, suggesting limited diagnostic utility in routine practice.

Disclosure: Nothing to disclose.

EPO-0117 | Diagnostic ultrasound pattern of fasciculations in amyotrophic lateral sclerosis

G. Zabrodzets; Y. Rushkevich
Republican Scientific and Practical Center of Neurology and Neurosurgery, Minsk, Belarus

Background and aims: Muscle ultrasound (MUS) is an effective technique for non invasive fasciculation detection. This study aimed to characterize the fasciculation distribution pattern in amyotrophic lateral sclerosis (ALS) compared to ALS mimicking disorders.

Methods: This prospective study included 182 patients with suspected ALS: 149 ALS patients (median age 57.0 years, ALSFRS R 42) and 33 served as controls (median age 49.0 years), spondylotic myelopathy ($n=17$), radiculopathy ($n=8$), spinal muscular atrophy ($n=5$) and multifocal motor neuropathy ($n=3$). All participants underwent standardized symmetric MUS of 14 muscle groups across bulbar, cervical, thoracic and lumbosacral levels.

Results: Fasciculations were significantly more frequent in the ALS group ($p<0.001$) and were generalized and symmetric with no significant side-to-side differences ($p>0.05$). Detection rates ranged from 59.7% to 94.0%, with the highest frequencies in proximal muscles: m. biceps brachii (91.9%), posterior forearm muscle group (89.0%) and m. quadriceps femoris (92.6%). Controls showed less frequent, distally predominant fasciculations (thenar muscles 30.3–39.4%; posterior calf muscles 45.5–48.5%). The risk of fasciculation was markedly elevated in ALS: proximal muscles had high odds ratios (OR) without side to side differences (m. deltoideus OR 78–100, m. biceps brachii OR 64–89, posterior forearm group OR 113–114, m. quadriceps femoris OR 70–71), while distal muscles had lower ORs (e.g. thenar OR 11–13). A strong association (Cramer's $V=0.60$ – 0.79) linked ALS with proximal fasciculations.

Conclusion: MUS identifies a distinct proximal predominant fasciculation pattern in ALS that robustly differs from mimicking disorders, supporting its value as an objective screening tool for early differential diagnosis.

Disclosure: Nothing to disclose.

EPO-0118 | Platform-based balance assessment in Parkinson's disease: A summary of tasks and parameters: A systematic review

C. Georgiou; S. Totou; A. Pilavas; G. Vavougiyos; A. Artemiadis; P. Zis; G. Hadjigeorgiou; P. Bargiotas
Neurology Clinic, Movement Disorders Group, Medical School, University of Cyprus, Nicosia, Cyprus

Background and aims: Postural Instability (PI) is one of the cardinal motor symptoms of Parkinson's Disease (PD). Force platforms (FP) can be used as an objective balance assessment tool during both the early and advanced phases of PD. This systematic review aims to identify FP-performed tests for PD balance assessment and summarize the most commonly calculated FP parameters.

Methods: We conducted a systematic review of studies published on Scopus, PubMed, and Embase from inception until September 2025. We screened 3204 articles using Rayyan, out of which 164 matched the inclusion criteria of performing FP-based balance assessment of an idiopathic PD (iPD) group. Following eligibility assessment, 113 eligible studies were included. Study quality was assessed using JBI Critical Appraisal Tools.

Results: A total of 3121 iPD patients were assessed. Static balance was mainly assessed by instructing the patients to maintain a feet apart position under the eyes open (EO) or eyes closed (EC) conditions, while standing on the FP or a compliant surface [Figure 1]. Dynamic balance of PD patients was assessed by a fewer number of studies [Figure 2]. The most frequently calculated FP-derived parameters were the Centre of Pressure (CoP) displacement, velocity, path length and the area encompassing all (total area) or 95% of all CoP points (ellipse) [Figure 3].

Conclusion: Force platforms can prove to be a valuable asset, not only for researchers, but also for clinicians. Further research is required to explore the use of FP for detecting subclinical PI in early PD, monitoring disease progression, and assessing the effectiveness of balance rehabilitation.

Background and aims: Evidence suggests that opicapone use in Parkinson's disease patients with recent-onset wearing-off yields a higher magnitude of effect than that observed in later stages. However, the long-term impact of earlier initiation is not well-studied. This post-hoc analysis assessed long-term outcomes of opicapone early initiation in levodopa-treated Parkinson's patients with early motor fluctuations.

Methods: Data were pooled from randomized, 3.5-month, double-blind, placebo-controlled opicapone trials and their

a) **Body weight and food intake.** The line graph shows body weight (g) on the left y-axis (0-250) and food intake (g chow) on the right y-axis (0-100) over 28 days. Flutamide treatment (25 and 50 mg/kg/day) significantly reduces both body weight and food intake compared to the vehicle group. The bar graph shows the change in body weight (g) and food intake (g chow) for the three groups. Significant differences are indicated by asterisks (*).

Group	Initial Weight (g)	Final Weight (g)	Change in Weight (g)	Initial Food Intake (g)	Final Food Intake (g)	Change in Food Intake (g)
Vehicle	~180	~200	~20	~40	~60	~20
25 mg/kg/day	~180	~190	~10	~30	~40	~10
50 mg/kg/day	~180	~185	~5	~20	~30	~10

b) **Energy expenditure.** The line graph shows energy expenditure (kcal/kg BW) on the left y-axis (0-10) over 28 days. Flutamide treatment (25 and 50 mg/kg/day) significantly reduces energy expenditure compared to the vehicle group. The bar graph shows the change in energy expenditure (kcal/kg BW) for the three groups. Significant differences are indicated by asterisks (*).

Group	Initial EE (kcal/kg BW)	Final EE (kcal/kg BW)	Change in EE (kcal/kg BW)
Vehicle	~4.5	~5.5	~1.0
25 mg/kg/day	~4.5	~4.5	~0.0
50 mg/kg/day	~4.5	~4.5	~0.0

Methods: EPSILON was a randomized, DB, placebo-controlled study followed by a 1-year OLE. Levodopa-treated PD patients without MCs received OPC 50mg or placebo during the DB phase, after which all patients received OPC 50mg. This post-hoc analysis assessed time to MCs, dyskinesia (MDS-UPDRS-IV item 4.1), and OFFs (item 4.3) over 1.5 years in patients initiating

a Progression-free survival (months) for all patients. The y-axis ranges from 0 to 12 months. The x-axis ranges from 0 to 100 months. The 'With anti-VEGF' group (n=100) shows a median PFS of approximately 8 months, while the 'No anti-VEGF' group (n=100) shows a median PFS of approximately 6 months.

b Progression-free survival (months) for patients with MGMT promoter methylation. The y-axis ranges from 0 to 12 months. The x-axis ranges from 0 to 100 months. The 'With anti-VEGF' group (n=50) shows a median PFS of approximately 9 months, while the 'No anti-VEGF' group (n=50) shows a median PFS of approximately 7 months.

c Overall survival (months) for all patients. The y-axis ranges from 0 to 12 months. The x-axis ranges from 0 to 100 months. The 'With anti-VEGF' group (n=100) shows a median OS of approximately 10 months, while the 'No anti-VEGF' group (n=100) shows a median OS of approximately 8 months.

d Overall survival (months) for patients with MGMT promoter methylation. The y-axis ranges from 0 to 12 months. The x-axis ranges from 0 to 100 months. The 'With anti-VEGF' group (n=50) shows a median OS of approximately 11 months, while the 'No anti-VEGF' group (n=50) shows a median OS of approximately 9 months.

75 of 642

OPC early (OPC-OPC) or after placebo (PLC-OPC), stratified by levodopa dose (<400 vs. ≥400 mg/day). Kaplan–Meier survival analyses with log-rank tests were used.

Results: Higher levodopa doses (≥400 mg/day) showed a trend for increased MCs risk, particularly in patients starting OPC later. Proportions of patients without MCs were 81.9% (<400 mg/day) and 79.0% (≥400 mg/day) in the OPC-OPC group, vs. 73.3% (<400 mg/day) and 66.7% (≥400 mg/day) in the PLC-OPC group ($p=0.04$). Dyskinesia followed a similar trend ($p=0.06$). Proportions of patients without OFFs were slightly higher in the OPC-OPC group but independent of levodopa dose ($p=0.4$); dystonia remained low in all groups (Figure 1a–d).

Conclusion: Most patients remained free of MCs with OPC; however, a trend toward higher MC risk was observed in patients on higher levodopa doses who initiated OPC later. Early OPC introduction may support motor stability, even at higher levodopa doses.

Disclosure: Supported by BIAL.

EPO-0121 | Beta and gamma local field potentials as biomarkers of motor and non-motor outcomes in Parkinson's disease: A systematic review

K. Aung¹; S. Lane²; J. Osman-Farah³; A. Macerollo⁴

¹*Institute of Systems, Molecular and Integrative Biology, The University of Liverpool, Liverpool, UK/ The Walton Centre NHS Foundation Trust for Neurology and Neurosurgery, Liverpool, UK;* ²*Institute of Data Health Sciences, The University of Liverpool, UK;* ³*The Walton Centre NHS Foundation Trust for Neurology and Neurosurgery, Liverpool, UK;* ⁴*Institute of Systems, Molecular and Integrative Biology, The University of Liverpool, UK/ The Walton Centre NHS Foundation Trust for Neurology and Neurosurgery, Liverpool, UK*

Background and aims: Deep brain stimulation (DBS) is an established therapy for idiopathic Parkinson's disease (PD). Sensing-enabled DBS systems facilitate the recording of local field potentials (LFPs), which represent synchronised population-level neuronal activity. Beta-band activity, defined as 13 to 30 hertz, strongly correlates with motor symptoms including bradykinesia and rigidity. Gamma-band oscillations of over 30 hertz have been proposed as potential complementary biomarkers. The objective of this study is to evaluate the clinical relevance of beta- and gamma-band LFP biomarkers derived from postoperative recordings in people living with PD.

Methods: Following PRISMA 2020 guidelines, searches of PubMed, Scopus and ClinicalTrials.gov for human studies published between January 2020 and October 2025 investigating sensing-enabled DBS of the subthalamic nucleus or globus pallidus internus were performed. Studies required quantitative beta and/or gamma analyses linked to validated motor or non-motor outcomes. Twenty-seven studies met the inclusion criteria. Significant methodological heterogeneity precluded quantitative meta-analysis; therefore, the analysis will consist of a systematic narrative review mapping methodological patterns. Risk of bias was assessed using the Newcastle-Ottawa Scale and Cochrane risk of bias tools.

Results: Beta burst-derived metrics were associated with motor impairment, supporting their relevance for adaptive DBS control variables. Gamma-related findings were heterogeneous and

most commonly reported in relation to dyskinesia. Non-motor outcomes were sparsely represented.

Conclusion: This review consolidates evidence on robust beta and gamma local field potential biomarkers. Findings will define methodological priorities and inform multi-feature biomarker models for precise and objective adaptive DBS programming.

EPO-0122 | Spontaneous blink dynamics reveal distinct subtypes of isolated REM sleep behaviour disorder

L. Kälble¹; D. Skrabal¹; J. Ruzs²; M. Novotny²

¹*Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic;* ²*Department of Circuit Theory, Faculty of Electrical Engineering, Czech Technical University, Prague, Czech Republic*

Background and aims: While distinct alterations of blinking and eyelid motor control have been described across different alpha-synucleinopathy phenotypes, eyelid motor behavior remains poorly characterized in isolated REM sleep behavior disorder (iRBD), a recognized prodrome of alpha-synucleinopathies. Given that the kinematics of blinking can index the function of cortical-basal ganglia networks, subtle alterations in blink dynamics may emerge prior to phenoconversion. Here, we investigated whether spontaneous blink subtypes can be identified in iRBD and whether their patterns differ from de novo, drug-naïve PD.

Methods: We analyzed single-camera video recordings of freely spoken monologues from 101 polysomnography-confirmed patients with iRBD and 57 patients with PD. Facial landmark tracking was used to extract nine spontaneous blink parameters, capturing: rate, amplitude, duration, opening and closing velocities, palpebral fissure width, and variability. Unsupervised k-means clustering identified iRBD blink subtypes, which we related to clinical markers and compared to the PD cohort.

Results: Two stable blink clusters were identified, comprising a hyperkinetic subtype (68%) and a hypokinetic subtype (32%) with similar demographics, sex distribution, motor severity, and cognitive performance. Blink rate did not differ between subtypes; however, palpebral fissure width, blink duration, and eyelid opening and closing velocities diverged in opposite directions. Clinically, the hypokinetic subtype was associated with higher autonomic dysfunction and stronger differentiation from the PD cohort.

Conclusion: Distinct spontaneous blink subtypes may reflect divergent underlying pathophysiology, potentially specific to synucleinopathy phenotype. Establishing discriminating blink characteristics may aid in identifying meaningful prodromal subgroups, supporting an earlier intervention time, and informing future neuroprotective or disease-modifying interventions.

Disclosure: This study received support from the Ministry of Health of the Czech Republic, grant no. NU23J-04-00042 and the Grant Agency of Charles University, project no. 604425.

Background and aims: Continuous dopaminergic infusion therapies are used in advanced Parkinson's disease (PD) to improve motor fluctuations; however, studies in patients treated with levodopa/carbidopa intestinal gel (LCIG) have reported peripheral neuropathies, including early small-fiber involvement [1,2]. We aimed at evaluating peripheral nerve involvement during continuous subcutaneous foslevodopa infusion (SC foslevodopa) using integrated electrophysiological and morphological evaluations.

Methods: In this prospective observational study, we enrolled PD patients initiating SC foslevodopa who underwent baseline and 6-month follow-up assessments. Large-fiber function was assessed by standard motor and sensory nerve conduction studies. Small-fiber involvement was evaluated by validated questionnaires and distal leg skin biopsy with quantification of intraepidermal nerve fiber density (IENFD).

Results: 21 patients completed baseline and follow-up nerve conduction studies: peripheral neuropathy was present in eight patients, including four sensory and four sensorimotor axonal neuropathies, at baseline. No new cases or progression of neuropathy were observed at follow-up. Skin biopsy data at baseline and 6 months were available in 21 patients. Asymptomatic pathological IENFD was detected in 2 patients at baseline, remaining stable over time, while two additional patients developed pathological IENFD at follow-up.

Conclusion: In this cohort SC foslevodopa was not associated with incident or progressive large-fiber peripheral neuropathy over medium-term follow-up while skin biopsy revealed small-fiber involvement in a subset of patients. Whether this reflects dissociated fiber involvement or disease-related small-fiber denervation remains to be elucidated. Combined electrophysiological and morphological monitoring may improve the detection of early peripheral nerve involvement during infusion therapies.

Disclosure: Nothing to disclose.

Background and aims: This study evaluated the safety and efficacy of staged-bilateral magnetic resonance-guided focused ultrasound (MRgFUS) Pallidothalamic-tractotomy (PTT) in patients with Parkinson's disease (PD) experiencing motor complications. MRgFUS is an incisionless technique that enables targeting of the Pallidothalamic-tract within the subthalamic region, offering a novel alternative for PD management.

Methods: In this prospective, open-label, single-arm, multicenter phase III trial (NCT04728295), 84 participants (≥30 years) were enrolled across nine international centers. Eligible subjects underwent first-side MRgFUS PTT followed, when appropriate, by staged-bilateral treatment after a minimum 6-month interval. The primary endpoint was change in MDS-UPDRS Part III OFF bilateral upper and lower extremities (ULE) 3 months after 2nd side treatment. Secondary measures included MDS-UPDRS Parts III total OFF and total IV scores, with safety assessed through treatment-emergent adverse events. Nonparametric tests were used for statistical analysis.

Results: Fifty-four subjects received unilateral MRgFUS PTT, and 40 underwent staged-bilateral treatment. Following second-side procedures, Part III OFF (ULE) improved by 32.1% [median 33 (IQR 28–40) to 21 (16–27); $p < 0.0001$] (Figure 1), total Part III OFF improved by 34% [median 50 (44–56) to 32 (26–40); $p < 0.0001$] (Figure 2), and Part IV improved by 67% [median 12 (9–13) to 4 (0–5); $p < 0.0001$] (Figure 3). Benefits persisted through 12 months. After unilateral treatment, 30 events occurred in 21 subjects (87% mild; non-severe), 60% resolving within 6 months; after bilateral, 43 events in 22 subjects (70% mild; 2% severe), 40% resolving within 12 months. The most frequent events were imbalance, dysarthria, and fatigue.

Conclusion: MRgFUS PTT significantly improved motor function and complications with a favorable safety profile, supporting its role as an incisionless therapy for advanced PD. The recent FDA approval enables real-world evaluation and larger confirmatory studies. These results may also support additional regulatory approvals; the full manuscript is under review.

EPO-0125 | Mapping the availability of palliative care for parkinsonian syndromes in African countries: A scoping review

N. Kouki¹; L. Ali²; N. kouki¹

¹University of Tunis El Manar, Faculty of Medicine of Tunis, Tunisia; ²University of Camerino, School of Advanced Studies, Macerata, Italy

Background and aims: Neurodegenerative disorders (NDDs) are progressive conditions leading to severe disability. They are

affecting patients and caregivers. Neuro-palliative care (NPC) aims to improve the quality of life of patients by addressing the multidimensional burdens of NDD, and reducing the burden on caregivers. Globally and especially in African countries, access to NPC in NDD is scarce both institutionally and professionally. This study aims to evaluate the availability and integration of NPC in the management of parkinsonian syndromes (PS) across African countries.

Methods: We conducted a scoping review following the Arksey and O'Malley framework, with Levac and JBI enhancements, to evaluate the availability and integration of palliative care in the management of parkinsonian syndromes across African countries. PubMed, Scopus, Web of Science, and Google Scholar were searched. Observational studies and grey literature were included. Two reviewers independently screened studies and extracted predefined data on degree of integration and reported barriers, with disagreements resolved by a third reviewer.

Results: Substantial gaps in the availability and implementation of NPC for PS across Africa were identified. NPC is rarely incorporated into NDD care pathways and remains poorly represented in national neurological policies. Services are limited, unevenly distributed, and primarily focused on oncology. Financial constraints, inadequate infrastructure, and high out-of-pocket costs further restrict access. Cultural beliefs, low awareness, and limited training in NPC significantly contribute to delayed referral and underutilization of palliative services.

Conclusion: NPC for PS in Africa remains critically insufficient. Increasing awareness and strengthening policies in sustainable palliative care models are essential to improve quality of life for affected individuals and their caregivers.

Disclosure: Nothing to disclose.

EPO-0126 | Safety and tolerability of opicapone in elderly Parkinson's disease patients: A single-center, real-life retrospective study

P. Lombardo; L. De Carolis; P. Pacilio; S. Galli; F. Garramone; A. Colucci; M. Giovannelli; D. Rinaldi

Department of Neuroscience, Mental Health and Sensory of Sapienza University of Rome, Sant'Andrea University Hospital, Rome, Italy

Background and aims: Opicapone is a Catechol-O-Methyltransferase inhibitor, used in patients with Parkinson's Disease (PwPD) experiencing motor fluctuations¹. Registrative trials of Opicapone demonstrated its effectiveness and its favorable profile of safety and tolerability. However, these trials primarily enrolled non-elderly patients, who represent a higher percentage of PwPD^{2,3}. Our aim was to assess safety and tolerability of Opicapone in elderly patients in a real-life clinical setting.

Methods: We retrospectively collected data from PwPD treated with Opicapone at our outpatient clinic. Patients were stratified according to age at drug initiation (60–75 vs ≥75 years). Comorbidities, time between fluctuation-onset and drug start, clinical assessments, including Hoehn and Yahr (H&Y) stage, MDS-UPDRS-III, LEDD, concomitant therapy and adverse events, were evaluated at baseline (T0) and at follow-up (T1; treatment discontinuation or last available visit).

Results: No statistically significant differences were observed between the two age groups regarding disease duration, H&Y stage, or total LEDD at either baseline (T0) or follow-up (T1). Adverse events were more frequent in patients aged ≥75 years (50% vs 19%, $p=0.02$), without significant difference in discontinuation rates. Subgroup analysis revealed that patients who discontinued Opicapone had higher disease severity (H&Y-stage, $p=0.01$; UPDRS-III at T0 and T1, $p=0.02$ and 0.01 , respectively), a lower increase of LEDD at T1 ($p=0.001$) and were more frequently female ($p=0.031$). A tendency towards significance was found for differences in age at visit ($p=0.005$).

Conclusion: These preliminary findings suggest that safety and tolerability were higher in patients with less advanced age and disease severity, with possible gender-related differences. Larger, multicenter prospective studies are warranted.

Disclosure: Nothing to disclose.

EPO-0127 | Family resilience, rights utilizations, dyadic relationship and caregiver care-efficacy in families of persons with Parkinson's disease

S. Freiman; V. Rozani

Gray Faculty of Medical and Health Sciences, The Stanley Steyer School of Health Professions, Department of Nursing Sciences, Tel Aviv University, Tel Aviv, Israel

Background and aims: Parkinson's disease (PD) is a chronic, progressive neurodegenerative disorder that severely affects daily functioning. Globally, an estimated 12–13 million people are currently living with PD, with numbers expected to double by 2050. Consistent with Aging in Place policies, most PDs remain at home, placing increasing physical and emotional demands on family members. Little is known about the factors that help family caregivers cope effectively with these ongoing challenges.

Methods: The study included 168 family caregivers of community-dwelling individuals with PD in Israel. Data were collected online (January–June 2025), and multiple regression analyses examined associations among caregiving efficacy, family resilience, rights utilization, and dyadic relationship.

Results: Caregivers were mostly women (80%), partnered (95%), and retired (58%), with a mean age of 66.7 ± 10.9 years. Care recipients with PD were predominantly men (84%) with a mean age of 72.6 ± 9.7 years. On average, caregivers provided 9.7 ± 7.0 hours of care per day. Caregiving care-efficacy was associated with family resilience ($r=0.68$, $p<0.001$), dyadic relationship ($r=0.35$, $p<0.001$), and emotional rights utilization ($r=0.22$, $p=0.014$). Multivariate analysis showed that caregiver care-efficacy was significantly associated with family resilience ($\beta=0.569$, $p<0.001$). Emotional rights utilization significantly moderated the relationship between family resilience and care-efficacy ($B=1.99$, $p=0.009$), while dyadic relationship did not show a moderating effect. Female caregivers reported higher care-efficacy ($\beta=.154$, $p=0.044$). The overall model explained 50.9% of the variance ($R^2=0.509$, $p<0.001$).

Conclusion: Within the Aging in Place framework, enhancing family resilience, emotional rights utilization, and Caregiver care-efficacy is essential to support family members in providing effective and sustainable home care for individuals with PD.

A. Bonfini Rendina¹; C. Pane¹; F. Saccà²

¹INSRO Department, Federico II University, Naples, Italy;

²GENESIS Department, Federico II University, Naples, Italy

Background and aims: Omaveloxolone is the first approved treatment for Friedreich Ataxia (FA), an autosomal recessive neurodegenerative disorder caused by a trinucleotide GAA expansion in FXN gene encoding frataxin. In FA, reduced frataxin levels and suppression of the Nrf2 pathway lead to oxidative stress, mitochondrial dysfunction, and cellular damage. Omaveloxolone, a synthetic oleanane triterpenoid, pharmacologically activates Nrf2 and enhances antioxidant effects (1). In a phase II trial, Omaveloxolone (150 mg/die) significantly improved neurological function compared to placebo (2). This retrospective study aimed to evaluate the efficacy and safety of Omaveloxolone in FRDA patients treated in clinical practice.

Methods: Patients underwent baseline and follow-up visits after 3 and 6 months. Neurological assessments included modified FA rating scale (mFARS) and FA activities of daily living (FA-ADL) scores. Serum laboratory analyses at baseline and months 1, 2, 3, and 6 included liver enzymes and lipid profile. Clinical scale change in time, and the interaction of factors and time were assessed with a linear mixed model for repeated measures.

Results: Fifty-seven patients (29 female, 28 male; mean age 41.3 ± 13.6 years; disease duration 22.1 ± 10.6 years) were enrolled. Baseline mFARS was 58.6 ± 16.9 , decreasing to 57.5 ± 16.7 after 3 months; 13 patients reached 6 months (59.7 ± 10.6 ; $p = 0.186$). FA-ADL slightly declined from 16.2 ± 7.4 to 15.8 ± 6.8 ($p = 0.547$). Higher baseline mFARS and FA-ADL scores predicted greater improvement ($p < 0.001$). AST/ALT increased by month 3, then decreased ($p < 0.001$). Eleven patients temporarily discontinued therapy; one permanently due to gastrointestinal side effects.

Conclusion: Omaveloxolone was safe and well tolerated, with mFARS and FA-ADL improvements more evident in patients with advanced disease and higher baseline scores.

EPO-0129 | Using of remote smartphone language screening can predict clinical markers in Huntington disease

T. Tykalová; M. Šubert; J. Rusz

Department of Circuit Theory, Faculty of Electrical Engineering, Czech Technical University in Prague, Prague, Czech Republic

Background and aims: Screening symptoms of Huntington's disease (HD) remains limited to infrequent, clinic-based evaluations. We evaluated whether fully automated linguistic analysis of speech tasks recorded via smartphone can remotely capture core clinical markers of HD severity.

Methods: In this cross-sectional multicenter study across Czech and German sites, 53 participants including 30 HD (ranging from 0 to 3 according to Integrated Staging System) and 23 healthy controls completed smartphone-based speech assessment, including spontaneous monologue and fairy tale retelling for 7

consequent days. Recordings were automatically transcribed and analyzed using natural language processing to derive 3 lexical and 3 syntactic features. Predictive models for clinical outcomes based on Unified Huntington's Disease Rating Scale were built using multivariate linear regression with cross-validation.

Results: Language features predicted HD severity across multiple domains with high accuracy, explaining up to 47% of the variance in cognitive performance, 63% in motor impairment, and 59% in functional capacity. Retelling required only 3 days of recordings to reach 90% of maximum predictive accuracy, while monologue required 6 days. Compared to controls, HD participants showed reduced vocabulary range and increase phrase repetition in both tasks ($p < 0.05$), with additional monologue-specific deficits in sentence length and syntactic complexity ($p < 0.05$).

Conclusion: Fully automated analysis of smartphone-based speech assessment can remotely quantify cognitive, motor, and functional impairment in HD, offering a scalable, low-burden digital biomarker for clinical trials and decentralized monitoring.

MS and Related Disorders 1

EPO-0130 | Shedding light on kappa free light chain index in multiple sclerosis: Experience from a Portuguese tertiary centre

A. Roldão Alferes¹; R. Martins²; Â. Maresch²; A. Mendes²;
R. Cunha²; I. Monteiro¹; R. Machado¹; I. Correia¹; C. Cecília Nunes¹; C. Macário¹; S. Batista¹

¹Serviço de Neurologia, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; ²Serviço de Patologia Clínica, Unidade Local de Saúde de Coimbra, Coimbra, Portugal

Background and aims: In the latest McDonald criteria update, Kappa Free Light Chain (k-FLC) index was considered a proper test for the diagnosis of multiple sclerosis (MS) and could be used instead of oligoclonal bands (OCBs) when using a cut-off point of 6.1. This study aims to describe the applications of this biomarker in MS diagnosis and to address potential correlations with disease characteristics.

Methods: We included all patients from our center who had an established diagnosis and underwent k-FLC index quantification from November 2019 to June 2025. Sensitivity and specificity of k-FLC index and OCBs were calculated. Relations with clinical, imaging and laboratory variables were addressed.

Results: Of the 500 patients eligible for analysis, 145 had MS, 10 CIS, 8 NMOSD, 7 MOGAD, 22 SNC infections and 308 other diagnoses. Using the cut-off point of 6.1, k-FLC index had higher sensitivity than OCB (86.45% vs 77.42%) but lower specificity (88.41% vs 92.46%). κ-FLC and OCBs concordance rate was 90.8%. In the univariate analysis, k-FLC index was significantly higher in patients with high MRI lesion load (Median $46.20 \pm \text{IQR } 79.08$ vs 29.82 ± 77.95 ; $p = 0.015$), with active lesions (53.50 ± 68.68 vs 31.55 ± 74.00 ; $p = 0.018$), with infratentorial lesions (44.27 ± 72.52 vs 28.62 ± 80.52 ; $p = 0.045$) and with spinal cord lesions (54.69 ± 96.65 ; $p = 0.020$ vs 32.03 ± 53.65).

Conclusion: k-FLC index may not only be used as an OCBs substitute for MS diagnosis but also as a biomarker for prognosis.

EPO-0131 | Dynamics of ratios T1/T2 for evaluation of multiple sclerosis (MS) activity

A. Buniak¹; A. Mikitchuk²; T. Charnukha¹; O. Pereverzeva¹
¹Neurological Department, Republican Research and clinical center of Neurology and Neurosurgery, Minsk, Belarus; ²Faculty of Radiophysics and Computer Technologies, Belarusian State University, Minsk, Belarus

Background and aims: T1/T2 ratio is a one of the markers, which is related to microstructural integrity for the cases of MS lesions and white matter in general. Lower T1/T2 ratios are named as associated with clinical disability as well as differential impact of neuroinflammation. Note, that T1 and T2 magnetic resonance images (MRI) are divided as a result there in no necessity to convert them into the similar brightness basis.

Methods: MR-data collected for 15 patients with RRMS (2023 – 2025) and 9 – with SPMS (2023 – 2025). T2FLAIR images (256×256×272) are recorded to be reference during the some consequential years as well as T1. T1 images are co-registered and re-sliced with reference (SPM12) to be located in the similar spatial basis (Figure 1). Then, T1[year 1]/T2[year 1], T1[year N]/T2[year 1] are slice-by-slice calculated to be in the same spatial basis. Consequently, temporal differences (calculated for each pair of years) are analyzed. This allows to check differences in T1/T2 ratios qualitatively and quantitatively.

Results: This approach allows to analyze both increasing of MR-density, which corresponds to growth of T1/T2 ratio (fig. 2), and decreasing T1/T2 ratio (fig. 3) Moreover, in accordance with publications, they can be qualified as signs of partial remyelination and neuroinflammation correspondingly.

FIGURE 1 Method of T1/T2 ratio MRI calculation.

FIGURE 2 The analyze of MR-density with growth of T1/T2 ratio.

FIGURE 3 The analyze of MR-density with decreasing of T1/T2 ratio

Conclusion: Increasing of T1/T2 ratio near lesions correspond to clinically confirmed remission in RRMS, decreasing – with progression is SPMS, that correlates well with increasing of neurological symptoms.

Disclosure: Nothing to disclose.

EPO-0132 | Dynamics of statistical properties of tract density as additional confirmation of fulfillment of NEDA for MS patients

A. Buniak¹; A. Mikitchuk²; T. Charnukha¹; O. Pereverzeva¹

¹Neurological Department, Republican Research and clinicfl center of Neurology and Neurosurgery, Minsk, Belarus; ²Faculty of Radiophysics and Computer Technologies, Belarusian State University, Minsk, Belarus

Background and aims: The concept of NEDA (no evidence of disease activity) is widely used to describe multiple sclerosis (MS) patients under treatment. Radiological sustainability is one of the most important factors for this criterion. Due to a set of factors residual white matter microstructural changes can be missed on the magnetic resonance imaging (MRI). This research is dedicated to demonstrate that usage of statistical properties of tract density allows to confirm of fulfillment of NEDA for MS patients.

Methods: MR-data collected for 15 patients with relapsing remitting (RR) MS (2023 – 2025), MRI is performed with GE SIGNA Pioneer (3T, 25 directions of b-value 1000 s/mm²). Tractography is realized by DSI Studio with RK4 method, 10⁸ tracts are calculated. For each slice, calculation of histogram gradients and both entropy and sum of TD are performed (Figure 1)

Results: This approach allows to directly compare histogram of gradients spatial distribution and of statistical properties of TD (entropy and sum). Additionally, histogram difference can be visualized. In the case under study, RRMS with confirmed NEDA is characterized by sustainable histogram gradients (Fig. 2, 3). E.g. average entropy has changed negligibly on ~2.9% (from 0.69 to 0.71 [bit]), as well as sum – on 0.8% (from 2.29 to 2.27

FIGURE 1 Calculation method of histogram gradients, entropy and sum of TD.

FIGURE 2 Histogram gradients in 1 and 2y.

FIGURE 3 Histograms of tract density entropy

[10⁹ tracts/voxel]) (fig. 3). Clinically all patients were stable and EDSS score didn't change.

Conclusion: It is shown that RRMS with confirmed NEDA also demonstrate sustainability of histogram of gradients spatial distribution, histogram difference, average entropy and sum of TD. This can be additional factor to confirm the fulfillment of NEDA

Background and aims: Tolebrutinib is an oral, brain-penetrant and bioactive Bruton's tyrosine kinase inhibitor that reduced the risk of disability accumulation by 31% versus placebo in non-relapsing secondary progressive multiple sclerosis (nrSPMS) and by 29% versus teriflunomide in relapsing multiple sclerosis (RMS) in phase 3 trials. This post-hoc analysis assessed the relationship between on-trial lesion formation and risk of disability accumulation in the phase 3 tolebrutinib trials in nrSPMS and RMS.

Methods: HERCULES (NCT04411641), GEMINI 1 (NCT04410978) and GEMINI 2 (NCT04410991) were phase 3, double-blind trials of tolebrutinib 60 mg once-daily taken with food. In HERCULES, participants with nrSPMS were randomised 2:1 to tolebrutinib or placebo. In GEMINI, participants with RMS were randomised 1:1 to tolebrutinib or teriflunomide (14 mg). We analysed the effect of tolebrutinib on time to onset of 6-month confirmed disability accumulation (CDA) by the presence/absence of on-trial new gadolinium-enhancing (Gd+) lesions and new/enlarging T2 lesions.

Results: In HERCULES, the formation of Gd+ or new/enlarging T2 lesions was associated with an increased risk of 6-month CDA in the placebo group, which was mitigated with tolebrutinib, particularly for participants with new/enlarging T2 lesions (15% risk reduction in those without vs 45% in those with on-trial lesions). In GEMINI, the risk of 6-month CDA was similar irrespective of lesion formation in the teriflunomide group, and all analyses favoured tolebrutinib.

Conclusion: This post-hoc analysis suggests that tolebrutinib decreases the risk of disability accumulation in participants with nrSPMS and RMS in both those who develop focal lesions while receiving treatment and those who do not.

EPO-0134 | Blood protein profiles are associated with brain atrophy in multiple sclerosis

C. Tafrali¹; E. Hofer²; M. Martinez-Serrat¹; M. Haindl²; T. Kaiser¹; R. Demjaha¹; S. Hechenberger³; B. Helmlinger³; D. Pinter³; P. Opriessnig²; B. Heschl²; A. Damulina²; G. Datta⁴; D. Brazel⁴; S. Ropele²; C. Enzinger²; F. Qureshi⁴; M. Khalil¹
¹Neurology Biomarker Research Unit, Department of Neurology, Medical University of Graz, Graz, Austria; ²Department of Neurology, Medical University of Graz, Graz, Austria; ³Research Unit for Neuronal Plasticity and Repair, Medical University of Graz, Austria; ⁴Octave Bioscience, Inc, Menlo Park, USA

Background and aims: Brain atrophy is a key determinant of long-term disability in multiple sclerosis (MS). While MRI-based volumetry provides prognostic information, its limited scalability makes blood-based biomarkers an attractive tool for monitoring neurodegeneration. The MS Disease Activity (MSDA) panel profiles 18 proteins reflecting key pathways, including neuroinflammation, immunomodulation, myelin biology, and neuro-axonal integrity. In this study, we investigate whether serum MSDA scores are predictive of subsequent brain atrophy.

Methods: In this retrospective study, 140 MS patients with paired serum samples and longitudinal 3T MRI (median follow-up 2.1 years, IQR: 1.2–3.2) were analyzed. Patients were stratified into high and low annualized brain volume change groups, matched for age, sex, treatment status, and disease duration ($n=70$; 35 per group). Protein levels were measured on the Olink™ platform. Group differences were assessed using

non-parametric tests and regression models adjusted for age and sex, with Bonferroni correction for multiple testing.

Results: Patients in the high-atrophy group showed greater loss of whole brain, white matter, deep gray matter, and thalamic volumes. All proteomic pathway scores, except for neuroinflammation, were significantly elevated in the high-atrophy group compared low atrophy group. At the individual protein level, serum neurofilament light chain (NfL) was increased and CXCL9 decreased in high-atrophy group. Higher NfL levels predicted greater brain volume loss, and combining with CXCL9 levels improved distinction between high- and low-atrophy patients.

Conclusion: These results demonstrate that distinct serum proteomic profiles are associated with accelerated brain atrophy in MS and support using multi-analyte blood biomarkers alongside MRI for early risk stratification and monitoring of neurodegeneration.

⁸Faculty of Medicine, Beni-Suef University, Beni-Suef, Egypt;
⁹Faculty of Medicine, Minya University, Minya, Egypt

Background and aims: Pediatric multiple sclerosis (MS) is a rare disease but increasingly reported, with higher inflammatory activity and relapses than adult-onset MS. Available treatments include interferon beta-1a, glatiramer acetate (GA), fingolimod, dimethyl fumarate (DMF), and teriflunomide, but comprehensive comparisons of disease-modifying therapies (DMTs) remain limited.

Methods: PubMed, Cochrane CENTRAL, Web of Science, and Scopus were searched for studies published up to December 2025. Outcomes assessed the efficacy of DMTs in pediatric MS, including annualized relapse rate (ARR), MRI lesion activity,

FIGURE 1 Graphical abstract.

FIGURE 2 Net graph.

FIGURE 3 Forest plot ARR.

safety, free relapse rate, and disability progression. All Analyses were conducted using R v4.3.1.

Results: Fifteen studies, including over 11,000 pediatric and young adult MS patients, were analyzed. Rituximab produced the largest ARR reduction (-1.12), followed by GA (-1.02) and natalizumab (-1.01), while ocrelizumab, DMF, and fingolimod also showed significant ARR reductions; interferon beta and teriflunomide were non-significant. At 24 months, the absence of gadolinium-enhancing lesions was most frequent with rituximab (89%), followed by natalizumab (84%) and ocrelizumab (81%). Fingolimod showed higher relapse-free rates than low-dose interferon beta (86% vs 39%) and ocrelizumab (77% vs 52%), and lower disability progression (4.7% vs 14.8%). Teriflunomide reduced disability progression versus placebo (11.9% vs 17.5%). Serious adverse events were more frequent with fingolimod than with low-dose interferon beta (17% vs 7%) but less frequent with DMF (23% vs 29%).

Conclusion: Rituximab was the most effective therapy for reducing relapse rates in pediatric and young MS patients, with additional MRI, relapse-free, and disability benefits observed across agents and variable safety profiles.

Disclosure: The authors declare no conflicts of interest.

Background and aims: A modified Delphi consensus program was conducted to generate evidence-based, practical clinical recommendations (CRs) for healthcare professionals (HCPs) to address gaps in the literature and guidelines relating to reproductive-life planning, pregnancy, and peri- and post-partum management for people with multiple sclerosis (PwMS).

Methods: A multidisciplinary steering committee (SC) of 14 international multiple sclerosis (MS) experts identified 14 key clinical questions across five themes. A total of 14 CRs were drafted, informed by evidence from a systematic literature review and expert insights. The SC and an extended faculty comprising 23 HCPs from 12 countries voted to ascertain expert agreement (≥75% scoring 7–9).

Results: Consensus was reached on all 14 CRs after two rounds of voting, with 13 achieving 90–100% agreement. CRs are provided across five themes: 1) General reproductive-life planning – timing for discussions, key counseling points, and challenges when adjusting treatment; 2) Trying to conceive – factors influencing fertility and MS treatment considerations; 3) Fertility treatments – when to consider them and best practices; 4) Pregnancy – pre-conception and early-pregnancy care, relapse risk, and pregnancy-related complications; and 5) Peri- and post-partum – labor and delivery, relapse risk, MS treatment considerations, and breastfeeding. An overarching CR provides expert guidance on comprehensive reproductive care and effective interdisciplinary coordination.

Conclusion: These recommendations underscore the importance of patient-centered reproductive-life planning for PwMS, providing expert guidance that supports timely counseling, safe management, and informed patient-driven clinical decisions across all reproductive stages.

Disclosure: This work was supported by Merck (CrossRef Funder ID: 10.13039/100009945), who provided funding for the project.

EPO-0137 | Rethinking annual MRI monitoring in ocrelizumab-treated multiple sclerosis patients: A real-world number needed to scan analysis

L. Schoof¹; R. Heijnen¹; L. Hogenboom¹; Z. van Kempen¹; B. van Oosten¹; J. Killestein¹; F. Barkhof²; E. Strijbis¹

¹MS Center Amsterdam, Neurology, Vrije Universiteit Amsterdam, Amsterdam Neuroscience, Amsterdam UMC location VUmc, the Netherlands; ²MS Center Amsterdam, Radiology and Nuclear Medicine, Vrije Universiteit Amsterdam, Amsterdam Neuroscience, Amsterdam UMC location VUmc, the Netherlands & UCL London, Institutes of Neurology and Healthcare Engineering, London, UK

Background and aims: Ocrelizumab is a widely used high-efficacy therapy for multiple sclerosis (MS). Although current guidelines recommend annual MRI-monitoring, the low rate of radiological disease activity during long-term ocrelizumab therapy suggests that this recommendation should be re-evaluated.

Methods: We included ocrelizumab-treated MS patients, both relapsing- and primary progressive-, from the Amsterdam MS Cohort with at least two brain MRI-scans performed during ≥3 months of treatment. Radiological activity and significant radiological activity were defined as either ≥1 or ≥2 CELs on a MRI-scan performed ≥3 months after ocrelizumab initiation or any or ≥3 new/enlarging T2 lesions on a subsequent MRI-scan compared with a scan performed at least ≥3 months after ocrelizumab initiation. The number needed to scan (NNS) was calculated as the inverse of the predicted probability of disease activity.

Results: Among 1,639 MRI-scans in 342 patients, (significant) radiological disease activity was detected in 27 scans in 23 patients (1.8% of scans; 6.8% of patients) over a median treatment duration of 49 months. All three patients in whom MRI findings prompted a treatment switch had clinical symptoms preceding the MRI scan. NNS increased with treatment duration. No new pharmacovigilance findings were identified.

Conclusion: Routine annual MRI-monitoring in asymptomatic patients never led to treatments changes in clinical practice. Increasing NNS over time, especially after two years of treatment, indicates that MRI intervals can be safely extended in stable patients; potentially doubling the interval from year 2 onwards. Radiological monitoring remains essential during early treatment and in clinically symptomatic patients to identify cases requiring treatment re-evaluation.

EPO-0138 | Relapse activity after ponesimod discontinuation in the OPTIMUM long-term extension study

L. Kappos¹; C. Pozzilli²; E. Havrdova³; R. Hohlfeld⁴; R. Fox⁵; M. Freedman⁶; A. Sarfati⁷; M. Heubl⁷; S. de Guitaut⁷; A. Atallah⁷; X. Montalban⁸
¹Neurology and Research Center for Clinical Neuroimmunology and Neuroscience Basel, Clinical Research, Biomedicine and Biomedical Engineering University Hospital and University of Basel, Basel, Switzerland; ²Sant'Andrea Multiple Sclerosis Centre, Sapienza University of Rome, Rome, Italy; ³Department of Neurology, First Medical Faculty, Charles University, Prague, Czech Republic; ⁴Institute of Clinical Neuroimmunology, Ludwig Maximilians University Munich, Munich, Germany; ⁵Cleveland Clinic, Cleveland, Ohio, USA; ⁶University of Ottawa, Department of Medicine, and The Ottawa Hospital Research Institute, Ottawa, Ontario, Canada; ⁷Medical Affairs Department, Juvisé Pharmaceuticals, Paris, France; ⁸Department of Neurology-Neuroimmunology, Multiple Sclerosis Center of Catalonia, Vall d'Hebron University Hospital, Barcelona, Spain

Background and aims: OPTIMUM was a 2-year phase 3 trial comparing ponesimod versus teriflunomide in relapsing multiple sclerosis. In the OPTIMUM Long-Term Extension (LTE), all participants received ponesimod 20 mg for up to 5 additional years. In the core study analysis there were no signals of rebound or reactivation after discontinuation. We assessed whether stopping ponesimod after longer exposure was followed by clinical reactivation.

Methods: This post-hoc analysis included participants who discontinued ponesimod in the OPTIMUM-LTE, which were followed per protocol for 30 to 44 days. Confirmed relapses were counted and annualized relapse rate (ARR) was estimated for the 6 months before discontinuation (on-treatment) and the available post-discontinuation period.

Results: Among 877 participants enrolled in the OPTIMUM long-term extension, 551 discontinued ponesimod and were included (core ponesimod: *n* = 265; core teriflunomide: *n* = 286). Median post-discontinuation follow-up was 38 days (IQR 31 – 48 days). There were 58 relapses during the on-treatment reference period versus 7 relapses post-discontinuation, corresponding to ARR 0.21 versus 0.11, respectively (RR 0.51; 95% CI [0.23 - 1.12]) (Table 1). No post-discontinuation relapse was associated with an Expanded Disability Status Scale (EDSS) increase ≥2 points (Figure 1). Subgroup analyses showed that 423 patients did not receive subsequent therapy within 30 days after discontinuation and had an ARR of 0.12 during this period, compared with 0.18 during the on-treatment period.

Conclusion: In this analysis, ARR and relapse EDSS did not suggest a clinically meaningful reactivation or rebound after ponesimod discontinuation within the available follow-up. Real-world data with longer follow-up are needed to confirm these findings.

Disclosure: L.K. declares no personal compensation. EPO-0139 | Automated analysis of natural speech reveals emotional alterations in multiple sclerosis

P. Mašková¹; M. Šubert¹; M. Novotný¹; T. Tykalová¹; B. Srpová²; L. Friedlová²; D. Horáková²; T. Uher²; J. Rusz¹

¹Czech Technical University in Prague, Faculty of Electrical Engineering, Department of Circuit Theory, Prague, Czech Republic; ²Charles University, First Faculty of Medicine, Department of Neurology and Centre of Clinical Neuroscience, Prague, Czech Republic

Background and aims: Speech conveys emotional states that standard clinical assessments often miss. In multiple sclerosis (MS), affective disturbances are common yet difficult to quantify objectively. This study investigated whether automated language-based emotion analysis can identify affective alterations in MS.

Methods: We analyzed speech from 240 native Czech speakers, including 120 patients with MS and 120 age-, sex-, and education-matched healthy controls. Participants completed two speech tasks: a spontaneous monologue and a story-telling narration. Speech recordings were automatically transcribed using an automatic speech recognition system. Emotional content was quantified using a fine-tuned multilingual BERT (mBERT) model adapted to recognize six emotional states: joy, surprise, love, anger, fear, and sadness.

Results: In spontaneous monologues, patients with MS demonstrated significantly higher levels of anger ($p=0.034$) and lower levels of joy ($p=0.003$) compared to controls (Figure 1). During the story-telling task, MS patients showed reduced joy ($p=0.024$) relative to controls. Anger was the dominant emotion in the MS group, accounting for 31% of the discourse, followed by joy (24%) and sadness (22%). In contrast, healthy controls exhibited joy as the predominant emotion (30%), followed by anger (29%) and sadness (21%). Surprise emotion was not analyzed because it was not detected in any sentence in 82% of participants.

Conclusion: Language-based emotion analysis revealed distinct affective alterations in individuals with MS, most notably reduced joy and increased anger. Fine-tuned large language model enables a fully automated and objective assessment of these changes and may complement and extend conventional clinical evaluations in MS.

FIGURE 1 Between-group differences in individual emotional features. Asterisks indicate statistically significant differences based on independent-samples *t*-tests (* $p < 0.05$, ** $p < 0.01$).

Disclosure: This project was supported by the ERC–CZ program from the Ministry of Education Youth and Sports (project no. LL2504).

EPO-0140 | Diffusion tensor image analysis along the perivascular space in multiple sclerosis: Microstructural influences & considerations for glymphatic function

R. Sharifpour¹; S. Elands¹; A. Rovai¹; X. De Tiege¹; M. Strauss²
¹Laboratoire de neuroanatomie et neuroimagerie translationnelles, ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium; ²Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), CUB Hôpital Érasme, Service de Neurologie, Bruxelles, Belgium

Background and aims: The glymphatic system facilitates waste clearance through perivascular pathways and has been implicated in multiple sclerosis(MS) pathophysiology. Diffusion tensor image analysis along the perivascular space(DTI-ALPS) has been proposed as a noninvasive marker of glymphatic function; however, its specificity in demyelinating disease remains uncertain. This study examined DTI-ALPS in MS and its associations with structural MRI markers and indicators of disease progression.

Methods: Twenty-six MS patients and 28 healthy controls (Table 1) underwent diffusion-weighted imaging. Bilateral DTI-ALPS indices were calculated for all participants. Structural MRI measures included lesion-load(LL), choroid-plexus volume(ChPV), and lateral-ventricle volume(LVV). Clinical measures included Expanded Disability Status Scale (EDSS) and disease duration. Group comparisons were performed (Table 2), and within the MS group, correlations between DTI-ALPS and imaging and clinical measures were assessed.

TABLE 1 Demographics of study participants. Abbreviations: PwMS = Patient with Multiple Sclerosis; HC = Healthy Control; SD = Standard Deviation; IQR = Interquartile Range; EDSS = Expanded Disability Status Scale; *p*-values calculated using *Chi-Squared Te.

	PwMS (n = 26)	HC (n = 28)	P-values
Sex, female, n (%)	18 (73.1)	20 (71.4)	0.89 ⁺
Age in years, mean (SD)	33.9 (9.6)	32.3 (5.5)	0.45 ⁺
Disease duration in years, median (IQR)	4.5 (3.6)	-	-
EDSS, median (IQR)	1.5 (1.0)	-	-

TABLE 2 MR Imaging Characteristics describing mean normalized volumetry results. Abbreviations: PwMS = Patient with Multiple Sclerosis; HC = Healthy Control; SD = Standard Deviation. *p*-values calculated using Independent Samples T-Test.

	PwMS (n = 26)	HC (n = 28)	P-values
T2 lesion volume, mL (SD)	7.79 (16.72)	0.07 (0.10)	<0.001
Lesion load, % (SD)	0.001 (0.001)	0.000 (0.000)	0.00
Total lateral ventricle volume, % (SD)	1.33 (0.55)	1.03 (0.54)	0.03
Choroid plexus volume, % (SD)	0.13 (0.04)	0.10 (0.02)	0.004

Results: DTI-ALPS indices did not differ significantly between MS patients and healthy controls (*p*-FDR > 0.4). Within the MS group, DTI-ALPS was not significantly associated with structural or clinical markers after correction for multiple comparisons (*p*-FDR > 0.76). Importantly, component analysis in patients showed that ALPS indices were strongly associated with diffusion perpendicular to the perivascular axis (the denominator of the ALPS ratio; *p*-FDR < 0.001). In contrast, correlations with diffusion along the perivascular direction (the numerator) were not significant (*p*-FDR > 0.1).

Conclusion: These findings suggest that DTI-ALPS in MS may be influenced by white matter microstructural alterations rather than reflecting perivascular glymphatic function. Caution is therefore warranted when interpreting DTI-ALPS as a marker of glymphatic function, especially in demyelinating disease, and complementary approaches may be required to assess glymphatic pathway involvement.

Disclosure: The authors report no conflicts of interest related to this work.

Muscle and Neuromuscular Junction Disorder 1

EPO-0141 | Steroids tapering among patients with generalized myasthenia gravis (gMG) receiving efgartigimod: Interim results from the STRIVE-gMG chart review

A. Habib¹; N. Silvestri²; C. Qi²; H. Yang³; A. Corse⁴; G. Smith⁵; T. Vu⁶; G. Wolfe⁷; L. Li²; S. Lee³; Y. Wu³; D. Ye³; D. Nowacek²; J. Aldridge²; A. Mahajerin²; G. Philips²; J. Howard⁴
¹University of California, Irvine, Irvine, USA; ²argenx US Inc, Boston, MA, USA; ³Analysis Group, Inc, Boston, USA; ⁴University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, USA; ⁵Virginia Commonwealth University School of Medicine, Richmond, USA; ⁶University of South Florida Morsani College of Medicine, Tampa, USA; ⁷University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, USA

Background and aims: Long-term steroids use among patients with gMG is associated with substantial complications. Efgartigimod, approved in the United States (US) in 2021 for AChR antibody-positive gMG, has demonstrated clinical benefits that may facilitate steroids reduction. This study evaluated real-world patterns of steroids tapering following efgartigimod initiation in the US.

Methods: STRIVE-gMG is a retrospective chart review of patients with gMG who received efgartigimod (≥2 cycles) and concurrent steroids at efgartigimod initiation. Data are collected from neurologists in a specialty panel and from participating medical centers. This interim analysis summarizes initial data from the neurologist panel.

Results: As of November 10, 2025, 41 patient charts from 15 neurologists were analyzed. All patients were AChR antibody-positive. At efgartigimod initiation, patients had a mean age of 48.9 years, mean disease duration of 3.7 years, and mean duration on current steroids of 1.1 years. Most (87.8%) had MGFA class II–III disease. Following efgartigimod initiation, all patients tapered steroids, with mean prednisone-equivalent dose decreasing from 30.4 mg/day at efgartigimod initiation to 8.6,

FIGURE 1 Steroids tapering while on efgartigimod.

4.9, and 4.0 mg/day at months 6, 12, and 18, respectively; 68.3% discontinued steroids entirely, primarily due to stable disease control. At the end of follow-up, 92.7% remained on efgartigimod, with a median treatment duration of 17.1 months. All patients showed improvements in functional limitations and muscle weakness.

Conclusion: In this interim analysis, efgartigimod was associated with profound reductions in steroids dose while maintaining clinical improvement among patients with gMG. Future studies are needed to examine the impacts of steroids reduction on comorbidities and healthcare utilization.

TABLE 2 Efgartigimod treatment response and steroids tapering while on efgartigimod.

	Patients (N=41)
Improvement in functional status, n (%)	
No functional limitations at any time during treatment	7 (17.1%)
Improvement, but some functional limitations remained	34 (82.9%)
Improvement in muscle weakness, n (%)	
No weakness or only some weakness during treatment	32 (78.0%)
Improvement, but moderate to severe muscle weakness remained	9 (22.0%)

Background and aims: Efgartigimod is a human immunoglobulin G1 (IgG1) Fc fragment that blocks the neonatal Fc receptor. ADAPT-SC+ (NCT04818671) was an open-label extension study evaluating long-term safety and efficacy of subcutaneous (SC) efgartigimod PH20 (coformulated with recombinant human hyaluronidase PH20) in participants with generalized myasthenia gravis (gMG).

Methods: Efgartigimod PH20 SC 1000 mg was administered in cycles of 4 once-weekly injections. Subsequent cycles were

initiated based on clinical evaluation (Year 1, ≥ 4 weeks between cycles; Year 2 and onward, ≥ 1 week between cycles following protocol amendment). Efficacy was assessed using Myasthenia Gravis Activities of Daily Living (MG-ADL). Quality of life (QoL) impact was assessed during Year 1 using Myasthenia Gravis Quality of Life 15-Item Questionnaire, Revised (MG-QoL15r).

Results: During ADAPT-SC+, 180 participants received ≥ 1 efgartigimod PH20 SC injection (mean [SD] study duration, 2.6 [0.9] years; 459.4 participant years of follow-up). Adverse events were predominantly mild/moderate (Table 1). After Year 1, efgartigimod remained well tolerated in both participants who averaged <4 weeks and ≥ 4 weeks between treatment cycles. Among anti-acetylcholine receptor antibody-positive (AChR-Ab+) participants, mean MG-ADL improvements were sustained from Week 1 through Week 163 (Figure 1). Most AChR-Ab+ participants (59.2%) achieved minimal symptom expression (MSE; MG-ADL score, 0–1) at least once, and 88.1% of those with MSE at least once sustained MSE during ≥ 4 weeks. Mean MG-QoL15r improvements were observed by Week 1 and sustained through Week 55 (Figure 2).

Conclusion: Long-term efgartigimod PH20 SC treatment was well tolerated and led to sustained efficacy and QoL improvements during ADAPT-SC+.

Disclosure: This study was sponsored by argenx. W-YH, RHJ, FMV, and LL are employees of argenx. CA, RB-S, JLDB, AM, KU, DK, AK-P, JJGMV, TV, HW, and JFH have reported financial/nonfinancial relationships with argenx at the time of submission.

TABLE 1 Summary of TEAEs: Overall Population.

	Efgartigimod PH20 SC (N=180; PYFU=459.4)	
	ER ^a	n (%)
Any TEAE	7.2	169 (93.9)
Any TEAE grade ≥ 3	0.3	62 (34.4)
Any serious TEAE	0.2	55 (30.6)
Fatal event ^b	<0.1	5 (2.8)
Discontinued study treatment due to TEAEs ^c	<0.1	8 (4.4)
Any injection site reaction ^d	2.6	63 (46.1)
Most commonly observed TEAEs ^e		
COVID-19	0.1	53 (29.4)
Headache	0.4	46 (25.7)
Nasopharyngitis	0.1	38 (20.0)
Diarrhea	0.1	32 (17.8)
Upper respiratory tract infection	0.2	32 (17.8)
Myasthenia gravis worsening	0.1	25 (13.9)
Back pain	0.1	22 (12.2)
Anemia	0.1	19 (10.6)

^aEvent rate (ER) was calculated as number of events per participant year of follow-up (PYFU). ^bFatal events (metastatic renal cell cancer, cardiac arrest, respiratory failure [$n=2$], and COVID-19/respiratory failure) were not related to efgartigimod PH20 SC treatment, as determined by investigators. ^cTreatment discontinuations were due to metastatic renal cell cancer (Cycle 1, fatal), cardiac arrest (Cycle 2, fatal), pulmonary mass (Cycle 3), COVID-19/respiratory failure (Cycle 3, fatal), and MG crisis (Cycle 1), thymoma (Cycle 4), metastatic renal cancer (Cycle 21 [Amended Cycle 6]), and Bouveret's disease (Cycle 16 [Amended Cycle 5]). Among injection site reactions, the most frequently reported were arthralgia (57.8%), edema (20.0%), and swelling (7.8%). ^dMost frequent TEAEs occurring in $>10\%$ of participants in the overall population: ER, event rate; MG, myasthenia gravis; PYFU, participant year(s) of follow-up; SC, subcutaneous; TEAE, treatment-emergent adverse event.

FIGURE 1 Mean Change from Baseline in MG-ADL Total Score Over Time: AChR-Ab+ Population.

FIGURE 2 Mean Change from Baseline in MG-QoL15r Score Over Time: AChR-Ab+ Population.

safety of efgartigimod in gMG, ITP, and CIDP, administered via varying dosing regimens.

Methods: Data were pooled per disease from global clinical trials investigating varying efgartigimod dosing regimens and administration routes (intravenous 10 mg/kg; subcutaneous 1000 mg PH20 [coformulated with recombinant human hyaluronidase PH20]). Event rates (ER) were reported per participant year of follow-up (PYFU).

Results: The analysis includes data from at least 874 patients representing ~1350 PYFU. Treatment-emergent adverse events (TEAE) were mostly mild-to-moderate in severity. During controlled trials, severe infection ERs were comparable between placebo- and efgartigimod-treated participants. Reported TEAE-related treatment discontinuation rates were consistently low. Rates of discontinuation and severe and serious TEAEs did not increase with additional treatment cycles (gMG) or prolonged exposure to weekly administration (ITP, CIDP). Further analyses of participant population subgroups are ongoing. No albumin reduction or increases in low-density lipoprotein cholesterol levels were reported in efgartigimod-treated participants. No vaccinations, laboratory value monitoring, or pretreatment medications are required to receive efgartigimod. Efgartigimod was consistently well tolerated across trials in autoimmune diseases, including those with subcutaneous administration of efgartigimod.

Conclusion: Efgartigimod was well tolerated and demonstrated a similar safety profile regardless of disease state, dosing regimen, and length of exposure.

Background and aims: Generalized Myasthenia gravis (gMG) is a rare chronic autoimmune disease affecting the postsynaptic membrane of the neuromuscular junction. New treatment options, such as the C5 inhibitors, are growing with promising results. In this study we investigated the real-world use of Zilucoplan for AChR-positive gMG in Italy.

Methods: Zilucoplan was self-administered by daily subcutaneous injections. Efficacy was assessed by Myasthenia Gravis Foundation of America Post-intervention status (MGFA-PIS), Myasthenia Gravis Activity of Daily Living (MG-ADL), Myasthenia Gravis Composite (MGC), Myasthenia Gravis quantitative (QMG) scales and 15-items Myasthenia Gravis Quality of Life (MG-QOL-15) questionnaire at baseline and after 1, 4, 12, 24 and 48 weeks.

Results: 54 patients (37 females, aged 57.3 years) were included in the follow-up analysis. Clinical improvements observed in the initial study were sustained over time, with stable or further reduced MG-ADL, QMG, MGC and MG-QOL-15r scored over weeks. Moreover, it was also observed a continued steroid-sparing effect and a reduction of hospitalization due to MG worsening. Treatment adherence remained high, and no new safety report emerged during the extended follow-up.

Conclusion: Zilucoplan has proven to be well-tolerated and effective in most patients with AChR-positive gMG. A clinical meaningful effect was reported since the first week and was sustained during the following weeks. Further studies are needed to confirm these preliminary real-life data.

Disclosure: Nothing to disclose.

EPO-0146 | Quality of gravis patients achieving sustained versus transient clinical outcomes in the phase 3 vivacity-MG3 trial

J. Vissing¹; C. Antozzi²; K. Gwathmey³; K. Gandhi⁴; I. Turkoz⁵; S. Pease⁶; N. Campbell⁴

¹University of Copenhagen, Copenhagen, Denmark; ²IRCCS Carlo Besta Neurological Institute Foundation, Milan, Italy;

³Virginia Commonwealth University, Richmond, USA; ⁴Johnson & Johnson, Horsham, USA; ⁵Johnson & Johnson, Titusville, USA; ⁶Johnson & Johnson, Raritan, USA

Background and aims: Minimal clinically important improvement in the Myasthenia-Gravis-Activities-of-Daily-Living (MG-ADL) score (MCI; ≥ 2 -point improvement) or a composite response (CR) of ≥ 2 -point improvement in MG-ADL and ≥ 3 -point improvement in Quantitative-Myasthenia-Gravis scores are plausible treatment goals in generalized myasthenia gravis (gMG). This Vivacity-MG3 posthoc analysis evaluated health-related quality of life (HRQoL) in patients achieving sustained versus transient MCI or CR.

Methods: Nipocalimab- and placebo-treated participants were stratified by MCI or CR status over the 24-week double-blind phase: never achieved MCI/CR (No-MCI/CR), achieved MCI/CR sustained ≥ 8 weeks (sustained-MCI/CR), or achieved MCI/CR ≥ 1 time but not sustained for ≥ 8 weeks (transient-MCI/CR). Mean changes from baseline (CFB) to week 24 (W24) in MGQoL-15r and Neuro-QoL Fatigue scores were compared across groups using ANCOVA models.

Results: The MCI analysis included 129 patients (91 sustained-MCI, 29 transient-MCI, 9 no-MCI) and the CR analysis included 125 patients (50 sustained-CR, 37 transient-CR, 38 no-CR). Sustained- versus transient-MCI patients demonstrated greater improvements in MGQoL-15r (least-square-mean CFB, -6.2 versus -2.0 , $p < 0.001$). Additionally, the sustained-MCI group had greater improvements in Neuro-QoL Fatigue (-19.5) versus transient-MCI (-7.5 , $p < 0.001$) and No-MCI (-8.5 , $p = 0.04$). Similarly, sustained-CR patients demonstrated greater improvements in MGQoL-15r (-9.6) versus transient-CR (-5.4 , $p < 0.001$) and No-CR (-3.6 , $p < 0.001$) and those with sustained-CR had greater improvements in Neuro-QoL Fatigue (-29.2) versus transient-CR (-16.4 , $p < 0.001$) and No-CR (-12.2 , $p < 0.001$).

Conclusion: Patients achieving sustained versus transient MCI or CR demonstrated greater improvements in HRQoL and fatigue, suggesting 8-week sustained outcomes may be more

impactful treatment goals than short-term transient response for gMG patients receiving advanced treatments.

EPO-0147 | Myasthenia gravis Inebilizumab trial: 26-week randomised-placebo controlled and 26-week open-label results in anti-muscle-specific kinase subgroup

J. Vissing¹; M. Leite²; J. Howard, Jr.³; M. Benatar⁴; E. Ciafaloni⁵; K. Utsugisawa⁶; S. Bray⁷; A. Bhambri⁸; A. Kiran Kanchi⁸; S. Cheng⁸; R. Nowak⁹

¹University of Copenhagen, Copenhagen, Denmark; ²University of Oxford, Oxford, UK; ³University of North Carolina, Chapel Hill, USA; ⁴University of Miami Miller School of Medicine, Miami, USA; ⁵University of Rochester, Rochester, USA; ⁶Hanamaki General Hospital, Hanamaki, Japan; ⁷Amgen Ltd, Cambridge, UK; ⁸Amgen Inc, Thousand Oaks, USA; ⁹Yale University, New Haven, USA

Background and aims: Generalised myasthenia gravis (gMG) is caused by anti-muscle-specific kinase (MuSK+) and anti-acetylcholine receptor (AChR+) antibodies targeting corresponding proteins in the synapse. The placebo (PBO)-controlled MG Inebilizumab (INEB) Trial (MINT) assessed INEB, a monoclonal antibody targeting CD19+ B cells, in patients with MuSK+ or AChR+ gMG. INEB vs PBO yielded significantly greater improvements in MG Activities of Daily Living (MG-ADL) and Quantitative MG (QMG) scores at week 26 in MINT. Here we report key outcomes for the MuSK+ subpopulation from the first 26 weeks of the open-label period (OLP).

Methods: Participants with MuSK+ gMG in MINT (NCT04524273) were randomised 1:1 to 300 mg intravenous INEB or PBO for 26 weeks. Participants underwent a protocol-specified steroid taper (≤ 5 mg/day by week 24). After the randomised, controlled period (RCP), participants could receive INEB in the OLP. This pre-specified, interim, descriptive analysis included participants who received any dose of INEB during MINT. No statistical testing was done.

Results: Overall, 48 participants with MuSK+ were enrolled and randomised: 46 entered the OLP and 44 completed 26 weeks. Baseline MG-ADL and QMG scores were similar between groups, and mean scores decreased from baseline to week 26 during the RCP (INEB -4.1 , -5.0 ; PBO -3.1 , -4.2 , respectively). During the initial 26-week OLP (week 52), the mean MG-ADL and QMG scores continued to decrease from baseline (INEB/INEB: -5.6 , -6.1 ; PBO/INEB: -5.1 , -7.4 , respectively; Figures 1–2; Table 1).

Conclusion: In this descriptive analysis, INEB demonstrated ongoing improvement in MG-ADL and QMG scores compared to baseline irrespective of initial randomisation.

Disclosure: JV has been a consultant for and/or received speaker honoraria from Alexion Pharmaceuticals, Amgen Inc, argenx, Dianthus Therapeutics, Johnson & Johnson, NMD Pharma, Novartis, Regeneron Pharmaceuticals, Roche, Toleranzia AB, and UCB. EPO-0148 | Multiple responder analyses with claspribart, an active C1s inhibitor, in patients with generalized myasthenia gravis

M. Dimachkie¹; F. Sacca²; M. Ait-Tihyaty³; C. Briggs³; U. Siddiqui³; L. Hickey³; M. Lalla³; M. Smilowski⁴
¹University of Kansas Medical Center, Kansas City, USA;
²Azienda Ospedaliera Universitaria (AOU) Federico II, Naples, Italy; ³Dianthus Therapeutics, New York, USA; ⁴Neurologia Śląska Centrum Medyczne, Katowice, Poland

Background and aims: The classical complement pathway plays a significant role in acetylcholine receptor-positive (AChR+) generalized myasthenia gravis (gMG) pathology. Claseprubart is an investigational, clinical-stage, potent monoclonal antibody engineered to selectively target the classical complement pathway, by selectively inhibiting activated C1s protein. The clinical benefit of claseprubart in gMG may be best supported by improvement across multiple validated scales to capture multi-dimensional improvement beyond single-scale analyses.

Methods: AChR+ gMG patients treated with 300 mg claseprubart subcutaneously once every 2 weeks in the MaGic study (NCT06282159) – a global Phase 2, randomized, double-blind, placebo-controlled trial – were analyzed for responses based on multiple assessments compared to placebo. *p*-values are one-sided, with nominal significance assessed at an alpha of 0.1. A responder was defined as achieving an improvement in MG-ADL ≥ 3 and QMG ≥ 4 . Endpoints include proportion of dual MG-ADL and QMG responders at Week 13, time to response, and proportion of responders sustaining response for at least 6 weeks.

Results: 63% of claseprubart patients had dual response improvement in MG-ADL ≥ 3 and QMG ≥ 4 , versus 14% for placebo (OR 29.00; *p* = 0.0006). Dual responders were seen as early as Week 1. The median time to response was Week 3. All claseprubart patients with dual response at Week 13 had maintained response for at least 6 weeks.

Conclusion: Claseprubart-treated patients were more likely to achieve multi-dimensional response than placebo. Responses emerged early and were sustained, confirming rapid, robust, and durable benefit from claseprubart across functional and quantitative measures from both patient and clinician perspectives.

EPO-0149 | Treatment response in anti-HMGCR and anti-SRP immune-mediated necrotizing myopathy: Impact of demographic and racioethnic factors

M. Seyam¹; N. Gonzalez Caldito²; J. Greenberg³; N. Goyal²; T. Mozaffar²; N. Goyal³; L. Chaiteipaseut⁴; C. Spahn⁴; S. Muppidi³

¹Graduate School of Life Sciences, Utrecht University, Netherlands & Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, USA;

²Department of Neurology, University of California, Irvine, USA;

³Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, USA; ⁴Department of Pharmacy, Stanford Health Care, Stanford, USA

Background and aims: Immune-mediated necrotizing myopathy (IMNM) associated with anti-HMGCR and anti-SRP autoantibodies is a rare autoimmune neuromuscular condition characterized by significant phenotypic heterogeneity. Despite varying clinical presentations, the impact of demographic and racioethnic factors on treatment response remains poorly characterized.

Methods: This multi-center retrospective study analyzed 56 patients with IMNM (48 anti-HMGCR, 8 anti-SRP). We assessed demographics, racioethnicity, number of immune therapies, and therapy escalations (defined as addition of therapy or increase in dose/frequency). Statistical analysis included Mann-Whitney U, Kruskal-Wallis, and Fisher's Exact tests. Significance was set at *p* < 0.05.

Results: The cohort (mean age 59.8 years, 54.6% female, 82.1% statin-exposed) predominantly included anti-HMGCR patients (85.7%). Anti-HMGCR patients were significantly older (mean 62.3 vs. 44.8 years, *p* = 0.003) with higher statin exposure (91.7% vs. 25.0%, *p* < 0.001) than anti-SRP patients. Mean time to diagnosis (12.3 months) was similar between groups. Peak CK levels varied significantly across racioethnic groups in the overall cohort, with the highest levels observed in Black (11,978 U/L) and Asian (10,332 U/L) patients compared to Hispanic (9,156 U/L) and White (6,751 U/L) patients. Younger patients (<59.8 years) required significantly more immune therapies (mean 3.4 vs. 2.8, *p* = 0.044) and treatment escalations (2.8 vs. 1.2, *p* = 0.025). Hispanic patients required significantly higher treatment escalations, nearly three times more than White patients (mean 2.9 vs. 0.9, *p* = 0.026). Subgroup analysis confirmed similar significant trends within the anti-HMGCR cohort.

Conclusion: Demographic and racioethnic factors significantly influence IMNM disease severity and treatment intensity. This study underscores the need for larger studies to validate these findings and guide personalized therapeutic strategies.

Disclosure: Nothing to disclose.

EPO-0150 | Efficacy of long-term zilucoplan treatment in subgroups of patients with generalised myasthenia gravis: A 120-week analysis of RAISE-XT

N. Savic¹; M. Freimer²; C. Hewamadduma³; M. Leite⁴; A. Maniaol⁵; K. Utsugisawa⁶; M. Weiss⁷; B. Boroojerdi⁸; P. Mahoney⁹; J. Howard¹⁰

¹UCB, Bulle, Switzerland; ²Department of Neurology, The Ohio State University Wexner Medical Center, Columbus, USA;

³Academic Neuromuscular Unit, Sheffield Teaching Hospitals NHS Foundation Trust & Sheffield Institute for Translational Neuroscience (SITraN), University of Sheffield, Sheffield, UK;

⁴Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK; ⁵Department of Neurology, Oslo University Hospital, Oslo, Norway; ⁶Department of Neurology, Hanamaki General Hospital, Hanamaki, Japan; ⁷Department of Neurology, University of Washington Medical Center, Seattle, USA; ⁸UCB, Monheim, Germany; ⁹UCB, Slough, UK; ¹⁰Department of Neurology, The University of North Carolina at Chapel Hill, Chapel Hill, USA

Background and aims: Clinically meaningful improvements in myasthenia gravis (MG)-specific outcomes were observed with zilucoplan treatment up to Week 120 in patients with

generalised MG (gMG) in the Phase 3, ongoing, open-label extension study, RAISE-XT (NCT04225871). Here, we evaluate the efficacy of long-term zilucoplan treatment in patients with gMG, stratified by specific disease characteristics.

Methods: Adults with anti-acetylcholine receptor antibody-positive gMG who completed a qualifying double-blind, placebo-controlled study (NCT03315130 or NCT04115293 [RAISE]) could enter RAISE-XT and self-administer once-daily subcutaneous zilucoplan 0.3 mg/kg injections. Change from baseline (CFB) to Week 120 in MG-specific outcome measure scores was assessed (data cut-off: 11 November 2023). Subgroups were prespecified according to the following baseline characteristics: age <65 or ≥65 years, MG Activities of Daily Living (MG-ADL) score ≤9 or ≥10, and disease duration <5.2 or ≥5.2 years.

Results: Overall, 200 patients enrolled. At Week 120, mean (standard error) CFB in MG-ADL scores across all subgroups were: age: <65 years, $n=64$: -7.3 (0.5) and ≥65 years, $n=22$: -6.7 (0.8); MG-ADL: ≤9, $n=68$: -7.0 (0.4) and ≥10, $n=18$: -7.6 (1.4); and disease duration: <5.2 years, $n=42$: -6.7 (0.7) and ≥5.2 years, $n=44$: -7.5 (0.6). Improvements were also observed at Week 120 for Quantitative MG, MG Quality of Life 15-item revised, and Quality of Life in Neurological Disorders Short Form Fatigue scores. Treatment-emergent adverse events occurred in 97.0% ($n/N=194/200$) of patients; most were mild or moderate and unrelated to the study drug.

Conclusion: Long-term zilucoplan treatment demonstrated consistent improvements in MG-specific outcomes up to Week 120, irrespective of disease severity, duration or patient age.

Disclosure: This study was funded by UCB. Natasa Savic, Babak Borojerdi and Paul Mahoney are employees and shareholders of UCB. Full disclosure of all industry relationships will be made during congress presentation if accepted.

EPO-0151 | Health-related quality of life in patients with generalised myasthenia gravis receiving gefurulumab in the PREVAIL trial

T. Ruck¹; F. Saccà²; T. Vu³; S. Rakhade⁴; A. Racine⁴; S. Pandeya⁴; A. Lizarraga⁵

¹Department of Neurology, Ruhr University Bochum, BG University Hospital Bergmannsheil, Bochum, Germany; ²NSRO Department, University of Naples Federico II, Napoli, Italy;

³Department of Neurology and Neuromuscular Medicine, University of South Florida Morsani College of Medicine, Tampa, USA; ⁴Alexion, AstraZeneca Rare Disease, Boston, MA, USA;

⁵Department of Neurology, University of Rochester, Rochester, USA

Background and aims: Gefurulumab is a novel dual-binding nanobody complement component 5 inhibitor. Efficacy and safety of gefurulumab in adults with anti-acetylcholine receptor antibody-positive (AChR-Ab+) generalised myasthenia gravis (gMG) were demonstrated in PREVAIL, a phase 3, randomised, placebo-controlled trial (NCT05556096). To provide a holistic view of the treatment effect, we present health-related (HR) quality of life (QoL) outcomes.

Methods: Patients with AChR-Ab+ gMG were randomised to receive weekly subcutaneous self-injection of gefurulumab or placebo. Exploratory endpoints assessed HRQoL changes from baseline through wk26 (randomised period completion) using: MG-QOL 15-Item Questionnaire-Revised (MG-QOL15r); QoL in

Neurological Disorders (Neuro-QoL) Fatigue Scale; EuroQol-5 Dimensions-5-Level (EQ-5D-5L) Visual Analogue Scale (VAS) and Health State Index (HSI).

Results: Overall, 260 patients (female, 60.4%; mean ± SD age, 52.8 ± 15.7 yrs; mean ± SD baseline MG-ADL total score, 9.0 ± 2.2) were randomised to gefurulumab ($n=131$) or placebo ($n=129$). Significantly greater improvements were observed with gefurulumab compared with placebo, starting at wk4 in MG-QOL15r and Neuro-QoL Fatigue and wk8 in EQ-5D-5L. These improvements were sustained throughout the randomised period. At wk26, the least squares mean (95% CI) changes from baseline among patients with available data receiving gefurulumab ($n=123$) vs placebo ($n=117$) were -4.9 ($-6.0, -3.8$) vs -2.3 ($-3.2, -1.4$) ($p=0.0005$) in MG-QOL15r; -4.8 ($-6.2, -3.4$) vs -2.5 ($-3.8, -1.1$) ($p=0.0164$) in Neuro-QoL Fatigue; 9.2 (6.2, 12.1) vs 4.6 (1.6, 7.6) ($p=0.0349$) in EQ-5D-5L VAS; 0.12 (0.076, 0.155) vs 0.04 ($-0.004, 0.079$) ($p=0.0088$) in EQ-5D-5L HSI.

Conclusion: In PREVAIL, patients with AChR-Ab+ gMG receiving gefurulumab had significant improvements in HRQoL compared with those receiving placebo, demonstrated by MG-specific and general HRQoL measures.

Disclosure: TR reports grants from the German Ministry of Education, Science, Research, and Technology; grants and personal fees from Alexion, AstraZeneca Rare Disease, argenx, Johnson & Johnson, Roche, Sanofi, and UCB; personal fees from Amgen, Merck, Novartis, and Roche outside of the submitted work. EPO-0153 | Compound POMGNT1 variants associated with muscle-eye-brain disease: Necessity of comprehensive genetic testing

A. Frontistis¹; V. Poulidou¹; E. Pityrigkas¹; S. Kalampokini¹; E. Liouta¹; G. Pepe²; M. Spilioti¹; V. Kimiskidis¹

¹First Department of Neurology, AHEPA University Hospital, Aristotle University of Thessaloniki, Greece; ²Genekor Medical S.A, Athens, Greece

Background and aims: Congenital muscular dystrophies (CMD) are a heterogeneous group of rare autosomal recessive myopathies. Subtypes like dystroglycanopathies, collagen VI-related dystrophies, and dystroglycan–sarcoglycan complex disorders pose significant diagnostic challenges due to overlapping ocular and neurological involvement.

Methods: We report a 32-year-old male patient presenting in a comatose and febrile state following status epilepticus. Neurological examination revealed spastic paraparesis with bilateral clonus and knee contractures, right-arm hypotonia, and horizontal nystagmus. His history included global neurodevelopmental delay with subsequent loss of ambulation and speech, drug-resistant epilepsy, and ophthalmological abnormalities including bilateral optic atrophy, severe refractive error, and cataract.

Results: Brain imaging demonstrated ventriculomegaly, lissencephaly and brainstem and cerebellum hypoplasia (Figure 1). Electroencephalography confirmed refractory epileptic encephalopathy, which ultimately responded to a four-drug antiepileptic regimen (valproate sodium, brivaracetam, zonisamide, lacosamide). Muscle biopsy revealed myopathic changes with reduced α -dystroglycan, laminin $\alpha 2$, and laminin $\beta 2$ expression on immunohistochemistry. Next-Generation-Sequencing identified compound heterozygosity in POMGNT1, comprising a nonsense variant (c.1282C>T, p.Gln428*) and a missense variant (c.793C>T, p.Arg265Cys) (Figure 2). The missense variant is predicted to preserve partial enzymatic activity and likely contributes to the patient's phenotype.

Conclusion: Combined genetic and histopathological results were consistent with Muscle-Eye-Brain disease (MEB), a dystroglycanopathy within the CMD spectrum. Over one-third of MEB patients have epilepsy, approximately 20% of which suffer from refractory seizures. This case illustrates how compound heterozygosity with residual POMGNT1 activity permits prolonged survival, while predisposing to severe adult-onset neurological

FIGURE 1 T1-weighted MRI imaging of the brain showing brainstem and cerebellar hypoplasia, ventricular enlargement and lissencephaly predominantly involving the frontal lobes (red arrows).

EPO-0154 | Diagnostic clues: A multidisciplinary review of 600 cases with suspected inherited white matter disorder

C. Wade¹; D. Lynch²

¹Department of Neuroinflammation, UCL Queen Square Institute of Neurology, London, UCL Queen Square Institute of Neurology, London, UK; ²National Institute for Health Research, University College London Hospitals, Biomedical Research Centre, London, UK

Background and aims: Adult patients with suspected inherited white matter disorders (IWMDs) present diagnostic challenges due to phenotypic overlap with acquired inflammatory, vascular, and toxic leukoencephalopathies. Delayed or incorrect classification may result in inappropriate treatment, missed therapeutic windows, and prolonged diagnostic odysseys. Multidisciplinary team (MDT) evaluation integrating clinical features, neuroimaging, cerebrospinal fluid (CSF) analysis, genetics, and longitudinal disease evolution is increasingly recognised as central to accurate diagnosis; however, real-world data quantifying which features most reliably contribute to diagnostic confidence remain limited.

Methods: We performed a retrospective review of approximately 600 consecutive cases discussed at a tertiary Inherited White Matter Disorders MDT. Clinical, radiological, laboratory, and genetic data were extracted from our IWMD database supplemented with up to date electronic health records. Variables included presenting phenotype, age at onset, family history, MRI pattern and distribution, CSF findings, genetic testing results, and use of ancillary investigations (e.g. brain biopsy). Cases were classified as inherited, acquired, in work-up, or unresolved following MDT consensus.

Results: Preliminary analysis demonstrates that no single clinical, radiological, or laboratory feature reliably distinguishes inherited from acquired white matter disease in isolation. Diagnostic confidence most commonly arose from the convergence of multiple domains, particularly characteristic MRI patterns, absence of inflammatory CSF markers, multisystem features, and longitudinal disease evolution. Brain biopsy was infrequently contributory and reserved for diagnostically ambiguous cases.

Conclusion: These findings highlight the value of integrated MDT assessment in complex adult white matter disorders and may inform more efficient diagnostic pathways, reducing unnecessary invasive investigations and supporting earlier recognition of genetic disease.

Disclosure: Nothing to disclose.

EPO-0155 | Miglustat in Alzheimer's disease associated with heterozygous NPC1 mutation: Exploratory case series and preliminary findings

D. Lopercolo¹; D. Gasparini¹; S. Bianchi¹; B. Pucci¹; D. Tripodi²; V. Leoni²; A. Chincari³; S. Sestini⁴; H. Zetterberg⁵; N. De Stefano¹; A. Mignarri¹

Stefano, Azienda U.S.L. Toscana Centro, Prato, Italy; ⁵Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, The Sahlgrenska Academy, University of Gothenburg, Mölndal, Sweden

Background and aims: Several studies have previously demonstrated an increased risk of dementia and brain amyloid deposition in individuals with heterozygous NPC1 mutations. Moreover, in a recent study, we identified the first family with autosomal dominant late-onset Alzheimer's disease (AD) caused by a heterozygous NPC1 mutation. Unfortunately, there are currently no effective treatments available for this condition. Miglustat, which impacts the metabolism of oxysterols, has been shown to exert an anti-amyloidogenic effect in a human cellular model of AD.

Methods: In our exploratory uncontrolled study, three patients from the previously published family were orally treated with miglustat for 12 months. They underwent monthly clinical evaluations and routine blood tests. Additionally, neuropsychological evaluations, brain amyloid-PET imaging, and biochemical analyses on plasma and CSF were performed.

Results: All three patients achieved clinical stability, showed a sustained reduction in serum oxysterol levels, and experienced a marked decrease in brain amyloid burden.

Conclusion: Based on our preliminary observations and hypothesis-generating findings, along with the growing evidence suggesting AD as a lipid disorder, miglustat should be further tested in a larger cohort of heterozygous NPC1 mutated patients and probably evaluated as a potential disease-modifying treatment for AD.

Disclosure: H.Z. has served on scientific advisory boards and/or as a consultant for Abbvie, Acumen, Alector, Alzinova, ALZPath, Amylyx, Annexon, Apellis, Artery Therapeutics, AZTherapies, Cognito Therapeutics, CogRx, Denali, Eisai,

EPO-0156 | Predicting neurodevelopmental outcome in KCNQ2-related disorders

E. Van Boxstael; C. Millevert; S. Weckhuysen

Department of Neurology, Antwerp University Hospital, Edegem, Belgium

Background and aims: KCNQ2-related disorders (RD) are a major cause of neonatal-onset epilepsy, presenting a spectrum from self-limited (familial) neonatal epilepsy (SeL(F)NE) to severe developmental and epileptic encephalopathy (DEE). Haploinsufficient variants typically cause milder SeL(F)NE, whereas dominant-negative variants often lead to DEE. Yet, clinical outcomes are variable, neonatal seizures occur across phenotypes, and functional data are often unavailable, complicating early prognostic assessment.

Methods: We performed a multicentric retrospective cohort study including patients with a (likely) pathogenic KCNQ2 variant and ≥ 3 years follow-up. Mosaic variants were excluded, yielding 235 patients. Ten neonatal predictors were selected based on statistical significance ($p \leq 0.01$), clinical relevance, and data availability. The cohort was randomly split into a training set (70%) and an independent validation set (30%). Three random forest models were trained using these predictors to forecast neurodevelopmental delay, age at first words, and age at walking.

Results: Six clinical predictors were retained: neonatal hypotonia, family history of neonatal seizures, EEG features, age at seizure onset, seizure type, and seizure frequency at onset. Four genetic predictors included exon location, truncating or de novo variant, and localization within KCNQ2-DEE hotspot regions. Models predicted neurodevelopmental outcome (normal, mild, moderate to profound intellectual disability), age of language acquisition (< 16 months, ≥ 16 months, never), and age of walking (< 18 months, ≥ 18 months, never) with validation accuracies of 74%, 80%, and 81%, respectively.

Conclusion: These prediction models offer a practical tool for early, individualized prognostic counselling in KCNQ2-RD, supporting patient stratification for early interventions, including sodium channel blockers, and guiding enrolment in precision medicine trials.

Disclosure: Nothing to disclose.

E. Gatto¹; M. Cesarini¹; N. Gonzalez Rojas¹; L. Schottlaender³; P. Iruzubieta Agudo⁴; S. Josefina²; M. Dicaire²; D. Pellerin⁵

¹Unidad de Trastornos del Movimiento, Instituto Neurociencias Buenos Aires (INEBA), Buenos Aires, Argentina; ²Servicio de Neurología, Sanatorio de la Trinidad Mitre, Buenos Aires, Argentina; ³Instituto de Investigaciones en Medicina traslacional (IIMT), CONICET-Universidad Austral, Pilar, Buenos Aires, Argentina; ⁴Dr. John T. Macdonald Foundation Department of Human Genetics and John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, USA; ⁵Montreal Neurological Hospital and Institute, McGill University, Montreal, Quebec, Canada

Background and aims: Deep intronic GAA repeat expansions in intron 1 of the FGF14 gene have recently been identified as a frequent cause of late-onset cerebellar ataxia (LOCA), known as GAA-FGF14-related ataxia (SCA27B). While SCA27B is increasingly recognized worldwide, data from South America remain scarce and limited to isolated reports.

Methods: We report the clinical, neuropsychiatric, neuroimaging, and genetic findings of a patient evaluated for progressive cerebellar ataxia. Molecular analysis of FGF14 was performed using PCR-based techniques to identify GAA repeat expansions.

Results: We report a 62-year-old man with Spanish and Italian ancestry, carrying a pathogenic FGF14 GAA repeat expansion of 331 repeats. Originally referred due to paroxysmal ataxia and dysphonia, in the context of a long-standing neuropsychiatric history and prolonged alcohol and substance abuse. Neurological examination revealed progressive cerebellar ataxia, multidirectional nystagmus, dysphonia, dysphagia, and autonomic dysfunction, including bladder urgency and orthostatic hypotension. Family history showed a maternal diagnosis of amyotrophic lateral sclerosis. Early clinical features and personal history led to an initial diagnosis of alcohol-related cerebellar degeneration. Brain MRI showed nonspecific cerebellar atrophy. Subsequent progression to a pancerebellar ataxia-plus syndrome and a marked symptomatic response to 4-aminopyridine prompted genetic testing, confirming SCA27B.

Conclusion: This case represents, to our knowledge, the first genetically confirmed report of SCA27B in Argentina, expanding the phenotypic spectrum of SCA27B by highlighting concomitant neuropsychiatric manifestations and vulnerability to alcohol use as early disease features. In regions where alcohol-related cerebellar ataxia is frequently diagnosed, careful phenotypic assessment may facilitate recognition of treatable late-onset ataxias such as SCA27B

Background and aims: Genome-wide association studies (GWAS) have substantially contributed to elucidating the genetic architecture of Parkinson's disease (PD). The present study investigated the burden of susceptibility variants associated with sporadic PD in the Italian population, with the goal of identifying specific genetic susceptibility profiles and candidate biomarkers.

Methods: A total of 180 Single Nucleotide Polymorphisms (SNPs) were analysed in 730 Italian patients with sporadic PD using OpenArray technology. Variants were selected from GWAS, meta-analyses, public databases and PD-related biological pathways. Case-control association analyses with multiple testing correction and odds ratio estimation were integrated with machine-learning and bioinformatic analyses.

Results: The study identified 72 SNPs significantly associated with PD susceptibility. Among the tested machine learning models, the neural network showed the best performance and identified five variants (rs2012070, ATP6V0A1; rs1800795, IL6; rs329652, MIR4697; rs2641116, PARK7; rs9275326, HLA-DRB6/HLA-DQA1) as the most predictive. eQTL analysis revealed predominant regulatory effects of six PD-associated variants in the basal ganglia, cerebellum, cerebral cortex, hippocampus and hypothalamus regions of the brain. Pathway enrichment analysis indicated that genes harbouring the associated variants are involved in PD-relevant biological processes, including immune and inflammatory response, neurodevelopment, synaptic function, protein degradation, cellular metabolism, membrane organization and intracellular trafficking, as well as regulation of neuronal survival and cell death.

Conclusion: These findings delineate a distinct genetic susceptibility profile for PD in the Italian population and provide a rationale for developing a population-tailored genetic card as a tool to support risk stratification and identify individuals who may benefit from closer monitoring.

Disclosure: Nothing to disclose.

EPO-0159 | Landscape of dystrophin variants in Hungary

P. Balicza¹; S. Udvari¹; A. Gal¹; A. Palasti¹; Z. Grosz¹; S. Ando²; B. Bessenyei²; K. Koczok²; H. Piko³; L. Szabo⁴; S. Dobner⁴; Z. Liptai⁴; V. Karcagi⁵; I. Balogh²; M. Molnar¹

¹Semmelweis University Institute of Genomic Medicine and Rare Disorders; ²University of Debrecen Clinical Genetics Centre;

³Semmelweis University Department of Internal Medicine and Oncology; ⁴Semmelweis University Pediatric Center; ⁵Istenhegyi Genetic Diagnostic Center

Background and aims: Dystrophinopathies are one of the most important causes of muscular dystrophies in boys. With the advent of targeted therapies, it became extremely important to know the exact molecular background of each patient.

Methods: We collected molecular results of patients across the country. We collected date of birth, date of diagnosis, and the genetic results from all patients. Cases, first tested by multiplex PCR, were retested with MLPA. For a subset of patients (cared at the Semmelweis University), we collected phenotypic data.

Results: Between 1992 and 2025, 558 DMD molecular tests were performed. Formerly, only copy number variant (CNV) analysis was easily available, but since 2020 single nucleotide variant (SNV) analysis is also more accessible. 169 in-frame CNV (30.3%), 306 out-of-frame CNVs (54.8%), and 55 SNVs (9.9%) were detected. Among the out-of-frame CNVs, 115 different events occurred: in 9.3% duplication, and in 90.7% deletion. Most common events were del45-50 (8% of cases), del45 (6.5%), and del48-50 (6.5%). The number of theoretically amenable patients for exon skipping therapy (exon skipping 45/51/53) would be 122 (39.9%). We have available phenotype data from 109 patients in the whole cohort, with 43 Becker and 66 Duchenne phenotypes.

Conclusion: Routine availability of CNV and SNV testing, including NGS, allows reliable incidence estimates and reveals an increasing number of rare damaging variants and clinically affected females. Twelve common variants accounted for half of the cases, and a substantial proportion of patients are theoretically eligible for targeted therapies.

Disclosure: First author received support for congress attendance from the Medis, Medical Marketing Company.

EPO-0160 | Hereditary spastic paraparesis type 18: Shedding light upon a novel mutation in the ERLIN2 gene

R. Manso Calderón¹; B. Garcia²

¹Neurology Department. Complejo Asistencial Universitario de Salamanca, Salamanca, Spain; ²Genetics Department. Complejo Asistencial Universitario de Salamanca, Salamanca, Spain

Background and aims: Hereditary spastic paraparesis (HSP) type 18 is caused by mutations in the ERLIN2 gene, which encodes a protein involved in the endoplasmic reticulum-associated degradation pathway. Autosomal recessive mutations are involved in complicated HSP, while autosomal dominant mutations present as pure HSP. We describe a case of a new mutation in the ERLIN2 gene.

Methods: A 60-year-old woman who developed progressive gait disturbance since the age of 16. At 50 years old, she also presented weakness in the lower limbs. Her maternal grandfather, a maternal great-aunt, and two second-degree cousins had gait abnormalities. However, her non-consanguineous parents, two siblings, and one daughter had no neurological symptoms. On examination, muscle strength 4/5 in lower limbs with spasticity, hyperreflexia, Babinski sign, and bilateral clonus were observed. Modified Ashworth Scale: 3, and Timed 25-Foot Walk Test (T25FW): 24 s.

Results: Brain and spinal MRI: normal. Whole exome sequencing (WES) identified the index case as a heterozygous carrier of the c.205G > C (p.D69H) mutation in the ERLIN2 gene. Previous treatments with oral baclofen, tizanidine, and botulinum toxin showed minimal response. Extended-release fampridine (10 mg b.i.d.) was administered as a therapeutic alternative.

Conclusion: The proband case confirms the genotype-phenotype correlation between monoallelic variants of the ERLIN2 gene and pure HSP. This finding suggests a potential dominant negative effect of the erlin2 protein on oligomerization, as the cause of a milder phenotype. Furthermore, this case introduces a new variant in the ERLIN2 gene, contributing to a better understanding of the genetic factors underlying HSP type 18.

Disclosure: Nothing to disclose.

EPO-0161 | Abstract withdrawn

EPO-0162 | Investigating natural history and genotype influence in ALS2-related infantile-onset ascending hereditary spastic paraplegia

S. Della Vecchia¹; E. NG'UMBI²; M. Rossi Sebastiano³; A. Vicidomini²; F. Cesca⁴; G. Caron³; G. Ermondi³; R. Battini¹; F. Santorelli¹

¹IRCCS Fondazione Stella Maris, Pisa; ²Università degli Studi di Trieste; ³Università di Torino; ⁴Università di Padova

Background and aims: Infantile-onset ascending hereditary spastic paraplegia (IAHSP) is a rare motor neuron disorder caused by biallelic ALS2 mutations. Despite a distinctive phenotype, quantitative data on disease progression and genotype-phenotype correlations remain limited, hindering clinical trial design.

Methods: We conducted a natural history study of 83 individuals with biallelic-ALS2 mutations, combining published cases with patients enrolled in a multicenter cohort. Collected variables included psychomotor development, age at onset of lower-limb, upper-limb and bulbar involvement, loss of independent ambulation, additional neurological features. Based on predicted residual protein function, patients were classified into three genotype groups: biallelic-loss-of-function{00},

mixed{01}, non-loss-of-function{11}. Disease progression was analyzed using Kaplan–Meier curves and Cox proportional hazards models. Functional progression was assessed with the SPATAX-disability score, allowing longitudinal modeling and preliminary sample size estimation. Unsupervised clustering was applied to identify phenotypic subgroups.

Results: Age at symptom onset was consistent across genotypes (median 1.4–1.6 years), identifying early lower-limb involvement as a genotype-independent hallmark of IAHS. In contrast, progression rates differed by genotype: {00}-patients showed faster and more homogeneous progression, {01}-patients an early but more gradual course, and {11}-patients the slowest progression. Longitudinal SPATAX analyses indicated a mean progression rate ~0.5 points/year. Based on this estimate, preliminary modeling suggested that approximately 10 patients may be sufficient to detect a 50% reduction in progression in an interventional trial. Unsupervised clustering identified three preliminary phenotypic groups that did not map one-to-one onto genotype classes, suggesting additional sources of clinical heterogeneity currently under further investigation.

Conclusion: These data support time-based endpoints and data-driven stratification for IAHS trials.

Disclosure: Nothing to disclose.

EPO-0163 | Applicability of PPCS as diagnostic biomarker for Niemann Pick type C2 patients

S. Fischer; A. Bertoli-Avella; L. Pardo; T. Böttcher; P. Bauer
Centogene GmbH, Rostock, Germany

Background and aims: N-palmitoyl-O-phosphocholineserine (PPCS) formerly known as Lyso-SM-509 has been shown to be a diagnostic marker for Niemann Pick type C1 (NPC1) with high sensitivity and specificity (Griese 2015). It has been reported to correlate in NPC1 patients with the annual severity increment score (Sidhu R 2020) and with disease severity (clinical presentation) and progression (measured in dried blood spot - DBS - samples) (Guatibonza 2023). So far, this biomarker has only been investigated for NPC1 patients. For NPC2 patients however, biomarker data is not yet publicly available since pathogenic NPC2 variants are accountable for only 5 percent of all NPC cases which corresponds to an incidence rate of only 1 of 2,858,998 (Wassif 2016).

Methods: With this work, we aim to establish a PPCS reference range for NPC2 patients based on data that has been acquired in our laboratories over 10 years from DBS samples of 33 patients.

Results: All patients were characterized genetically with the predominant variants being p.Cys47Ter, p.Cys99Arg, and p.Ser63fs. The PPCS blood levels of all NPC2 patients were above the diagnostic cut-off and hence above the 97th percentile of values measured in blood of healthy individuals. Furthermore, clinical data was dissected using HPO terms, and genotype-phenotype analysis was performed.

Conclusion: This work should serve as evidence for the applicability of PPCS as diagnostic biomarker for NPC2 and should be the starting point for investigation of its use as monitoring biomarker in treatment efficacy studies.

Disclosure: Steffen Fischer, Luba Pardo, Aida Bertoli-Avella and Peter Bauer are employees of Centogene GmbH.

EPO-0164 | Genetic, biochemical and clinical properties of GLA p.Asp313Tyr variant in a large global cohort – No indication of Fabry disease

T. Böttcher¹; C. Beetz²; D. Schulze³; E. Zonic²; S. Schroeder²; A. Kaune²; L. Bauer⁴; J. Pinto Basto²; P. Bauer⁵

¹Centogene GmbH, Rostock, Germany and Dept. Neurology, Medical Faculty, University of Greifswald, Germany; ²Centogene GmbH, Rostock, Germany; ³Institute of Biometry and Clinical Epidemiology, Charité-University Medicine Berlin, Germany; ⁴Sigmund Freud Private University, Vienna, Austria; ⁵Centogene GmbH, Rostock, Germany and Pomeranian Medical University, Szczecin, Poland

Background and aims: Fabry disease (FD) is a multisystemic disorder caused by pathogenic variants in the GLA gene. Premature stroke and neuropathic pain are typical for neurological involvement. The disease-causing properties of the GLA variant c.937G > T (p.Asp313Tyr), reclassified from “Variant of uncertain significance” to “Benign” by our lab, are still debated. Recently, we demonstrated no specific phenotype for this variant in a large German cohort. To confirm the data globally we extended our evaluation.

Methods: Leveraging Centogene’s Biodatabank we analyzed all samples (n = 154,447) molecularly tested for Fabry disease during 2015 and 2020 from 72 countries for GLA genotypes, clinical presentations, and biochemical phenotypes.

Results: The allele frequency of GLA variant p.Asp313Tyr in this cohort was increased compared to gnomAD v4.1.0 data resulting in an odds ratio of 3.77 (95% CI: 3.61–3.94; p < 0.0001). Again, there

FIGURE 1

FIGURE 2 Integrated evidence.

FIGURE 3 Clinical evidence.

was no specific clinical nor biochemical phenotype compared to GLA reference individuals, supporting a diagnosis of FD.

Conclusion: The GLA variant p.Asp313Tyr is classified as a benign variant and does not cause FD. Neither clinical symptoms nor biochemical characteristics evidenced a specific effect in our cohort. The fact that the allele frequency here is higher than expected from general population reference data and publications describing a higher prevalence of GLA p.Asp313Tyr in patients with peripheral nervous system involvement or cerebrovascular disease, demand further clarification of a potential role as risk factor for a microangiopathic/neurological dysfunction, possibly comparable to the role of GBA1 variants in Parkinson's disease, must be elucidated. Therefore, properly designed case-control studies are needed.

Disclosure: No support has been received to conduct the study. T.B, C.B, E.Z, S.S, A.K, J.P.B. and P.B. are employees of Centogene GmbH.

Ageing and dementia 2

EPO-0165 | Mapping causal pathways from traumatic brain injury to dementia a systematic synthesis with computational inference

A. Shaheen¹; Dennstädt²; I. Filchenko²

¹Alexandria Faculty of Medicine, Egypt; ²Bern University Hospital and University of Bern, Switzerland

Background and aims: Traumatic brain injury (TBI) represents a critical global health burden, and serves as an environmental risk factor for neurodegenerative diseases, and increasing dementia risk. However, the mechanistic heterogeneity linking acute injury to chronic neurodegeneration remains poorly integrated across the vast clinical and preclinical literature.

Methods: 1,347 abstracts screened using a validated prompt engineering system, extracting structured biomedical triples from 823 relevant studies. Semantic path analysis was performed

using SapBERT embeddings, dimensionality reduction (PCA-UMAP), and hierarchical clustering (HDBSCAN) to construct directed acyclic graphs (DAGs) of causal evidence.

Results: Our analysis reconstructed the causal map of the post-TBI events leading to dementia, delineating distinct phases of pathogenesis. Primary axonal degeneration is driven by SARM1-mediated NAD⁺ depletion and calpain-dependent spectrin proteolysis, distinct from classical apoptosis. This transitions into a chronic neuroinflammatory phase characterized by HMGB1-TLR4 signaling, NF-κB activation, and the assembly of the NLRP3 inflammasome, which drives gasdermin-D mediated pyroptosis. We identified critical failures in clearance mechanisms, specifically AQP4 mislocalization leading to glymphatic dysfunction, which exacerbates the accumulation of hyperphosphorylated cis-tau, amyloid-beta, and TDP-43. Furthermore, our synthesis highlights the integrated stress response (ISR) and mitochondrial fission (Drp1) as central metabolic drivers of synaptic failure. The constructed causal maps identify specific therapeutic targets, including SARM1 inhibitors, NLRP3 antagonists, and senolytics, and validate fluid biomarkers such as NfL and GFAP for prognostic stratification.

Conclusion: This computational synthesis bridges the gap between molecular reductionism and clinical phenomenology, offering a unified framework for precision intervention in TBI-associated dementia.

Disclosure: Nothing to disclose.

EPO-0166 | Regional amyloid-PET dynamics in patients treated with anti-Aβ monoclonal antibody therapy

Background and aims: Anti-amyloid-β monoclonal antibodies (AAA) have demonstrated substantial reductions in cerebral amyloid burden in early symptomatic Alzheimer's disease (AD). However, interpretation of amyloid PET changes largely relies on global metrics that may mask regional heterogeneity of amyloid clearance.

Methods: We analyzed real-world amyloid PET data from 19 patients treated with Lecanemab or Donanemab who completed six months of therapy. Global Centiloid values and regional standardized uptake value ratios were quantified at baseline and follow-up using [18F]flutemetamol or [18F]florbetaben. Regional amyloid changes were examined according to treatment, clinical diagnosis, and clinical disease stage using ANCOVA models adjusted for tracer and AAA.

Results: Amyloid reduction showed pronounced regional variability, with the largest decreases in anterior cingulate, caudate and precuneus, and smaller changes in mesial temporal and occipital regions. Patients with early-onset AD showed higher baseline amyloid burden than those with late-onset disease but similar longitudinal reductions. Despite comparable baseline amyloid burden, patients with mild cognitive impairment demonstrated greater cortical amyloid reduction than patients with mild dementia. Among patients reaching global amyloid positivity thresholds, residual regional uptake—most consistently in the occipital cortex—was frequently observed.

Conclusion: Early amyloid clearance following AAA therapy is regionally heterogeneous and incompletely captured by global amyloid PET measures.

EPO-0167 | Family history and associated risk factors in patients with dementia with Lewy bodies

C. Teles¹; J. Durães¹; P. Faustino¹; C. Bernardes²; M. Coelho¹; C. Cunha¹; M. Almeida³; D. Duro¹; I. Baldeiras⁴; M. Tábuas Pereira¹; I. Santana¹

¹Neurology Department, Local Health Unit of Coimbra, Coimbra, Portugal; ²Neurology Department, Local Health Unit of Alto Ave, Guimarães, Portugal; ³Centre for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal; ⁴Centre for Innovative Biomedicine and Biotechnology (CIBB), University of Coimbra, Coimbra, Portugal

Background and aims: Dementia with Lewy bodies (DLB) is one of the most common neurodegenerative diseases. Its aetiology and possible risk factors remain largely unclear. Evidence on whether general family history of dementia confers higher risk of DLB remains scarce. We aim to assess whether family history of dementia is associated with increased risk of DLB. We explore inheritance patterns (maternal, paternal, and siblings), and possible link to consanguinity.

Methods: We conducted a tertiary hospital-based cohort study with 1836 participants, including 152 patients with DLB, 843 patients with Alzheimer's disease (AD) and 841 sex- and age-matched cognitively healthy controls over 75 years old. Participants were questioned regarding family history of dementia (maternal, paternal, siblings). Parental birthplace and history of consanguinity was also registered. Binary logistic regressions and comparative analyses were performed between DLB, AD, and controls.

Results: In the total 1836 participants, 152 had DLB, with mean current age 80.2 years (SD: 5.9), mean onset age 74.3 years (SD: 6.2), and 62.1% were women. We found that having a sister with dementia was associated with higher odds of DLB compared with controls (OR 51.33, 95% CI=20.02–131.65) and AD (OR 2.61, 95% CI=1.66–4.10). Higher odds of DLB were also associated with maternal dementia history (OR 1.89, 95% CI=1.16–3.08) versus controls.

Conclusion: This study provides new evidence that maternal and sibling family history of dementia may be associated with an increased risk of DLB, refining our understanding of a possible heritable architecture, highlighting the importance of detailed family history in clinical assessment and risk stratification.

Background and aims: The Boston Criteria v2.0 integrates clinical-radiological features to diagnose Cerebral Amyloid Angiopathy (CAA), with deep hemorrhagic manifestations, the so-called mixed small vessel disease (SVD), precluding a CAA diagnosis, given the high likelihood of underlying hypertensive SVD. This study aims to evaluate whether the A β 42/40 ratio outperforms isolated biomarkers (A β 42, A β 40) as a proxy of neuropathology in a heterogeneous SVD cohort.

Methods: We analyzed a cohort of patients with probable CAA (Boston Criteria v2.0) or mixed SVD with available CSF biomarkers (A β 42, A β 40). We quantified MRI markers of SVD, including cerebral microbleeds (CMB), cortical superficial siderosis (cSS), enlarged perivascular spaces (EPVS), and the CAA-SVD score. Associations between MRI scales and Z-score normalized CSF biomarkers were evaluated using logistic regression models.

Results: We included 79 patients (58 probable CAA, 21 mixed SVD). A β 40 showed a significant association with cSS (OR = 0.54; p = 0.005), A β 42 with cSS (OR = 0.40; p < 0.001), CAA-SVD score (OR = 0.55; p = 0.003), and deep EPVS (OR = 2.45; p < 0.001), while the A β 42/40 ratio was associated with cSS (OR = 0.54; p = 0.010), CAA-SVD score (OR = 0.63; p = 0.021), deep EPVS (OR = 2.42; p < 0.001), and deep CMBs (OR = 3.29; p < 0.001). The only CSF biomarker that showed a bimodal distribution was the A β 42/40 ratio.

Conclusion: In our cohort, lower levels of A β 42 and A β 40 are closely linked to specific CAA features. However, the A β 42/40 ratio gains more reliability in relation to deep hemorrhagic markers. This suggests, given also the binomial distribution, that the A β 42/40 ratio may better differentiate the underlying SVD compared to isolated CSF biomarkers. This should be confirmed in further studies, verifying also the diagnostic accuracy of a biology-integrated approach compared to the current radiological classification.

G. Lepeu¹; A. Rossetti¹; O. Rouaud²; A. Griffa²; G. Allali²

¹Service of Neurology, Department of Clinical Neurosciences, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; ²Leenaards Memory Center, Department of Clinical Neurosciences, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland

Background and aims: Epilepsy is common in neurodegenerative diseases, particularly Alzheimer's disease (AD). However, the impact of amyloid- β on epilepsy prevalence in clinical populations remains uncertain, as does the association between epilepsy and specific cognitive profiles or brain atrophy. This study aimed to compare cognitive characteristics, AD cerebrospinal fluid (CSF) biomarkers, and brain morphometry between patients with neurodegenerative diseases with and without epilepsy. Additionally, we examined whether epilepsy prevalence differs between patients with AD (as confirmed by CSF biomarkers) and patients with non-Alzheimer's neurodegenerative diseases (Non-AD).

Methods: In a cross-sectional study, we retrospectively analyzed well-characterized patients in a University Memory Clinic cohort (Leenaards Memory Center; Lausanne University Hospital, Switzerland). CSF biomarkers, global cognitive functioning, dominant impaired cognitive domain, brain morphometry, epilepsy diagnosis and EEG report were assessed. Patients were classified using the ATN system to differentiate AD from other neurodegenerative conditions (Non-AD).

Results: In a Memory Clinic cohort (n = 479, age: 69.1 $\pm$ 9.2, 44% female), no significant differences were found in either cognitive impairment, brain morphometry, CSF amyloid- β and phosphorylated Tau levels or ATN classification between patients with or without epilepsy. In addition, epilepsy prevalence was comparable between AD and Non-AD groups (5.2% and 5.4% respectively, p = 0.965).

Conclusion: Epilepsy was not associated with a distinct cognitive, morphometric, AD CSF biomarker or ATN profile. Importantly, Alzheimer's disease did not correlate with an increased prevalence of epilepsy. These findings point toward mechanisms beyond amyloid- β - potentially shared across neurodegenerative diseases - as contributors to epileptogenesis, emphasizing the need for further targeted research.

Department of Neurology, Motol and Homolka University Hospital, Prague, Czech Republic

Background and aims: Limbic-predominant age-related TDP-43 encephalopathy (LATE) is a recently recognised neurodegenerative disease with clinical characteristics, cognitive deficits, and structural brain changes similar to those seen in Alzheimer's disease (AD). The diagnosis of LATE is challenging due to the absence of validated specific biomarkers. This study evaluated diagnostic and clinical usefulness of non-invasive biomarkers in a memory clinic cohort, exploring the potential of these biomarkers as tools for the early diagnosis of LATE and for differentiating it from AD.

Methods: 83 participants from the Czech Brain Aging Study, including individuals with amnesic mild cognitive impairment (aMCI) and biomarker-confirmed AD ($n=27$), individuals with aMCI meeting criteria for probable LATE ($n=33$), and cognitively normal older adults (CN, $n=23$), underwent cognitive assessment, structural brain MRI, blood-based biomarker assessment, and genetic testing. Additionally, the aMCI participants underwent amyloid PET imaging and cerebrospinal fluid biomarker assessment.

Results: Participants with LATE aMCI outperformed AD aMCI and were similar to CN on visuospatial tests (Figure 1), exhibited greater reductions in entorhinal cortical thickness and a lower ratio of entorhinal-to-parahippocampal cortical thickness compared to AD aMCI and CN (Figure 2), and had lower plasma glial fibrillary acidic protein levels and a lower frequency of the APOE4 allele than AD aMCI, and similar to CN (Figure 3). A combination of these markers differentiated between LATE and AD aMCI with 86% sensitivity and 74% specificity.

Conclusion: A combination of specific non-invasive biomarkers may distinguish early LATE from early AD, providing moderate-to-high sensitivity and specificity. This makes them valuable tools for differential diagnosis in clinical settings.

EPO-0171 | GALECTIN-3 as an emerging biomarker of neuroinflammation in Alzheimer's disease and frontotemporal dementia

L. Bonino¹; S. Boschi¹; F. Roveta¹; E. Piella¹; G. Brodini¹; A. Agostinelli¹; G. Mengozzi²; I. Rainero³; E. Rubino¹

¹Department of Neuroscience "Rita Levi-Montalcini", University of Turin, Turin, Italy; ²Department of Medical Sciences, University of Turin, Turin, Italy; ³Department of Neuroscience and Mental Health, AOU Città della Salute e della Scienza di Torino, Turin, Italy

Background and aims: Frontotemporal dementia (FTD) and Alzheimer's disease (AD) are the most common causes of dementia and neuroinflammation plays an important role in their pathogenesis. Elevated levels of Galectin-3 (a galactoside-binding lectin expressed by activated microglia, Gal-3), were reported elevated in the cerebrospinal fluid (CSF) of AD and FTD patients. This study aims to evaluate CSF Gal-3 levels in AD, FTD and patients without diagnosed neurodegenerative disorders (NND), and to investigate its relationship with established biomarkers of neurodegeneration.

Methods: CSF samples were collected from 118 patients recruited at Turin University Dementia Center: 51 with AD, 40 with FTD and 27 classified as NND. Gal-3 concentrations were measured using an Enzyme-Linked Immunosorbent Assay (ELISA) kit (Abcam, Cambridge, UK) while CSF Amyloid-beta-42 (A β 42), Amyloid-Beta-42/40 ratio (A β 40/42), total-tau (t-Tau), phosphorylated-tau-at-threonine-181 (p-Tau181), and neurofilament-light-chain (NFL) using a Lumipulse platform (Fujirebio, Ghent, Belgium).

Results: Mean Gal-3 levels were higher in the FTD group (562.1 ± 226.1 pg/mL) and in the AD group (473.1 ± 128.3 pg/mL) compared to the NND group (256.7 ± 164.6 pg/mL; $p < 0.001$). Gal-3 levels did not differ between the FTD and AD groups ($p = 0.064$). In the FTD subgroup Gal-3 showed a significant

correlation with t-Tau ($r=+0.33$, $p=0.045$), while in the overall population Gal-3 correlated with NfL ($r=+0.28$, $p=0.039$).

Conclusion: CSF Gal-3 levels were elevated in patients with AD and FTD, supporting the contribution of neuroinflammation to neurodegeneration and reinforcing Gal-3 as a potential biomarker. The correlation between Gal-3 and t-Tau further suggests a relationship between microglial activation and tau-related pathology.

Disclosure: Nothing to disclose.

EPO-0172 | Gut-brain communication via extracellular vesicles enables amyloid- β transport to the central nervous system

M. Munir; T. Davis; I. Javed

Australian Institute for Bioengineering and Nanotechnology, The University of Queensland, St. Lucia, Queensland, Australia

Background and aims: Alzheimer's disease (AD) is defined by progressive neurodegeneration and cerebral deposition of amyloid- β (A β). While central amyloid pathology has been extensively studied, emerging evidence suggests that peripheral tissues may contribute to disease initiation and progression. However, the cellular pathways enabling amyloid proteins to traverse the gut-brain axis remain poorly defined.

Methods: Gut-to-brain transport was examined using complementary in vitro and in vivo models. A co-culture was established to model directional transport. Epithelial barrier integrity was confirmed using TEER measurements, Dextran-FITC permeability assays, and ZO-1 immunostaining. EV involvement in A β transport was assessed by tracking EV-associated A β transfer. Neuronal oxidative stress and cytotoxicity were quantified following exposure to free or EV-associated A β . In vivo validation was performed in zebrafish larvae.

Results: Intestinal barriers remained structurally and functionally intact across in vitro models. A β was preferentially packaged into EVs released by intestinal epithelial cells and subsequently internalized by neurons. Neurons exposed directly to free A β exhibited significantly higher oxidative stress and cytotoxicity compared to neurons receiving EV-associated A β through epithelial-neuronal interfaces. In vivo imaging demonstrated that A β delivered into the zebrafish gut accumulated in the brain.

Conclusion: These findings establish extracellular vesicles as critical mediators of amyloid- β transport from the gut to the brain via transcellular pathways, independent of intestinal barrier disruption.

EPO-0173 | Neurological perspectives in solid organ transplantation: Advancing ethical and equitable care for people with cognitive impairment

V. Lo Re¹; A. Grossi²

¹*Neurology Service, IRCCS ISMETT (Istituto Mediterraneo per i Trapianti e Terapie ad Alta Specializzazione), Palermo, Italy;*

²*Department of Human Sciences, Innovation and Territory, University of Insubria, Varese-Como, Italy*

Background and aims: Cognitive impairment (CI) affects a significant proportion of liver (up to 80%), kidney (up to 55%), lung (45%), and heart transplant candidates (25–74%). As organ failure increasingly affects older adults, the number of solid organ transplant candidates with CI is expected to increase. However, the lack of standardized cognitive assessments leads to variability across centers, potentially resulting in inequities in transplant accessibility and outcomes. Incorporating CI assessments into pre-transplant evaluations is therefore crucial to better predict post-transplant outcomes and to support ethically sound decision-making.

Methods: We reviewed the available literature on the debated issue of organ allocation for patients with CI, synthesizing arguments both in favor of and against transplantation, as well as proposed approaches to address these challenges.

Results: It has been recommended to establish independent regional boards to address allocation challenges and reduce the risk of discrimination against patients with CI. These boards should include transplant and non-transplant professionals (e.g. social workers, psychologists, bioethicists) and other relevant stakeholders (e.g. patients and family members) to enhance transparency and consensus. Integrating ethical assessments and review into pre-transplant evaluations may further support multidisciplinary discussions.

Conclusion: We propose that transplant eligibility for individuals with CI would be approached as a specialized clinical evaluation, conducted early in the transplant process by experts in cognitive disorders to assess factors relevant to perioperative and long-term outcomes, including severity, etiology, and prognosis of the CI; this clinical assessment should be systematically integrated with structured ethical evaluation to support fair and transparent decision-making.

Disclosure: The authors have nothing to disclose.

EPO-0174 | Plasma metabolic profiles predict future dementia and dementia subtypes: A prospective analysis of 274,160 participants

X. He

Department of Neurology and National Center for Neurological Disorders, Huashan Hospital, State Key Laboratory of Medical Neurobiology and MOE Frontiers Center for Brain Science, Shanghai Medical College, Fudan University, Shanghai, China.

Background and aims: Blood-based biomarkers for dementia are gaining attention due to their non-invasive nature and feasibility in regular healthcare settings. Here, we explored the associations between 249 metabolites with all-cause dementia (ACD), Alzheimer's disease (AD), and vascular dementia (VaD) and assessed their predictive potential.

Methods: This study included 274,160 participants from the UK Biobank. Cox proportional hazard models were employed to investigate longitudinal associations between metabolites and dementia. The importance of these metabolites was quantified using machine learning algorithms, and a metabolic risk score (MetRS) was subsequently developed for each dementia type. We further investigated how MetRS stratified the risk of dementia onset and assessed its predictive performance, both alone and in combination with demographic and cognitive predictors.

Results: During a median follow-up of 14.01 years, 5,274 participants developed dementia. Of the 249 metabolites examined, 143 were significantly associated with incident ACD, 130 with

FIGURE 1 Dementia-associated metabolites in the association analysis.

FIGURE 2 Metabolites importance ranking and SHAP visualization of modeling based on incident ACD populations.

FIGURE 3 Prediction of incident ACD, AD, and VaD.

AD, and 140 with VaD. Among metabolites significantly associated with dementia, lipoprotein lipid concentrations, linoleic acid, sphingomyelin, glucose, and branched-chain amino acids ranked top in importance. Individuals within the top tertile of MetRS faced a significantly greater risk of developing dementia than those in the lowest tertile. When MetRS was combined with demographic and cognitive predictors, the model yielded the area under the receiver operating characteristic curve (AUC) values of 0.857 for ACD, 0.861 for AD, and 0.873 for VaD.

Conclusion: We conducted the largest metabolome investigation of dementia to date, for the first time revealed the metabolite importance ranking, and highlighted the contribution of plasma metabolites for dementia prediction.

Disclosure: Nothing to disclose.

EPO-0175 | Serum clinical laboratory tests and risk of incident dementia: A prospective cohort study of 407,190 individuals

X. He
Department of Neurology and National Center for Neurological Disorders, Huashan Hospital, State Key Laboratory of Medical Neurobiology and MOE Frontiers Center for Brain Science, Shanghai Medical College, Fudan University, Shanghai, China.

Background and aims: Prevention of dementia is a public health priority, and the identification of potential biomarkers may provide benefits for early detection and prevention.

Methods: This study investigates the association of common serum laboratory tests with the risk of incident dementia. Among 407 190 participants from the UK Biobank (median follow-up of 9.19 years), we investigated the linear and nonlinear effects of 30 laboratory measures on the risk of all-cause dementia using Cox models and restricted cubic spline models.

Results: We found that dementia incidence was associated with low vitamin D concentration (hazard ratio 0.994, 95% confidence interval 0.993–0.996), indicators of endocrine disorders: IGF-1 level (*P* for non-linearity=1.1E-05), testosterone level (*p* for non-linearity=0.006); high sex-hormone-binding globulin level

FIGURE 1 Linear associations between serum laboratory tests and risk of incident dementia.

FIGURE 2 Nonlinear associations between serum laboratory tests and risk of incident dementia.

FIGURE 3 Heatmap to overview the associations of serum laboratory tests with dementia risks.

(HR 1.004, 95% CI 1.003–1.006); reduced liver function: lower alanine aminotransferase (HR 0.990, 95% CI 0.986–0.995); renal dysfunction: cystatin C level (p for non-linearity = 0.028); oxidative stress: lower urate level (HR 0.998, 95% CI 0.998–0.999); lipids dysregulation: lower LDL (HR 0.918, 95% CI 0.872–0.965) and triglycerides (HR 0.924, 95% CI 0.882–0.967) concentrations; insulin resistance: high glucose (HR 1.093, 95% CI 1.045–1.143) and HbA1c (HR 1.017, 95% CI 1.009–1.025) levels; immune dysbiosis: C–reactive protein (p for non-linearity = 5.5E-09).

Conclusion: In conclusion, markers of vitamin D deficiency, GH-IGF-1 axis disorders, bioactive sex hormone deficiency, reduced liver function, renal abnormalities, oxidation, insulin resistance, immune dysbiosis, and lipids dysregulation were associated with incident dementia. Our results support a contributory role of systemic disorders and diverse biological processes to onset of dementia.

Disclosure: Nothing to disclose.

Neurotoxicology/Occupational Neurology

EPO-0176 | Cannabis-induced PRES with acute cerebral infarctions involving the bilateral posterior territories and left thalamus

A. Jamal Eddine
Neurology Department, Klinik Hietzing, Vienna, Austria

Background and aims: Posterior Reversible Encephalopathy Syndrome (PRES) is an uncommon but clinically significant condition characterized by headache, visual disturbances, seizures,

altered mental status, and posterior white-matter changes. Cerebral infarction occurs in a minority of cases. Although many triggers have been described, cannabis-associated PRES remains rare.

Methods: Case report.

Results: A 36 year old patient was admitted after mixed alcohol and cannabis intoxication. On admission, he reported several days of headache, vertigo, and visual perceptual disturbances. Blood pressure was 161/91 mmHg. Due to markedly elevated urinary tetrahydrocannabinol levels and recent heavy cannabis use, symptoms were initially attributed to intoxication. Because neurological symptoms persisted, MRI was performed and revealed subacute infarctions in the bilateral posterior territories and the left thalamus, with PRES-compatible changes and minor bilateral haemorrhagic transformation. Transcranial and extracranial Doppler studies showed normal flow without vasospasm or stenosis. During monitored care, mildly elevated blood pressure stabilized under calcium channel blocker therapy. A follow up CT after three days confirmed stable haemorrhagic findings, allowing initiation of aspirin for secondary stroke prevention. With ongoing visuospatial rehabilitation, the patient showed gradual but incomplete improvement. Visual agnosia partially resolved, but deficits in colour discrimination and prosopagnosia persisted. He was discharged with a structured outpatient neurorehabilitation program.

Conclusion: This case illustrates an atypical form of PRES with concurrent posterior infarctions, reflecting severe autoregulatory dysfunction. Early recognition and blood pressure control supported partial recovery. The case highlights the importance of considering PRES in patients presenting with neuropsychiatric symptoms after substance use, where initial impressions may be misleading.

FIGURE 1 MRI FLAIR.

G. Diniz de Pinho; S. Nunes Oliveira

Neurology Department, Hospital da Luz, Lisbon, Portugal

Background and aims: Hyperacute hour-lasting confusional states frequently suggest exposure to intoxicating substances, but associations may be hard to establish outside the typical contexts.

Methods: We discuss a case of a healthy 69-year-old Portuguese female patient.

Results: She was brought to the emergency department after sudden confusion. Hypertension, sinus tachycardia and flushed skin were noted. Temperature was normal and she did not have headache or vomiting. Neurologic and mental exams were remarkable for disorientation, periods of delusional incoherent and disconnected ideas in between regular thought processing, slurred speech and extremity/truncal ataxia, with no other focal deficits. Laboratory tests were normal including: no detectable alcohol, amphetamines, cocaine, cannabinoids, opioid and barbiturates. Brain CT/MRI were unremarkable. She was kept under surveillance and all symptoms subsided within 12 hours. She recalled only parts of the episode, but remembered having eaten locally bought sprouts that day. Her son whom she had had lunch with described a dry mouth feeling afterwards. She was discharged upon clinical stability and photographed the greens, where different-looking fragments with bristly stems could be seen among the other tuberous roots and leaves.

Conclusion: Fragments of *Ecballium elaterium* (squirting cucumber), a flowering plant found in some parts of southern

FIGURE 2 MRI DWI.

FIGURE 3 MRI ADC.

Disclosure: Nothing to disclose.

EPO-0177 | Abstract withdrawn

FIGURE 1 Patient's own vegetable mix (the dark leaves are the sprouts, and the different-looking tuberous root fragments are the lighter green, bulkier ones).

FIGURE 2 Closer look at the fragments (1).

FIGURE 3 Closer look at the fragments (2).

Europe, including Portugal, and northwestern Africa, were probably inadvertently consumed by our patient. It is allergenic and a strong purgative but, unlike plants of the Solanaceae family, has not been implicated in anticholinergic or central nervous system toxicity. We emphasize reviewing the proliferation of these species in some rural areas for both health and cultivation control.

Disclosure: Nothing to disclose.

EPO-0179 | Neurological spectrum of recreational nitrous oxide use: A case series including monozygotic twins

L. Donneys Martán¹; M. De la Calle Cuevas²; L. Martín Gil²; D. Pérez Gil²; A. Gómez Domínguez¹; B. Estrella León¹; A. Díaz Negrillo¹; T. Montalvo Moraleda³; L. López Trashorras³; I. Llera López³; N. Fontana García⁴; E. Escario Méndez⁴; L. Santos Sánchez de las Matas²

¹Department of Clinical Neurophysiology, Hospital Infanta Elena, Madrid, Spain; ²Department of Neurology, Hospital Infanta Elena, Madrid, Spain; ³Department of Neurology, Hospital Rey Juan Carlos, Madrid, Spain; ⁴Department of Clinical Neurophysiology, Hospital Rey Juan Carlos, Madrid, Spain

Background and aims: Nitrous oxide (N₂O) is a gas widely used in medical and dental practice that has gained increasing popularity as a recreational substance due to its euphoric effects, earning the nickname “laughing gas.” Its abuse can induce a functional vitamin B12 deficiency through oxidation of the cobalt ion, reducing myelin synthesis and leading to neurological manifestations. The aim of this study is to describe the clinical presentations associated with recreational N₂O use.

Methods: Case series of four patients with neurological impairment following prolonged N₂O consumption.

Results: Four male patients aged 18 to 28 years were included, with an average N₂O use of four months, presenting with muscle weakness and/or sensory symptoms. Neurological outcomes varied: one patient was asymptomatic, one presented with axonal polyneuropathy, another with cervical subacute combined degeneration (SCD), and another with both conditions. The series included monozygotic twins with identical exposure: one developed combined SCD and motor axonal polyneuropathy with elevated homocysteine and reduced B12 levels, whereas the twin who intermittently self-supplemented with B-group vitamins showed only mild hypoesthesia and had normal MRI,

FIGURE 1 Cervical MRI in SCD. (A) Sagittal T2-weighted of Patient 1: longitudinal hyperintense signal in posterior columns. (B) Axial T2-weighted of Patient 4: bilateral and symmetric posterior column hyperintensity forming the “inverted V sign”.

electromyography (EMG), nerve conduction studies (NCS) and B12 values. Clinical improvement was observed following N2O cessation and vitamin supplementation.

Conclusion: Inhalation of N2O may cause a spectrum of neurological injury ranging from axonal polyneuropathy to myelopathy. Normal B12 levels do not exclude neurotoxicity, limiting their usefulness as a sole diagnostic marker. Vitamin

supplementation may delay symptom onset, but cessation of N2O use is essential to halt disease progression.

Disclosure: Nothing to declare.

EPO-0180 | Curcumin exhibits comparable effects to rapamycin in reducing neuronal soma size and intracellular calcium expression in SH-SY5Y cells

M. Husna¹; R. Rakhmatiar¹; A. Nur Rakhmani²; H. Anggu Maliga¹

¹Department of Neurology, Faculty of Medicine, Brawijaya University/Saiful Anwar General Hospital, Malang, East Java, Indonesia; ²Department of Family Medicine, Faculty of Medicine, Brawijaya University, Malang, Indonesia

Background and aims: The mTORC2 complex is vital for neuronal function and structure. There are no specific inhibitors for mTORC2; however, chronic high-dose rapamycin and curcumin may have indirect effects. This study compares their impact on mTORC2 inhibition in neuronal cells, focusing on calcium levels and soma size.

Methods: This in vitro study involved SH-SY5Y neuroblastoma cell cultures divided into four groups: a control, one treated with 100 nM rapamycin, and two treated with curcumin at 5 µM and 10 µM for 48 hours to target mTORC2. Soma size was measured in µm², and intracellular calcium levels were labeled with Fluo-4 and quantified with confocal laser scanning microscopy (CLSM). Statistical analysis assessed data differences.

Results: Soma sizes were measured as: control (7892.07 µm²), 5 µM curcumin (6101.25 µm²), 10 µM curcumin (3413.44 µm²), and rapamycin (3341.95 µm²). Intracellular calcium intensities were: control (29.35 nPhoton), rapamycin (7.69 nPhoton), 10 µM curcumin (3.80 nPhoton), and 5 µM curcumin (2.19 nPhoton). Significant differences ($p < 0.001$) were found between all treatment groups and the control for both parameters. The 5 µM curcumin group differed significantly from rapamycin ($p < 0.001$), but there was no significant difference between the 10 µM curcumin and rapamycin groups ($p = 0.84$). The 5 µM curcumin had the lowest calcium intensity, indicating a non-linear dose-dependent effect

Conclusion: Rapamycin is comparable to 10 µM curcumin in inhibiting mTORC2, which reduces neuronal soma size and calcium levels. This suggests that curcumin may naturally modulate the mTOR pathway, highlighting its potential for treating neurological disorders related to mTOR.

Disclosure: Nothing to disclose.

EPO-0181 | Boldine and the nervous system: A case of reversible myoneuropathy

M. Verdeguer¹; M. García¹; G. Esparza¹; J. Cabello²; D. Górriz¹; J. Jiménez²; E. Millet³; N. Muelas²; T. Sevilla²; R. Sivera²

¹Hospital Universitario y Politécnico la Fe, Neurology department, Valencia, Spain; ²Hospital Universitario y Politécnico la Fe, Neurology department. CIBER de enfermedades raras - CIBERER, EURO-NMD, Valencia, Spain; ³Hospital Universitario y Politécnico la Fe, Neurophysiology department, Valencia, Spain

Background and aims: Phytotherapeutic preparations are widely used and often perceived as safe; however, many contain bioactive compounds with potential neuromuscular toxicity that remains poorly characterized. Boldine is an aporphine alkaloid extracted from *Peumus boldus* and commonly used for its presumed hepatoprotective properties. We report a case of reversible myoneuropathy associated with rhabdomyolysis, likely related to boldine consumption.

Methods: A comprehensive clinical, laboratory, neurophysiological, and radiological evaluation was performed, including brain, spinal cord, and muscle magnetic resonance imaging (MRI), lumbar puncture, neurophysiological studies, serial measurements of creatine kinase (CK) and serum neurofilament light chain (sNfL).

Results: A 55-year-old man with alcoholic cirrhosis presented with a three-week history of bilateral proximal lower limb weakness and ascending paresthesias. Neurological examination revealed weakness of hip and knee movements, thigh hypoesthesia, stocking-type sensory loss in the feet, and absent lower limb reflexes. Symptom onset temporally coincided with the initiation of boldine for liver function improvement. Acute inflammatory polyradiculoneuropathy was initially suspected, and intravenous immunoglobulins were administered; however, this diagnosis was excluded due to normal electrophysiological findings and the absence of albuminocytological dissociation. Laboratory tests showed elevated CK levels, peaking at 4,176 U/L. Whole-body MRI demonstrated focal muscle edema involving the right scalene, pectoral, vastus medialis, and left rectus femoris muscles, consistent with rhabdomyolysis. sNfL were elevated.

Conclusion: The clinical and laboratory course was favorable after discontinuation of boldine, with near-complete recovery within one month, normalization of biomarkers, and electrophysiological improvement. The temporal relationship with

boldine exposure, absence of alternative etiologies, and reversibility support a probable toxic myoneuropathic mechanism.

Disclosure: Nothing to disclose.

EPO-0182 | Wernicke encephalopathy: Learning from experience

N. Marginean; C. Herghelegiu; A. Niculae; A. Scurtu; L. Dumitrescu; E. Davidescu; B. Popescu
“Carol Davila” University of Medicine and Pharmacy, Faculty of Medicine, Clinical Neuroscience Department, Bucharest, Romania; Colentina Clinical Hospital, Neurology Department, Bucharest, Romania

Background and aims: Wernicke encephalopathy (WE) is a neurological emergency caused by thiamine deficiency, frequently associated with heavy alcohol drinking, malnutrition or consumptive diseases. Not all cases manifest with the complete classical triad (i.e, ophthalmoplegia, gait ataxia and encephalopathy), leading to underdiagnosis.

Methods: We conducted a descriptive study using the electronic medical record database of Colentina Clinical Hospital, Bucharest, Romania. We included data from patients admitted between January 2019 and December 2025 with a diagnosis of WE (ICD-10 code E51.2). For statistical analysis we used Microsoft Excel and IBM SPSS.

Results: Datasets from 41 patients (90% male, 10% female) complied with the inclusion criteria. The median age was 66 years. Alcohol use disorder was the main identified risk factor for WE in 95% of cases. Gait ataxia was the most frequent sign upon evaluation. Only 21% of patients exhibited the full classical triad. All patients received high doses of intravenous thiamine for several days (mean total dose 5634 mg +/-3607 mg). Brain MRI was performed in 12 patients (29%), of whom only 2 had typical signs of WE. Clinical improvement at discharge was observed in 82% of patients, only a third achieving previous neurological status. We found no significant correlation between the degree of clinical improvement and initial clinical presentation or dose of thiamine administered.

Conclusion: Our findings are in line with the published literature. We reinforce the importance of maintaining a high index of clinical suspicion and prompt initiation of parenteral thiamine treatment, particularly in patients with known risk factors for WE.

Disclosure: Nothing to disclose.

EPO-0183 | Chronic noise exposure induces cis-P-tau accumulation, an early Alzheimer's disease-related pathological marker, and cognitive deficits in rats

S. Nabavi
Department of Regenerative Medicine, Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology, ACECR, Tehran, Iran

Background and aims: Chronic noise exposure is a stressor linked to central nervous system dysfunction and cognitive decline, including Alzheimer's disease (AD). Hyperphosphorylation of tau protein, particularly Thr231, is a hallmark of AD. Cis

FIGURE 1 Edema of the left quadriceps.

FIGURE 2 Edema of the right pectoral muscle.

p-tau is highly neurotoxic and an early driver of tauopathy, causing microtubule disruption and neurodegeneration, a process termed Cistauosis.

Methods: Rats were exposed to 95 dB SPL white noise for 4 hours daily over 15 days. Cognitive and anxiety-related behaviors were assessed using the elevated plus maze and Y-maze. Western blotting and immunohistochemistry were performed to evaluate tau pathology.

Results: Noise-exposed rats exhibited increased anxiety-like behaviors and memory deficits. Molecular analyses demonstrated that chronic noise significantly induced cis p-tau accumulation and Cistauosis in multiple brain regions.

Conclusion: Chronic noise exposure promotes Cistauosis, linking environmental stress to neurodegeneration and AD development. These findings highlight the potential role of noise-induced tau pathology in the early stages of Alzheimer's disease.

Disclosure: The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

EPO-0184 | Neurological manifestations related to toxic exposure in children: A clinical study

S. Hachicha; M. Ben Hafsa; T. Ben Younes; Z. Miladi; A. Zyoudi; M. Jamoussi; H. Ben Rhouma; H. Klai; I. Kraoua
Department of Pediatric Neurology, LR18SP04, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia

Background and aims: Neurological manifestations due to toxic exposure in children represent a significant cause of pediatric morbidity. Their clinical heterogeneity often complicates diagnosis and delays appropriate management. This study aimed to describe the epidemiological characteristics, clinical presentation, management, and outcomes of toxic-induced neurological manifestations in a pediatric population.

Methods: We conducted a retrospective study including patients aged under 18 years, hospitalized between 2017 and 2025 in the Pediatric Neurology Department of the National Institute of Neurology in Tunis, for neurological symptoms attributed to toxic exposure. Demographic, clinical, paraclinical, therapeutic, and outcome data were collected and analyzed.

Results: Eighteen patients were included, with a median age of 6 years. Toxic exposure was drug-related in 13 cases, including chemotherapy (5 cases), antiepileptic drugs (4 cases), haloperidol (1 case), and flunarizine (1 case). One case each was attributed to carbon monoxide and N-hexane exposure. The circumstances were iatrogenic in nine cases, accidental in six cases, and intentional in five cases. Five patients presented with an encephalitic-like syndrome. Peripheral neuropathy, movement disorders, and ataxia were each observed in four patients. The outcome was favorable in 13 cases, while two patients required admission to the intensive care unit.

Conclusion: In our series, neurological manifestations related to toxic exposure in children were predominantly iatrogenic. Early recognition and prompt discontinuation of the offending agent are crucial for a favorable prognosis. These conditions should be systematically considered in the differential diagnosis of acute or subacute neurological presentations in children.

Disclosure: The authors declare no conflicts of interest.

Cerebrovascular Diseases 2

EPO-0185 | Asymptomatic hemorrhagic transformation after mechanical thrombectomy is not benign: Early and long-term outcomes

A. Dębiec¹; K. Boniecka¹; J. Winnicka¹; P. Piasecki²; A. Stępień¹

¹Clinic of Neurology, Military Institute of Medicine- National Research Institute, Warsaw, Poland; ²Department of Radiology, Military Institute of Medicine- National Research Institute, Warsaw, Poland

Background and aims: The prognostic relevance of asymptomatic hemorrhagic transformation (aHT) after mechanical thrombectomy (MT) for acute ischemic stroke (AIS) remains uncertain and is often considered clinically benign. We evaluated the impact of aHT on early and long-term outcomes after MT.

Methods: We retrospectively analyzed consecutive patients with AIS treated with MT at a comprehensive stroke center. A follow-up CT scan was performed after 24 hours and hemorrhagic transformation was assessed using Heidelberg Bleeding Classification. Patients were followed up for 12 months. Associations between aHT, functional outcomes, and mortality were analyzed using multivariable regression models.

Results: Among 363 patients, 237 (65.3%) had no HT, 84 (23.1%) developed aHT, and 35 (9.6%) developed symptomatic HT. Patients with aHT had worse functional outcomes than those without HT. Functional independence (mRS 0–2) at 90 days was achieved in 45.1% of patients without HT (23.8% with aHT). After adjustment, aHT was independently associated with reduced odds of functional independence at 90 days (OR 0.29, 95% CI 0.15–0.57), a shift toward worse functional outcome at 12 months (common OR 2.11, 95% CI 1.30–3.41), and increased mortality during follow-up (HR 1.64, 95% CI 1.07–2.52). Patients developing aHT more frequently presented with higher baseline NIHSS, while no single baseline clinical or treatment-related variable emerged as a strong independent predictor of aHT.

Conclusion: aHT after MT is associated with worse early and long-term functional outcomes and increased mortality. Further validation of our findings in large cohort studies of MT-treated patients is warranted.

Disclosure: Nothing to disclose.

EPO-0186 | Epidemiological trends in intracerebral haemorrhage: A decadal analysis of aetiology, prior blood pressure control, and direct oral anticoagulant use

A. Leung; Z. Ren; K. Teo

Division of Neurology, Department of Medicine, Queen Mary Hospital, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong

Background and aims: The incidence of intracerebral haemorrhage (ICH) in Hong Kong remains high compared to developed countries globally. As the most severe form of stroke, where treatment offers only modest benefit, ICH prevention is crucial to reducing disease burden. We aim to study changes in ICH epidemiology, particularly focusing on pre-ICH blood pressure (BP) control, direct oral anticoagulants (DOAC) use, and

TABLE 1 Baseline demographic and clinical characteristics of ICH patients over 3 temporal groups.

1. Hypertensive ICH defined by ICH site and/or vessel, including thalamus, basal ganglia, brainstem, cerebellum and cerebellum.
2. Cerebral amyloid angiopathy defined by presence with imaging, and/or clinical findings, following modified Boston criteria.
3. Uncontrolled hypertension defined by recorded blood pressure consistently greater or above 140/90 mmHg (supine/standing).

the cause of ICH. Our findings will help inform public health strategies to prevent ICH.

Methods: We conducted a single-centre observational study of spontaneous ICH patients admitted from 2014 to 2022. Demographic and clinical data were collected, including pre-ICH BP control, anticoagulant use and ICH aetiology using the modified Boston criteria. Temporal shifts in the aetiology of ICH and BP control were analysed.

Results: A total of 1,044 ICH patients were categorised into three temporal groups: 2014–16, 2017–19, and 2020–22. There was a numerical increase in the proportion of ICH attributed to cerebral amyloid angiopathy (CAA) from 19.8% (75/379; 2014–16) to 25.8% (86/333; 2020–22) ($p=0.110$). The rate of undiagnosed/uncontrolled hypertension decreased from 67.3% (255/379; 2014–16) to 62.2% (207/333; 2020–22) ($p=0.023$) but remained high. The prevalence of anticoagulant-associated ICH roughly doubled from 2014–16 to 2020–22 (7.1% vs 13.0%, $p=0.028$), driven by DOAC-ICH. Among DOAC-ICH, 54.3% had uncontrolled/ undiagnosed hypertension and 30.6% had CAA.

Conclusion: Pre-ICH BP control had slightly improved over the decade, but the rate of undiagnosed/uncontrolled hypertension remains unacceptably high. Strengthening hypertension control in both the general population and, as importantly, DOAC users, is essential to reduce ICH burden.

Disclosure: Nothing to disclose.

EPO-0187 | Comparative cardiovascular and bleeding outcomes with PPIs versus H2-receptor blockers: A nationwide cohort study in Korea

B. KIM¹; S. Cho²

¹Nowon Eulji Medical Center, Seoul, Republic of Korea;

²UiJeongbu Eulji Medical Center, UiJeongbu, Republic of Korea

Background and aims: Among stroke survivors on anti-thrombotic therapy, gastroprotection is common, yet the cardiovascular safety of proton pump inhibitors (PPIs) relative to H2-receptor blockers (H2Bs) remains debated.

Methods: We performed a retrospective cohort study using linked Korean National Health Insurance claims and national stroke registry data. Adults with imaging-confirmed index ischemic stroke (2016–2020) who received antithrombotics and

initiated either a PPI or an H2B within 30 days after the index event were included. The primary outcome was major adverse cardiovascular events (MACE)—composite of myocardial infarction, recurrent stroke, or all-cause death. Secondary outcomes were gastrointestinal (GI) bleeding, intracranial hemorrhage, and other bleeding. Propensity-score matching balanced baseline covariates, and Cox models estimated hazard ratios (HRs).

Results: From 850,053 screened records, 4,569 eligible patients were identified and grouped as PPI ($n=2,515$) and H2B ($n=2,054$). After propensity-score matching, there was no significant difference in MACE between PPI and H2B users across crude, PS-matched, and fully adjusted analyses. In contrast, GI bleeding was significantly lower with PPIs than with H2Bs, while intracranial hemorrhage and other bleeding showed no excess risk with PPIs. Findings were consistent across sensitivity analyses.

Conclusion: In ischemic stroke patients treated with anti-thrombotics, PPIs did not increase MACE risk compared with H2Bs and were associated with lower GI-bleeding risk. These results support the cardiovascular safety of PPIs and suggest they may be the preferred gastroprotective option in this setting, particularly for patients at heightened risk of GI bleeding.

Disclosure: Nothing to disclose.

EPO-0188 | Impact of tenecteplase implementation in a remote region without on-site thrombectomy

C. Vera-Cáceres; M. Regalado; D. Chi; A. López Traba; D. Vargas; Y. Aguilera; R. Mora; C. Marrero; D. Ramos; M. González Platas

Neurology Department, General Hospital of Fuerteventura, Canary Islands, Spain

Background and aims: Intravenous thrombolysis (IVT) remains the main treatment for acute ischemic stroke (AIS) in hospitals without endovascular treatment (EVT). Tenecteplase may simplify workflow and reduce treatment delays compared with alteplase. We aimed to evaluate the impact of switching from alteplase to tenecteplase on workflow metrics, safety, and early clinical outcomes in an insular hospital.

Methods: An observational study including consecutive patients with AIS treated with IVT at a hospital without on-site EVT. Two periods were compared: 2024 (alteplase) and 2025 (tenecteplase). The primary outcome was DTN time. Secondary outcomes included the proportion treated <60 minutes, intracranial hemorrhage, in-hospital mortality, and functional outcomes at discharge.

Results: 14 patients in the alteplase group and 7 in the tenecteplase group. Mean age was 69 and 62 years, respectively ($p=0.18$), and mean baseline NIHSS was 12.5 vs 9 ($p=0.17$). Median DTN was significantly shorter with tenecteplase (45 vs 71 minutes), representing a reduction of 26 minutes ($p<0.01$). The proportion treated within 60 minutes increased from 35.7% to 71.4% ($p=0.04$). Intracranial hemorrhage rates were similar (21.4% vs 14.3%; $p=1$). One in-hospital death occurred in the alteplase group. NIHSS at discharge did not differ between groups (mean 5.4 vs 4.1; $p=0.29$). Functional independence at discharge (mRS 0–2) was observed in 61.5% of the alteplase group and 57.1% of the tenecteplase group.

Conclusion: In remote regions without onsite EVT, implementation of tenecteplase for IVT was associated with a significant improvement in workflow efficiency, particularly door-to-needle time, without compromising safety.

Disclosure: Nothing to disclose.

EPO-0189 | External validation of ASPECTS–NIHSS clinical-imaging equations for predicting 90-day outcome after endovascular thrombectomy in acute ischemic stroke

H. Savsin¹; T. Homa³; A. Slowik²
¹Student Scientific Group of Cerebrovascular Diseases, Jagiellonian University Medical College, Krakow, Poland;
²Department of Neurology, Jagiellonian University Medical College, Krakow, Poland; ³Department of Neurology, University Hospital, Krakow, Poland

Background and aims: Despite the widespread adoption of endovascular thrombectomy (EVT) in acute ischemic stroke (AIS) patients with large vessel occlusions, rapid bedside tools for prognostication are limited. Novel simple clinical-imaging equations based on Alberta Stroke Program Early CT Score (ASPECTS) and National Institutes of Health Stroke Scale (NIHSS) were recently developed (Nie et al, 2025) to predict post-EVT outcomes. We aimed to externally validate the equations and the published logistic model for predicting 90-day functional independence in an independent cohort.

Methods: Consecutive AIS patients undergoing anterior circulation EVT within 24 hours at the University Hospital Krakow (January–December 2023) with available NIHSS, ASPECTS and 90-day modified Rankin Scale (mRS) were included. Three predictive approaches were validated: (1) clinical–imaging equation (CIE=ASPECTS –0.5×NIHSS), (2) age-adjusted-CIE (AdjCIE = ASPECTS–0.5×NIHSS–0.2×Age), and (3) published logistic model probability (p_FI). Primary outcome was functional independence (mRS 0–2). Discrimination was assessed using area

TABLE 1 Baseline characteristics of the study cohort stratified by modified Rankin Score.

Variable	Total Cohort (n=149)	mRS 0–2 (n=101)	mRS 3–6 (n=48)
Demographics

FIGURE 1 ROC curves of (A) the published logistic regression model probability of functional independence (p_FI), (B) age-adjusted clinical–imaging equation (AdjCIE) and (C) clinical–imaging equation (CIE) for 90-day functional independence.

FIGURE 2 Calibration plot for the published logistic model predicting functional independence after 90 days. Predicted probabilities grouped into quintiles of predicted risk in the validation cohort (n=149). The dashed line is perfect calibration.

under the ROC curve (AUC), calibration using intercept and slope and, overall accuracy using Brier score.

Results: 149 of 361 patients were included (mean age 72, 60.4% female, median NIHSS 15 [9]) and 67.8% achieved functional independence. Discriminative ability was good for p_FI (AUC 0.761; 95% CI 0.676–0.846) and AdjCIE (AUC 0.763; 95% CI 0.679–0.847), and moderate for CIE (AUC 0.705; 95% CI 0.616–0.793). Calibration of p_FI showed systematic underprediction (intercept 1.805, slope 1.404) and Brier score was 0.281.

Conclusion: Proposed clinical-imaging equations show good discrimination for 90-day functional independence in our cohort but systematic underprediction in calibration, indicating the possible requirement for regional recalibration before clinical application.

Disclosure: Nothing to disclose.

EPO-0190 | Cancer-related stroke in esus patients: A Tunisian cross-sectional study

L. Bouafia¹; H. Slimene; K. Jemai; A. Mili; E. Jarrar; A. Rekik; A. Hssine; S. Najja; S. Benamor
Neurology department, Sahloul University Hospital, Sousse, Tunisia

Background and aims: Malignancy is identified in ~10% of patients with embolic stroke of undetermined source (ESUS).

Ischemic stroke (IS) may precede or follow cancer diagnosis, yet no consensus exists on systematic malignancy screening in stroke patients. This study aimed to evaluate the clinical, biological, and radiological features of cancer-related stroke (CRS) in a Tunisian cohort.

Methods: We conducted a 4-year cross-sectional study including patients with acute IS confirmed by CT or MRI and admitted to the Neurovascular Unit of Sahloul University Hospital, Tunisia. CRS was defined as ESUS with a negative etiological workup (brain MRI, CT angiography, 48-hour Holter monitoring, transthoracic and transesophageal echocardiography) in patients with active cancer diagnosed before or during stroke evaluation.

Results: Twenty-four patients were included (median age 66.2 ± 9.1 years; male-to-female ratio 3.8). Cancer was revealed during stroke workup in 16 patients (66.7%). Common malignancies were lung (41.7%), pancreatic (20.8%), colon (12.5%), and prostate (8.3%). Median NIHSS was 6. Five patients had prior venous thrombosis or pulmonary embolism, suggestive of Trousseau syndrome. Imaging showed multiple infarcts in ≥ 2 vascular territories in 50% and the Three Territory Sign in 37.5%. Median D-dimer was $4.0 \mu\text{g/mL}$ [IQR 1.93–13.1], and mean fibrinogen was $3.18 \pm 1.89 \text{ g/L}$. Eight patients (33.3%) died shortly after stroke; eleven received curative anticoagulation.

Conclusion: Elevated D-dimer levels and embolic infarct patterns, particularly the three territory Sign, are key markers of CRS in ESUS patients. D-dimer alone lacks specificity, but combined markers improve risk stratification and enable earlier detection in high-risk patients.

Disclosure: Nothing to disclose.

EPO-0191 | Serum brain-derived tau in moyamoya angiopathy: A case-control study of associations with cognitive impairment

J. Norsted Sørmark¹; M. Skjelland¹; B. Halvorsen²; T. Ueland²; V. Bjerkeli²; P. Aukrust³; T. Nordenmark⁴; M. Wiedmann⁵; A. Aamodt¹

¹Dpt. of Neurology, Oslo University Hospital, Oslo, Norway;

²Research Institute for Internal Medicine, Oslo University Hospital, Rikshospitalet, Faculty of Medicine, Institute of Clinical Medicine, University of Oslo, Oslo, Norway; ³Institute of Clinical Medicine, University of Oslo, Oslo, Norway, Section of Clinical Immunology and Infectious Diseases, Oslo University Hospital Rikshospitalet, Oslo, Norway; ⁴Department of Psychology, Oslo University Hospital, Ullevål, Oslo, Norway; ⁵Department of Neurosurgery, Oslo University Hospital, Rikshospitalet, Oslo, Norway

Background and aims: Brain-derived tau (BD-tau) is a sensitive blood-based biomarker of neuronal injury in acute ischemic stroke; but its relevance in conditions characterized by chronic cerebral hypoperfusion remains unclear. Moyamoya angiopathy (MMA) is a progressive steno-occlusive disorder causing regional cerebral hypoperfusion, impaired vasomotor reserve, and heterogenous clinical phenotypes, including cognitive impairment, complicating risk stratification. Biomarkers reflecting hypoperfusion-related neuronal injury may complement imaging and clinical assessment in neurosurgical decision-making. We investigated serum BD-tau levels in MMA

patients and healthy controls and explored relations with cognitive performance.

Methods: This cross-sectional, register-based case-control study included MMA patients without recent stroke ($n=37$) and healthy controls ($n=14$). Serum total BD-tau levels were compared using Mann-Whitney U test. MMA patients underwent comprehensive neuropsychological assessment across nine cognitive domains. A Global Cognitive Impairment Index (GCII) was calculated as the proportion of domains with at least one test score ≥ 1 standard deviation below normative means. Associations between BD-tau and GCII were assessed using Spearman's rank correlation.

FIGURE 1 Box-plot comparing BD-tau total levels between MMA-patients ($n=37$) and healthy controls ($n=14$). Difference was non-significant ($p=0.263$, Mann-whitney U test). S-BD-tau: serum brain-derived tau total. MMA: moyamoya angiopathy.

FIGURE 2 Scatterplot demonstrating no statistical correlation between GCII and BD-tau levels in MMA patients ($n=37$, Spearman $\rho=0.311$ $p=0.061$). S-BD-tau: serum brain-derived tau. MMA: moyamoya angiopathy. GCII: Global Cognitive Impairment Index.

Results: Median serum BD-tau levels were 12.38 [9.40–14.96] pg/mL in the MMA group and 9.97 [9.27–13.77] pg/mL in the control group, without significant between-group difference ($p=0.263$). Within the MMA group, BD-tau levels showed no significant correlation with GCII ($p=0.061$).

Conclusion: Serum BD-tau levels were not elevated in MMA patients and were not associated with global impairment. Despite small sample size, these findings suggest limited general utility of BD-tau in MMA, though its potential in selected subgroups warrants further investigation in larger cohorts.

EPO-0192 | Determinants of functional outcome in patients with intracranial atherosclerotic stenosis: Analysis of the bernese intracranial stenosis study

K. Antonenko¹; P. Radojewski²; A. Hoffmann³; S. Fenzel³; J. Kaesmacher³; M. Arnold¹; R. Wiest²; P. Mordasini⁴; M. Heldner¹

¹Department of Neurology, Inselspital, Bern University hospital and University of Bern, Bern, Switzerland; ²Institute of Diagnostic and Interventional Neuroradiology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; ³Translational Imaging Center, siten-insel, Bern, Switzerland; ⁴Institute of Diagnostic and Interventional Neuroradiology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; ⁵Institute of Diagnostic and Interventional Neuroradiology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; Department of Diagnostic and Interventional Neuroradiology, Cantonal Hospital Aarau, Aarau, Switzerland

Background and aims: Functional outcome after intracranial atherosclerotic stenosis (ICAS) is highly variable, yet the prognostic determinants of outcome in these patients are still not well defined. Ultra-high-field 7-Tesla MRI enables detailed evaluation of ICAS.

Methods: We analyzed 131 ICAS patients (of which $n=58$ symptomatic) under best medical management from the prospective Bernese Intracranial Stenosis Study, dichotomized by 1-year functional outcome (favorable: mRS 0–1, $n=58$; unfavorable: mRS 2–6, $n=73$). Group comparisons were performed for demographics, vascular risk factors, laboratory values, and 3/7T MR imaging markers at baseline and follow-up.

Results: At baseline, the unfavorable vs. favorable outcome group had a significantly higher prevalence of symptomatic ICAS (52.1% vs. 34.5%, $p=0.044$), diabetes mellitus (39.7% vs. 20.7%, $p<0.02$), physical inactivity (30.1% vs. 5.2%, $p<0.001$), peripheral artery disease (15.1% vs. 3.4%, $p=0.027$), higher median baseline NIHSS (1 vs. 0, $p=0.012$), median baseline BDI

(7 vs. 3, $p<0.001$), alongside lower median baseline MoCA (26 vs. 27, $p=0.001$) and median baseline EuroQoL VAS (70 vs. 83, $p<0.001$). At 1-year follow-up, the unfavorable outcome group had significantly worse median NIHSS (2 vs. 1, $p<0.001$), BDI-II (6 vs. 3, $p=0.005$), MoCA (26 vs. 28, $p<0.001$), and EuroQoL VAS (75 vs. 87, $p<0.001$) in univariable analysis. In multivariable analysis, symptomatic ICAS (OR 2.74, 95% CI 1.11–6.80, $p=0.029$) remained to be the only independent predictor of unfavorable outcome.

Conclusion: In summary, symptomatic ICAS was independently associated with 2.74-fold increased odds of an unfavorable functional outcome. This highlights the importance of early identification and close monitoring of symptomatic ICAS patients to optimize functional recovery.

Disclosure: Nothing to disclose.

EPO-0193 | Tenecteplase in the extended treatment window for acute ischemic stroke: Evidence from randomized trials

K. Moghib¹; M. Meshref²

¹Kasralainy medical school, Cairo University, Cairo, Egypt;

²Department of Neurology, Faculty of Medicine, Al-Azhar University, Cairo, Egypt

Background and aims: The role of intravenous tenecteplase (TNK) for acute ischemic stroke treated between 4.5 and 24 hours remains debated, particularly across healthcare settings with variable access to endovascular thrombectomy (EVT).

Methods: Randomized controlled trials comparing TNK (0.25 mg/kg) with placebo or standard care in adults treated 4.5–24 hours after stroke onset were systematically reviewed. The primary outcome was excellent functional recovery (mRS 0–1) at 90 days. Secondary outcomes included recanalization, neurological improvement, and safety endpoints. Random-effects meta-analyses were performed overall and stratified by EVT availability. PROSPERO (CRD420251274200)

Results: Four multicenter RCTs ($n=1,278$) were included. TNK significantly increased the likelihood of excellent functional outcome and vessel recanalization. Overall differences in good functional outcome and early neurological improvement were not significant. In settings without EVT access, TNK improved multiple functional and early recovery outcomes, whereas benefits in EVT-capable settings were limited to recanalization. Rates of symptomatic intracerebral hemorrhage and 90-day mortality were similar between groups.

Conclusion: TNK improves excellent functional recovery and recanalization in the 4.5–24-hour window, particularly where EVT is unavailable, supporting its role as a pragmatic reperfusion option in resource-limited contexts.

Disclosure: Nothing to disclose.

EPO-0194 | Greater occipital nerve block as a treatment for non-traumatic subarachnoid haemorrhage related headache: Systematic review of the available evidence

M. Delgado-Romeu¹; Á. Lambea-Gil¹; M. Guasch-Jimenez¹; P. Carbonell-Fernández¹; Ó. López-Lombardía¹; G. Ezcurra-Díaz¹; L. Prats-Sánchez¹; A. Martínez-Domeño¹; J. Fernández-Vidal¹; N. Morollón Sánchez-Mateos²; N. Pérez de la Ossa¹; P. Camps-Renom¹; A. Ramos-Pachón¹
¹Stroke Unit, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; ²Headache and Neuralgia Unit, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background and aims: Non-traumatic subarachnoid haemorrhage (SAH) is characterized by severe headache refractory to conventional analgesia, leading to frequent use of opioids. Greater occipital nerve blocks (GONB) are commonly used in migraine and other headache disorders with great success. The goal of this study was to review available evidence on the use of GONB in the treatment of SAH-related headache.

Methods: Systematic review of available evidence following the PRISMA-2020 guidelines from inception to 01/2026 with a narrative synthesis of the results. We included studies with adult patients with non-traumatic SAH-related headache, which used GONB (with/without other nerve blocks) as adjunctive

analgesia and monitored headache intensity with validated scores (VAS, NPRS [both 0–10]). The search was performed in electronic databases (PubMed, Embase, Cochrane CENTRAL, ClinicalTrials.gov) using controlled terms related to SAH, headache and GONB. Bias risk was assessed using validated tools (JBI/ROBINS-I).

Results: 48 studies were identified, of which three met inclusion criteria (Figure 1). Two were case series ($n=2$, $n=10$) and one was a non-randomized observational study with historical controls ($n=10$). All studies reported a decrease in headache intensity scores after the procedure (Δ NPRS 2.67–6, timeframe 1 h–1 week), and a reduced need for rescue analgesia. No significant adverse events were reported. All studies had a moderate-to-high bias risk due to lack of proper controls and small sample sizes (Table 1).

Conclusion: Current evidence on GONB for treating non-traumatic SAH-related headache is limited due to small-sample non-controlled studies, but consistently suggests potential analgesic benefits. Randomized controlled data are needed to further examine its efficacy.

Disclosure: The authors declare no conflicts of interest.

EPO-0195 | Predicting neurological functional improvement using machine learning in acute minor stroke: A Vietnamese cohort study

M. Tran Nguyen Tuan¹; T. Duy Mai²; D. Tien Nguyen²; P. Viet Dao²; M. Cong Tran³; H. Xuan Nguyen¹
¹London Digital Twin Research Center, Middlesex University, London, UK; ²Stroke Center, Bach Mai Hospital, Hanoi, Vietnam; ³Department of Clinical Neuroscience, University of Oxford, Oxford, UK

Background and aims: Although acute minor stroke is often considered benign, many patients develop persistent functional limitations. Early prediction of neurological functional improvement, assessed by the 90-day modified Rankin Scale (mRS), may support treatment decisions and rehabilitation planning. This study aimed to develop machine learning models to predict 90-day mRS improvement in patients with acute minor stroke using newly collected data from Vietnam.

Methods: We analyzed data from 736 patients with acute minor stroke admitted to Bach Mai Hospital, Vietnam, between 2023 and 2024. The dataset was split into a training set (70%, $n=515$) and a test set (30%, $n=221$). Predictor selection was performed in the training set using LASSO regression with 5-fold cross-validation. Four binary classifiers - Extra Trees, Random Forest, Extreme Gradient Boosting, and Support Vector Machine with a Radial Basis Function kernel - were trained using the selected predictors. Hyperparameters were optimized using GridSearch cross-validation, and performance was evaluated in the test set.

Results: Fourteen predictors were identified. All models achieved an area under the receiver operating characteristic curve above 0.75. The Extra Trees model showed the best performance, with an Area Under the Receiver Operating Characteristic Curve (AUC) of 0.780 (95% CI, 0.704–0.854), Precision-Recall AUC of 0.890, accuracy of 0.810, and F1-score of 0.878.

Conclusion: Machine learning models may help predict 90-day functional improvement in patients with acute minor stroke

EPO-0196 | ATAD3A stabilizes Drp1 via lysosome-dependent regulation to sustain pathological mitochondrial fission after cerebral ischemia/reperfusion

T. Xiong¹; X. Wu¹; Q. Wu¹; H. Liang¹; X. Luo¹; M. Yang²; J. Wang¹; N. Qin¹; L. Tan²; L. Fu¹; X. Qin¹; **R. Zhang¹**
¹Department of Neurology, Chongqing Key Laboratory of Neurology, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China; ²Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China

Background and aims: Excessive mitochondrial fission is a key driver of neuronal death after cerebral ischemia/reperfusion (I/R), yet the mechanisms sustaining this process beyond the acute phase remain unclear. Dynamin-related protein 1 (Drp1) is central to mitochondrial fission, but how its pathological activation is maintained following I/R is poorly understood. This study investigated whether ATPase family AAA domain-containing protein 3A (ATAD3A) regulates mitochondrial fission and neuronal death through control of dynamin-related protein 1 stability.

Methods: Mouse middle cerebral artery occlusion/reperfusion (MCAO/R) and neuronal oxygen–glucose deprivation/reoxygenation (OGD/R) models were established. ATPase family AAA domain-containing protein 3A was suppressed genetically in vivo and in vitro. Protein interaction, degradation pathways, mitochondrial dynamics, and neuronal apoptosis were analyzed using biochemical, imaging, and functional approaches.

Results: Cerebral I/R induced sustained upregulation of ATAD3A in neurons. ATAD3A interacted with Drp1 and inhibited its lysosome-dependent degradation, thereby preserving Drp1 protein stability. Persistent stabilization of Drp1 promoted excessive mitochondrial fission and disruption of mitochondrial dynamics, leading to increased neuronal apoptosis. Suppression of ATAD3A accelerated Drp1 degradation, attenuated pathological mitochondrial fission, and reduced neuronal apoptosis after ischemia/reperfusion.

Conclusion: ATAD3A sustains pathological mitochondrial fission after cerebral I/R by preventing lysosome-dependent degradation of Drp1. This proteostatic mechanism represents a key driver of persistent mitochondrial dynamics disruption and neuronal death following ischemic injury.

Disclosure: Nothing to disclose.

FIGURE 1 ATAD3A is upregulated in neurons after and knockdown of ATAD3A improves neurological function and ameliorates neuronal apoptosis following cerebral ischemia/reperfusion injury.

FIGURE 2 ATAD3A promotes mitochondrial fission and suppresses mitochondrial fusion.

FIGURE 3 ATAD3A interacts with and stabilizes Drp1 by inhibition of lysosome-mediated degradation.

EPO-0197 | Recovery of post-stroke dysphagia: A 16-month follow-up study in 455 post stroke patients using the Functional Oral Intake Scale (FOIS)

A. Dine; O. Çibuku; E. Ranxha

Neuro vascular Service, University Hospital “Mother Teresa”
Tirane, Albania

Background and aims: Tracking swallowing function with validated tools is essential for understanding recovery patterns and guiding care. To evaluate the progression and predictors of dysphagia recovery in stroke patients over 16 months using the Functional Oral Intake Scale (FOIS).

Methods: This prospective cohort study included 455 patients with ischemic or hemorrhagic stroke and clinically confirmed dysphagia, admitted between June 2023 and January 2025. Swallowing ability was assessed at baseline, 1, 3, 6, 12, and 16 months post-stroke using the FOIS score. Recovery was defined as reaching FOIS level ≥ 6 . Multivariate logistic regression identified factors associated with persistent dysphagia (FOIS ≤ 5) at 16 months.

Results: At baseline, all patients scored between FOIS 1 and 3. At 3 months, 54.1% had reached FOIS ≥ 4 . By 6 months, 68.3% had achieved FOIS ≥ 6 , and by 16 months, 82.2% of patients reached FOIS levels 6–7, indicating functional oral intake. Persistent dysphagia (FOIS ≤ 5) at 16 months was independently associated with brainstem stroke (OR 3.5, $p < 0.001$), higher NIHSS scores on admission ($p = 0.003$), and age > 75 ($p = 0.01$). A total of 28 patients (6.2%) remained dependent on partial or full enteral feeding at the end of the follow-up.

Conclusion: The majority of patients with post-stroke dysphagia demonstrate significant improvement on the FOIS within the first 6 months, with gradual gains continuing through 16 months. Severe stroke, brainstem involvement, and advanced age are predictors of poor recovery.

Disclosure: Nothing to disclose.

FIGURE 1 FOIS in months.

EPO-0198 | Explainable machine learning-based prediction of poor functional outcome after ischemic stroke using routine clinical data

B. Özdemir

Ankara University Medical Faculty, Neurology Department,
Ankara, Türkiye

Background and aims: Early prediction of poor functional outcome after ischemic stroke remains challenging. Conventional prognostic models show limited performance in heterogeneous real-world populations. We aimed to evaluate whether a machine learning model using routinely available clinical variables improves prediction of poor functional outcome compared with logistic regression.

Methods: We retrospectively analyzed 642 ischemic stroke patients with available baseline clinical, laboratory, electrocardiographic, and imaging data. Poor functional outcome was defined as modified Rankin Scale score greater than 3 at follow-up. Data were split into training and test sets. A Random Forest classifier was developed and compared with logistic regression. Model performance was evaluated using receiver operating characteristic area under the curve. Model interpretability was assessed using SHapley Additive exPlanations.

Results: The Random Forest model showed good discriminative performance with a receiver operating characteristic area under the curve of 0.87 on the test set, outperforming logistic

regression. Sensitivity and specificity varied according to probability thresholds. SHapley Additive exPlanations identified stroke severity, mortality, functional status, and selected laboratory markers as key contributors to model predictions.

Conclusion: Explainable machine learning using routine clinical data improved prediction of poor functional outcome after ischemic stroke. Explainable models may support individualized risk stratification in clinical practice.

Disclosure: Nothing to disclose.

FIGURE 1 Mean absolute SHAP values showing the relative contribution of each variable to poor outcome prediction. NIHSS had the strongest impact, followed by glucose, renal function, premorbid disability, and age.

FIGURE 2 SHAP summary plot illustrating direction and magnitude of feature effects. Higher NIHSS and glucose values increased poor outcome risk, while better renal function shifted predictions toward favorable outcome.

FIGURE 3 Receiver operating characteristic curve demonstrating strong discrimination for poor outcome (area under the curve 0.87). SHAP importance confirms NIHSS as the dominant predictor.

EPO-0199 | The impact of advanced practice nurse-led follow-up model on medication adherence for secondary prevention in patients with acute ischaemic stroke

D. Hou
Department of Nursing, Beijing Tsinghua Changgung Hospital,
School of Clinical Medicine, Tsinghua Medicine, Tsinghua University

Background and aims: This study explores the impact of a follow-up model led by advanced practice nurses on medication adherence for secondary prevention in patients with acute ischaemic stroke, aiming to provide a reference for long-term medication management in this patient group.

Methods: A follow-up programme led by advanced practice nurses was developed, encompassing both in-hospital and post-discharge management. In-hospital management involved advanced practice nurses providing structured health education and guidance during the patient's hospital stay. Upon discharge, patients were given personalised medication management plans. Post-discharge management included follow-ups conducted by advanced practice nurses at 1 month, 3 months, 6 months, and 1 year after discharge via telephone, WeChat, and online platforms. During these follow-ups, individualised education and guidance were provided, and assistance with outpatient appointment bookings was offered when necessary.

Results: A total of 190 patients were included. After one year of intervention, the adherence rates to antithrombotic medication at 3 months, 6 months, and 1 year post-discharge were 94.7% (180/190), 94.2% (179/190), and 95.3% (181/190), respectively; adherence rates to statins were 95.3% (181/190), 92.1% (175/190), and 89.5% (170/190), respectively; adherence rates to hypoglycaemic drugs were 100% (52/52), 96.2% (50/52), and 92.3% (48/52), respectively; adherence rates to antihypertensive drugs were 96.5% (110/114), 99.1% (113/114), and 96.5% (110/114), respectively.

Conclusion: The advanced practice nurse-led follow-up model has a positive impact on medication adherence for secondary prevention in patients with acute ischaemic stroke and merits further promotion and application.

Disclosure: Nothing to disclose.

F. Mazzacane¹; A. Dell'Orco²; B. Del Bello³; G. Busto⁴; E. Fainardi⁵; M. Wattjes²; A. Morotti⁶; J. Nawabi²

¹Department of Emergency Neurology and Stroke Unit, IRCCS Mondino Foundation, Pavia, Italy; ²Department of Neuroradiology, Charité - Universitätsmedizin Berlin, Humboldt-Universität zu Berlin, Freie Universität Berlin, Berlin Institute of Health, Germany; ³Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; ⁴Neuroradiology, Department of Radiology, AOU Careggi, Italy; ⁵Department of Biomedical Experimental and Clinical, Neuroradiology, University of Firenze, AOU Careggi, Firenze, Italy; ⁶Department of Clinical and Experimental Sciences, Neurology Unit, University of Brescia, Italy

Background and aims: Venous outflow (VO) is essential for maintaining cerebral hemodynamics. Impaired venous outflow (VO) has been associated with poor outcomes and hemorrhagic transformation in ischemic stroke; however, its prevalence and determinants in acute intracerebral hemorrhage (ICH) remain understudied.

Methods: We retrospectively included patients admitted to Charité University Hospital, Berlin (January 2019-June 2025) with supratentorial ICH and available baseline CT angiography. VO assessment was performed according to the validated Comprehensive Venous Outflow (CVO) score of the ipsilateral hemisphere. The association between clinical and radiological variables and the CVO score was assessed using a multivariable Bayesian beta-binomial model to account for overdispersion in the bounded count outcome. The variables included in the model were age, systolic blood pressure, ICH volume, intraventricular hemorrhage, and edema volume.

Results: A total of 533 patients were included in this analysis. Baseline characteristics revealed a mean age of 73 years (SD 13.8) and mean ICH volume of 41.41 ml (SD 42.9). A total of 300 (56.3%) patients had deep ICH. The median CVO was 8 (IQR 5–8), with a score <6 in 149 (27.9%) patients, indicating significant impairment. ICH volume (aOR for 1 point reduction for 1 SD increase, 1.84, 95%CrI 1.34–2.49), IVH volume (aOR 1.41, 1.27–1.57), and edema volume (aOR 1.29, 0.95–1.77) along with deep location (aOR 1.54, 1.16–2.06) were associated with a decrease in the CVO score.

Conclusion: VO impairment is common in patients with ICH and is associated with ICH features such as ICH volume, edema, and location. Further research is warranted to evaluate its clinical significance.

Disclosure: F. Mazzacane was supported by EAN Research Fellowship grant. A. Dell'Orco: Nothing to disclose. B. Del Bello: Nothing to disclose. G. Busto: Nothing to disclose. E. Fainardi: Nothing to disclose. M. Wattjes: Nothing to disclose. A. Morotti: Nothing to disclose. J. Nawabi: Nothing to disclose.

¹College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Jeddah, Saudi Arabia; ²College of Pharmacy, Umm Al-Qura University, Makkah, Saudi Arabia; ³Faculty of Medicine, Jeddah University, Jeddah, Saudi Arabia

Background and aims: Atrial fibrillation (AF) is a major cause of ischemic stroke and is associated with higher rates of recurrence and worse outcomes. Oral anticoagulation is essential for secondary prevention; however, the optimal timing of initiation following acute ischemic stroke remains uncertain due to concerns regarding hemorrhagic complications. This study aims to evaluate the safety and efficacy of early compared with delayed initiation of oral anticoagulant therapy in patients with AF-related ischemic stroke.

Methods: A systematic review and meta-analysis were conducted following PRISMA guidelines. Randomized controlled trials and observational studies involving adult patients with ischemic stroke and non-valvular AF were included. Studies comparing early and delayed initiation of oral anticoagulants were analyzed. Primary outcomes included recurrent ischemic events or transient ischemic attacks, intracranial hemorrhage, major bleeding, and all-cause mortality. Random-effects models were used for pooled analyses, with sensitivity analyses performed to assess result robustness.

Results: Seventeen studies met inclusion criteria, with thirteen eligible for quantitative synthesis, comprising more than 32,000 patients. Early initiation of oral anticoagulation was not

FIGURE 1 PRISMA flow diagram illustrating the study selection process for included randomized controlled trials and observational studies.

FIGURE 2 Forest plot comparing early versus delayed initiation of oral anticoagulation for ischemic events or transient ischemic attack in patients with atrial fibrillation related ischemic stroke.

FIGURE 3 Forest plot showing the risk of intracranial hemorrhage associated with early versus delayed oral anticoagulation initiation after atrial fibrillation related ischemic stroke.

associated with increased all-cause mortality or major bleeding compared with delayed initiation. Sensitivity analyses demonstrated a lower risk of recurrent ischemic events without an increased risk of intracranial hemorrhage among patients receiving early therapy.

Conclusion: Early initiation of oral anticoagulation following AF-related ischemic stroke appears safe and may offer superior protection against recurrent ischemic events. These findings support early, individualized, imaging-guided anticoagulation strategies and may inform future clinical guideline updates.

Disclosure: Nothing to disclose.

EPO-0202 | Endovascular treatment for anterior circulation strokes beyond 6 hours: Better late than never

I. Stoican¹; R. Stanculescu²; R. Neamtu²; A. Cristache²; S. Dumitrescu²; A. Dimancea¹; R. Naum¹; S. Tuta¹; M. Manea¹
¹National Institute of Neurology and Neurovascular Diseases, Neurology Department, Bucharest, Romania; ²National Institute of Neurology and Neurovascular Diseases, Radiology Department, Bucharest, Romania

Background and aims: Endovascular treatment beyond 6 hours has been shown to improve outcomes in selected stroke patients, usually based on advanced imaging. This study aimed to evaluate the outcomes of patients undergoing thrombectomy beyond 6 hours without the use of advanced imaging.

Methods: We retrospectively included patients with anterior circulation strokes who underwent thrombectomy without prior thrombolysis and divided them into late window (LW) and non-late window (NLW) groups. Baseline characteristics included age, sex, National Institutes of Health Stroke Scale (NIHSS), and Alberta Stroke Program Early CT Score (ASPECTS). Outcomes were assessed using parenchymal hemorrhagic transformation (PHT), ASPECTS at 24 hours, and modified Rankin Scale (mRS) at discharge. In the LW group, associations between age, baseline ASPECTS, number of thrombectomy passes and outcomes were analyzed.

Results: A total of 117 patients were included (47 LW, 70 NLW), with no significant baseline differences between groups. No statistically significant differences were observed in PHT rates ($p=0.3649$) or mean ASPECTS at 24 hours ($p=0.12356$). Mean mRS at discharge was $3.4043 (\pm 1.6896)$ in the LW group and $3.9857 (\pm 1.9523)$ in the NLW group ($p=0.05118$). In the LW group, mRS at discharge was not associated with age but showed significant correlations with baseline ASPECTS ($r = -0.30732$, $p=0.03562$) and number of thrombectomy passes ($r=0.41476$, $p=0.00375$).

Conclusion: Thrombectomy beyond 6 hours without advanced imaging resulted in outcomes comparable to those achieved within the conventional time window. Higher baseline ASPECTS and fewer thrombectomy passes were associated with better functional outcomes.

Disclosure: Nothing to disclose.

EPO-0203 | Cardiac ultrasound in stroke by neurologists: A comparative study of diagnostic accuracy

J. Thillen; Y. Winter; P. Mencke; L. Schwindling; G. Sergiu; P. Lochner
 Saarland University Center, Saarbrücken, Germany

Background and aims: Cardioembolic stroke is one of the most prevalent causes of ischemic stroke, making it crucial to identify cardiac embolic sources accurately. Transthoracic echocardiography (TTE) is widely used for this purpose, but logistical barriers often delay its use when performed outside neurology departments, potentially, reducing the rate of cardiac imaging in stroke patients. Thus, the objective of the present study was to evaluate the diagnostic accuracy of neurologist-performed TTEs

following specialised training, using cardiologist readings as the reference standard.

Methods: Neurologists were trained using a simplified 10-point echocardiographic protocol developed by the ESNCH Working Group. A total of 74 TTEs performed by neurologists in ischemic stroke patients were compared by cardiologists. Diagnostic sensitivity, specificity, interobserver agreement (Cohen's kappa), accuracy and predictive values were calculated.

Results: Perfect interobserver agreement was found for pericardial fluid ($k=1.0$; accuracy 100%) and left atrial (LA) enlargement ($k=0.832$; sensitivity 90.5%, specificity 93.9%). Moderate agreement was observed for significant valvular dysfunction ($k=0.572$) and left ventricular (LV) function impairment ($k=0.489$). Notably, the negative predictive value (NPV) was high ($\geq 95\%$) for seven out of nine parameters, suggesting Neurologist-performed TTE is a reliable tool for ruling out major structural pathologies.

Conclusion: Trained neurologists can accurately identify significant cardiac abnormalities on TTE relevant to stroke care, with strong specificity across parameters. Neurologist-performed TTE may serve as a reliable diagnostic component in acute stroke settings, improving access and efficiency in interdisciplinary stroke care.

Disclosure: Nothing to disclose.

EPO-0204 | Adjunctive hypothermia after endovascular reperfusion therapy for acute ischemic stroke: Evidence from a meta-analysis

K. Sarhan; R. Mohamed

Faculty of Medicine, Mansoura University, Mansoura, Egypt

Background and aims: Endovascular thrombectomy (EVT) is the standard of care for acute ischemic stroke due to large vessel occlusion; however, reperfusion injury limits neurological recovery. Selective or mild therapeutic hypothermia has emerged as a potential neuroprotective adjunct to EVT, aiming to mitigate ischemia-reperfusion injury while preserving procedural safety.

Methods: We conducted a systematic review and meta-analysis of clinical studies evaluating therapeutic hypothermia combined with EVT in patients with acute ischemic stroke. PubMed, Embase, Scopus, and Web of Science were searched from inception to December 2025. Primary outcomes were favorable functional outcome (modified Rankin Scale [mRS] 0–2 at 90 days). Secondary outcomes included excellent functional outcome (mRS 0–1), mortality, and symptomatic intracranial hemorrhage (sICH).

Results: Seven studies comprising 603 patients were included, of whom 294 received therapeutic hypothermia combined with EVT and 309 underwent thrombectomy alone. The addition of hypothermia was associated with a significantly higher rate of favorable functional outcome at 90 days (mRS 0–2: 59.2% vs 49.2%; RR=1.23, 95% CI 1.06–1.42). Patients treated with hypothermia also demonstrated a greater likelihood of excellent functional recovery (mRS 0–1: 48.6% vs 33.1%; RR=1.45, 95% CI 1.12–1.88). There were no significant differences between groups in mortality (RR=0.97, 95% CI 0.75–1.26) or symptomatic intracranial hemorrhage (RR=0.78, 95% CI 0.50–1.21). Statistical heterogeneity was low to moderate across outcomes.

Conclusion: Therapeutic hypothermia combined with EVT is associated with improved functional outcomes without increased mortality or hemorrhagic risk. Larger randomized trials are needed to confirm efficacy and optimize cooling strategies.

Disclosure: Nothing to disclose.

EPO-0205 | MicroRNA-based point-of-care potential for stroke subtype differentiation

M. Nath; D. Vibha

Department of Neurology, Neurosciences Center, All India

Institute of Medical Sciences, New Delhi, India

Background and aims: Timely differentiation between acute ischemic stroke and intracerebral hemorrhage is essential for safe treatment. However, neuroimaging may delay care in resource-limited settings. Circulating microRNAs (miRNAs) are stable and linked to cerebrovascular injury, making them promising diagnostic markers.

Methods: Adults presenting within six hours of stroke onset were enrolled before neuroimaging, with STARD guidelines as reference. The diagnosis was confirmed with standard imaging. Blood samples were collected at presentation and analyzed via next-generation sequencing to identify miRNA, then validated by qRT-PCR. Participants included patients with acute ischemic stroke ($n=15$), intracerebral hemorrhage ($n=15$), and healthy controls ($n=30$). miRNA cycle thresholds were normalized. Diagnostic performance was evaluated using nonparametric analysis, ROC curves, PCA, and machine-learning classifiers. Pathway enrichment supported biological plausibility.

Results: Distinct circulating miRNA expression patterns were observed across stroke subtypes and controls. miR-21 and miR-146a were significantly downregulated, whereas miR-155 was upregulated in stroke cohorts relative to healthy individuals. Diagnostic performance analyses demonstrated robust discriminatory capacity, with miR-21 achieving the highest classification accuracy (AUC=0.80). PCA revealed clear separation between ischemic, hemorrhagic, and control groups. Among machine-learning approaches, Random Forest models achieved superior predictive performance, particularly in differentiating intracerebral hemorrhage from controls (AUC=0.79). Pathway analyses linked these miRNAs to inflammatory signaling, immune modulation, and cell survival mechanisms relevant to acute cerebrovascular injury.

Conclusion: Circulating miRNA signatures enable early discrimination between ischemic and hemorrhagic stroke before imaging confirmation. These findings support further validation of miRNA-based assays as adjunctive diagnostic tools to accelerate stroke triage and precision care.

Disclosure: Nothing to Disclose.

Background and aims: Intracranial atherosclerotic stenosis (ICAS) and chronic kidney disease (CKD) are both significant contributors to stroke risk and poor outcomes.

Methods: In this retrospective observational cohort study, 488 first-ever ischemic stroke patients from the Bernese Stroke Registry (April 2021 – March 2023) were analyzed. Patients were stratified into four groups based on ICAS presence and eGFR: no ICAS/eGFR ≥ 60 ($n = 226$), no ICAS/eGFR < 60 ($n = 73$), ICAS/eGFR ≥ 60 ($n = 107$), and ICAS/eGFR < 60 ($n = 82$). Data on demographics, vascular risk factors, stroke aetiology, ICAS location, acute treatment, and 3-month outcomes (mRS) were analyzed.

Results: Patients with ICAS and eGFR < 60 were the oldest (median 83.9 years, range 55.4–99.5) and had significantly worse renal function (median creatinine 117 $\mu\text{mol/L}$, median eGFR 44 ml/min/1.73 m^2) compared to other groups ($p < 0.001$). Arterial hypertension was significantly more prevalent in the ICAS/eGFR < 60 group (85.4%) than in the no ICAS/eGFR ≥ 60 group (63.1%) ($p < 0.001$). Diabetes mellitus prevalence was highest in the ICAS/eGFR < 60 group (37.8%, $p = 0.009$). According to TOAST classification, large artery atherosclerosis was the dominant stroke mechanism in ICAS groups (44.9% in ICAS/eGFR ≥ 60 vs. 7.5% in no ICAS/eGFR ≥ 60 , $p < 0.001$). At 3-month follow-up, patients with ICAS/eGFR < 60 had the poorest functional outcomes, with only 58.2% achieving a favourable mRS (0–2) compared to 81.3% in the no ICAS/eGFR ≥ 60 group ($p < 0.001$).

Conclusion: The co-existence of ICAS and impaired renal function identifies a high-risk stroke group characterized by a greater burden of vascular risk factors, large artery atherosclerosis as stroke aetiology, and worse short-term functional recovery. These findings underscore the importance of integrated vascular risk assessment and tailored management strategies in this vulnerable patient group.

Background and aims: Hematoma growth occurs in approximately one-third of patients with intracerebral hemorrhage (ICH) and is associated with a high rate of morbidity and mortality. However, radiological hematoma growth does not always coincide with neurological deterioration. This study aimed to differentiate symptomatic and asymptomatic hematoma growth and examine their respective clinical implications using data from the Antihypertensive Treatment of Acute Cerebral Hemorrhage 2 (ATACH-2) trial.

Methods: Among 917 ICH patients (568 male patients) from ATACH-2 with complete clinical and imaging data, hematoma growth was defined as a $> 33\%$ relative or $> 6 \text{ mL}$ absolute increase in volume on 24-hour computed tomography. Symptomatic hematoma growth was defined by concurrent neurological deterioration (≥ 1 -point NIHSS increase), while asymptomatic growth occurred without NIHSS worsening. Associations between hematoma growth types and 90-day functional outcomes (modified Rankin Scale [mRS]) were evaluated using multivariable logistic regression.

Results: Symptomatic hematoma growth occurred in 5.9% and asymptomatic growth in 16.7% of patients. Both were independently associated with poor functional outcomes (mRS 4–6), with the strongest effect observed for symptomatic growth (adjusted OR 6.891; 95% CI 3.411–13.921). Mortality was highest among symptomatic patients (25.9%), compared with asymptomatic (10.5%) and no-growth groups (3.7%). Larger baseline hematoma volume, ultra-early hematoma growth, and intraventricular hemorrhage growth were significantly more frequent in symptomatic hematoma growth.

FIGURE 1 Flow diagram of the study participants.

TABLE 1 Relationship between different types of hematoma growth and prognosis.

Variable	Subtype	Adjusted odds ratio	95% confidence interval	P value
90-day major disability (mRS 3-5)	Asymptomatic	1.307	0.764-1.987	0.341
	Symptomatic	1.844	1.073-3.527	0.029
90-day unfavorable outcome (mRS 3-6)	Asymptomatic	1.444	0.977-2.135	0.063
	Symptomatic	10.659	4.032-28.041	<0.001
90-day poor outcome (mRS 4-6)	Asymptomatic	2.114	1.402-3.188	<0.001
	Symptomatic	6.891	3.411-13.921	<0.001
90-day mortality (mRS 5)	Asymptomatic	2.810	1.402-5.632	0.004
	Symptomatic	7.840	3.443-17.848	<0.001

mRS: modified Rankin Scale.

Conclusion: Asymptomatic hematoma growth is not uncommon and predicts poor outcomes after ICH, although symptomatic growth carries a substantially higher risk of death and disability. Early identification through integrated clinical-radiological assessment and vigilant monitoring may improve prognostication and facilitate timely intervention.

Disclosure: JNG has received consulting from AstraZeneca, CSL Behring, Octapharma, Takeda, and Cayuga.

EPO-0208 | Morbidity and mortality of ruptured cerebral aneurysms in patients aged over 80 years: A systematic review and meta-analysis

S. Soleimani¹; M. Dabbagh Ohadi¹; R. Dashti²; M. Niemelä¹; E. Winkler³; B. Rezai Jahromi¹

¹1. Department of Neurosurgery, Helsinki University Hospital and University of Helsinki, Helsinki, Finland; ²2. Department of Neurosurgery, Stony Brook University Hospital, Stony Brook, USA; ³3. Department of Neurosurgery University of California-San Francisco San Francisco, USA

Background and aims: Aneurysmal subarachnoid hemorrhage (aSAH) in patients over 80 years is associated with high mortality and morbidity, yet evidence guiding management in this population is limited. As life expectancy increases,

clarifying outcomes of different treatment strategies in very elderly patients has become increasingly important.

Methods: PubMed, Embase, Scopus, and Web of Science were systematically searched till October 2025 in accordance with PRISMA guidelines. Studies reporting outcomes of ruptured intracranial aneurysms in patients aged ≥ 80 years were included. Primary outcomes were favorable functional outcome and mortality and complications of ruptured cerebral aneurysms. Clinical severity was assessed using Hunt & Hess, or WFNS grading systems. Random-effects meta-analyses were performed, and study quality was evaluated using the ROBINS-I tool.

Results: 26 retrospective studies including 14,469 patients were analyzed; approximately two-thirds were female, and the mean age was 84.3 years. Surgical clipping was performed in 4,863

TABLE 1 Favorable Outcome in SAH patients ≥ 80 years old.
Meta-Analysis: Favorable Outcome in SAH Patients ≥ 80 Years

TABLE 2 Mortality in SAH patients ≥ 80 years old.

Meta-Analysis: Mortality in SAH Patients ≥ 80 Years

TABLE 3 Odds Ratios between Intervention and Conservative management in SAH patient ≥ 80 years.

Meta-Analysis: Odds Ratios (Intervention vs. Conservative) in SAH Patients ≥ 80 Years

patients, endovascular treatment in 5,444, and conservative management in 4,135. Among 1,252 patients with reported admission grade, 577 had poor-grade SAH. Interventional treatment was associated with a higher pooled rate of favorable outcomes than conservative management (28.6% vs 9.2%) and significantly improved odds of favorable outcome (OR 3.18) and reduced mortality (OR 0.16). Benefits were greatest in patients with good initial clinical grades. The pooled complication rate was 49%, with cerebral vasospasm and hydrocephalus each affecting about one-quarter of patients.

Conclusion: Despite high overall mortality, selected very elderly patients, particularly those with good clinical grades, may benefit from interventional treatment. Treatment decisions should be individualized rather than based on age alone.

Disclosure: Behnam Rezai Jahromi and Mika Niemelä have patents pending on aneurysm imaging.

Neuropathies 2

EPO-0209 | Management of disabling spasticity with functional neurosurgery (selective microsurgical neurotomy)

A. Afif

Department of Neurosurgery, Department of Anatomy, INSERM U 1028, Pain Center, Pierre Wertheimer Hospital, Lyon 1 University; European Hospital, Paris, France

Background and aims: Spasticity is one of the most common sequelae of central neurological disorders. It is defined as a motor disorder characterized by a velocity-dependent increase in the tonic stretch reflex associated with an exaggeration of deep tendon reflexes. When disabling spasticity is focused on one or a few muscle groups, selective peripheral neurotomy may be considered.

Methods: Before undergoing these surgical programs, patients undergo a complete preoperative assessment using a block test of the targeted nerves using local anesthetics. After an approach tailored to the targeted nerve, the first step is microsurgical dissection of the nerve branches and the fascicles of each branch. The study of motor responses allows for the differentiation of motor fascicles from sensory fascicles, and then hyperexcited fascicles from others. After this identification, the fascicles are partially transected according to the preoperative plan.

Results: In our series, patients who underwent selective neurotomy of the upper and lower limbs experienced significant suppression or reduction of spasticity and a reduction or disappearance of spasticity-induced pain. Functional improvement was significant (upper limb flexibility, hand and finger opening, limb reuse, improved gait and foot stability during stance and walking), with improvements in body image, comfort when dressing, and shoe fitting.

Conclusion: In the management of spasticity, selective microsurgical neurotomy has predictable effects based on preoperative testing. By eliminating excessive spasticity, correcting abnormal postures, and reducing associated pain, neurotomy allows for the resumption of active and effective rehabilitation

and, in some cases, the reappearance or improvement of voluntary and useful motor skills.

Disclosure: Selective Microsurgical Neurotomy is a modular and adaptable technique for each patient. It allows for the long-term reduction of focal spasticity at the cost of low morbidity.

EPO-0210 | Silent dysphagia in CANVAS: Videofluoroscopic abnormalities despite low EAT-10

A. Alungulese; I. Catalina Alvarez; L. Del Pino Tejado
Department of Neurology, Gregorio Marañón University Hospital, Madrid, Spain

Background and aims: Dysphagia has been reported within the clinical spectrum of cerebellar ataxia, neuropathy and vestibular areflexia syndrome (CANVAS), but it is often unrecognized and not systematically assessed. The objective of this study was to characterize dysphagia in genetically confirmed CANVAS and evaluate concordance between symptom-based screening and instrumental assessment.

Methods: We conducted a retrospective case series of 12 adult patients with CANVAS. All patients underwent dysphagia screening using the Eating Assessment Tool-10 (EAT-10) and videofluoroscopic swallowing study (VFSS). VFSS reports were reviewed for swallowing safety (laryngeal penetration, aspiration, cough reflex) and efficiency (pharyngeal residue), with analysis according to bolus consistency.

FIGURE 1 Screening versus instrumental swallowing assessment in CANVAS.

FIGURE 2 Key videofluoroscopic swallowing findings in CANVAS.

Results: The cohort comprised 12 patients (8 women), with a mean age of 66.5 years. Chronic cough was present in most patients (10/12). All patients exhibited sensory axonal polyneuropathy and bilateral vestibular hypofunction, consistent with the CANVAS phenotype. Cerebellar involvement, defined by neurological examination and/or brain MRI findings, was identified in 2/12 patients. EAT-10 scores were below the pathological cut-off (<3) in 11/12 patients, while one patient had advanced dysphagia requiring percutaneous endoscopic gastrostomy. In contrast, VFSS demonstrated objective abnormalities in 10/12 patients (83.3%) (Figure 1) Laryngeal penetration was predominantly observed with thin liquids. All patients with abnormal VFSS lacked an effective cough reflex (10/10, 100%). Aspiration occurred in 2/12 patients (16.7%). Minimal pharyngeal residue was reported in 2/12 patients (16.7%) (Figure 2).

Conclusion: In RFC1-CANVAS, dysphagia appears to follow a silent progression, with normal EAT-10 scores preceding objective videofluoroscopic abnormalities and aspiration risk.

Disclosure: Nothing to disclose.

EPO-0211 | Clinical characteristics and therapeutic response in patients with autoimmune nodopathies: A multi-center study from the US

C. Koutsoumpa¹; M. Weisman²; A. Morrison³; W. Khan⁴; S. Muppidi⁵; N. Chahin⁶; L. Davalos⁷; A. Deifes²; R. Sadjadi⁴; K. Gable⁸; M. Dimachkie⁷; C. Karam²; J. Allen⁹; B. Roy¹
¹Department of Neurology, Yale University, New Haven, USA;
²Department of Neurology, Perelman School of Medicine, Philadelphia, USA; ³Department of Neurology, The Ohio State University, Columbus, USA; ⁴Department of Neurology, Mass General Hospital, Boston, USA; ⁵Department of Neurology, Stanford School of Medicine, Stanford, USA; ⁶Department of Neurology, Oregon Health and Science University, Oregon, USA; ⁷Department of Neurology, University of Kansas Medical Center, Kansas City, USA; ⁸Department of Neurology, Duke University Medical Center, Durham, USA; ⁹Department of Neurology, University of Minnesota Medical School, Minneapolis, USA

Background and aims: Autoimmune nodopathies (AINs) with circulating IgG4 autoantibodies targeting nodes of Ranvier antigens are rare. About 5–10% of patients with electrodiagnostic features of a demyelinating neuropathy have autoimmune nodopathies. AINs usually have distinct clinical features and often don't respond to intravenous immunoglobulin (IVIg), but improve with B-cell-depleting therapy. Most of the current literature on AIN came from Europe and Japan, and data from the US is limited.

Methods: This multi-center study, including over 12 centers in the US, is actively capturing the clinical features and therapeutic responses of patients with AINs.

Results: To date, we have included 33 patients, 25 (76%) with anti-neurofascin 155 (NF155) and six (18%) with anti-Contactin IgG4 autoantibodies, and two patients positive for both autoantibodies. The average age of disease onset was 50.3 ± 19.6 years, and 18 (54.5%) patients were male. About 55% of patients had both distal and proximal weakness, and 36% had predominant distal weakness. Distal loss of vibration sensation and ataxia were common. Areflexia was observed in >80% patients. Over 90% of this cohort received IVIg, but only 33% had partial benefit. Steroids were used in 50% of cases, neonatal Fc receptor

(FcRn) inhibitors in 13% of cases, and PLEX in 20% of cases. Over 70% of patients were treated with rituximab, and most showed objective benefit on clinical examination.

Conclusion: This important collaborative effort will provide new insights into the clinical characteristics of AIN and critical information on management strategies.

Background and aims: Chronic inflammatory demyelinating polyneuropathy (CIDP) is a heterogeneous immune-mediated neuropathy requiring long-term immunomodulatory treatment. Although different effective therapies are available, real-world data on treatment-sequencing, dosing patterns, and escalation strategies remain limited.

Methods: This multicenter retrospective observational study included patients with CIDP fulfilling the 2021 EAN/PNS diagnostic criteria treated at specialized German centers (Neuritis Network). Individual treatment sequences and dosages across consecutive therapy lines were reconstructed. Disability and functional impairment were assessed using the Inflammatory Neuropathy Cause and Treatment (INCAT) score and the Inflammatory Rasch-built Overall Disability Scale (RODS).

Results: 511 patients were included (median age at diagnosis 59 years, 29% female) with 79% diagnosed with typical CIDP and a median follow-up of 80 months. Initial treatment consisted mostly of intravenous immunoglobulins (IVIg, 47%) or intravenous glucocorticoids (46%). While most patients starting on IVIg remained on immunoglobulin therapy, the majority of those initially treated with glucocorticoids later switched to IVIg. Over the disease course, IVIg was used in 90% of patients, intravenous glucocorticoids in 56%, subcutaneous immunoglobulins (SCIg) in 17%, and oral glucocorticoids in 8%. At data cut-off, 62% of patients were treated with IVIg and 17% with SCIg. IVIg dosing was highly variable, ranging from 0.12 to 2.9 g/kg body weight per four weeks. Escalation therapies were applied in 24% of patients, most commonly rituximab.

Conclusion: These findings highlight immunoglobulin therapy as the cornerstone of CIDP management in real-world practice, while heterogeneous dosing patterns and frequent escalation underscore ongoing disease activity and the need for more targeted therapeutic options.

Disclosure: The study received no external commercial or institutional funding. FFK received honoraria for lectures and travel compensation from Alexion, Argenx, Merck, Novartis, and Takeda. He received research support as fellow of the German Research Foundation (DFG)– and Hannover Medical School (MHH)-funded Clinician Scientist Program (PRACTIS) at MHH and from Merck, Siemens and Erwin-Röver-Foundation. EPO-0213 | Therapeutic effects of repeated immunoadsorption in CIDP: A long-term, prospective, observational study

J. Dorst; Z. Elmas

Department of Neurology, University of Ulm, Ulm, Germany

Background and aims: Corticosteroids, intravenous immunoglobulins (IVIGs), and plasma exchange (PLEX) constitute the main therapeutic options in CIDP, but immunoadsorption (IA) represents a noteworthy alternative to PLEX due to its excellent tolerability. In this study, we sought to evaluate the short- and long-term therapeutic effects of IA in CIDP compared to PLEX and preceding therapies (IVIGs and corticosteroids).

Methods: Between 02/12/2013 and 03/03/2025, we prospectively evaluated the course of disease of patients with CIDP who received at least one cycle of IA or PLEX. One cycle of IA or PLEX consisted of 5 treatments on 5 consecutive days. As the primary outcome parameter, we used a combined CIDP score of 3 validated scales comprising disability (Inflammatory Neuropathy Cause and Treatment (INCAT) score), motor score (Medical Research Council, MRC), and vibration sensitivity (tuning fork test).

FIGURE 1 Study flow diagram.

FIGURE 2 Short-term effects.

FIGURE 3 Long-term effects.

Results: In total, 80 patients were included. We observed improvements of CIDP scores post-treatment in the IA group (median improvement from 310 (224–374) to 321 (234–373) points; $p < 0.0001$), but not in the PLEX group (median 254 (214–358) vs. 254 (209–351), $p = 0.12$). Long-term progression rates compared to preceding corticosteroid and IVIG therapies decreased from 3.8 (2.2–9.1) to 0.2 (–0.5–2.2) points/month in the IA group, and from 4.2 (2.6–17.2) to –1.1 (–1.6–0.5) points/month in the PLEX group, corresponding to a clinical stabilization of disease progression.

Conclusion: Our results suggest that repeated IA might constitute promising therapeutic options in patients with CIDP who do not sufficiently respond to corticosteroids and IVIGs, stabilizing the disease in the majority of patients.

EPO-0214 | Paediatric genetic neuropathies: Characterisation and molecular diagnosis in Central Portugal

J. Alves¹; J. Amaral²; A. Matos¹; L. Almendra¹; A. Geraldo¹; I. Videira¹; P. Almeida³; L. Ramos³; J. Ribeiro²

¹Neurology Department, Coimbra University Hospital, Coimbra Local Health Unit, Coimbra, Portugal; ²Paediatric Neurology Department, Child Development Centre, Coimbra Paediatric Hospital, Coimbra Local Health Unit, Coimbra, Portugal; ³Medical Genetics Department, Child Development Centre, Coimbra Paediatric Hospital, Coimbra Local Health Unit, Coimbra, Portugal

Background and aims: Paediatric genetic neuropathies are a group of heterogeneous neuromuscular diseases that are often diagnosed late. This study aims to characterise patients with genetic neuropathy and evaluate the genetic tests that enabled diagnosis.

Methods: A retrospective study of cases since 2000 was conducted, focusing on those with genetic confirmation, with descriptive analyses of demographic, clinical data and diagnostic methods.

Results: We obtained a sample of 68 patients (53.5% male) with suspected genetic neuropathy, in which we identified pathogenic or likely pathogenic variants in 43 (median age of 20.9 years (IQR 16.0–29.5)). The median age at symptom onset was 4.5 years (1.7–8.0), and the median diagnostic delay was 6.7 years

FIGURE 1 Distribution of diagnoses by age at symptom onset.

FIGURE 2 Distribution of genetic testing types by diagnosis.

FIGURE 3 Cumulative incidence of diagnosis: Pre- vs. Post-2015 first visit cohorts.

(IQR 2.3–11.8). A family history was present in 50% and consanguinity in 11.6%. Isolated neuropathies accounted for 81.4%, while 18.6% were associated with complex syndromes. Fifteen diagnoses were identified, most commonly CMT1A (48.8%), followed by HNPP (9.3%), and CMT4C, CMT-SORD, CMT2A, Friedreich's ataxia and ARSACS (4.7% each); remaining diagnoses were single cases. Electrophysiology showed demyelinating neuropathy in 58.1%, axonal in 27.9% and intermediate in 2.3%, with sensory-motor involvement in 76.7%. Genetic diagnosis was achieved by single-gene testing in 65.1%, exome sequencing in 16.3%, gene panels in 11.6% and microarray in 4.7%. Prior genetic testing had been performed in 37.2%. Seven (10.8%) variants of uncertain significance were identified, for which we cannot reclassify their pathogenicity.

Conclusion: Paediatric genetic neuropathies show marked heterogeneity and prolonged diagnostic delay. While targeted testing remains valuable in selected scenarios, advanced sequencing techniques are essential in complex cases, supporting individualised diagnostic strategies.

Disclosure: Nothing to disclose.

Background and aims: Intravenous immunoglobulin (IVIg) is recommended as a first-line therapy for chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) and multifocal motor neuropathy (MMN) according to EAN/PNS and EFNS/PNS guidelines. However, long-term real-world data on IVIg treatment and treatment decision-making are limited and have thus been investigated during this study.

Methods: This non-interventional, multicenter, longitudinal study evaluated treatment patterns in 84 patients (65 typical CIDP, 9 CIDP variants, 10 MMN) treated with IVIg (Gamunex® 10%) across 1,192 visits over up to 18 months. At each infusion cycle, physicians documented criteria for individual treatment decision making with regard of IVIg therapy.

Results: Patient and treatment characteristics are shown in Table 1. Treatment was continued without modification in 1,112 (93.3%) visits of which patients were evaluated clinically stable in 1,051 visits, supported by stable INCAT scores over time (Figure 1). Adaptations for medical reasons occurred in 22/84 (26.2%) patients, which were more frequent in patients with shorter time since diagnosis (≤ 1 year: adaptations in 36.4% of patients; > 1 year: 22.6%) and in patients with CIDP variants (adaptations in 55.6%) compared to typical CIDP (21.5%). Adverse drug reactions occurred in 8/1,176 Gamunex® 10% infusions (0.7%), were mild or moderate, and did not lead to any discontinuation.

FIGURE 1 INCAT measures remained stable over the course of the study (18 months).

Total documented visits, n	1,192
Previous immunoglobulin, n (%)	79 (94.0)
Time since therapy start with Gamunex® 10%, median (range), y	2.3 (0 – 22.0)
Treatment characteristics	
Loading dose (IVG naïve), mean ± SD, g/kg BW	2.0 ± 0.0
Maintenance dose, median (range), g/kg BW	1.0 (0.2 – 2.0)
Number of infusion days per cycle, mean ± SD	1.5 ± 0.7
Infusion cycle intervals, median (range), days	28 (10 – 126)
Visits with stable dosing and intervals, n/N (%)	1,112/1,192 (93.3)
[Physician's] decision due to stability of the patient, n/N (%)	1,051/1,112 (94.5)

Abbreviations: CIDP, chronic inflammation demyelinating polyradiculoneuropathy; MMN, multifocal motor neuropathy; IVG, intravenous immunoglobulin; BW, body weight; SD, standard deviation.

Conclusion: Therapeutic decisions were individualized, and therapy was adjusted during the observation period in a significant proportion of patients. Most patients remained clinically stable over 78 weeks. IVIg 10% demonstrated a favorable safety profile in real-world practice.

Disclosure: The study was supported by Grifols, manufacturer of Gamunex® 10%. SP: Employee at Grifols FK: Honoraria for lecturing and advisory activities from Abbvie, Stadapharm, Esteve, CSL Behring, Takeda, Zambon, Octapharma, and Argenx. EPO-0216 | Neuropathic pain in RFC1-related CANVAS: A systematic review and meta-analysis

P. Neophytou¹; C. Avraam³; P. Zis²
¹Neurology Department, Nicosia General Hospital, Nicosia, Cyprus; ²Medical School, University of Cyprus, Nicosia, Cyprus; ³Neurosurgery Department, Nicosia General Hospital, Nicosia, Cyprus

Background and aims: Cerebellar ataxia, neuropathy and vestibular areflexia syndrome (CANVAS), caused by biallelic intronic repeat expansions in RFC1, is a multisystem neurological disorder in which sensory neuronopathy is a core feature. Although neuropathic pain is increasingly reported in clinical cohorts and narrative reviews of RFC1-related disease, its prevalence has not been systematically evaluated. We conducted a systematic review and meta-analysis to determine the prevalence of neuropathic pain in RFC1-related CANVAS.

Methods: A systematic literature search was performed on 13/01/26 using the terms (pain OR painful OR neuropathy OR ganglionopathy OR neuronopathy) AND (CANVAS OR RFC1). The search identified 243 records. After title and abstract screening, 146 articles underwent full-text review. Eligible studies included genetically confirmed CANVAS reporting the presence neuropathic pain. Study selection followed PRISMA guidelines. Data were extracted independently by two reviewers. Statistically pooled proportion calculations were conducted in R language using the default settings of the “meta” package and the “metaprop” function with a random effects model, with heterogeneity assessed using the I² statistic.

Results: The meta-analysis included 433 patients with CANVAS. The pooled prevalence of sensory neuronopathy was 94.7% (95% CI 85.9%–98.2%). The pooled prevalence of neuropathic pain was 46.6% (95% CI 35.6%–57.9%). The heterogeneity was moderate (I² = 73%).

Conclusion: Neuropathic pain is common as it affects a substantial proportion of patients with RFC1-related CANVAS. This systematic review and meta-analysis provides the first pooled prevalence estimate of neuropathic pain in this disorder, highlighting the need for routine pain assessment and increased clinical awareness.

Disclosure: Nothing to disclose.

FIGURE 1 Forest plot showing the pooled prevalence of sensory neuronopathy in patients with CANVAS across 14 studies. The pooled prevalence of sensory neuronopathy was 94.7% (95% CI 85.9%–98.2%).

FIGURE 2 Forest plot showing the pooled prevalence of pain in patients with CANVAS across 14 studies. The pooled prevalence of neuropathic pain was 46.6% (95% CI 35.6%–57.9%). The heterogeneity was moderate ($I^2 = 73\%$).

EPO-0217 | Electrical stimulation of spinal cord alleviates pain and restores sensory and autonomic functions in painful diabetic peripheral neuropathy

R. Martínez Marín¹; C. Rizea¹; G. Gutiérrez²; B. Mansilla³; M. Román de Aragón³; H. Scholtes⁴; Q. Doan⁴; I. Huertas⁴; J. Paz Solís³
¹Servicio de Neurología. Hospital Universitario La Paz, Madrid, Spain; ²Servicio de Neurología. Hospital Universitario Infanta Sofía. San Sebastian de los Reyes (Madrid). Spain; ³Servicio de Neurocirugía. Hospital Universitario La Paz, Madrid, Spain; ⁴Boston Scientific Neuromodulation, Valencia, USA

Background and aims: Effective management of pain and other neurological symptoms remains challenging in painful Diabetic Peripheral Neuropathy (pDPN). We investigated the clinical and physiological effects of Spinal Cord Stimulation (SCS) in pDPN. **Methods:** Twelve patients with “stocking-and-glove” pDPN were implanted with epidural electrodes at thoracic (T10-T12) level. Assessments were performed pre- and post-SCS implantation (3-, 6- and 12-months) and included questionnaires related to pain, neuropathic and autonomic symptoms and neurological tests examining large- and small-fibers such as sensory and motor nerves conduction studies (NCS), sensorimotor physical exam, limbs skin conductance and thermography. **Results:** Baseline assessments confirmed a severe neuropathy profile denoted by impaired pin sensation test and abundant NCS abnormalities: 40/96 of sensory and 15/72 of motor nerves with absent response. After implant, patients reported significant relief in pain (VRS from 8.2-to-2.0) neuropathic (NPSI from 50-to-15) and autonomic symptoms (BASQ from 28-to-14). We observed a progressive recovery in nerve function at both large- and

FIGURE 2 Neuropathic symptoms and clinical examination.

FIGURE 3 Nerve conduction-response recovery studies.

small-fibers. Specifically, to last visit, 29/40 (72%) of sensory and 3/15 of motor responses became detectable (Δ SNAP-2 μ V). Also, in responding nerves, there were noticeable conduction improvements (e.g. $\sim$ Δ SNCV at sural (+2.7 m/s), sup. peroneal (+4.1 m/s) and radial (+5.5 m/s)). This was congruent with improvements in large-fiber-related symptoms (e.g. dysesthesia from 7.2-to-2.5). **Conclusion:** Our results indicate that SCS is able to not only effectively treat pain and other neurological symptoms but also to produce a quantifiable gain in nerve function in pDPN. This suggests that SCS might cause changes in excitability as well as, potentially, some degree of regeneration of nerve fibers. **Disclosure:** This study was sponsored by Boston Scientific.

EPO-0218 | Empasiprubart versus placebo (EMNERGIZE) or immunoglobulin (EMVIGORATE) in chronic inflammatory demyelinating polyradiculoneuropathy: Study designs

S. Rinaldi¹; T. H. Brannagan²; P. Doneddu³; K. L. Gable⁴; L. Querol⁵; M. Stettner⁶; K. Budding⁷; S. Ellor⁷; H. Haddad⁷; M. Markov⁷; R. Patel⁷; O. Van de Steen⁷; I. Van de Walle⁷; J. A. Allen⁸
¹University of Oxford, Oxford, UK; ²Vagelos College of Physicians & Surgeons, Columbia University Irving Medical Center, Columbia University, New York, USA; ³Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Research Hospital, Milan, Italy; Humanitas University, Pieve Emanuele, Milan, Italy; ⁴Duke University Medical Center, Duke University, Durham, USA; ⁵Neuromuscular Diseases Unit, Hospital de La Santa Creu I Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain; ⁶University Medicine Essen, Essen, Germany; ⁷argenx, Ghent, Belgium; ⁸University of Minnesota, Minneapolis USA

FIGURE 1 Pain results.

Background and aims: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is an immune-mediated neuropathy involving complement-driven macrophage-mediated demyelination. Empasiprubart binds complement C2, blocking activation of classical and lectin complement pathways. Two phase 3, randomised, double-blinded studies in participants with CIDP will compare intravenous (IV) empasiprubart versus placebo (EMNERGIZE, NCT07091630) and IV empasiprubart versus IV immunoglobulin (IVIg) (EMVIGORATE, NCT06920004).

Methods: EMNERGIZE (placebo-controlled) will randomise ~160 adults with CIDP 2:1 to receive either empasiprubart or placebo on Days 1 and 8 then once every 4 weeks in a 24-week double-blind treatment period (part A) (Figure 1). EMVIGORATE (double-dummy) will randomise ~218 adults with CIDP 1:1 on stable maintenance IVIg to receive either empasiprubart or continue the stable IVIg dose in a 24-week double-blind treatment period (part A) (Figure 2). Both studies are followed by a 4-week double-blind rollover, 23-month open-label period (part B) and 15-month safety follow-up.

Results: The primary endpoint for both studies is a reduction of ≥ 1 point versus baseline in adjusted Inflammatory Neuropathy Cause and Treatment (aINCAT) score at Week 24. Key secondary endpoints (Week 24) include changes from baseline in Inflammatory Rasch-built Overall Disability Scale score, Medical Research Council sum score, dominant hand grip strength, Timed Up and Go and time to reduction of ≥ 1 point versus baseline in aINCAT score.

Conclusion: These two global phase 3 studies will evaluate the efficacy and safety of empasiprubart in participants with CIDP. Similar designs and endpoints with complementary study populations support the potential role of empasiprubart as a reference treatment across patients with CIDP, regardless of treatment status.

EPO-0219 | NF 140 and NF 186 positive nodopathy masquerading as GBS

S. Ratnasababathy

Department of General Medicine, Sundaram Medical Foundation, Chennai, India

Background and aims: Nodal and para-nodal disorders are often misdiagnosed as GBS or CIDP. Diagnosis relies on clinical suspicion and re-calibration of decisions in patients earlier diagnosed as GBS or CIDP not responding to treatment.

Methods: Nodal and para-nodal disorders can have clinical features and nerve conduction abnormalities that mimic GBS or CIDP but there is no demyelination. The pathology is at the level of the node of Ranvier. These patients have poor responses to IVIG. This case report describes a 19 year old boy who presented after 10 days of difficulty walking and a preceding history of respiratory infection. He was diagnosed initially with GBS based on nerve conduction studies and CSF analysis. 1 year later, on further evaluation considering poor response to IVIG he was found to be positive for antibodies to Neurofascin 140 and 186 and was diagnosed with nodopathy.

Results: The patient was treated with 2 doses of Rituximab and he improved neurologically from mobility with walker to independent ambulation.

Conclusion: Nodal and para-nodal disorders are now part of the spectrum of inflammatory neuropathies. This case reiterates the need to suspect nodopathies among other causes in patients earlier diagnosed with GBS/ CIDP with inadequate response to conventional IVIG or steroids. Whether antibody testing for nodopathy should be part of initial evaluation in patients with features of GBS/ CIDP needs further speculation.

Disclosure: Nothing to disclose.

EPO-0220 | Cerebellar cognitive affective syndrome in hypertrophic olivary degeneration associated progressive ataxia and palatal tremor – A case series

B. Vlad¹; J. Hartung¹; C. Sommer²; K. Schregel²; A. Günther¹; P. Bublak¹

¹Department of Neurology, Jena University Hospital, Jena, Germany; ²Department of Neuroradiology, Institute of Diagnostic and Interventional Radiology, Jena University Hospital, Jena, Germany

Background and aims: Hypertrophic olivary degeneration (HOD) is a rare trans-synaptic degeneration of the inferior olivary nucleus caused by lesions within the Guillain–Mollaret triangle (GMT). This pathway, connecting inferior olivary nucleus, red nucleus, and dentate nucleus, plays a key role in cerebellar motor control. Lesions of the GMT may impair coordination, articulation, and precision movements. Previous studies have focused primarily on motor manifestations of HOD, particularly progressive ataxia and palatal tremor (PAPT), the characteristic clinical features. Potential cognitive consequences of cerebellar involvement remain largely unexplored. Only a single case report has described a cerebellar cognitive affective syndrome in HOD. We aimed to systematically assess cerebellar cognitive impairment in a series of three patients with HOD.

Methods: We conducted a monocentric retrospective case series of three patients with HOD who underwent multiparametric brain MRI including diffusion tensor imaging (DTI) and comprehensive neuropsychological assessment.

Results: All patients were male, aged 57–75 years. An autoimmune-paraneoplastic etiology was suspected in two patients, and one had a post-hemorrhagic structural lesion. Clinically, all presented with PAPT, with disease duration of 1.5–2 years. MRI revealed bilateral HOD in two patients. None of the patients reported subjective cognitive complaints, and global cognitive status was normal. However, all fulfilled criteria for definite cerebellar cognitive impairment on the CCAS-Scale. Notably, despite normal semantic fluency and absence of language impairment, all showed deficits in switching between semantic categories.

Conclusion: This case series suggests that HOD-associated PAPT may involve the GMT in cognitive functions, particularly executive aspects of language production, highlighting a broader cerebellar role beyond motor control.

Disclosure: The authors report nothing to disclose.

EPO-0221 | Emotion recognition deficits in frontotemporal degeneration: Exploring brain functional connectivity and emotional reserve

Background and aims: By examining emotion recognition (ER), direct functional connectivity (dFC) of ER-related networks, and their relationship in frontotemporal degeneration (FTD), this study uncovers the neural underpinnings of socio-emotional variability and explores emotional reserve, defined as better-than-predicted ER based on dFC.

Methods: 109 FTD patients [46 behavioral (bvFTD) and 10 semantic behavioral (sbvFTD); 13 nonfluent (nfvPPA) and 18 semantic (svPPA) primary progressive aphasia; 22 progressive supranuclear palsy (PSP)] and 109 HC completed the Comprehensive Affect Testing System-abbreviated (CATS-A), yielding discrete and composite ER scores. Resting-state functional MRI was analyzed in 92 patients and 97 HC, by extracting dFC and nodal graph metrics across six ER-related networks [salience (SN), semantic appraisal, anterior default mode (aDMN), visuo-associative, sensorimotor (SMN), basal ganglia] reconstructed in 50 independent HC. Correlations between ER scores

and network properties were examined. Emotional reserve was evaluated using a residual-based approach.

Results: All FTD showed reduced positive and negative ER versus HC. SvPPA outperformed bvFTD and nfvPPA in happiness; sbvFTD performed worse than svPPA in disgust. FTDs exhibited altered dFC properties in SN, SMN, visuo-associative and aDMN. In FTD, lower negative ER correlated with reduced aDMN integration. Emotional reserve analysis revealed lower residuals in FTD versus HC, for comparable SN connectivity, reflecting reduced emotional reserve.

Conclusion: FTD showed widespread ER deficits, particularly for negative emotions, with distinct temporal-variants (svPPA vs sbvFTD) profiles. Findings highlight aDMN involvement in negative ER and identify reduced emotional reserve as a potential marker of socioemotional vulnerability in FTD.

EPO-0222 | Identifying individuals at-risk for Alzheimer's Disease: The role of eye-tracking in the NAP4A digital platform

C. Tripodi¹; E. Canu²; A. Gilioli³; S. Musicco³; L. Flematti⁴; M. Nouri Janian⁴; M. Zullo⁴; A. Sanna⁴; F. Agosta⁵; M. Filippi⁶
¹Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ²Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁴Center for Advanced Technology in Health and Wellbeing, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ⁶Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and aims: Early identification of individuals with amnesic mild cognitive impairment (aMCI) at risk of Alzheimer's disease (AD) requires sensitive digital biomarkers beyond standard neuropsychological testing. Eye-tracking may detect subtle changes in attentional and mnemonic processing preceding overt cognitive decline. This study reports the first validation of the Neurocognitive Assessment Platform for Alzheimer's disease (NAP4A), integrating eye-tracking and cognitive assessment.

Methods: Twenty-one healthy controls were assessed at baseline, 6 months, and 12 months using the NAP4A platform, which collects physiological and behavioral data during cognitive tasks. Participants completed the CANTAB battery and a visual memory task involving personal/autobiographical and unfamiliar neuroaesthetic ("Neffie") images. Eye movements were recorded with a TOBII™ eye tracker (90 Hz). Fixation number, fixation duration, saccade number, and saccade distance were analyzed. Wilcoxon signed-rank tests compared encoding versus recall phases and stimulus types. Cognitive performance was examined longitudinally.

Results: CANTAB performance remained stable across time-points, with no significant cognitive changes ($p > 0.05$). Eye-tracking showed greater visual exploration during encoding than recall, with increased fixation number, fixation duration, saccade number, and saccade distance ($p < 0.001$). Neffie images elicited more fixations and shorter fixation durations than personal stimuli ($p < 0.001$), with no saccade differences.

Conclusion: Stable cognition over 12 months aligns with expected trajectories in healthy individuals. Eye-tracking findings indicate higher attentional demands during encoding and greater exploration of unfamiliar stimuli, supporting eye-tracking as a sensitive marker for early AD risk detection.

Background and aims: The increasing availability of disease-modifying therapies for neurocognitive disorders has

intensified the need for accurate and timely diagnosis supported by biomarker-based approaches. Recent European intersocietal recommendations (Frisoni, 2023) proposed a structured, phenotype-driven diagnostic workflow embedding biomarker use within a stepwise clinical pathway. This preliminary analysis from the EuroValiCo study aim to characterise real-world diagnostic pathways in European memory clinics and to evaluate concordance between recommended and observed biomarker use.

Methods: EuroValiCo is an ongoing multicentre observational study, aiming at validating the European recommendations in clinical practice. Medical charts of consecutive patients at first clinical access for cognitive complaints in 2022 and 2024 are retrospectively reviewed, representing pre- and post-recommendation cohorts. Demographic, clinical, neuropsychological, imaging, and biomarker data are collected. Process discovery techniques were applied to reconstruct real-world diagnostic pathways and assess concordance between recommended and observed biomarker use.

Results: Recommendations indicate cerebrospinal fluid (CSF) analysis as the first-line biomarker for suspected Alzheimer's disease (AD), FDG-PET for frontotemporal lobar degeneration (FTLD) and tauopathies, and DAT-SPECT for Lewy body disease (LBD). In a preliminary cohort of 268 patients (49% women; median age 72 years, range 48–85), concordance with recommendations was observed in 71% of suspected AD cases, 57% of FTLD cases, 0% of tauopathy cases, and 50% of LBD cases.

Conclusion: These findings provide insight into the alignment between guideline-recommended and real-world biomarker use, revealing substantial condition-specific differences, with the highest concordance observed in suspected AD. Future analyses will assess adherence across the full diagnostic process, inter-centre variability, and the impact of recommendation implementation.

EPO-0224 | Data-efficient AI models for predicting three-year cognitive decline in early Alzheimer’s disease

M. Zeynali¹; X. Deng²; N. Kandiah³; S. Saffari¹
¹Centre for Biomedical Data Science, Duke-NUS Medical School, National University of Singapore, Singapore, Singapore;
²Department of Neurology, National Neuroscience Institute, Singapore, Singapore; ³Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore

Background and aims: Alzheimer’s disease has a prolonged preclinical phase in which pathological changes precede cognitive symptoms by many years. Blood-based biomarkers offer a scalable and minimally invasive opportunity for early risk stratification; however, small sample sizes and cohort heterogeneity limit the clinical translation of advanced machine learning models.

Methods: Using the Alzheimer’s Disease Neuroimaging Initiative (ADNI) dataset, Baseline blood biomarkers, including pTau217–amyloid beta interaction terms, along with demographics and cognitive assessments, were analysed. Cognitive decline was defined as a sustained decrease of 2 or more points on the Montreal Cognitive Assessment across two consecutive years. Artificial Neural Networks (ANNs) and Support Vector Machines (SVMs) were trained on original and synthetically augmented datasets using Conditional Tabular Generative Adversarial Networks (CTGAN), Tabular Variational Autoencoders (TVAE), and Synthetic Minority Over-sampling Technique for Nominal and Continuous features (SMOTENC). Model performance was evaluated using area under the curve (AUC), sensitivity, and specificity, with Shapley value analysis used to assess feature importance.

Results: CTGAN augmentation achieved optimal performance with AUC improvements of 5.6% (ANN) and 3.2% (SVM) vs non-augmented models. Models demonstrated the ability to predict cognitive decline outcomes over a three-year period. Shapley analysis identified pTau217–amyloid beta interaction terms, baseline diagnosis, and age as primary predictors, with significant biomarker interaction effects.

FIGURE 1 Youden-threshold performance comparison across models and augmentation strategies. ANN with CTGAN achieves the best balance of AUC, sensitivity, and specificity, while SMOTENC underperforms.

FIGURE 2 ΔAUC relative to baseline across augmentation methods. CTGAN consistently improves performance in both ANN and SVM, whereas TVAE shows minor gains and SMOTENC reduces AUC.

FIGURE 3 SHAP summary plot for the ANN model predicting three-year cognitive decline. Points represent individual participants; colors indicate feature values (blue = low, red = high).

Conclusion: Despite sample size limitations, synthetic data augmentation enables robust prediction of cognitive decline risk over three years using baseline blood biomarkers. This methodology supports translation of AI-based screening tools into clinical practice, facilitating early identification of at-risk patients and timely intervention strategies.

Disclosure: Nothing to disclose.

EPO-0225 | Associations between carotid atherosclerosis, dyslipidemia, activity of daily living and cognitive decline

M. Militaru¹; D. Lighezan²; A. Militaru²
¹Department of Neuroscience, Neurology II University Clinic, Victor Babes University of Medicine and Pharmacy Timisoara, Municipal Emergency Hospital Timisoara, Timisoara, Romania;
²Department of Internal Medicine I, Medical Semiology I University Clinic, Victor Babes University of Medicine and Pharmacy Timisoara, Municipal Emergency Hospital Timisoara, Timisoara, Romania

Background and aims: According to recent studies cardiovascular-risk-factors (CVRFs) and carotid-atherosclerosis may contribute to cognitive-decline (CD). The aim of the study

is to evaluate the CD, instrumental-activity-of-daily-living (IADL), signs of depression, subclinical-atherosclerosis (intima-media-thickness (IMT))/carotid-atherosclerosis < 50% stenosis in carotid-atherosclerosis/dyslipidemia patients versus patients without carotid-atherosclerosis/dyslipidemia.

Methods: We included in the study 156CVRFs-patients mean-age 70.83 ± 9.35 (92(59.00%) female/64 (41.00%) male), with/without carotid-atherosclerosis/dyslipidemia, without stroke/cardiovascular-disease/carotid-atherosclerosis > 50%stenosis. We compared the results from the CD, IADL and signs-of-depression-screening of the 79 (50.60%) carotid-atherosclerosis/dyslipidemia-patients versus 77 (49.40%) patients-without-carotid-atherosclerosis/dyslipidemia. They underwent clinical-examination, BP, HR, lipid-profile, Montreal-Cognitive-Assessment (MOCA), IADL and Geriatric-Depression-Scale (GDS-15). We measured IMT (mm)/carotid-plaque using a carotid-duplex-scan in both groups of patients.

Results: From 79 (50.60%) carotid-atherosclerosis/dyslipidemia patients (34 (43.00%) male/45 (57.00%) female), there were 71 (89.90%) hypertension-patients, 28 (35.40%) with obesity, 27 (34.20%) smokers, 43 (54.40%) with atrial-fibrillation, 42 (53.20%) diabetes-mellitus-type-II patients. MoCA, IADL, DBP (mmHg), LDL-cholesterol (mg/dl) significant-decrease and IMT (mm), GDS-15 significant-increase in carotid-atherosclerosis/dyslipidemia patients versus patients without-carotid-atherosclerosis/dyslipidemia ($p < 0.05$). In carotid-atherosclerosis/dyslipidemia patients we determined a significant-weak-negative-correlation between age and MoCA ($p = 0.027$), a weak-significant-positive-correlation with SBP (mmHg) ($p = 0.002$), IMT (mm) ($p < 0.05$) and moderate-significant-positive with GDS-15 ($p < 0.001$).We determined a moderate-positive-statistically-significant correlation between MoCA and IADL ($p < 0.001$) and weak-positive with total-cholesterol/LDL-cholesterol (mg/dl) ($p < 0.05$) and a strong-statistically-significant-negative correlation with GDS-15 ($p < 0.001$), moderate-negative with SBP (mmHg) ($p < 0.05$)/DBP (mmHg) ($p < 0.001$) and IMT (mm) ($p < 0.001$) and weak-negative with HR (b/min.) ($p < 0.05$).We found a moderate-statistically-significant-negative correlation between left/right IMT (mm) with MoCA, IADL ($p < 0.05$) and a moderate-positive-statistically-significant correlation between left/right IMT with GDS-15 ($p < 0.001$).

Conclusion: Early evaluation of CD, activities of daily-living, and depressive symptoms is essential in patients with carotid-atherosclerosis and dyslipidemia, as these patients are at increased risk of cognitive-impairment. Correlating these findings with carotid-atherosclerosis severity, age, BP, HR, lipid-profile alterations and CVRFs may improve early identification and management of CD.

Disclosure: Nothing to disclose.

EPO-0226 | Neuropsychiatric symptoms and structural MRI correlates in major dementia subtypes: A retrospective cohort study

M. Canbuldu; S. Sahin; O. Totuk
University of Health Sciences, Hamidiye Faculty of Medicine,
Prof. Dr. Ilhan Varank Training and Research Hospital,
Department of Neurology, Istanbul, Türkiye

FIGURE 1 Depression and anxiety scores across dementia subtypes. Depression peaked in vascular dementia, while anxiety was highest in dementia with Lewy bodies. Source: Created by the authors. Author's own analysis and visualization.

Background and aims: This study aimed to investigate the distribution of depression and anxiety symptoms among major dementia subtypes and to explore their associations with structural magnetic resonance imaging findings.

Methods: We retrospectively analyzed clinical and imaging data from 1,450 patients followed in a tertiary dementia clinic. Diagnoses included Alzheimer disease, vascular dementia, frontotemporal dementia, and dementia with Lewy bodies. Depression and anxiety were measured using the Geriatric Depression Scale and Geriatric Anxiety Scale. Structural brain changes were rated with the Medial Temporal Atrophy scale, Fazekas score, orbitofrontal sulcus score, collateral sulcus score, and Koedam posterior atrophy score. Group comparisons were conducted using the Kruskal–Wallis test; correlations were assessed with Spearman coefficients. A p -value < 0.05 was considered statistically significant.

Results: Depression scores varied significantly across dementia types ($p = 0.043$), with the highest scores in vascular dementia. Anxiety scores also differed significantly ($p = 0.007$), being highest in dementia with Lewy bodies. Depression correlated positively with Fazekas score ($r = 0.27$, $p = 0.01$), while anxiety showed a weaker but significant association with Koedam posterior atrophy score ($r = 0.18$, $p = 0.04$).

Conclusion: Distinct dementia subtypes exhibit heterogeneous neuropsychiatric profiles and imaging markers. The findings suggest different underlying mechanisms, such as white matter changes linked to depression and posterior atrophy linked to anxiety. Integrating neuroimaging and symptom data may aid personalized dementia care.

Disclosure: Nothing to disclose.

EPO-0227 | Probiotic *Lactiplantibacillus plantarum* KABP051 prevents depressive-like symptoms in *drosophila melanogaster* and murine models of depression

P. Huedo¹; A. Castells-Nobau²; R. Mariné-Casadó³; J. Teichenné³; M. Martín⁴; J. del Bas⁵; A. Caimari⁶; J. Mayneris-Perxachs²; J. Espadaler-Mazo¹

¹R&D Department, AB-Biotics S.A. (Part of Kaneka Corporation), Barcelona, Spain; Basic Sciences Department, Universitat Internacional de Catalunya, Barcelona, Spain; ²Integrative Systems Medicine and Biology Group, Girona Biomedical Research Institute (IDIBGI-CERCA), Salt, Spain; ³Eurecat-Centre Tecnològic de Catalunya, Unitat de Nutrició i Salut, Reus, Spain; ⁴Eurecat-Centre Tecnològic de Catalunya, Unitat de Nutrició i Salut, Reus, Spain; Department of Morphological Sciences, Unit of Human Anatomy and Embryology, Faculty of Medicine, Universitat Autònoma de Barcelona, Bellaterra, Spain; ⁵Biotechnology Area, Centre Tecnològic de Catalunya, Eurecat, Reus, Spain; Department of Biochemistry and Biotechnology, Center of Environmental, Food and Toxicological Technology, Universitat Rovira i Virgili, Tarragona, Spain; ⁶Biotechnology Area, Centre Tecnològic de Catalunya, Eurecat, Reus, Spain

Background and aims: Previous clinical evidence indicated that *Lactiplantibacillus plantarum* KABP051 may alleviate stress and anxiety in adults in association to modulation of serotonergic and kynurenine pathways. This study investigated its potential to prevent depressive-like behaviors using two validated animal models.

Methods: Adult germ-free flies and flies mono-colonized with different probiotics (10⁸ CFU) were subjected to a 4-day consecutive mechanical stress protocol to induce depression-like states. Subsequently, voluntary behavioural responses were assessed using the gap climbing (GAP) and stop-for-sweet (SFS) test. Adult male C57BL/6 mice were administered with probiotic formulations (10⁹ CFU/day) for 43 days. From day 22, all groups except placebo-unstressed underwent water avoidance stress (WAS) for seven days. Depressive-like behaviors were evaluated using the open field (OFT) and forced swim (FST) tests on days 39 and 40.

FIGURE 1 Graphical abstract of the *D. melanogaster* (A) and mice (B) models of depression. *L. plantarum* KABP051 showed the greatest efficacy in preventing depressive-like symptoms in both animal models.

Results: Mechanical stress and WAS induced depressive-like phenotypes in flies and mice, respectively. Among the tested probiotics (including additional *L. plantarum* strains), strain KABP051 showed the strongest reduction of the susceptibility to depression index in both GAP and SFS tests ($p < 0.0001$ vs stressed germ-free flies). In mice, all probiotics showed minor effects on OFT, but only KABP051 significantly reduced immobility time in FST ($p < 0.05$ vs stressed group), mirroring unstressed animals.

Conclusion: *L. plantarum* KABP051 exhibits cross-species depression-preventive activity, likely via conserved pathways such as kynurenine modulation. Further research should elucidate underlying mechanisms and confirm translational benefits in humans.

EPO-0228 | Early identification of cognitive impairment in elderly patients with HFpEF: A simple clinical risk score

S. Arnautu¹; D. Jianu²; M. Andor¹; D. Arnautu¹

¹Department V Internal medicine, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania; ²Department of Neurosciences, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania

Background and aims: Cognitive impairment is a frequent yet under-recognized comorbidity in elderly patients with heart failure with preserved ejection fraction (HFpEF), contributing to functional decline and poor outcomes. Simple and clinically applicable tools for early identification of patients at risk are currently lacking. We aimed to develop a practical clinical risk score for predicting cognitive impairment in elderly patients with HFpEF.

Methods: We conducted a cross-sectional observational study including 326 HFpEF patients aged ≥ 65 years. Cognitive function was assessed using the Mini-Mental State Examination-2 (MMSE-2), with cognitive impairment defined as a score < 24 . Clinical, laboratory, vascular, and functional parameters were collected. Independent predictors were identified using multi-variable logistic regression, and a point-based clinical risk score was derived. Discriminative performance was evaluated using receiver operating characteristic (ROC) analysis.

Results: Cognitive impairment was identified in 9.8% of patients. Independent risk predictors included diabetes mellitus, prior stroke or transient ischemic attack, carotid artery disease, elevated NT-proBNP levels, and reduced estimated glomerular filtration rate. Higher Kansas City Cardiomyopathy Questionnaire (12-KCCQ) scores and anticoagulant therapy for atrial fibrillation were independently associated with lower cognitive risk. The clinical risk score demonstrated strong discriminative ability (AUC=0.84). A threshold of ≥ 2 points identified cognitive impairment with 75% sensitivity and 83% specificity.

Conclusion: We propose a simple, clinically applicable risk score that enables early identification of cognitive impairment in elderly HFpEF patients and may support targeted cognitive screening within an integrated heart-brain care approach.

Disclosure: Nothing to disclose.

S. Buscarnera
Department of Human Neuroscience, La Sapienza University,
Rome, Italy

Background and aims: Complaints about cognitive performance in the absence of cognitive impairment represent the core feature of subjective cognitive decline (SCD), a common complaint in older adults and a potential risk factor for future cognitive impairment. This study examined clinical and psychological correlates of self- and partner-reported cognitive complaints, as well as awareness of personal cognition, in SCD.

Methods: Data of 789 participants with SCD were obtained from the Alzheimer's Disease Neuroimaging Initiative 2 (ADNI2). Cognitive complaints were assessed using the Everyday Cognition scale, completed by both participants (ECog-P) and

Figure 1 Box plot showing the distribution of age according to Mini-Mental State Examination-2 (MMSE-2) score categories. The central line within each box indicates the median; the box limits represent the interquartile range (IQR); whiskers denote the range excluding outliers. Bonferroni-corrected p-values are displayed for each pairwise comparison between MMSE groups. *** = $p < 0.005$, ns = not significant.

FIGURE 1 Age distribution.

Table 1. Univariate logistic regression results predicting cognitive impairment (MMSE < 24).

Univariate Regression Analysis			
Variable	OR	95% CI	p-Value
Age	1.07	1.05–1.12	0.005
ECOG	0.18	0.08–0.39	<0.001
TIA/stroke	2.44	1.17–5.11	0.01
Stroke/TIA	4.78	2.08–10.91	<0.001
Carotid artery disease	5.43	2.12–13.67	0.001
Depression	3.16	1.81–11.45	<0.05
eGFR mL/min/1.73 m ²	0.95	0.93–0.98	<0.05
Total Cholesterol	1.01	0.66–1.59	<0.05
Triglycerides	1.02	1.01–1.09	0.03
Uric acid	2.44	2.13–8.90	0.04
NT-proBNP	1.02	1.0–1.03	<0.0001
Anticoagulants for AIT	0.47	0.18–1.19	<0.04

Abbreviations: Depressive variable: MMSE group: 0 = normal, 1 = mild cognitive impairment, 2 = suspected dementia; Alzheimer's Disease Neuroimaging Initiative 2 (ADNI2); ECOC, Kansas City Cognitive Quality Questionnaire; eGFR, estimated glomerular filtration rate; TIA, transient ischaemic attack; MMSE, Mini-Mental State Examination; NT-proBNP, N-terminal pro-B-type natriuretic peptide; AIT, atrial fibrillation or flutter; TIA, transient ischaemic attack; eGFR, estimated glomerular filtration rate.

FIGURE 2 Logistic regression.

Figure 3 The distribution of the key predicting factors among the 1191 participants. Histograms (top row) display the distribution of continuous variables: ECOC score, eGFR, and NT-proBNP. ECOC scores are generally high, with most patients scoring above 40, indicating preserved quality of life. eGFR values show a moderate spread, reflecting variation in renal function across the cohort. NT-proBNP levels exhibit a right-skewed distribution, consistent with clinical variability observed in heart failure. The plots (bottom row) show the frequency of binary variables: diabetes mellitus, history of stroke or transient ischaemic attack (TIA), and anticoagulant use for atrial fibrillation. These categorical predictors demonstrate distinct group distributions, supporting their relevance in the assessment of cognitive risk in HFpEF.

FIGURE 3 Distribution of key predicting factors.

FIGURE 1 Correlations of ECOG Patient (blue circles) and ECOG Study Partner (red triangles) scores with FAQ.

FIGURE 2 Correlations of ECOG Patient (blue circles) and ECOG Study Partner (red triangles) scores with FAQ.

FIGURE 3 Correlation of awareness with FAQ and GDS.

study-partners (ECog-SP). Awareness of cognitive functioning was operationalized as the difference between ECog-P and ECog-SP scores (awareness). Additional measures included the Geriatric Depression Scale (GDS) and the Functional Activities Questionnaire (FAQ). Descriptive statistics summarized demographic and clinical characteristics. Linear regression models, adjusted for age, sex, and education, were used to examine associations between ECog-P, ECog-SP, awareness, and the clinical variables.

Results: The mean age was 71.0years (SD=6.3), with a mean education of 16.7years (SD=2.4). Higher FAQ scores were significantly associated with worse ECog-P ($\beta=0.04$, $p < 0.001$), ECog-SP ($\beta=0.14$, $p < 0.001$) (Figure 1), and greater awareness ($\beta=0.10$, $p < 0.001$) (Figure 3). Depressive symptoms were positively associated with both ECog-P ($\beta=0.05$, $p < 0.001$) and ECog-SP ($\beta=0.03$, $p=0.02$) (Figure 2). No correlation was found with cognitive awareness (Figure 3).

Conclusion: Cognitive complaints SCD are influenced by multiple factors. Understanding the clinical correlates of perceived cognitive decline can offer valuable insights into the complexity of SCD, supporting both prognosis and management.

Disclosure: Nothing to disclose.

EPO-0230 | Persistent cognitive, functional, and fatigue deficits in post-COVID-19 individuals: A comparative study

S. Hangün¹; Z. Kunduracılar²; E. Koca³; E. Yildirim⁴

¹Gulhane Faculty of Physiotherapy and Rehabilitation, University of Health Sciences, Ankara, Türkiye; ²Faculty of Health Sciences, Istanbul Gelisim University, Istanbul, Türkiye; ³Suleyman Yalcin City Hospital Psychiatry Clinic, Medeniyet University, Istanbul, Türkiye; ⁴Süreyyapaşa Chest Diseases And Thoracic Surgery Training and Research Hospital, Istanbul, Türkiye

Background and aims: The long-term impact of COVID-19 extends beyond respiratory symptoms. This study aimed to compare cognitive function, functional capacity, fatigue, and healthy lifestyle behaviors between individuals with a history of COVID-19 and healthy controls

Methods: We included 40 individuals with a history of COVID-19 and 40 healthy controls. Cognitive status was assessed using the Montreal Cognitive Assessment (MoCA), and functional capacity was measured via the 2-Minute Walk Test. Additional evaluations included the Fatigue Severity Scale,

Pittsburgh Sleep Quality Index, Beck Depression Inventory, and Healthy Lifestyle Behaviors Scale II (HLBS-II).

Results: The clinical characteristics of COVID-19 infection in the study group are presented in Table 1. The study group demonstrated significantly lower scores on the MoCA and 2-Minute Walk Test compared to controls ($p < 0.05$) (Table 2). Similarly, they reported higher fatigue levels and lower scores in the physical activity, stress management and interpersonal relations subdomains of the HLBS-II ($p < 0.05$). Conversely, sleep quality and depression scores showed no significant differences between the groups ($p > 0.05$).

Conclusion: Individuals with a history of COVID-19 exhibit persistent deficits in cognitive function and functional capacity, accompanied by increased fatigue. These impairments appear independent of sleep quality or depression. Clinicians should prioritize long-term monitoring and implement targeted rehabilitation strategies focused on neuro-cognitive recovery and lifestyle modification for this population.

Disclosure: Nothing to disclose.

Background and aims: Neuropsychological impairments are common in glioma patients, but their links to specific clinical and molecular features, beyond tumor location, remain unclear. This study examined whether molecular profiles influence pre-operative neuropsychological function more than tumor location alone.

Methods: We prospectively assessed 99 preoperative glioma patients and 52 healthy controls with a comprehensive neuropsychological battery. After controlling for demographics, patients with insular (deep) and fronto-temporo-parietal (superficial) tumors were compared. Subgroup analyses were then conducted separately for insular and frontal gliomas to examine associations with molecular markers and clinical factors.

Results: Patients showed broad cognitive-emotional impairments compared to controls. However, no significant difference was found between insular and superficial tumor groups.

IDH Mutation Status Mutant (n=20) Wild-type (n=23)	Attention-TMTA [†]	2.710	0.010

Low-grade WHO grade 1-2; High-grade WHO grade 3-4.
[†] No-epilepsy group scored higher than epilepsy group.
[‡] Low-grade group scored higher than high-grade group.
^{||} Co-deletion group required less time to complete the task.
[†] Co-deletion group scored higher than non-co-deletion group.
[‡] Wild-type group scored higher than TERT-mutant group.
^{||} IDH-mutant group required less time to complete the task.
The two groups showed no significant differences in demographic factors.

Subgroup analysis revealed: (1) Within insular gliomas, dominant hemisphere involvement correlated with poorer global cognition. Notably, IDH mutation here associated with worse attention and empathy, yet higher positive and lower negative affect. (2) In frontal gliomas, molecular and clinical features showed stronger associations: absence of epilepsy, lower grade, 1p19q codeletion, lack of TERT mutation, and presence of IDH mutation each linked to better performance across multiple cognitive and emotional domains.

Conclusion: This study indicate that molecular profiles and key clinical factors outweigh tumor location in shaping preoperative neuropsychological function in glioma. This argues for a molecularly-informed framework to better understand neurobehavioral manifestations and guide patient assessment and intervention.

EPO-0232 | Systematic review of Epilepsia partialis continua: Clinical profile, neurophysiological findings and etiological spectrum in a cohort of 287 patients

P. Miranda Cabral¹; E. Reyes Almonte¹; C. Peralta Sousa¹; J. Pineda Amarilla¹; E. Patricio¹; A. Reyes¹; A. Tejada Henriquez¹; C. Perez Lizardo¹; K. Yorro¹; M. Rodriguez²
¹Synaptic Research League; ²Hospital Universitario Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic

Background and aims: Epilepsia partialis continua (EPC), also known as Kojevnikov epilepsy, is a rare form of focal status epilepticus with an incidence greater in males than females [1], characterized by continuous or near-continuous focal motor seizures [2]. It affects both adults and children and is associated with diverse etiologies, including structural, inflammatory, and metabolic brain disorders [3].

Methods: We performed a systematic literature review following the PRISMA guidelines. S PubMed and BVS were searched using the keywords “Kojevnikov epilepsy”, “focal status epilepticus”, “physiopathology”, “continuous focal seizures”, “etiology”, and “neurophysiology”. Nonexperimental, nonanimal, English-written studies were included.

Results: We included 287 patients. The mean age was 31 years. Sex was reported in a minority of cases (33 females, 17 males), and was not reported for the remaining cases. Continuous focal epileptiform activity (97.6%) and focal epileptic status (99.3%) were more often reported in most of the cases, commonly involving the cortical regions (96.9%). Structural brain lesions represented the most frequent etiologies (86.7%), preceded by autoimmune diseases (21.1%), of which Rasmussen syndrome is the most frequent (20.2%). Metabolic (0.70%) and mitochondrial (5.2%) causes were less commonly identified. Genetic involvement was uncommon and included POLG (0.7%), GFAP (0.3%), and DNMT1L (0.3%), as well as ARF6 dysfunction. One case (0.3%) of anti-GABA-A receptor antibodies following alemtuzumab treatment was identified.

Conclusion: EPC is predominantly a cortical focal status epilepticus with mainly structural etiologies, followed by autoimmune and inflammatory causes. These findings support a diagnostic approach and highlight the need for further research into less common immunological and genetic mechanisms.

Disclosure: Nothing to disclose.

EPO-0233 | Disconnection surgeries in refractory epilepsy: A retrospective study from a Tertiary Epilepsy Center

B. Turk¹; M. Iris¹; H. Cerci²; E. Taskiran¹; M. Delil¹; C. İslar²; T. Tanriverdi²; S. Yeni¹; C. Ozkara¹; M. Uzan²

¹Department of Neurology, IUC-Cerrahpasa Faculty of Medicine, Istanbul, Türkiye; ²Department of Neurosurgery, IUC-Cerrahpasa Faculty of Medicine, Istanbul, Türkiye

Background and aims: Disconnection surgery is an established treatment option for selected patients with drug-resistant epilepsy in whom resective surgery is not feasible. This study aimed to evaluate postoperative prognosis according to different disconnection surgery subtypes.

Methods: Patients followed between 2000 and 2023 at the Epilepsy Unit of Istanbul University-Cerrahpasa Faculty of Medicine were retrospectively reviewed. Fifty-five patients who underwent disconnection surgery were included. Patients were classified into four subgroups based on surgical technique: Functional Hemispherectomy (FH), Posterior Quadrant Disconnection (PQD)—including temporo-parietal (TP-PQD) and parieto-occipital disconnection (PO-PQD)—and Subtotal Hemispherotomy (SH). Demographic and clinical characteristics were analyzed in relation to postoperative outcomes.

Results: The cohort consisted of 32 males and 23 females, with a mean age of 20.7 ± 12.5 years. Mean age at surgery was 14.2 ± 12.7 years, and the mean duration between seizure onset and surgery was 10.2 ± 10.8 years. FH was performed in 24 patients, PQD in 17 patients, and SH in 8 patients. At final follow-up, Engel class I outcome was achieved in 38 patients, class II in 7, class III in 5, and class IV in 5. No statistically significant differences were observed in postoperative Engel outcomes or complication rates among the different surgical subgroups.

Conclusion: Disconnection surgery is an effective therapeutic option for refractory epilepsy, with favorable seizure outcomes across different techniques. Surgical strategy should be

individualized based on patient characteristics and the anatomical localization of the epileptogenic zone.

Disclosure: Nothing to disclose.

EPO-0234 | A new non-invasive approach to quantify pharmacological modulation of cortical excitability

C. Friedrichs-Maeder^{1,2}; V. Santoro²; B. Clennell³; H. Clark²; L. Rocchi^{2,4,5}; M. P. Richardson²

¹Sleep-Wake-Epilepsy Center, Center for Experimental Neurology, Department of Neurology, Inselspital Bern, University Hospital, University of Bern, Switzerland; ²Department of Basic and Clinical Neuroscience, Institute of Psychiatry, Psychology and Neuroscience (IoPPN), King's College London, London, UK; ³Centre for Human & Applied Physiological Sciences, King's College London, London, UK; ⁴Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy; ⁵Department of Clinical and Movement Neurosciences, UCL Queen Square Institute of Neurology, University College London, London, UK

Background and aims: Cortical excitability (CE)—the cortex's responsiveness to perturbation—is fundamental and altered in neurological and psychiatric disorders, making it a pharmacological target. Yet a robust, scalable, drug-sensitive marker is lacking. CE can be probed non-invasively with transcranial magnetic stimulation combined with electroencephalography (TMS-EEG), but standard comparisons of evoked amplitudes in predefined time windows are variable and may miss medication effects. We introduce and validate an excitability index (ExI) derived from TMS-EEG stimulus-response curves (SRCs) across intensities to quantify pharmacological modulation of CE.

Methods: In a placebo-controlled crossover study, 12 healthy men received levetiracetam (LEV; 3000 mg) and placebo (10 completed both). Single-pulse TMS over left M1 at seven intensities (70–130% resting motor threshold) was delivered before and 2 h after intake while EEG was recorded. Responses were quantified using global mean field amplitude (GMFA) and ExI (area under the normalized SRC using EEG line-length response magnitude). Wilcoxon signed-rank tests assessed within-session changes; precision-recall (PR) analyses compared ExI versus GMFA for discriminating LEV from placebo.

Results: LEV reduced GMFA in selected time windows with medium-to-large effect sizes, without consistent latency shifts. ExI significantly decreased following LEV ($p < 0.01$) but not placebo, and showed superior discrimination (AUC-PR 0.79, baseline prevalence = 0.27) versus GMFA (AUC-PR 0.27–0.43).

Conclusion: ExI is a scale-free, medication-sensitive marker of CE that outperforms standard TMS-EEG metrics, providing a non-invasive readout of pharmacological effects on human cortical physiology. ExI could serve as a translational biomarker to monitor drug engagement and optimize dosing for epilepsy and other excitability disorders.

Disclosure: Nothing to disclose.

EPO-0235 | Early use of Cenobamate in a case of non-convulsive status epilepticus in a woman with progressive multifocal leukoencephalopathy

E. Gentile¹; A. Alicino²; E. Colombo³; A. Campomori¹; D. Lomonaco¹; E. Mazzotta¹; E. Rigoni³; E. Tartara²

¹Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; ²Epilepsy Center, IRCCS Mondino Foundation, ERN Epicare Full Member, Pavia, Italy; ³Multiple Sclerosis Center, IRCCS Mondino Foundation, Pavia Italy

Background and aims: Non-convulsive status epilepticus (NCSE) is a type of status epilepticus (SE) with no prominent motor signs. In NCSE without coma that is refractory to first and second line treatment, therapy with anaesthetics is less appropriate. ASMs are therefore used sequentially. Cenobamate (CNB) efficacy in SE is supported by limited data. We present a case of NCSE in which CNB was used early.

Methods: A 54-year-old woman with multiple sclerosis received natalizumab until she was diagnosed with progressive multifocal leukoencephalopathy (mRS4). One year later, she was admitted with acute aphasia, right head deviation, and impaired consciousness (GCS10). Brain MRI revealed hyperintensities and edema in the right hemisphere. EEG showed right focal SE with prominent contralateral motor signs, resistant to benzodiazepines, levetiracetam, and lacosamide.

Results: After a few days, the EEG evolved into NCSE with preserved consciousness, repetitive right and head deviation, and an inability to walk (mRS5). Despite the introduction of a third ASM (perampanel, 8 mg/day), there was no electroclinical

FIGURE 1 EEG performed while taking levetiracetam and lacosamide.

FIGURE 2 Follow-up EEG during levetiracetam and lacosamide treatment.

FIGURE 3 Follow-up EEG during treatment with levetiracetam, lacosamide, peramppanel, and cenobamate.

improvement until CNB was added and titrated up to 200 mg/day within one month. The MRI scan showed resolution of the perictal alterations in the right hemisphere. A two-month EEG follow-up excluded NCSE relapse.

Conclusion: Currently, it is not possible to recommend the use of cenobamate in NCSE, as only anecdotal cases have been reported to date. An important limitation is its slow titration, but it can be considered as a third-line therapy in selected cases with subtle clinical manifestations. Furthermore, CNB may modulate the GABAergic dysfunction described in NCSE.

Disclosure: Nothing to disclose.

EPO-0236 | A retrospective cohort study of valproate and infertility in men with epilepsy or bipolar disorder using international health data

G. Mbizvo¹; S. Duncan²; L. Nancarrow¹; T. Sagarino³; L. Watkins⁴; M. Mbizvo⁵; S. Lip¹; T. Marson¹

¹The University of Liverpool, Liverpool, UK; ²The University of Edinburgh, Edinburgh, UK; ³TriNetX LLC, Cambridge, USA; ⁴University of South Wales, Pontypridd, UK; ⁵Population Council, Lusaka, Zambia

Background and aims: Against a background of limited animal data and existing restrictions, we assessed infertility in men with epilepsy or bipolar disorder exposed and unexposed to valproate.

Methods: We conducted a retrospective cohort study using data from TriNetX, an international network of healthcare organisations. Men aged <55 years were identified in three cohorts: (A) epilepsy or bipolar disorder, (B) epilepsy, and (C) bipolar disorder. Validated diagnostic and prescription codes were used. Valproate-exposed and unexposed men were compared for life-time risks of infertility outcomes. Follow-up began from the second valproate prescription (exposed) or second disease code (unexposed). Propensity-score matching balanced >140 baseline covariates. Survival analysis was undertaken using Cox proportional hazards models, generating hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: Among 627,720 men with epilepsy or bipolar disorder, 91,917 were exposed and 535,803 unexposed to valproate. Serum valproate was detectable in 98% of tested exposed individuals. After matching, 78,971 men were included in each group. There was a <1% difference in infertility outcomes between those exposed and unexposed to valproate (not significant):

male infertility HR 1.057; CI 0.864–1.295, testicular hypofunction HR 0.916; CI 0.824–1.019, testicular atrophy HR 1.000; CI 0.682–1.465, and composite low sperm concentration, motility, vitality, normal forms, or semen volume HR 0.856; CI 0.613–1.196. Total testosterone was modestly lower in valproate-exposed men but remained within the normal range; other hormones did not differ. Analyses stratified by diagnosis were similarly null.

Conclusion: Our findings do not support an association between valproate and infertility in men with epilepsy or bipolar disorder in real-world settings.

EPO-0237 | Beyond neuroprotection: A context-dependent view of GLP-1 receptor agonists and seizure susceptibility

J. Findeis; F. Kerling; M. Winterholler
Department of Neurology, Sana Hospital Rummelsberg, Schwarzenbruck, Germany

Background and aims: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are widely used in type 2 diabetes mellitus and obesity and are increasingly discussed for potential neuroprotective properties. Large-scale clinical and real-world studies from 2024/2025 report a predominantly neutral to protective association between GLP-1 RA use and seizure- or epilepsy-related endpoints. However, the effects of GLP-1 RAs on neuronal excitability in patients with established epileptogenic circuitry remain insufficiently characterized.

Methods: We conducted a narrative review critically examining experimental and clinical evidence regarding the impact of GLP-1 RAs on seizure propensity, with particular emphasis on discrepancies between population-level outcomes and individual network-level vulnerability.

Results: Preclinical studies demonstrate heterogeneous, network-dependent actions of GLP-1 RAs. Anticonvulsant properties are observed in chemically induced seizure models, whereas paradoxical pro-seizure responses have been reported in genetic absence epilepsy models, suggesting circuit-specific directionality. In contrast, population-level analyses consistently report no increased risk of incident seizure-related events under GLP-1 RA therapy. However, these findings are largely derived from administrative diagnostic codes, lack epileptological phenotyping and are not designed to capture transient, exposure-dependent alterations in ictogenic potential. Additional factors, including delayed gastric emptying affecting antiseizure medication absorption, rapid metabolic shifts during titration, blood-brain barrier dysfunction and agent-specific pharmacokinetics may further modulate individual susceptibility.

Conclusion: GLP-1 RA effects on neuronal excitability appear highly context-dependent, shaped by epilepsy subtype, network vulnerability, exposure dynamics and treatment phase. Prospective studies with higher temporal and clinical resolution, incorporating detailed phenotyping, therapeutic drug monitoring and longitudinal seizure assessment, are required to ensure neurological safety in patients with epilepsy.

Disclosure: Nothing to disclose.

EPO-0238 | A systematic review of Lamotrigine overdose: From uneventful to ICU admission and cardiac arrest

L. Taruffi¹; N. Orlandi²; M. Pugnaghi²; M. Burani¹; L. Affronte²; A. Vaudano³; G. Giovannini²; S. Meletti³

¹Post-graduate School of Neurology, Department of Biomedical Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Italy; ²Neurophysiology Unit, Neuroscience Dept, AOU Modena, Italy; ³Department of Biomedical Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Italy

Background and aims: Lamotrigine (LTG) is a widely used drug to treat epilepsy and depression. We performed a systematic review of studies reporting LTG overdose. Additionally, we reported an original case.

Methods: PubMed was searched without date limits. 103 records were screened, of which 40 studies were finally included in the systematic review, and results reported according to PRISMA guideline, adding seven studies identified from included articles. We extracted demographics, LTG indication, overdose reason, complications, EEG findings, and outcomes.

Results: Forty-seven patients (27 female; mean age 28.3 years) were included. Nineteen patients co-ingested substances in addition to lamotrigine. Intent was suicidal in 33 cases. Lamotrigine was mainly prescribed for bipolar disorder (55%) and epilepsy (28%). Seizures occurred in 45% of overdoses (5 single, 10 cluster, 11 status epilepticus), including 6/13 patients with epilepsy. Median ingestion was 4.7 g (IQR 2.7 to 9.5) and median plasma concentration was 35.75 mg/L (IQR 25.3 to 52.8). There were 3 deaths and 5 cardiac arrests. Twenty-five patients required ICU

admission. Electroencephalography was reported in 23/47: 3 showed ongoing seizure, 12 with slowing pattern or epileptiform abnormalities, and the remainder unremarkable. Personal case: 75-year-old man with temporal lobe epilepsy admitted for tonic-clonic status epilepticus. LTG concentration was 39.73 mg/L after erroneous intake. Patient required rehabilitation after prolonged ICU staying.

Conclusion: LTG overdose can result in severe neurotoxicity, coma, status epilepticus and death (6%). Cardiac arrest was reported 11% of cases. Suicidal ideation was the most common reason for overdose but also erroneous intake in children and elders.

Disclosure: Nothing to disclose.

EPO-0239 | Does time since diagnosis or the number of failed ASMs matter more in people with DRE receiving VNS therapy?

M. Boffini¹; P. Kwan²; G. Giannicola¹; X. Zhou³; S. Baeesa⁴; S. Shimada⁵; G. Morris⁶; G. Motamedi⁷; K. Myers⁸; F. Beraldi⁹; L. Acciari⁹; M. Dibue¹; R. Verner¹; C. Gordon¹; K. Nichol¹; A. Sen¹⁰

¹LivaNova PLC (or a subsidiary); ²The Alfred Hospital, Monash University, and The Royal Melbourne Hospital, University of Melbourne, Melbourne, Victoria, Australia; ³Upstate University Hospital and SUNY Upstate Medical University, Syracuse, New York; ⁴Neurosciences Department, King Faisal Specialist Hospital & Research Centre, Jeddah, Saudi Arabia; ⁵The University of Tokyo Hospital, Tokyo, Japan; ⁶St. Mary's Hospital, Ascension, USA; ⁷Department of Neurology, Medstar Georgetown University Hospital, Washington, DC; ⁸Research Institute of the McGill University Medical Center, Montreal, Quebec, Canada; ⁹Valos, LivaNova Partner CRO, Genoa, Italy; ¹⁰Oxford Epilepsy Research Group, John Radcliffe Hospital, Oxford, UK

Background and aims: Time since diagnosis and number of failed ASMs may have an impact of the outcomes of people who receive VNS Therapy for DRE.

Methods: Participants with DRE enrolled into the CORE-VNS study and who were naïve to VNS Therapy were grouped into early (EI), < 5 years; intermediate (II), 5 to < 10 years; or late (LI), > 10 years. Participants were also grouped by number of failed ASMs: < 3, 4–6, 7–10, 11–16, or > 16. Clinical outcomes were assessed across seizure-related (frequency) and non-seizure (quality of life) domains at 3, 6, 12, 24, and 36 months.

Results: EI tended to have greater seizure frequency reduction than LI: median percentage change from baseline in seizure frequency at 36 months for the EI group was –88.2% (95% CI –100% to –76.5%) versus –71.4% (95% CI –81.6% to –55.0%) in the LI group. 40.2% of EI achieved a 100% reduction in seizure frequency at 36 months, compared to 22.6% in the LI group. Despite this, participants treated with fewer ASMs had a significant greater likelihood of response than those with more failed ASMs when adjusted for covariates including age and time since diagnosis ($p < 0.05$). At 36 months, participants implanted after 2–3 failed ASMs had a median change from baseline in seizure frequency of –94.4% compared with a –57.4% who failed 11–16 ASMs.

Conclusion: The benefits of VNS Therapy on seizure outcomes are better when initiated promptly. Continued trials of ASMs may limit the benefit of early implantation following DRE diagnosis.

Disclosure: GG, MD, RV, CG, and KN are employees of LivaNova PLC (or a subsidiary) and hold stock or stock options with the company, who is the manufacturer of the VNS Therapy System. All other authors are investigators associated with the CORE-VNS Study, and in that capacity they or their institutions receive compensation from LivaNova for study-related activities. No author received direct compensation from LivaNova.

EPO-0240 | VNS therapy is associated with a decrease in health care resource utilization over 36 months in people with drug-resistant epilepsy

M. Dibue¹; J. Freeman²; K. Myers³; N. Kurwale⁴; G. Giannicola¹; G. Motamedi⁵; P. Kwan⁶; Y. Al-Said⁷; G. Delougne¹; S. Shimada⁸; C. Gordon¹; A. Sen⁹; K. Nichol¹
¹LivaNova PLC (or a subsidiary); ²The Royal Children's Hospital, Melbourne, Australia; ³Research Institute of the McGill University Medical Center, Montreal, Quebec, Canada; ⁴Deenanath Mangeshkar Hospital and Research Centre, Pune, India; ⁵Department of Neurology, Georgetown University Hospital, Washington, DC; ⁶The Alfred Hospital, Monash University, and The Royal Melbourne Hospital, University of Melbourne, Melbourne, Victoria, Australia; ⁷Department of Neurosciences, King Faisal Specialist Hospital & Research Center, Jeddah, Saudi Arabia; ⁸The University of Tokyo Hospital, Tokyo, Japan; ⁹Oxford Epilepsy Research Group, John Radcliffe Hospital, Oxford, UK

Background and aims: VNS Therapy is important for people resistant to antiseizure medications and for those in whom surgery is not feasible. People with DRE have increased HCRU due to seizures and seizure-related health events. The impact of any therapy on HCRU is an important consideration when evaluating total benefit and costs of an intervention.

Methods: People with DRE were enrolled into a prospective, observational, multicenter, international study called the CORE-VNS (NCT03529045). HCRU was evaluated for 12 months before baseline and at 12-month intervals over the duration of the CORE-VNS study. For this analysis, the HCRU related to seizure activity in people with DRE from baseline to 36 months was analyzed.

Results: 526 participants met the study criteria. Participants who reported seizure-related ER visits and the number of events decreased from 32.3% at baseline ($n=599$) to 14.8% at 36 months ($n=128$). Participants with seizure-related ER visits due to status epilepticus decreased from 12.2% at baseline ($n=195$) to 3.6% at 36 months ($n=42$), and those with seizure-related ER visits leading to hospitalization decreased from 15.8% at baseline ($n=201$) to 6.2% at 36 months ($n=32$). Participants reporting seizure-related hospitalizations decreased from 27.0% at baseline ($n=312$) to 7.4% at 36 months ($n=45$). Participants reporting hospitalizations due to status epilepticus decreased from 9.5% at baseline ($n=129$) to 2.1% at 36 months ($n=11$).

Conclusion: The use of VNS Therapy is associated with a decrease in HCRU in people with DRE.

Disclosure: PT, GG, MD, GD, CG, and KN are employees of LivaNova PLC (or a subsidiary) and hold stock or stock options with the company, who is the manufacturer of the VNS Therapy System. All other authors are investigators associated with the CORE-VNS Study, and in that capacity they or their institutions receive compensation from LivaNova for study-related activities. No author received direct compensation from LivaNova.

EPO-0241 | First Antiseizure medication choice in older adults with seizures: An observational cohort study based on a claims database

P. Vassallo^{1,2,3}; R. Thijs^{1,2,3}; J. van der Palen^{4,5}; J. Sander^{1,2,6}

¹UCL Queen Square Institute of Neurology, London, and Chalfont Centre for Epilepsy, Chalfont St Peter, UK; ²Stichting Epilepsie Instellingen Nederland (SEIN), Heemstede, Netherlands; ³Department of Neurology, Leiden University Medical Centre, Leiden, Netherlands; ⁴Department of Epidemiology, Medisch Spectrum Twente, Enschede, The Netherlands; ⁵Section Cognition, Data and Education, Faculty of Behavioural, Management, and Social Sciences, University of Twente, Enschede, The Netherlands; ⁶Department of Neurology, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background and aims: Data on first-line antiseizure medication (ASM) use in older adults with new-onset epilepsy are limited. Enzyme-modulating ASMs may affect cholesterol levels, which is relevant in patients with cardiovascular comorbidity. We examined sex differences and cardiovascular risk profiles, focusing on enzyme-modulating ASM use.

Methods: This nationwide, claims-based study included adults aged ≥ 50 years with seizures diagnosed in 2014, using Diagnosis Treatment Combination codes in the Dutch health insurance database (Vektis). Pharmacy claims documented ASM prescriptions. Analyses were restricted to incident cases with ASM after diagnosis. Descriptive statistics explored prescribing patterns and sex differences. Cox regression assessed associations between ASM class and initiation of lipid-lowering therapy. Consent was waived due to anonymization.

Results: Among 8728 adults with incident seizures, 3,583 received a single ASM after diagnosis. 42.5% ($n=1,524$) were female; median age was 70 years (range 60–102). Levetiracetam (53%) and valproic acid (30%) were the most prescribed ASMs across sexes. Enzyme-modulating ASMs were frequently used despite cardiovascular comedication. Carbamazepine was more often prescribed to women, while lamotrigine ranked fifth overall. Males had longer prescription intervals than females. Daily doses were similar between sexes, but lower in adults over 70. No

significant association was found between enzyme-modulating ASMs and time to lipid-lowering agent initiation.

Conclusion: Nationwide claims data offer insights into real-world ASM prescribing. Treatment remains conservative, with older ASMs prescribed despite cardiovascular co-medications. Women and the oldest adults may receive shorter treatment intervals and lower doses. Clinical linkage is lacking, but these findings may guide optimization of epilepsy management in specific subgroups.

EPO-0242 | A ferroptosis-based diagnostic index for severity stratification in symptomatic epilepsy

R. Azizova; F. Mallaev; A. Abboskhonov
Tashkent State Medical University, Uzbekistan

Background and aims: Reliable biomarkers for assessing disease severity in symptomatic epilepsy are limited. Given the emerging role of ferroptosis in neurological disorders,

integrating ferroptosis-related biomarkers into a composite diagnostic index may improve epilepsy severity stratification and support personalized management.

Methods: This prospective study included 103 patients with symptomatic epilepsy and 20 healthy individuals. Serum markers of iron metabolism (total iron, ferritin, transferrin), lipid peroxidation (MDA, 4-HNE), and antioxidant defense (GSH, GPX4, SOD) were measured using standardized biochemical methods. A ferroptosis index (FI) was calculated using a composite formula incorporating pro-oxidant and antioxidant parameters. Patients were stratified according to disease severity. Diagnostic performance was evaluated using ROC analysis.

Results: The ferroptosis index demonstrated progressive elevation with increasing epilepsy severity. Based on FI values, patients were classified into mild (FI < 2.5), moderate (FI 2.5–7.5), and severe epilepsy (FI > 7.5). ROC analysis revealed high diagnostic accuracy of the FI for identifying severe epilepsy, with an area under the curve of 0.89 (95% CI: 0.82–0.96), sensitivity of 87%, and specificity of 83%. Higher FI values were associated with increased seizure frequency and more pronounced cognitive impairment.

Conclusion: The proposed ferroptosis-based diagnostic index is a reliable and clinically applicable tool for severity stratification in symptomatic epilepsy and may facilitate individualized therapeutic decision-making.

EPO-0243 | Utility of the IsCHEMiA score in predicting post-stroke epilepsy after stroke reperfusion therapy

W. Leung¹; T. Tanaka²; I. Leung¹; R. Ho¹; F. Chu¹; A. Leung¹; E. Yip³; M. Ihara²; K. Fukuma²; K. Teo¹; G. Lau¹

¹Division of Neurology, Department of Medicine, Queen Mary Hospital, University of Hong Kong, Hong Kong SAR, China; ²Department of Neurology, National Cerebral and Cardiovascular Center, Osaka, Japan; ³Department of Medicine and Geriatrics, Ruttonjee Hospital, Hong Kong SAR, China

Background and aims: The IsCHEMiA score is a newly developed, internationally validated tool for predicting post-stroke epilepsy (PSE) after acute ischemic stroke. We aimed to study its predictive performance in stroke patients after reperfusion therapy compared to existing risk scores.

Methods: We reviewed clinical and imaging features of patients with first-ever acute ischemic stroke who received intravenous thrombolysis (IVT) and/or endovascular thrombectomy (EVT) at Queen Mary Hospital (Hong Kong), Ruttonjee Hospital (Hong Kong), and National Cerebral and Cardiovascular Center (Japan). We calculated the IsCHEMiA, SeLECT, and SeLECT 2.0 scores, and compared their performances using discrimination (c statistic).

Results: We included 627 patients with a mean age of 72.1 years, where 421 (67.1%) received IVT and 349 (55.7%) underwent EVT (Table 1). PSE, defined as the occurrence or recurrence of unprovoked seizure > 7 days after stroke, occurred in 42 (6.7%) patients. Haemorrhagic transformation (of any grade) occurred in 154 (24.6%) patients. The IsCHEMiA score outperformed the SeLECT score (c=0.806 vs. 0.729, z=2.772; p=0.006)

TABLE 1 Baseline Characteristics of overall cohort.

	Overall cohort (n = 927)
Age at stroke	
< 50 years	12.1 ± 13.3
≥ 50 years	799 (85.4)
Gender	
Male	535 (57.8)
Female	392 (42.2)
First medical history	
Hypertension	380 (40.9)
Diabetes mellitus	251 (27.1)
Hyperlipidemia	176 (18.9)
Atrial fibrillation	173 (18.6)
Stroke recurrence	138 (14.8)
Major health history	
Coronary atherosclerosis	441 (47.6)
Other atherosclerotic disease	385 (41.5)
Previous major thrombotic risk factors	154 (16.6)
Mean follow-up duration (days)	722 ± 21.5
Any post-stroke outcome	417 (44.9)
First post-stroke outcome	
Early (< 7 days after stroke)	141 (15.1)
Late (≥ 7 days after stroke)	276 (29.7)
Early symptomatic chronic epileptiform (≥ 7 days after stroke)	145 (15.6)
Any stroke subcategory	349 (37.6)
Post-stroke mortality	42 (4.5)

Data presented as n (%) or mean ± standard deviation. Post-stroke outcome is defined as the occurrence of recurrent or prolonged stroke, TIA, or other stroke.

FIGURE 1 Receiver Operating Characteristic (ROC) Curves of IsCHEMiA, SeLECT, and SeLECT2.0.

and SeLECT 2.0 score ($c=0.806$ vs. 0.718 , $z=2.784$; $p=0.005$) (Figure 1).

Conclusion: The IsCHEMiA score further improved the prediction of PSE in the stroke population who received acute reperfusion therapy. This reflects the strength of the IsCHEMiA score by accessing the characteristics of the final infarct instead of stroke severity. Our findings further suggest an important role haemorrhagic lesions in epileptogenesis. Future research is warranted to study the role of preventing post-reperfusion haemorrhagic transformation in reducing the risk of PSE.

North Chicago, IL, USA; ³Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy; ⁴Department of Neurology, Seoul National University Hospital, Seoul, South Korea; ⁵Seoul National University College of Medicine, Seoul, South Korea; ⁶Headache Center and Department of Neurology, Tominaga Hospital, Osaka, Japan; ⁷Department of Neurology, West German Headache and Vertigo Center Essen, University of Essen, Essen, Germany; ⁸Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; ⁹Headache Science & Neurorehabilitation Centre, IRCCS C. Mondino Foundation, Pavia, Italy

Background and aims: Atogepant is an FDA/EMA approved calcitonin gene-related peptide receptor antagonist for migraine preventive treatment. This analysis evaluated within-participant consistency of effect (CoE) of atogepant 60 mg in the acute treatment of migraine headache and its effect across multiple migraine attacks.

Methods: ECLIPSE was a double-blind (DB), placebo-controlled, multiple-attack, crossover trial evaluating atogepant's efficacy, safety, and tolerability for acute treatment of migraine. Adults with 2–8 monthly moderate-to-severe attacks were randomised to receive atogepant for three qualifying attacks and placebo for one attack during the up to 16-week DB period. CoE was assessed by six prespecified supportive secondary endpoints, defined as achievement of key outcomes in ≥ 2 out of 3 atogepant-treated attacks, pain freedom at 2 hours postdose, pain relief at 2 hours, and sustained pain freedom/pain relief (from 2–24 to 2–48 hours postdose). Efficacy of atogepant versus placebo was evaluated for each of these endpoints across multiple attacks (Attacks 1–4).

Results: Atogepant demonstrated CoE for pain freedom and pain relief at 2 hours, as well as sustained pain freedom and relief from 2–24 to 2–48 hours (Table 1). Across all 4 treated attacks, atogepant demonstrated improvements versus placebo for pain freedom and pain relief at 2 hours, and sustained pain

TABLE 1 Supportive endpoints for consistency of effect: Responder rates across multiple attacks treated with double-blind atogepant.

Supportive Endpoints – Efficacy	Responder Rate n/N1 (%)	95% CI
Pain freedom at 2 hours after receiving DB atogepant for at least 2 out of 3 attacks	288/381 (75.6)	(73.7, 77.5)
Pain relief at 2 hours after receiving DB atogepant for at least 2 out of 3 attacks	375/487 (76.9)	(75.0, 78.7)
Sustained pain freedom 2 to 24 hours after receiving DB atogepant for at least 2 out of 3 attacks	151/191 (78.9)	(76.1, 81.6)
Sustained pain freedom 2 to 48 hours after receiving DB atogepant for at least 2 out of 3 attacks	145/188 (77.1)	(74.3, 79.9)
Sustained pain relief 2 to 24 hours after receiving DB atogepant for at least 2 out of 3 attacks	327/406 (80.5)	(78.7, 82.3)
Sustained pain relief 2 to 48 hours after receiving DB atogepant for at least 2 out of 3 attacks	304/399 (76.2)	(74.3, 78.1)

N1: number of participants who achieved consistent pain freedom or pain relief for the specified endpoint; N2: number of participants who experienced at least 2 successes (responses) or failures (non-responses) in the endpoints across all treated attacks treated with atogepant during the double-blind period; CI, confidence interval; DB, double-blind; Percentages are calculated as N1/N2 (95% CI) for the consistency of response endpoint

FIGURE 1: Proportion of participants achieving pain freedom (A) at 2 hours after double-blind dose, (B) from 2 to 24 hours after double-blind dose, and (C) from 2 to 48 hours after double-blind dose.

FIGURE 2: Proportion of participants achieving pain relief (A) at 2 hours after double-blind dose; (B) from 2 to 24 hours after double-blind dose, and (C) from 2 to 48 hours after double-blind dose.

freedom and relief from 2–24 to 2–48 hours (Attack 1, adjusted $P < 0.0001$; Attacks 2–4, nominal $P < 0.0001$) (Figures 1 and 2).

Conclusion: Among adults with migraine headache, atogepant demonstrated consistency of within-participant effect and showed reliable efficacy compared with placebo across multiple migraine attacks.

EPO-0245 | Efficacy of acute treatment with Atogepant on migraine symptoms and rescue medication use across multiple attacks: Results from the ECLIPSE trial

A. Van Dycke¹; K. Carr²; R. Ornello³; M. Lee^{4,5}; L. Luo²; T. Takeshima⁶; D. Holle-Lee⁷; C. Tassorelli^{8,9}; E. Brand-Schieber²; K. Nagy²

¹Department of Neurology, General Hospital Sint-Jan Bruges, Brugge, Belgium; ²AbbVie Inc. North Chicago, IL, USA; ³Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy; ⁴Department of Neurology, Seoul National University Hospital, Seoul, South Korea; ⁵Seoul National University College of Medicine, Seoul, South Korea; ⁶Headache Center and Department of Neurology, Tominaga Hospital, Osaka, Japan; ⁷Department of Neurology, West German Headache and Vertigo Center Essen, University of Essen, Essen, Germany; ⁸Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; ⁹Headache Science & Neurorehabilitation Centre, IRCCS C. Mondino Foundation, Pavia, Italy

Background and aims: Atogepant, an FDA/EMA approved migraine preventive treatment, has recently demonstrated efficacy for the acute treatment of a single migraine attack. This analysis evaluated the efficacy of atogepant 60mg versus placebo for the acute treatment of migraine-related symptoms and rescue medication use across multiple attacks in double-blind (DB) trial.

Methods: ECLIPSE was a DB, placebo-controlled, multiple-attack, crossover trial evaluating atogepant's efficacy, safety, and tolerability for acute treatment of migraine. Adults with 2–8 monthly moderate-to-severe attacks were randomised to receive atogepant for three qualifying attacks and placebo for one attack during the up-to-16-week DB period. This analysis evaluated the proportion of participants achieving absence of the

*Absence of the most bothersome symptom 2 hours postdose during the first treated attack is a secondary endpoint (co-primary for China). All other P-values are nominal. Participants were randomized in a 3:1:1:1 ratio to one of four treatment sequences in which each participant received placebo for 1 qualifying migraine attack and atogepant 80 mg for 3 qualifying migraine attacks during the double-blind period; participants were treated 1:1 with atogepant or placebo, respectively, for attack 1, and 3:1 with atogepant or placebo, respectively, for attacks 2-4. Odds ratio presented with 95% confidence interval; MBS, most bothersome symptom; OR, odds ratio.

FIGURE 1: Proportion of participants free from the most bothersome symptom at 2 hours postdose during the double-blind period across multiple attacks.

FIGURE 2: Proportion of participants with absence of photophobia, phonophobia, and nausea at 2 hours postdose during the double-blind period across multiple attacks.

	Atogepant	Placebo	Odds Ratio (95% CI)	P-value
Use of rescue medication within 24 hours, n/N (%)				
Attack 1	8/602 (1.3)	32/672 (4.8)	0.34 (0.11-0.99)	<.001
Attack 2	18/327 (5.5)	14/654 (2.1)	0.35 (0.11-0.99)	<.001
Attack 3	10/322 (3.1)	10/569 (1.8)	0.34 (0.10-0.99)	<.001
Attack 4	15/859 (1.7)	16/621 (2.6)	0.34 (0.10-0.99)	<.001
Use of rescue medication within 48 hours, n/N (%)				
Attack 1	18/602 (3.0)	33/672 (4.9)	0.39 (0.12-0.99)	<.001
Attack 2	18/327 (5.5)	14/654 (2.1)	0.35 (0.11-0.99)	<.001
Attack 3	10/322 (3.1)	10/569 (1.8)	0.34 (0.10-0.99)	<.001
Attack 4	15/859 (1.7)	16/621 (2.6)	0.34 (0.10-0.99)	<.001

Over the course of the study, 24-hour and 48-hour rescue medication rates were significantly lower in the atogepant group compared to the placebo group for all attacks (P < .001 for all comparisons). Participants who received atogepant for all attacks had significantly lower rates of rescue medication use compared to participants who received placebo for all attacks (P < .001 for all comparisons). Odds ratio presented with 95% confidence interval; OR, odds ratio.

FIGURE 3: Proportion of participants using rescue medication within 24 and 48 hours postdose during the double-blind period across multiple attacks.

most-bothersome symptom (MBS: photophobia, phonophobia, or nausea) at 2-hours postdose across attacks 1-4. Additionally, the absence of photophobia, phonophobia, and nausea at 2-hours

postdose, as well as rescue medication use within 24- and 48-hours postdose, were examined across attacks.

Results: Atogepant resulted in a significantly ($P < 0.0001$, nominal or ranked secondary as indicated) higher proportion of participants achieving absence of the MBS (OR: 1.77-3.09), photophobia (OR: 1.74-2.77), and phonophobia (OR: 1.96-3.43) 2 hours postdose across attacks 1-4 compared to placebo (Figures 1, 2). Participants had lower rates of nausea with atogepant, but these results were not significant for the ranked attack (Figure 2). Rescue medication use was lower with atogepant versus placebo across both 24 and 48 hours postdose period amongst all attacks (OR: 0.13-0.16; all $P < 0.0001$) (Figure 3).

Conclusion: Atogepant demonstrated reliable treatment effect compared to placebo by reducing migraine-related symptoms and the need for rescue medication use across multiple migraine attacks.

Background and aims: Atogepant is approved for the preventive treatment of migraine in adults and has recently demonstrated its efficacy and safety for the acute treatment of migraine. This analysis evaluated the impact of atogepant 60mg administered as needed (PRN) for acute treatment of migraine on cognitive function assessed by the ability to think clearly.

Methods: ECLIPSE was a double-blind (DB), placebo-controlled, multiple-attack, crossover trial evaluating atogepant's efficacy, safety, and tolerability for acute migraine treatment. Adults with 2–8 monthly moderate-to-severe attacks were randomised to receive atogepant for three qualifying attacks and placebo for one attack during the up to 16-week DB period. Cognitive function scale is a single-item, patient-reported questionnaire measuring participants' difficulty in ability to think clearly, rated from 0 (not difficult at all) to 3 (very difficult). The proportion of participants achieving the ability to think clearly at 2-, 4-, and 8-hours postdose across attacks 1–4 was an additional (exploratory)

FIGURE 1: Proportion of participants who reported “not difficult at all” in ability to think clearly at 2-, 4-, and 8-hours postdose in the first migraine attack.

FIGURE 2: Proportion of participants who reported “not difficult at all” in ability to think clearly at 2-, 4-, and 8-hours postdose across attacks 2, 3, and 4 (A, B, and C, respectively).

efficacy endpoint. Data for atogepant and placebo are presented with nominal *p*-values.

Results: Atogepant treatment resulted in a nominally significant higher proportion of participants achieving the ability to think clearly compared with placebo as early as 2-hours postdose in the first treated attack (OR: 1.78, Figure 1); this effect increased over time through 4- and 8-hours postdose (OR: 3.39, 3.73, respectively; Figure 1). A similar reliable response was observed across attacks 2–4 (Figure 2).

Conclusion: A greater proportion of participants treated with atogepant achieved the ability to think clearly compared to placebo as early as 2-hours and up to 8-hours postdose across multiple attacks.

EPO-0247 | Longitudinal shifts in migraine frequency patterns: Transition from chronic to episodic migraine in a pooled analysis of the PEARL and FINESSE studies

M. Ashina¹; G. Broessner²; C. Tassorelli³; C. Gaul⁴; P. Pozo-Rosich⁵; L. Neeb⁶; P. Kolturk⁷; X. Hamann⁸; H. Akcicek⁷; A. Straube⁹
¹Department of Neurology, Danish Headache Center, Copenhagen University Hospital–Rigshospitalet Glostrup, Copenhagen, Denmark; ²Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; ³Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria; ⁴Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; IRCCS C. Mondino Foundation, Pavia, Italy; ⁵Headache Center Frankfurt, Frankfurt am Main, Germany; ⁶Headache Unit and Research Group, Vall d’Hebron Hospital and Research Institute, Universitat Autònoma de Barcelona, Barcelona, Spain; ⁷Department of Neurology, Brandenburg Medical School Theodor Fontane, University Hospital Brandenburg/Havel, Brandenburg/Havel, Germany; ⁸Teva Pharmaceuticals Europe B.V., Haarlem, The Netherlands; ⁹Teva GmbH, Ulm, Germany; ⁹Department of Neurology, Ludwig-Maximilians-University Munich, Munich, Germany

Background and aims: Chronic migraine (CM) is associated with increased disability, greater reductions in health-related quality of life and higher rates of medication overuse compared with episodic migraine (EM). Consequently, achieving reversion from CM to EM is an important therapeutic goal. This analysis assessed long-term changes in migraine frequency among participants with CM in PEARL and FINESSE.

Methods: The 24-month, prospective, observational, real-world PEARL (pan-European) and FINESSE (Germany and Austria) studies evaluated the effectiveness and tolerability of fremanezumab in routine clinical practice among adults with migraine. Mean monthly migraine days (MMD) were assessed using daily headache diaries completed by participants throughout the study. In this pooled analysis, the proportions of participants shifting from CM (diagnosed at baseline) to high-frequency EM (HFEM; ≥ 8 and <15 MMD), moderate-frequency EM (MFEM; ≥ 4 and <8 MMD) and low-frequency EM (LFEM; <4 MMD) were assessed over time.

Results: Of 2145 participants included in the pooled analysis, 1212 had CM at baseline (Table 1). By Month 6, 20.4%, 25.0% and 39.5% of participants with available data ($n=1070$) had transitioned to HFEM, MFEM and LFEM, respectively (Table 2). At Month 24, 49.5% of participants with available data ($n=641$) had shifted to LFEM and only 7.6% of participants still had >15 MMD.

TABLE 2 Proportion of participants transitioning from CM at baseline to HFEM, MFEM and LFEM at Months 6, 12, 18 and 24.

	Baseline	Month 6	Month 12	Month 18	Month 24
Participants with available data, n (%)	1212 (56.3)	1070 (50.1)	1070 (50.1)	1070 (50.1)	641 (30.0)
Participants with available data, n (%)	1212 (56.3)	1070 (50.1)	1070 (50.1)	1070 (50.1)	641 (30.0)
Participants with available data, n (%)	1212 (56.3)	1070 (50.1)	1070 (50.1)	1070 (50.1)	641 (30.0)
Participants with available data, n (%)	1212 (56.3)	1070 (50.1)	1070 (50.1)	1070 (50.1)	641 (30.0)
Participants with available data, n (%)	1212 (56.3)	1070 (50.1)	1070 (50.1)	1070 (50.1)	641 (30.0)

Conclusion: Fremanezumab facilitated meaningful reductions in migraine frequency over time, with nearly half of the participants with CM who persisted with treatment up to Month 24 transitioning to LFEM. These findings highlight the long-term benefit of fremanezumab and its potential to restore low disease burden in a relevant subset of patients.

Mondino Foundation, Pavia, Italy; ⁵Headache Center Frankfurt, Frankfurt am Main, Germany; ⁶Headache Unit and Research Group, Vall d’Hebron Hospital and Research Institute, Universitat Autònoma de Barcelona, Barcelona, Spain; ⁷Department of Neurology, Brandenburg Medical School Theodor Fontane, University Hospital Brandenburg/Havel, Brandenburg/Havel, Germany; ⁸Teva Pharmaceuticals Europe B.V, Haarlem, The Netherlands; ⁹Teva GmbH, Ulm, Germany; ⁹Department of Neurology, Ludwig-Maximilians-University Munich, Munich, Germany

Background and aims: With advances in preventive therapy, treatment goals for migraine have evolved from reduced migraine frequency toward optimal disease control. To evaluate disease control among participants in the long-term, real-world PEARL and FINESSE studies, this pooled analysis assessed mean monthly migraine days (MMD) according to IHS-defined migraine control categories in adults treated with fremanezumab.

Methods: The prospective, observational PEARL (pan-European) and FINESSE (Germany and Austria) studies evaluated the effectiveness and tolerability of fremanezumab in routine clinical practice among adults with episodic or chronic migraine (EM; CM), over 24 months. MMD were assessed using daily headache diaries completed by participants throughout the study. In this pooled analysis, the proportions of participants achieving different treatment outcomes categories (migraine freedom [0MMD], optimal [<4MMD], modest [4–6MMD] or insufficient [>6MMD] control) were assessed over 24 months.

TABLE 1 Baseline characteristics.

	Participants in the PEARL & FINESSE studies N=2145
Age	
Mean (SD)	45.96 (12.17)
Median (Min, Max)	47 (18, 85)
Past preventive migraine treatment attempts, n (%)	
<4	1397 (65.1)
≥4	748 (34.9)
Time from initial migraine onset date to fremanezumab initiation, years	
Mean (SD)	20.72 (13.53)
Median (Min, Max)	26 (0, 70)
Time from date of migraine diagnosis to first fremanezumab initiation, years	
Mean (SD)	16.12 (12.79)
Median (Min, Max)	17 (0, 65)
Presence of onabotulinumtoxinA failure as a past preventive treatment, n (%)	791 (36.4)
Migraine diagnosis, n (%)	
CM	1212 (56.5)
EM	933 (43.5)

CM, chronic migraine; EM, episodic migraine; Max, maximum; Min, minimum; SD, standard deviation.

FIGURE 1 MMD control over time.

FIGURE 2 Participants achieving ≥ 50 reduction from baseline in MMD within each control category at Month 12 and Month 24

Results: A total of 2145 participants were included in the pooled analysis (Table 1). Optimal migraine control and migraine freedom was achieved by 28.0% and 11.2% of participants, respectively, as early as 1 month after starting fremanezumab and by 41.5% and 18.7% of participants at Month 24 (Figure 1). Among the subset of participants who had modest or insufficient control at Months 12 and 24 respectively, a substantive proportion achieved $\geq 50\%$ reduction from baseline in MMD (Figure 2).

Conclusion: Using an outcome measure that aligns with individualised treatment goals beyond traditional responder rates, this pooled analysis of the PEARL and FINESSE studies demonstrated the early and sustained effectiveness of fremanezumab in substantially improving migraine control.

Lundbeck A/S, Copenhagen, Denmark; ¹⁴Department of Neurology, Leiden University Medical Centre, Leiden, Netherlands

Background and aims: This phase 4 trial evaluated the 24-week impact of eptinezumab on acute medication use in adults with chronic migraine (CM) and medication-overuse headache (MOH) who also received patient education.

Methods: RESOLUTION (NCT05452239) included a 12-week double-blind placebo-controlled period and 12-week open-label extension (OLE). At baseline, adults with CM and MOH were randomized 1:1 to IV eptinezumab 100mg or placebo; all participants received a brief educational intervention on MOH before infusion. At Week 12, all participants received eptinezumab 100mg. Acute medication use was captured daily via electronic diary. Analyses applied inferential statistics to the placebo-controlled analyses and descriptive methods to the OLE.

Results: Participants randomized: $n=608$; treated, baseline: $n=604$; full-analysis set, placebo-controlled period: $n=602$; treated/analyzed, OLE: $n=593$; completed: $n=584$. Baseline

mean monthly acute medication days: 20.1 across arms. Eptinezumab was more favourable than placebo in reducing monthly acute medication use days over Weeks 1–4 (–11.3 vs. –7.7) and 1–12 (–11.2 vs. –7.8), particularly triptan days ($p < 0.01$ all comparisons). During the OLE, improvements were sustained for participants continuing eptinezumab; participants started on placebo and switched to eptinezumab achieved similar changes as those continuing eptinezumab. Eptinezumab provided greater decreases in mean Severity of Dependence Scale for Headache medication score than placebo at Week 12 (–2.2 vs. –1.2; $p = 0.0002$).

Conclusion: In participants with CM and MOH who also received patient education, eptinezumab resulted in greater reductions than placebo in acute medication use and dependence over Weeks 1–12. Similar reductions in acute medication use were seen during open-label eptinezumab treatment, irrespective of treatment in the placebo-controlled period.

Disclosure: CL has participated on an advisory board and received payment for lectures arranged by AbbVie, Lundbeck, Novartis, Pfizer, and Roche, and has received research sponsorship from AbbVie. RHJ has given lectures for Allergan, ATI, Eli Lilly, Lundbeck, Merck, Novartis, Pfizer, and Teva; served as investigator in clinical trials with ATI, Eli Lilly, Lundbeck, Novartis, and Novo Nordisk; is the director of the Danish Headache Center, Lifting The Global Burden of Headache, and Founder of Master of Headache Disorders at University of Copenhagen; and has received research funding from ATI, Lundbeck Foundation, Rigshospitalet, The Medical Society in Copenhagen, Novo Nordisk Foundation, Tryg Foundation, and University of Copenhagen. HWS has received personal fees from AbbVie, Eli Lilly, Lundbeck, Novartis, and Teva, and has received research grants from Novartis and Novo Nordisk Foundation. Supernus, and Teva; and has received funding for speaking from AbbVie, Amgen, Avanir, Biohaven, Depomed, Eli Lilly, Impel, Lundbeck, Pernix, Promius, Supernus, and Teva. [Disclosures for the remaining authors will be included in the presentation].

EPO-0250 | Real-world effectiveness and adherence of atogepant in chronic and episodic migraine: Results from the ATOMUR study

D. López Segura¹; L. Calderón Soriano²; F. Salazar Hernández¹; M. Ruiz Perelló¹; J. Marín Marín²; S. Marín Balbuena³; I. Jiménez Díaz¹; A. Torres Perales⁴; C. Lucas Ródenas³; M. Frutos Alegría⁵; M. Lozano Caballero³; H. Rodríguez Hilario⁵; J. García-Carmona¹

¹Department of Neurology, Santa Lucía University Hospital, Cartagena; Spain; ²Department of Neurology, Reina Sofía University Hospital, Murcia; Spain; ³Department of Neurology, Arrixaca University Hospital, Murcia; Spain; ⁴Department of Neurology, Los Arcos-Mar Menor University Hospital, San Javier; Spain; ⁵Department of Neurology, Morales Meseguer University Hospital, Murcia; Spain

Background and aims: Atogepant, an oral CGRP receptor antagonist, has shown efficacy in migraine prevention in clinical trials. Nonetheless, real-world data on its long-term effectiveness and treatment adherence in chronic (CM) and episodic migraine (EM) remain limited. We evaluated treatment compliance and changes in monthly migraine days (MMDs), MIDAS score and its side effects in patients with CM and EM treated with atogepant in clinical practice.

Methods: 101 patients diagnosed with chronic or episodic migraine who initiated preventive treatment with atogepant were included and followed at 3, 6, and 12 months.

Results: 57 (56.4%) patients had CM and 44 (43.6%) EM. Mean baseline MMDs were 18.6 ± 4.9 in CM and 9.8 ± 2.7 in EM patients. At 3 months, mean MMDs were reduced to 10.2 ± 4.6 in CM and 5.4 ± 2.9 in EM, corresponding to a reduction of 45% and 44%, respectively. These reductions were sustained at 6 months (CM: 9.6 ± 4.8 ; EM: 5.1 ± 2.6) and 12 months (CM: 9.1 ± 5.0 ; EM: 4.9 ± 2.8). At 12 months, 68% of patients achieved a $\geq 50\%$ reduction in MMDs. Mean MIDAS scores decreased significantly from baseline (48.2 ± 19.6) to 3 months (28.5 ± 17.3 ; $p < 0.001$), with further reductions at 6 months (24.1 ± 16.8 ; $p < 0.001$) and 12 months (21.6 ± 17.1 ; $p < 0.001$). Treatment adherence remained high, with 80% of patients continuing therapy at 6 months and 66% at 12 months. Discontinuations were mainly due to lack of effectiveness or mild adverse events (nausea).

Conclusion: Atogepant showed sustained effectiveness in reducing monthly migraine days and high adherence over 12 months in patients with chronic and episodic migraine. These findings support its role as a long-term preventive treatment.

Disclosure: Nothing to disclose.

Background and aims: The International Classification of Headache Disorders, 3rd edition (ICHD-3), defines migraine at the diagnostic level but is not suited for qualifying individual headache attacks, limiting accurate evaluation of acute treatments. This study aimed to construct an expert-derived ground-truth dataset of individual attacks and to compare three artificial intelligence (AI)-based classifications of each attack with specialist judgment.

Methods: Patients from headache-specialized clinics in Japan completed standardized clinical questionnaires and recorded attacks in a smartphone diary (Migraine Buddy) for 3 months. Three board-certified headache specialists independently evaluated 10 attacks from each of 10 patients (100 attacks total), using full clinical context and diary data. Each attack was rated on a five-level migraine-probability scale. Majority voting classified attacks as migraine or non-migraine and served as the ground truth. We evaluated three AI approaches against this reference: (1) a rule-based ICHD-3 decision tree, (2) large language models (LLMs), and (3) supervised machine-learning models trained on expert labels.

Results: Ninety-eight attacks were eligible for analysis; 82 were classified as migraine and 16 as non-migraine. The ICHD-3 rule-based approach showed high specificity (0.81) but low sensitivity

(0.43). LLMs demonstrated high sensitivity (0.95) and moderate specificity (0.69), with notable variability across repeated runs. XGBoost models achieved balanced performance, with sensitivity of 0.84 and specificity of 0.88.

Conclusion: Automated approaches can approximate specialist-level classification of individual headache attacks, with XGBoost showing the most robust performance. These findings support the use of AI for per-attack migraine qualification while reinforcing the continued role of expert clinical judgment.

EPO-0252 | Magnetic resonance-guided focused ultrasound (MRgFUS) in pharmacoresistant trigeminal neuralgia: A single-center pilot feasibility and safety study

P. Gutierrez Bedia¹; L. Franco Rubio¹; M. Yus²; A. Lopez-Frías²; C. Pérez García²; M. Valles¹; J. Matías-Guiú¹; J. Porta-Etessam³; N. González García¹

¹Neurology, Hospital Clínico San Carlos, Madrid, Spain;

²Radiology, Hospital Clínico San Carlos, Madrid, Spain;

³Neurology, Hospital Fundación Jiménez Díaz, Madrid, Spain

Background and aims: Pharmacoresistant trigeminal neuralgia (TN) represents a severe form of neuropathic pain and poses a major therapeutic challenge. Functional neurosurgery has identified central targets involved in pain perception, such as the central lateral nucleus (CLN) of the thalamus. Magnetic resonance-guided focused ultrasound (MRgFUS) enables precise thermal lesioning of deep brain structures, including the thalamus, in a non-invasive manner. This technique is an innovative and expanding therapeutic option for refractory neuropathic pain.

Methods: This is a prospective, single-center, uncontrolled pilot study designed to assess the feasibility and safety of MRgFUS targeting the CLN. Patients with pharmacoresistant TN evaluated at our Headache Unit are included. Clinical screening, neuroimaging, psychopathological and neuropsychological assessments are performed. The procedure is conducted under conscious sedation, with monitoring of adverse events and postoperative MRI. Validated scales are used for baseline and follow-up assessments (CBD, DN4, PainDETECT, EQ-5D-5L, PDQ, PCS, PGIC, HADS).

Results: To date, one patient (male, 52years) has been successfully treated. One week after the procedure, complete resolution of trigeminal pain and paroxysms was observed, with no clinically relevant adverse events. Additional patients will be included in the coming months.

Conclusion: MRgFUS targeting the CLN demonstrated good tolerability, absence of complications, and a relevant analgesic effect in this first case. This ongoing study aims to confirm the feasibility of MRgFUS as a non-invasive therapeutic alternative for pharmacoresistant trigeminal neuralgia.

Disclosure: Nothing to disclose.

Department of Brain and Behavioral Sciences, University of Pavia & Headache Science and Neurorehabilitation Unit, IRCCS Mondino Foundation, Pavia, Italy

Background and aims: Atogepant is an oral CGRP receptor antagonist approved for migraine prevention. The aim of this study was to investigate the biomolecular changes induced by atogepant in individuals with high-frequency episodic migraine (HFEM).

Methods: In this prospective study, 40 participants (age 35.5 ± 21.9 years, 30 females) underwent blood sampling in the interictal phase at baseline (T0) and after a 3-month-daily atogepant 60 mg treatment (T1). The biomolecular assessment included: (i) monoacylglycerol lipase (MAGL) and fatty acid amid hydrolase (FAAH) gene expression (mRNA) in peripheral blood mononuclear cells (PBMCs); (ii) microRNAs expression in PBMCs, namely miR-382-5p, miR-34a, and miR-155; and (iii) plasma levels of CGRP and PACAP (pg/mL).

Results: At T1, 70% of participants qualified as Responders ($> 50\%$ reduction in monthly migraine days). MAGL expression only decreased in Responders (Responders: T0: 9.8 ± 5.4 vs. T1: 13.2 ± 7.9 relative quantification – RQ, $p=0.021$, Non-Responders: T0: 7.4 ± 4.3 vs. T1: 8.3 ± 4.4 RQ, $p=0.552$). At T0 MAGL was higher in Responders compared to Non-Responders ($p=0.022$). At T1, we did not find modifications in FAAH and microRNAs expression or CGRP and PACAP levels.

Conclusion: After a 3-month atogepant treatment, we described a modulation of MAGL expression in Responders. Along with clinical benefit, atogepant treatment was associated with an improvement in the homeostasis of our pain-control system. It remains unclear whether the MAGL change reflects a direct pharmacological effect or, more plausibly, a downstream consequence of clinical improvement.

Disclosure: RDI received honoraria from AbbVie for advisory board participation and speaker invitation. The ATOM project was funded by a CORE – AMD Resident Research Grant (application ID#: 1273396).

EPO-0254 | Indomethacin for the symptomatic treatment of migraine: A clinical reappraisal

S. Braca; C. Russo; C. Giannini; G. Cretella; A. Stornaiuolo; R. De Simone

Department of Neuroscience, Reproductive Sciences and Odontostomatology, University of Naples “Federico II”, Naples, Italy

Background and aims: Indomethacin is a potent NSAID with distinctive neurovascular pharmacology, including interactions with nitric oxide pathways and significant effects on intracranial pressure regulation. Despite long-standing clinical use in headache disorders, evidence supporting indomethacin for the symptomatic treatment of migraine remains limited. This study

aims to provide new clinical data on its effectiveness and tolerability in the symptomatic treatment of migraine.

Methods: This is a pilot, observational, open-label, head-to-head study. We enrolled adults with low-frequency episodic migraine (2–8 attacks/month). Participants were sequentially assigned in alternating order to indomethacin 50 mg or ibuprofen 600 mg, taken at attack onset. The primary endpoint was 2-hour pain freedom during the first treated attack. We also recorded the rate of adverse events.

Results: A total of 120 participants were included (indomethacin $n=60$; ibuprofen $n=60$). Two-hour pain freedom occurred more frequently with indomethacin (43.3%) than with ibuprofen (21.7%) ($p=0.01$). Adverse events were numerically more common with indomethacin (36.7%) than with ibuprofen (21.7%), although without a statistically significant difference ($p=0.07$).

Conclusion: Indomethacin showed superior outcomes versus ibuprofen, supporting a clinical reappraisal of this drug as an acute migraine option. Its higher efficacy might relate not only to anti-inflammatory activity but, importantly, also to modulation of nitric oxide-mediated neurovascular signaling and intracranial pressure dynamics. Although not statistically significant, indomethacin was associated with a higher number of adverse events, so its use should be preferably considered in more severe or refractory cases.

Disclosure: Nothing to disclose.

Background and aims: To compare the real-world effectiveness of Erenumab and OnabotulinumtoxinA in reducing triptan use among patients with migraine

Methods: We used nationwide Norwegian health registry data to emulate a target trial comparing initiation of Erenumab with OnabotulinumtoxinA. Propensity score overlap weighting was applied to balance baseline characteristics. Outcomes were assessed over 12 months and included absolute change in triptan defined daily doses (DDD) and achievement of $\geq 50\%$ reduction in triptan use. Weighted linear mixed effects models were used for continuous outcomes, and weighted logistic mixed effects models for binary outcomes. Both intention-to-treat and per-protocol analyses were conducted.

TABLE 1 Primary outcome: Absolute change in triptan daily defined doses (DDD).

Follow-up interval	ITT: Difference in DDDs (Erenumab - Botex)	95% CI	p-value	PP: Difference in DDDs	95% CI	p-value
0-3 months	-6.36	-10.69 to -2.01	<0.001	-6.59	-12.22 to -0.97	<0.001
3-6 months	-6.38	-10.65 to -2.11	<0.001	-6.37	-12.05 to -0.68	<0.001
6-9 months	-5.21	-9.72 to -0.69	<0.001	-7.09	-12.93 to -1.25	0.001
9-12 months	-4.24	-8.91 to -0.57	0.002	-6.01	-12.34 to -0.28	0.013

TABLE 2 Secondary outcome: $\geq 50\%$ reduction in triptan use.

Follow-up interval	ITT: OR (Erenumab vs Botex)	95% CI	p-value	PP: OR	95% CI	p-value
0-3 months	1.49	1.31 - 1.69	<0.001	1.66	1.42 - 1.93	<0.001
3-6 months	1.61	1.42 - 1.84	<0.001	1.81	1.55 - 2.17	<0.001
6-9 months	1.39	1.18 - 1.64	<0.001	1.63	1.32 - 2.02	<0.001
9-12 months	1.18	1.02 - 1.35	0.027	1.55	1.29 - 1.86	0.001

FIGURE 1 Weighted mean triptan daily defined doses over time (ITT).

Results: A total of 3,062 Erenumab users and 2,431 OnabotulinumtoxinA users were included. After weighting, baseline characteristics were identical. As shown in Table 1, Erenumab produced greater reductions in triptan DDDs. In the intention-to-treat analysis, adjusted between-group differences ranged from -8.35 (95% CI -10.69 to -6.01) at 0–3 months to -4.24 (-6.91 to -1.57) at 9–12 months; per-protocol differences ranged from -9.59 to -6.01 . For the secondary outcome (Table 2), Erenumab users had higher odds of achieving a $\geq 50\%$ reduction in triptan use, with intention-to-treat ORs from 1.49 to 1.18 and per-protocol ORs from 1.66 to 1.55. Triptan utilization trajectories are shown in Image 1.

Conclusion: Erenumab showed a consistent advantage over OnabotulinumtoxinA in reducing triptan use, particularly among adherent patients. These findings support the superior real-world effectiveness of Erenumab.

Disclosure: The author receives a PhD stipend from Helse Vest and this is a part of the NorHead project.

EPO-0256 | Overtreatment and delays in antiviral therapy for suspected herpesvirus CNS infections

B. Nieuwenhuijsen; M. Brouwer; S. Staal; D. van de Beek
Neuroinfection centre, Amsterdam UMC, Amsterdam, The Netherlands

Background and aims: Herpesviruses are a common cause of CNS infections. Guidelines recommend empirical antiviral therapy when herpesvirus encephalitis is suspected. This practice often results in treatment of patients without herpesvirus CNS infection.

Methods: We analysed adults with suspected CNS infection enrolled in two prospective cohorts (2012–2025). All patients receiving antiviral therapy for suspected CNS infection were included. All PCR-confirmed herpesvirus CNS infections were considered as appropriately treated, and all others were classified as overtreatment. We quantified overtreatment and undertreatment, and examined the clinical context of delayed therapy and prolonged therapy. In addition, the use of dexamethasone was evaluated in patients with confirmed herpesvirus CNS infection.

Results: Among 1,785 patients, 506 (28%) received antiviral therapy. Of these, 436 (86% of treated; 24% of total) did not have herpesvirus CNS infection, while 70 (14% of treated; 4% of total) had PCR-confirmed herpesvirus CNS infection. All patients with herpesvirus encephalitis received antiviral treatment. Delayed treatment (> 1 day after presentation) occurred in 9/70 (17%) herpesvirus CNS infection cases, mostly due to concurrent or alternative diagnoses. Continued treatment (≥ 7 days) in non-herpesvirus cases occurred in 18/436 (4%), predominantly while awaiting repeat PCR results. Dexamethasone was administered in 20/70 (29%) patients with herpesvirus CNS infection and was not associated with differences in GOS at discharge.

Conclusion: In order to ensure all herpesvirus encephalitis cases were treated, nearly one-quarter of patients with suspected CNS infection received antiviral therapy, exposing many to potential adverse effects. Nevertheless, delayed therapy remained

EPO-0257 | **Optimal timing of ARV initiation among patients with toxoplasma encephalitis: A meta-analysis**

C. Plan; K. San Diego; A. Barlin; A. Dimaano
Department of Neurology, The Medical City – Ortigas, Pasig City, Philippines

Background and aims: Toxoplasma encephalitis (TE) affects 10–40% of AIDS patients worldwide, with mortality rates of 10–50%. The optimal timing of antiretroviral therapy (ART) initiation remains controversial, balancing early immune recovery benefits against immune reconstitution inflammatory syndrome (IRIS) risks.
Methods: A meta-analysis of six studies (2009–2025) encompassing 710 HIV patients with TE was conducted. Studies compared early (≤ 10 days) versus delayed (> 21 days) ART initiation after anti-toxoplasma treatment. Primary outcomes included mortality and neurological sequelae. Random-effects models were used with heterogeneity assessed by I^2 statistics.

TABLE 1 Critical appraisal of studies.

FIGURE 1 Optimal timing of antiretroviral therapy initiation based on mortality and neurological sequelae.

Results: Early ART initiation showed no significant overall mortality difference (pooled OR: 0.85, 95% CI: 0.42–1.72, $p=0.65$) but demonstrated significant mortality reduction at 24-week follow-up (pooled OR: 0.65, 95% CI: 0.50–0.83, $p<0.001$). Neurological sequelae increased non-significantly with early initiation (pooled OR: 1.28, 95% CI: 0.97–1.67, $p=0.07$). IRIS occurrence showed no significant difference between groups. Optimal outcomes occurred with ART initiation at 10–21 days post-diagnosis, balancing mortality reduction with minimized complications. The mortality benefit of early ART supports immune reconstitution advantages, while increased neurological sequelae raise safety concerns. The absence of significant IRIS differences suggests concurrent anti-toxoplasma therapy may reduce inflammatory responses. Study heterogeneity, timing definitions and geographic diversity affect interpretation.
Conclusion: ART initiation between 10–21 days after anti-toxoplasma treatment provides optimal risk-benefit balance for most patients. Clinical decisions should incorporate individual factors including CD4 count, neurological severity, and health-care resources. Standardized timing definitions and long-term outcome studies are needed.
Disclosure: The authors declare no conflicts of interest, external funding, and followed PRISMA guidelines. Ethical approval attained.

E. Schepers; V. Boon; E. Drost; M. Brouwer; D. van de Beek
Neurology, Amsterdam UMC, Amsterdam, The Netherlands

Background and aims: Bacterial meningitis is a serious disease characterized by high rates of complications and adverse outcomes. Disfunction of the spleen is a known risk factor for developing bacterial meningitis.

Methods: Patients with cerebrospinal fluid culture-confirmed bacterial meningitis were enrolled in a nationwide prospective cohort study between March 1, 2006, and April 1, 2025. Splenectomy or conditions associated with functional hyposplenia were scored for each patient. Clinical characteristics and outcome of patients with a history of splenectomy or functional hyposplenia were assessed and compared with normosplenic patients.

Results: Hundred-four of 3165 patients (3.3%) had an abnormal splenic function: 52 had a history of splenectomy and 52 had functional hyposplenia. Vaccination status was known for 76 patients – 26 of 45 splenectomized (58%) and 4 of 31 hyposplenic patients (13%) were vaccinated. The most common causative organisms were *Streptococcus pneumoniae* in splenectomized patients (51 of 52 patients, 98%), while 18 of 52 hyposplenic patients were infected with *Listeria monocytogenes* (35%). Asplenic patients presented with higher serum leukocytes ($P < 0.01$) and C-reactive protein ($P < 0.01$), but lower levels of leukocytes in cerebrospinal fluid ($P < 0.001$) compared to normosplenic patients. Outcome was unfavorable in 47 patients (45%) and 17 patients died (16%).

Conclusion: Bacterial meningitis in splenectomized patients is caused by *S. pneumoniae* and is associated with a more severe systemic inflammatory response. In hyposplenic patients *L. monocytogenes* was a frequent cause of meningitis, likely due to a combination of immunocompromising factors and spleen dysfunction. Enhanced vaccination strategies should be employed to reduce the disease burden in these patients.

Disclosure: Nothing to disclose.

EPO-0259 | Influenza B-related mild encephalopathy with reversible splenial lesion Type II in an adult

F. Günel

Department of Neurology, Ondokuz Mayıs University, Samsun, Türkiye

Background and aims: Mild encephalopathy with a reversible splenial lesion (MERS) is a rare clinico-radiological syndrome characterized by transient neurological symptoms and

FIGURE 1 Initial brain MRI demonstrating DWI hyperintense and ADC hypointense lesions in the splenium of the corpus callosum and bilateral frontoparietal deep white matter.

FIGURE 2 Follow-up brain MRI performed 4 days later demonstrating regression of the lesions observed on the initial MRI.

reversible lesions of the splenium of the corpus callosum. It is classified into Type I, limited to the splenium, and Type II, involving the entire corpus callosum and adjacent white matter. Adult cases associated with influenza infection are uncommon.

Methods: We report a case of influenza B-associated type II MERS in a 35-year-old woman.

Results: A previously healthy 35-year-old woman presented with acute upper respiratory tract symptoms and fever, followed by rapid onset of confusion on the same day. On examination, she was disoriented to time, place, and person, with a body temperature of 38°C. There were no signs of meningeal irritation. Cranial magnetic resonance imaging revealed hyperintense lesions on diffusion-weighted imaging involving the splenium of the corpus callosum and bilateral frontoparietal deep white matter. Cerebrospinal fluid analysis, routine laboratory investigations, and electroencephalography were unremarkable. Polymerase chain reaction testing of a nasopharyngeal swab was positive for Influenza B virus. The patient was managed with supportive treatment alone. Her neurological symptoms resolved completely within two days. A follow-up MRI demonstrated marked regression of the previously noted lesions.

Conclusion: Influenza B-associated MERS Type II is exceedingly rare in adults. This case highlights the importance of diffusion-weighted MRI in diagnosis and emphasizes that MERS typically follows a self-limiting course with excellent clinical and radiological recovery under supportive management.

Disclosure: Nothing to disclose.

EPO-0260 | Can we predict meningitis before the tap? A machine learning approach to lumbar puncture decision-making

G. Tsur¹; M. Schwartz Yoskovitz¹; B. Yacobi²; S. Yust-Katz¹; E. Auriel¹; K. Pardo¹

¹*Neurology, Rabin Medical Center, Petach Tikva, Israel;*

²*Beilinson Medical Center Innovation, Artificial Intelligence Center, Rabin Medical Center, Petach Tikva, Israel*

Background and aims: Diagnosis of meningitis in the emergency department (ED) presents a challenge due to variable clinical presentations that overlap with other neurological and systemic conditions. The diagnosis today relies mostly on lumbar puncture (LP). Our aim was to develop clinical decision support tool for managing suspected meningitis patients in the ED.

Methods: Retrospective data of patients who underwent LP in the ER for suspicion of meningitis between 2019 and 2024 was collected. We used clinical and laboratory data to train machine learning (ML) model to predict meningitis prior to LP results. Model performance was evaluated using accuracy, precision, recall, and the area under the curve (AUC). Shapley value was used to identify important features in meningitis prediction.

TABLE 1 Demographic and characteristics.

	Meningitis n=344	non meningitis n=1183	P value
Age, median (IQR)	36 (30-57)	52 (34-71)	>0.001
Sex (F), n (%)	159 (46.2)	581 (49.1)	0.377
Background, n(%)			
DM	42 (12.2)	222 (18.8)	0.006
Hypertension	50 (14.5)	322 (27.2)	>0.001
Dyslipidemia	43 (12.5)	225 (19)	0.007
Prior_Stroke	8 (2.3)	61 (5.2)	0.038
IHD	9 (2.6)	95 (8.)	0.001
Migraine	27 (7.9)	68 (5.8)	0.196
Epilepsy	11 (3.2)	50 (4.2)	0.483
Anxiety	3 (0.9)	25 (2.1)	0.2
Depression	5 (1.5)	34 (2.9)	0.202
Fibromyalgia	2 (0.6)	17 (1.4)	0.325

FIGURE 1

Results: 1526 patients were included, among them 344 (22.54%) had meningitis. Most were aseptic meningitis ($n=270$, 78.49%), followed by meningoencephalitis ($n=49$, 14.24%), bacterial ($n=24$, 6.97%) and brain abscess ($n=1$, 0.29%). Meningitis patients were younger compared to non-meningitis [median age of 36 (IQR30-57) and 52 (IQR34-71), respectively, $p < 0.001$] and had less cerebrovascular risk factors. Our ML model achieved AUC of 0.87 and accuracy of 0.85 for the diagnosis of meningitis.

FIGURE 2

The most important features in our model were number of symptomatic days prior to ED visit, temperature, CRP, photophobia and absolute lymphocytes.

Conclusion: Our ML model was able to successfully predict patients with meningitis, providing a tool in clinical management of meningitis patients in the ED. Such tool can help determine whether a LP is indicated, avoiding unnecessary invasive tests.

EPO-0261 | **Beta-blockers in tuberculous meningitis associated cerebral salt wasting: An open label randomized controlled trial**

J. Kalita; F. M Nizami; P. C Pandey; R. Mahajan; R. Kumar; U. Misra
Department of Neurology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India

Background and aims: More than 50% tuberculous meningitis (TBM) patients have hyponatremia. Cerebral salt wasting (CSW) is the commonest cause of hyponatremia, and has been attributed to higher catecholamine level as a result of stress response. Beta-blockers may reduce stress response, and may be effective in TBM associated CSW. We report the efficacy and safety of propranolol in TBM associated CSW compared to placebo in a randomized placebo-controlled trial.

Methods: Thirty-eight TBM associated CSW patients were included, and were randomized to tablet propranolol 10mg twice daily on day 1, and 20mg twice daily from day 2 till one month or placebo. Both the arms received sodium chloride 10gm/day and normal saline till the normalization of serum sodium and fluid deficit. The primary outcome was day of normalization of serum sodium, and secondary outcomes were day of correction of fluid deficit and polyuria, adverse effects and a modified Rankin Scale (mRS) score at 1, 3 and 6 months. Both the groups received standard antitubercular treatment.

Results: Nineteen patients each received propranolol and placebo, and their baseline clinical, MRI, and laboratory findings were comparable. The propranolol group had an earlier normalization of serum sodium (median days 8vs20; $P < 0.01$), fluid deficit (median days 11vs42; $P < 0.01$) and polyuria (median days 4vs16; $P < 0.01$) compared to the placebo group. Death at 1 month and mRS score at 3 and 6 months were comparable between the

two groups. Two patients required reduction of propranolol dose due to hallucinations and bradycardia.

Conclusion: Adjunctive propranolol results in earlier resolution of CSW in TBM patients

Disclosure: Nothing to disclose.

Background and aims: Post-COVID-19 condition (PCC) includes persistent neurological symptoms, raising concerns about long-term neurodegeneration. Brain-derived tau (BD-tau) is a novel plasma biomarker with improved brain specificity compared to traditional tau assays. This study evaluated BD-tau as a marker of cognitive impairment and symptom persistence in PCC.

Methods: We conducted a longitudinal analysis within the Norwegian NeuroCOVID cohort, including adults with SARS-CoV-2 infection and neurological symptoms ($n=112$) and recovered controls without persistent symptoms ($n=33$). Plasma BD-tau, p-tau217, p-tau181, and total tau were measured at 6 and 12 months using ultrasensitive immunoassays. Clinical outcomes included modified Rankin Scale and neuropsychological testing. Associations were assessed using regression and correlation analyses.

Results: BD-tau, p-tau217, p-tau181, and total tau remained stable between 6 and 12 months, regardless of symptom remission (43% at 12 months) or cognitive impairment (39% at 6 months; 25% at 12 months). None of the tau biomarkers correlated with cognitive domains. BD-tau showed strong correlations with total tau ($\rho=0.66$ at 6 months; $\rho=0.61$ at 12 months, $p<0.001$) and moderate associations with p-tau217 and p-tau181, but no significant relationship with cognitive scores or headache persistence. Higher BD-tau was predicted by age, creatinine levels,

FIGURE 1 (A) Plasma concentrations of BD-tau, total tau (t-tau), phosphorylated tau 181 (pTau181), and phosphorylated tau 217 (pTau217) in individuals with post-COVID condition (PCC) compared to recovered controls at 6 months post-infection. (B) Distribution of plasma BD-tau, t-tau, pTau181, and pTau217 in participants with and without symptom remission at 12 months post-COVID-19 infection. Biomarker concentrations remained stable over time, with no significant differences between groups, despite clinical remission in nearly half of the cohort ($n=48$; 43.2%).

comorbidities, and COVID-19 severity, explaining up to 26% of variance at 6 months and 38% at 12 months.

Conclusion: Plasma BD-tau does not reflect remission or cognitive impairment in PCC, suggesting tau-driven neurodegeneration is not a dominant mechanism. Larger studies with extended follow-up are needed to clarify long-term neurocognitive risk.

EPO-0263 | Neurological manifestations of dengue: Clinical spectrum, imaging diagnosis, and response to immunomodulatory treatment

P. Tejada¹; J. Baez¹; G. Fernández¹; A. Tejada¹; Y. Rodríguez¹; L. Jiménez¹; A. Reyes¹; K. Yorro¹; C. Pérez Lizardo¹; M. Rodríguez²

¹Synaptic Research League, Santo Domingo, Dominican Republic;

²Neurology Department, Hospital Universitario Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic

Background and aims: Dengue virus infection is described as systemic febrile illness. Increasing evidence shows that the nervous system is a frequent and clinically relevant target. Neurological manifestations include encephalitis, encephalopathy, myelitis and demyelinating syndromes, cerebrovascular events, and immune-mediated neuropathies, occurring during acute infection or post-infectious complications, often

FIGURE 1 Prisma-P flowchart of the process of inclusion of studies in the systematic review.

FIGURE 2 Neurological manifestations of dengue, neuroimaging findings and immunomodulatory treatment.

remaining underrecognized [1–3]. This study describes clinical profile and symptomatic treatment of cases of neurological dengue, aiming to better define its spectrum and outcomes.

Methods: We conducted a PRISMA systematic review. Pubmed was searched using the keywords “dengue fever” and “neurological complications”. Studies reporting clinical, radiological, or laboratory data on dengue-associated neurological manifestations were included, excluding non-human and literature reviews studies.

Results: We analyzed 142 patients with neurological complications of dengue infection. Mean age was 28 years. Neurological symptoms developed at a mean of 10.9 days after fever onset. The most frequent manifestations were encephalopathy (40%), seizures (25%), and focal neurological deficits (20%). The overall mortality rate was 5.6%. Diagnosis was confirmed by serology (NS1 and/or IgM) in 90% of cases and by cerebrospinal fluid PCR in 30%. MRI revealed abnormalities in 70% of patients, most commonly thalamic edema, myelitis, and corpus callosum lesions. Treatment with corticosteroids or intravenous immunoglobulins was administered in 50% of cases, with complete recovery observed in 60%.

Conclusion: Neurological complications of dengue are frequent and diverse, with significant mortality. Diagnosis is based on serology and neuroimaging, and immunomodulatory treatment is associated with high rates of complete recovery, highlighting the need for early recognition.

Disclosure: Nothing to disclose.

EPO-0264 | How long MRI abnormality persists in Tuberculous meningitis?

P. Chandra Pandey¹; F. M Nizami²; R. Mahajan³; J. Kalita⁴

¹Department Of Neurology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; ²Department Of Neurology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; ³Department Of Neurology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; ⁴Department Of Neurology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Background and aims: There is paucity of information regarding resolution of MRI abnormalities, and its clinical relevance in patients with Tuberculous meningitis (TBM). We report the resolution of MRI abnormality at 6 and 12 months of treatment, and association with admission clinic-laboratory findings.

Methods: 115 patients with TBM diagnosed on the basis of clinical, CSF and MRI findings were included during 2018–2024, and followed up clinically and radiologically at 3, 6 and 12 months. The baseline clinical severity, and MRI findings (exudates, Infarcts, hydrocephalous and granuloma) were noted. Patients were treated with four antitubercular drugs, prednisolone and aspirin. The outcome was assessed using modified Rankin Scale (mRS) and categorized into death, poor (3–5) and good (0–2). The predictors of complete resolution of MRI at one year was evaluated including baseline findings.

Results: Their median age was 25 years, and 45.2% were females. The median duration of illness was 60 days and majority were in stage II ($n = 78$ (67.8%) at admission). MRI revealed exudates in 103 (89.6%), Infarcts in 51 (44.3%), granuloma in 93 (80.9%) and hydrocephalous in 32 (27.8%) patients. The complete resolution occurred at 3 months in 10 (8.7%), 6 months in 25 (27.1%) and at 12 months 25 (27.1%) patients. Enhancing granuloma was seen at 12 months in 62 (53.9%), and exudates in 7 (6.1%) patients. On multivariate analysis, the predictors of abnormal MRI at one year included seizure ($p = 0.026$) and lymphopenia in blood ($p = 0.005$) at baseline.

Conclusion: Complete resolution of MRI abnormality at year occurs in 33.9% patients especially in nonlymphopenic and non-seizure patients

Disclosure: Nothing to disclose.

FIGURE 1 PRISMA flow diagram illustrating study identification, screening, eligibility assessment, and inclusion for the scoping review of opportunistic CNS infections and transplant rejection in solid organ transplant recipients.

Background and aims: Opportunistic central nervous system (CNS) infections are uncommon but devastating complications of solid organ transplantation (SOT), accounting for up to 10% of transplant-associated complications and carrying disproportionate morbidity and mortality. While prior studies have emphasized short-term neurologic outcomes, the impact of immunosuppressive modulation on graft rejection and longer-term outcomes remains poorly characterized. To map and synthesize the existing literature describing transplant rejection in the setting of CNS infections among SOT recipients.

Methods: A scoping review was conducted following the Arksey and O'Malley framework, refined by the Joanna Briggs Institute, and reported according to PRISMA-ScR guidelines (Figure 1). PubMed, EMBASE, and Scopus were searched from inception through October 2025. Eligible studies included human experimental and observational designs describing both opportunistic CNS infection and transplant rejection in SOT recipients of any age. Two reviewers independently screened studies and extracted data using a standardized form. Findings were synthesized narratively using the Population–Concept–Context framework.

Results: CNS infections frequently occurred years after transplantation, often following intensified immunosuppression for rejection. Immunosuppressive regimens including calcineurin inhibitors and corticosteroids were consistently associated with pathogen-specific CNS infections. Reduction of immunosuppression during infection management was followed by acute rejection in approximately 25–35% of patients within one year. Neurologic outcomes ranged from full recovery to permanent neurologic injury and graft dysfunction.

Conclusion: The literature addressing transplant rejection in the context of opportunistic CNS infections is limited and heterogeneous. Significant gaps remain regarding standardized immunosuppressive management and long-term outcomes, highlighting the need for prospective studies and consensus-based guidance.

Disclosure: Nothing to disclose.

Background and aims: Neurobrucellosis is a rare but severe complication of systemic brucellosis, accounting for 3–10% of cases. Clinical presentations range from meningitis to stroke, mimicking neuro-tuberculosis in endemic countries, leading to delayed and often misdiagnosis.

Methods: A 58-year-old man presented with intermittent fever, polyarthralgia, and headache for three weeks. General and neurological examinations were unremarkable. Evaluation for pyrexia of unknown origin revealed lymphocytic pleocytosis, elevated protein, and hypoglycorrhachia on cerebrospinal fluid analysis, suggestive of infection. Blood cultures grew *Brucella*, and serum agglutination testing was positive. MRI of the spine demonstrated thoracic discitis. Treatment with ceftriaxone, rifampicin, and doxycycline was initiated.

Results: Four weeks later, despite appropriate antimicrobial therapy, he developed recurrent transient neurological episodes followed by persistent dysarthria and right hemiparesis. Brain MRI revealed acute lentiform nucleus infarcts, and MR angiography showed focal stenosis of the left middle cerebral artery (M1 segment). Vessel wall imaging demonstrated concentric enhancement, consistent with cerebral vasculitis. High-dose corticosteroids were added while continuing antibiotics. The patient stabilized without further neurological deterioration. Steroids were gradually tapered over six months, ceftriaxone was continued for six months, and doxycycline with rifampicin for one year. At one-year follow-up, he had minimal residual dysarthria without limb weakness.

Conclusion: Vasculitis in neurobrucellosis is very rare, with no consensus on treatment protocol. Starting steroids is a cliff-hanger with the risk of worsening an active systemic infection and the presumed benefit of neurological improvement. Our experience highlights that steroids, when judiciously used in

FIGURE 1 Axial CT sections of CT angiogram study (a) and 3D reconstruction of intracranial vessels show paucity of left middle cerebral artery (MCA) territory M3 and M4 cortical branches (double headed arrow) and stenosis at distal left M1 MCA on 3D images (arrow).

EPO-0267 | Functional status and prognostic predictors in the final six months of life in ALS: A retrospective analysis of 703 patients

B. Machado Antunes¹; M. Oliveira Santos¹; V. Barão de Sá²; D. Lopes²; I. Alves²; M. de Carvalho¹

¹Department of Neuroscience and Mental Health, Santa Maria Local Health Unit, Academic Center of Medicine of Lisbon, Lisbon, Portugal; ²Institute of Physiology, Egas Moniz Research Center, Faculty of Medicine, University of Lisbon, Lisbon, Portugal

Background and aims: In advanced Amyotrophic Lateral Sclerosis (ALS), transition to palliative care often leads to formal neurological follow-up discontinuation. Consequently, revised ALS Functional Rating Scale (ALSFRS-R) data near the end of

life are scarce. This study aimed to characterize ALSFRS-R total and subdomain scores during the final six months of life and evaluate their independent prognostic value.

Methods: We retrospectively analysed 703 patients with ALS (including progressive muscular atrophy) who underwent ALSFRS-R assessment within six months of death. Clinical and functional data were analysed using descriptive statistics; scores were compared by onset site (spinal vs. bulbar) using the Mann-Whitney U test. Cox proportional hazards models were employed to evaluate the association between functional scores and mortality risk, adjusting for age at onset, sex, onset region, and the use of gastrostomy and non-invasive ventilation.

Results: Median age at onset was 66.7 years and median survival was 29 months. Near death, median ALSFRS-R total score was 20, with no significant differences between onset types. Notably, respiratory and bulbar subscores remained higher relative to limb and global domains. Multivariate analysis revealed that higher total ALSFRS-R scores (HR 0.988, 95% CI 0.979–0.998) and higher bulbar subscores (HR 0.965, 95% CI 0.939–0.992) were independently associated with reduced risk of death. Other subscores did not significantly predict survival in this late stage.

Conclusion: Quantifying functional decline in the terminal phase of ALS is vital for informed end-of-life clinical decision-making. In advanced disease, overall functional status and, specifically, bulbar dysfunction emerge as the most robust predictors of mortality.

Disclosure: The author has applied for a research grant related to this work and is currently awaiting the outcome.

EPO-0268 | Therapeutic comparison of edaravone and riluzole in amyotrophic lateral sclerosis: A systematic review and meta-analysis

C. De Souza Pavao¹; Y. Bastos Faller²; N. Belen Toca²; J. Ferreira Jasmineiro Pitanga¹; C. Rocha Dantas²; M. Sánchez espuelas²

¹Department of Microbiology, Parasitology and Immunology, University of Buenos Aires, Buenos Aires, Argentina; ²Faculty of Medicine, University of Buenos Aires (UBA), Buenos Aires, Argentina

Background and aims: Amyotrophic lateral sclerosis (ALS) is a rapidly progressive neurodegenerative disorder. Riluzole is the standard therapy, while edaravone is an approved adjunct treatment; however, the clinical benefit of combination therapy remains uncertain. This meta-analysis evaluates the effect of riluzole plus edaravone versus riluzole alone on disease progression in ALS according to the Revised Amyotrophic Lateral Sclerosis Functional Rating Scale (ALSFRS-R).

Methods: A systematic search was performed for studies published through October 2025 comparing combination therapy with riluzole monotherapy in patients with ALS. Extracted outcomes included ALSFRS-R and all-cause mortality. Standardized mean differences (SMDs) and odds ratios (ORs) with corresponding 95% confidence intervals (CIs) were calculated using random-effects models. Statistical heterogeneity was assessed using the I² statistic. All analyses were performed using RStudio.

Results: Five studies comprising 548 patients were included, of whom 39.4% received riluzole plus edaravone. For functional progression, pooled analysis showed no significant

FIGURE 1 Forest plot of all-cause mortality comparing combination therapy (edaravone plus riluzole) versus riluzole monotherapy in patients with ALS.

FIGURE 2 Forest plot comparing functional progression (ALSFRS-R scores) between edaravone plus riluzole combination therapy and riluzole monotherapy.

difference between combination therapy and riluzole monotherapy (SMD=0.20, 95% CI -0.37 to 0.77; $p=0.49$), with moderate heterogeneity ($I^2=63\%$). Similarly, no significant difference in all-cause mortality was observed between treatment strategies (OR=1.37, 95% CI 0.25 to 7.44; $p=0.71$), also with moderate heterogeneity ($I^2=60\%$). Heterogeneity likely stemmed from differences in study design and disease stage at treatment initiation.

Conclusion: Riluzole plus edaravone did not demonstrate a significant advantage over riluzole alone in ALS. This quantitative synthesis clarifies the absence of a population-level benefit of combination therapy. However, larger and standardized randomized trials are required to inform future treatment recommendations.

Disclosure: Nothing to disclose.

EPO-0269 | NLRP3 inflammasome and pyroptosis as contributors to neuroinflammation in amyotrophic lateral sclerosis

D. Shevchuk¹; I. Dolzhikova²; A. Kovyshina²; M. Zakharova¹
¹6th neurological department, Russian Center of Neurology and Neurosciences, Moscow, Russian Federation; ²N. F. Gamaleya National Research Center for Epidemiology and Microbiology, Moscow, Russian Federation

Background and aims: Amyotrophic lateral sclerosis is a fatal neurodegenerative disorder in which growing evidence points to a contributory role of innate immune mechanisms. Activation of inflammasome-dependent inflammatory pathways and pyroptotic cell death has been demonstrated in experimental models; however, clinical evidence in patients remains scarce. This study

FIGURE 1 Cerebrospinal fluid levels of interleukin-1 beta, gasdermin D, and interleukin-18 in patients with ALS and controls.

FIGURE 2 Serum gasdermin D and CSF interleukin-18 levels across ALS clinical phenotypes: lower motor neuron-predominant, classic, and upper motor neuron-predominant.

FIGURE 3 CSF interleukin-1 beta levels in ALS patients with and without c9orf72 repeat expansion.

aimed to evaluate circulating and cerebrospinal fluid markers related to NLRP3 inflammasome activation and pyroptosis in amyotrophic lateral sclerosis and to explore their clinical and genetic associations.

Methods: A total of 100 patients with amyotrophic lateral sclerosis and 36 neurologically healthy controls were enrolled. Serum and cerebrospinal fluid levels of interleukin-1 beta, interleukin-18, and gasdermin D were quantified using ELISA. Clinical phenotypes, disease staging, and progression characteristics were analyzed. Molecular genetic testing was performed to identify SOD1 mutations and c9orf72 repeat expansion. Group and subgroup comparisons were conducted using appropriate statistical methods.

Results: Compared with controls, patients with ALS exhibited higher serum concentrations of gasdermin D and increased cerebrospinal fluid levels of interleukin-1 beta. Elevated cerebrospinal fluid interleukin-1 beta was observed in carriers of c9orf72 repeat expansion. Serum gasdermin D concentrations varied across clinical phenotypes, with higher levels in patients with predominant lower motor neuron involvement. Interleukin-18 levels did not significantly differ between groups. Associations between peripheral and central inflammatory markers were identified.

Conclusion: The results indicate activation of inflammasome-related inflammatory pathways and pyroptosis in amyotrophic lateral sclerosis. These findings support a role for innate immune dysregulation in disease pathogenesis and suggest that inflammasome-associated molecules may represent promising biomarkers and therapeutic targets.

Disclosure: Nothing to disclose.

EPO-0270 | Efficacy of immunoglobulin in participants with post-polio syndrome: Results from the multicenter, randomized, placebo-controlled FORCE trial

Background and aims: Post-Polio Syndrome (PPS) is a chronic, slowly progressive neuromuscular condition with no specific medical treatments. This study evaluated intravenous immunoglobulin (IVIG, Flebogamma® 5% DIF) in participants with PPS, based on observations of immune/inflammatory markers activation.

Methods: This Phase II/III multicenter, randomized, double-blind, placebo-controlled trial included adult participants with PPS across Europe, Canada, and the US. Participants received monthly infusions of IVIG (1 g/kg) or placebo for 52 weeks, followed by a 24-week observation. The primary endpoint was change from baseline in Two-Minute Walking Distance (2MWD) at Week 52. Secondary and exploratory endpoints included Six-Minute Walking Distance (6MWD), fatigue (Fatigue Severity Scale and Borg scale), muscle strength (Medical Research Council scale), and pain (Visual Analog Scale).

Results: 149 participants were randomized to IVIG 1 g/kg ($n=75$) or placebo ($n=74$). Mean age 63.2 years, 61.7% female. IVIG significantly improved 2MWD vs placebo at Week 52 ($p=0.0469$), which was further confirmed in a sensitivity analysis (least squares mean difference [LSMD]: +6.07 m; $p=0.0147$) (Figure 1). A clinically meaningful improvement in 6MWD was observed in the IVIG group vs placebo (+15.8 m; $p=0.1205$); IVIG improvement from baseline was twice that of placebo (Figure 2). Muscle strength decreased in placebo group and increased in IVIG group ($p=0.0220$). No notable differences were observed in fatigue or pain (Table 1). IVIG 1 g/kg was well tolerated.

Conclusion: Monthly IVIG infusions demonstrated statistically and clinically meaningful improvements in walking capacity in

EPO-0271 | Neutrophil percentage-to-albumin ratio as a possible prognostic biomarker in amyotrophic lateral sclerosis: A PRO-ACT study cohort

L. Ferullo¹; E. Olivieri²; B. Risi¹; L. Poli³; A. Padovani²; M. Filosto¹

¹NeMO-Brescia Clinical Center for Neuromuscular Diseases, Brescia, Italy; ²Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy; ³Unit of Neurology, ERN Euro-NMD Center, ASST Spedali Civili, Brescia, Italy

Background and aims: Increasing evidence suggests that immune dysregulation contributes to the pathophysiology and progression of amyotrophic lateral sclerosis (ALS), underscoring the need for inflammatory biomarkers to monitor

disease progression. The neutrophil percentage-to-albumin ratio (NPAR) has been proposed as a marker of systemic inflammation and has shown prognostic relevance in ischemic stroke, intracerebral hemorrhage, and cognitive decline. However, its role in ALS remains unclear. This study aimed to investigate longitudinal changes in NPAR and to evaluate its prognostic value in ALS.

Methods: We conducted a retrospective longitudinal analysis of 917 ALS patients, comprising 2,168 NPAR measurements collected at baseline and at 6 and 12 months. NPAR values were log-transformed to improve normality. Longitudinal trajectories of log-NPAR were modeled using linear mixed-effects models with random intercepts and slopes, adjusted for age, sex, site of onset, riluzole treatment, baseline ALSFRS-R score, and body mass index. Survival was analyzed using Cox proportional hazards models with NPAR as a time-dependent covariate, considering a composite endpoint of death or tracheostomy. Data were obtained from the PRO-ACT database.

Results: Log-NPAR increased significantly over time across the entire cohort (slope: 0.036/year, $p < 0.001$). Patients who reached the endpoint of death or tracheostomy exhibited a steeper increase in log-NPAR ($p = 0.0003$). In survival analyses, higher time-dependent NPAR was associated with an increased risk of death or tracheostomy (hazard ratio [HR] 12.75, 95% [CI] 3.09–52.57, $p < 0.001$), with attenuation of the effect over time.

Conclusion: NPAR demonstrates longitudinal changes in ALS, particularly among patients with poorer outcomes, supporting its potential role as a prognostic blood biomarker.

Disclosure: Nothing to disclose.

EPO-0272 | Tofersen in the treatment of SOD1 ALS – A two year experience from the Polish Early Access Program

M. Kuzma-Kozakiewicz

Department of Neurology, Medical University of Warsaw, Warsaw, Poland

Background and aims: Tofersen, an ASO against SOD1, is now registered by FDA and EMA. Some patients obtained tofersen in the EAP and/or rescue therapy. The aim of the study was to follow up on clinical outcomes and NfL concentration in patients participating in the EAP in Poland for 24 months.

Methods: 20 SOD1-ALS patients qualified to EAP (10 FALS and 10 SALS, a male:female ratio of 2.2:1) carried 11 SOD1 mutations (45% – L145S and 10% – K4E). Median age of onset was 49.1 years, age of introducing tofersen was 52.6 years. From the original cohort, 1 patient resign after the first dose of treatment, two withdrew (due to severe adverse event or respiratory insufficiency) and 2 passed away due to disease progression. The analysis included the demographic and genetic data, ALSFRS-R, delta ALSFRS-R, FVC and NfL CSF concentration.

Results: Mean treatment was 17 months (16–24 months), delta ALSFRS-R ranged from 0.46 prior to treatment to 0.15 at the last assessment. Seven patients (37%) showed increase of ALSFRS-R by 1–2 points in the treatment period, six patients (31%) stabilized, while 6 patients (31%) showed further progression. Mean ALSFRS-R was stable after 6 and 24 months, and increased after 12 and 18-months. NfL concentration decreased in 5/7 of analyzed patient. Treatment was well tolerated in 78% of patients.

FIGURE 1 Disease progression prior and after tofersen treatment.

Three patients experienced SAE– two transverse myelitis, one exacerbation of colitis ulcerosa and one poliradiculopathy.

Conclusion: The data from a long term follow-up supports the efficiency of tofersen in SOD1-ALS.

Disclosure: MKK obtained lecture grants from Biogen.

EPO-0273 | Sensor-based real-world gait metrics as sensitive mobility outcomes in amyotrophic lateral sclerosis

¹CRMN, University department of neurology, Citadelle Hospital of Liège, Belgium; ²Sean M. Healey and AMG Center for ALS at Massachusetts General Hospital, USA; ³Synav, Vernon, France; ⁴Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano, Milan, Italy; ⁵MDUK Oxford Neuromuscular Centre, John Radcliffe Hospital, Oxford, UK

Background and aims: Amyotrophic lateral sclerosis (ALS) is a heterogeneous, rapidly progressive neurodegenerative disease. Clinical trials rely mainly on the Revised ALS Functional Rating Scale (ALSFRS-R), which is subjective and often insensitive to subtle changes in ambulation. This study aimed to evaluate the analytical validity, feasibility, and clinical validity of real-world gait outcomes derived from wearable digital health technology (wDHT) in ALS.

Methods: One analytical validation study and three longitudinal observational studies were conducted in Belgium and the United States. Ambulatory adults with ALS wore ankle-mounted wDHTs daily for repeated 30-day periods. Three digital

FIGURE 1 Bland Altman plots for the error of the stride velocity and length.

FIGURE 2 Digital outcome measures by ALSFRS-R walking score and disease onset type ($p < 0.05^*$, $p < 0.01^{**}$, $p < 0.001^{***}$, $p < 0.0001^{****}$, ns = not significant). ALSFRS-R Question 8 – Walking assessment: 4 = normal, 3 = early ambulation difficulties.

FIGURE 3 Box plots with change at 3, 6, and 9 months for each digital and clinical outcome ($p < 0.05^*$, $p < 0.01^{**}$).

mobility outcomes were derived: stride velocity 95th centile (SV95C), number of strides per hour, and peak walking distance. Analytical validation against optical motion capture assessed stride detection and gait parameter accuracy. Reliability, construct validity and sensitivity to change were evaluated.

Results: Analytical validation showed excellent precision and recall for stride detection (> 0.97), and mean error of 2.2cm and 1.7cm/s for stride length and velocity measurements, respectively ($N = 10$). In the longitudinal study ($N = 46$), adherence rate exceeded 80% over 9 months and SV95C demonstrated outstanding reliability (intraclass correlation coefficient of 0.99). SV95C correlated strongly with the ALSFRS-R gross motor subscore ($R = 0.67$) and 6MWT ($R = 0.89$; $p < 0.001$), but weakly with ALSFRS-R total score. SV95C declined significantly over 3, 6, and 9 months and showed greater sensitivity to change than ALSFRS-R and 6MWT.

Conclusion: Continuous real-world gait monitoring using wDHTs is feasible in ALS. SV95C provides a reliable and sensitive measure of ambulatory decline and represents a promising outcome for ALS clinical trials.

Disclosure: This project received funding from Belgian Association for Neuromuscular Disease (ABMM) and Muscular Dystrophy Association (MDA).

EPO-0274 | The role of hsa-miR-21-5p, hsa-miR-210-3p, hsa-miR-197-3p, hsa-miR-125a-5p and hsa-miR-206-3p as potential biomarkers in amyotrophic lateral sclerosis

M. Sokratous¹; P. Stamati¹; I. Liampas¹; C. Marogianni¹; D. Bogdanos²; E. Dardiotis¹; V. Siokas¹

¹Department of Neurology, University Hospital of Larissa, Faculty of Medicine, University of Thessaly, Larissa, Greece;

²Department of Rheumatology and Clinical Immunology, Faculty of Medicine, University of Thessaly, Larissa, Greece

Background and aims: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease characterized by progressive loss of motor neurons. MicroRNAs (miRNAs) are small, non-coding RNA molecules that regulate gene expression. The purpose of this study is to identify selected miRNAs in the cerebrospinal fluid (CSF) and serum as biomarkers for ALS.

Methods: A total of 50 ALS patients and 50 age and sex-matched non-ALS controls were enrolled. MiRNAs were isolated from serum and CSF samples and quantified using quantitative reverse transcription polymerase chain reaction (qRT-PCR) with specific primers for hsa-miR-21-5p, hsa-miR-210-3p, hsa-miR-197-3p, hsa-miR-125a-5p and hsa-miR-206-3p. Internal and spike-in controls were used for normalization. ΔC_t values were compared between ALS and non-ALS groups using non-parametric tests with covariates for age, gender, amyotrophic lateral sclerosis functional rating scale – revised (ALSFRS-R), disease duration and progression rate.

Results: Hsa-miR-210-3p and hsa-miR-206-3p were markedly up-regulated in ALS CSF and serum and correlated with disease duration. Hsa-miR-210-3p also correlated with progression rate in the CSF ($p < 0.001$). Hsa-miR-210-3p exhibited the highest diagnostic performance, with an area under curve (AUC) of 0.925 in the serum and 0.902 in the CSF. Hsa-miR-21-5p showed up-regulation in ALS CSF and serum and strong association with poorer ALSFRS-R. Hsa-miR-125a-5p was significantly down-regulated in ALS serum but remained stable in the CSF. Hsa-miR-197-3p showed no diagnostic or prognostic value in either material.

Conclusion: Serum and CSF hsa-miR-210-3p and hsa-miR-206-3p could serve as strong diagnostic ALS biomarkers, while hsa-miR-21-5p as a robust disease-severity indicator. The combination of up-regulated and down-regulated miRNAs suggests a multimarker panel.

FIGURE 1 Distribution of ΔC_t values across all the examined miRNAs in the CSF of ALS patients and non-ALS controls.

FIGURE 2 Distribution of ΔC_t values across all the examined miRNAs in the serum of ALS patients and non-ALS controls.

Disclosure: All authors declare that they have nothing to disclose and there is no conflict of interest.

EPO-0275 | Elevated CSF GFRA1 and NFL levels: A comparative study on ALS biomarkers

P. Bakkal¹; Ş. Aydın Türkoğlu¹; T. Bakkal²; N. Yıldız³

¹Department of Neurology, Bolu Abant İzzet Baysal University Faculty of Medicine, Bolu, Türkiye; ²Department of Neurology, İzzet Baysal State Hospital, Bolu, Türkiye; ³Department of Neurology, Liv Hospital Ulus, İstanbul, Türkiye

Background and aims: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by complex axonal degeneration and impairments in neurotrophic support mechanisms, leading to the progressive loss of motor neurons.

Methods: In this study, cerebrospinal fluid (CSF) levels of GFAP, IL-1B, IL-22, IL-6, GFRA1, and NFL were investigated using the ELISA method in 6 patients with ALS (2F, 4M) and 6 healthy controls (3F, 3M).

Results: The median age of the ALS group was 67 years (range: 38–73), while the median age of the healthy control group was 51 years (range: 23–72), no significant difference in age was found between the groups ($p = 0.35$). In the ALS group, cerebrospinal fluid (CSF) levels of GFRA1 and NFL ($10.16 \text{ ng/L} \pm 1.16$ and 20.95 ± 6.29) were significantly higher compared to the control group ($5.30 \text{ ng/L} \pm 3.23$ and 13.37 ± 2.46) ($p = 0.01$, $p = 0.02$). No statistically significant differences were detected between the groups regarding CSF levels of GFAP, IL-1B, IL-22, IL-6, or total protein ($p = 0.85$, $p = 0.85$, $p = 0.68$, $p = 0.87$). Furthermore,

FIGURE 1 Comparative analysis of CSF GFRA1 and NFL levels between ALS patients and healthy controls.

a statistically significant, moderate-to-strong positive correlation was identified between GFRA1 and NFL levels ($r=0.64$; $p=0.03$).

Conclusion: The significant elevation of GFRA1 accompanying the increase in NFL, coupled with the identified positive correlation, reflects a dynamic neurotrophic response that intensifies as motor neuron destruction deepens. This increase may represent a compensatory mechanism aimed at protecting motor neurons from apoptosis. The absence of inflammation suggests that the pathology is driven by an axis of neuronal integrity rather than glia-mediated neuroinflammation. This pathogenic link holds significant potential for both understanding ALS pathogenesis and formulating novel therapeutic strategies.

Disclosure: Nothing to disclose.

EPO-0276 | Respiratory function improvement in spinal muscular atrophy patients after long-term risdiplam treatment: The experience of two Italian centers

M. Sframeli¹; N. Brolatti²; F. Trucco⁴; E. La Rosa¹; R. Lauro¹; R. Materia¹; M. Maniaci¹; N. Longoni¹; I. Said¹; C. Allegra¹; M. Pedemonte³; C. Bruno⁴; S. Messina¹

¹Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; ²Center of Translational and Experimental Myology and Maternal and Child Health, IRCCS Istituto Giannina Gaslini; ³Pediatric Neurology and Muscular Diseases Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy; ⁴Department of Neuroscience, Rehabilitation, Ophthalmology Genetics, University of Genoa, Genoa, Italy

Background and aims: Risdiplam is an available treatment of all patients with spinal muscular atrophy (SMA). Although the respiratory impairment is inevitably progressive also in later-onset SMA, no studies report the effect of this drug on respiratory function.

Methods: We report a case series of 14 patients, followed at two different Italian Centre, with long-term disease duration, treated with risdiplam for more than 5 years. We describe changes in respiratory and motor function and the need for non-invasive ventilation (NIV).

Results: Patients (mean age: 19.7 years, range: 14–28), 11 SMA2 (78.6%) and 3 SMA3 (21.4 %), were sitter (57.1%) or non-sitter (43.9%). The Hammersmith Functional Motor Scale Expanded (HFMSE) score was ≤ 8 in 13/14 patients, and did not show significative changes after treatment ($p=0.9$). Mean FVC at baseline was 1.27 l (SD: 1.02). After more than 5 years (mean follow-up 5.3 years) the mean FVC improved significantly (1.41 l; SD: 1.06, $p=0.04$). Overall 4 patients (28%) showed minimal FVC decrease (-0.12 l; $p=0.09$), while the other 10 patients (72%) showed a significative improvement in FVC ($+0.24$; $p=0.009$). None of the patients on NIV at baseline ($n=8$) required changes in ventilation regime at follow-up.

Conclusion: We report longer-term respiratory follow-up in treated patients and, for the first time, an improvement in commonly used pulmonary function tests, in contrast to motor functional outcome measures. Therefore, we propose to explore a high responsiveness of the FVC, mostly in severely affected SMA patients, in which commonly used motor functional outcome measures might not detect changes.

Disclosure: The study has been founded by Italian Health Ministry project PNRR-MR1-2022-12376937. Nothing else to disclose.

EPO-0277 | Autologous SVF therapy modulates neuroinflammation in ALS: Phase I trial demonstrating safety and CSF biomarker dynamics

Z. Cai; R. Li; X. Li; J. Li

Department of Neurology, Suzhou Hospital, Affiliated Hospital of Medical School, Nanjing University, Suzhou, China

Background and aims: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder with limited treatments. Stromal vascular fraction (SVF), a cell population derived from autologous adipose tissue, exhibits multimodal immunomodulatory and neuroprotective properties, positioning it as a promising therapeutic candidate. This trial aimed to assess autologous stromal vascular fraction (SVF) safety and efficacy in patients with ALS.

Methods: This trial aimed to assess autologous stromal vascular fraction (SVF) safety and efficacy in patients with ALS. 26 patients received combined intravenous (0.5×10^6 cells/kg) and intrathecal (20×10^6 cells) autologous SVF.

Results: SVF administration was well-tolerated. Five mild adverse events (AEs) (subcutaneous bleeding, headache, and low-grade fever) occurred, with no serious AEs reported. Although ALSFRS-R scores showed non-significant improvement post-treatment, 15/26 participants (57.7%) self-reported symptomatic improvement after treatment. Critically, cerebrospinal fluid biomarker analysis revealed significant reductions in neurofilament light chain (NfL; $\Delta 530.29$ pg/mL, $P=0.039$) and glial fibrillary acidic protein (GFAP; $\Delta 622.23$ pg/mL, $P=0.038$), indicating attenuation of neuroaxonal degeneration and astroglial activation. While ALSFRS-R scores showed no significant change ($\Delta -0.53$, $P=0.384$), prognostic modeling identified female sex (OR=0.011, $p=0.008$) and shorter disease duration (OR=1.35/month, $P=0.005$) as predictors of response.

Conclusion: These findings support Autologous SVF therapy demonstrates an acceptable safety profile in patients with ALS. The significant reduction in CSF NfL and GFAP levels provides objective evidence of their potential neuroprotective effects that

FIGURE 2 The experimental process of this study.

FIGURE 1 CSF biomarker changes after SVF therapy.

modulates ALS-relevant neuroinflammation pathways. Female participants and those with shorter disease duration may derive greater benefits.

Disclosure: Nothing to disclose.

EPO-0278 | Real-world outcomes of subcutaneous foslevodopa/foscarbidopa therapy in Parkinson's disease (DuoPark study)

C. Correia^{*1}; A. Costa^{*3}; I. Pereira¹; S. Lopes³; F. Ferreira¹; A. Oliveira¹; S. Varanda³; O. Costa³; A. Fernandes¹; G. Carneiro³; M. Rosas¹; M. Rodrigues⁴; C. Soares¹

¹Serviço de Neurologia, Hospital Universitário de São João, Porto; ³Serviço de Neurologia, ULS Braga, Braga; ⁴CNS – Campus Neurológico, Braga

Background and aims: Subcutaneous foslevodopa/foscarbidopa (fLD/fCD) is a continuous infusion therapy for Parkinson's disease (PD) with motor complications. Real-world data are essential to assess its effectiveness and safety in clinical practice.

Methods: Interim analysis of a prospective, multicenter, observational study including people with PD treated with fLD/fCD between April/2024-December/2025. Clinical and socio-demographic variables, “off” and “on” times, and MDS-UPDRS scores (parts III–IV) at 3 and 6 months were analyzed. Infusion rates, levodopa equivalent daily dose, discontinuation of dopaminergic drugs, adverse events, and treatment discontinuation were also assessed. The effectiveness and safety of fLD/fCD for motor symptoms of PD were evaluated.

Results: Forty-one patients were included (48.8% women; age 75 ± 15 years; MDS-UPDRS-III score: “off” 56.16 ± 15.65 ; “on” 34.5 ± 13.34). Mean daily “off” time was 6.02 ± 2.69 h/day, decreasing by 20.32% (-2.38 h/day, $p=0.017$) and 14.10% (-2.08 h/day, $p=0.005$) at 3 and 6 months, respectively. “On” time without troublesome dyskinesia increased by 35.26% ($p=0.003$) and 33.08% ($p=0.002$) at 3 and 6 months. MDS-UPDRS-IV scores improved significantly at both time points, with no significant differences in MDS-UPDRS-III “on” scores. Adverse events occurred in 26 patients (63.4%), mainly infusion-site skin reactions, and neuropsychiatric symptoms. Seven patients (17.1%) discontinued treatment: 4 (9.8%) due to adverse events, 2 (4.9%) due to death, and 1 (2.4%) due to lack of family support.

Conclusion: fLD/fCD infusion significantly reduces “off” time and increases “on” time without troublesome dyskinesia during the first 6 months of treatment. Despite frequent but mostly mild to moderate adverse events, fLD/fCD demonstrated a favorable effectiveness and safety profile.

Disclosure: Nothing to disclose.

EPO-0279 | Neuroinflammatory marker MCP-1 and its correlation with motor and non-motor dysfunction in Parkinson's disease and atypical parkinsonism

D. Akramova; G. Rakhimbaeva; T. Bobomuratov; D. Bobamuratova; N. Vakhabova; U. Shamsieva; B. Ibodov
Tashkent State Medical University, Uzbekistan

Background and aims: Parkinson's disease (PD) and atypical parkinsonism (AP) represent a heterogeneous group of neurodegenerative disorders with overlapping motor manifestations but markedly different disease trajectories and prognoses. Increasing evidence highlights neuroinflammation as a central mechanism driving disease progression.

Methods: A total of 163 patients were enrolled, including 80 with PD and 83 with AP (MSA, PSP, CBD, DLB). Comprehensive neurological assessments were conducted using the Unified Parkinson's Disease Rating Scale (UPDRS) and standardized non-motor symptom questionnaires. Serum MCP-1 concentrations were measured by enzyme-linked immunosorbent assay. Correlation and multivariate regression analyses were applied to explore associations between MCP-1 levels and clinical parameters. Statistical significance was defined as $p < 0.05$.

Results: MCP-1 levels were significantly higher in AP compared to PD patients ($p < 0.01$). Elevated MCP-1 concentrations demonstrated a strong positive correlation with non-motor symptom severity ($r=0.46$, $p < 0.001$), particularly cognitive decline and autonomic dysfunction. Moderate correlations were observed with motor disability ($r=0.29$, $p < 0.05$). Patients with high MCP-1 levels exhibited accelerated clinical progression and reduced functional independence. Multivariate analysis confirmed MCP-1 as an independent predictor of disease severity after adjustment for age, disease duration, and genetic status.

Conclusion: This study provides the first comprehensive evidence from a Central Asian cohort demonstrating that MCP-1 is a robust biomarker of neuroinflammatory activity and neurological deterioration in parkinsonian disorders. Our findings support the integration of MCP-1 into prognostic models for early risk stratification and personalized management. Presenting these results at an international congress will facilitate cross-regional collaboration, enhance global data diversity, and promote precision medicine approaches in neurodegenerative diseases.

Disclosure: Nothing to disclose.

EPO-0280 | Mapping spatial and temporal evolution of dystonia in atypical parkinsonisms: A retrospective longitudinal cohort study

G. Vadi; J. Pasquini; E. Benevento; G. Palermo; E. Del Prete; E. Unti; R. Ceravolo

Center for Neurodegenerative diseases – Parkinson's disease and Movement disorders, Unit of Neurology, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background and aims: Dystonia is a frequent yet inconsistently characterized feature of atypical parkinsonian disorders (APDs), including progressive supranuclear palsy (PSP), multiple system atrophy (MSA), and corticobasal syndrome (CBS). The objective of this study was to provide a first systematic, longitudinal

comparison of dystonia across APDs focusing on its prevalence, topography, and timing of onset.

Methods: We retrospectively analysed longitudinal clinical data from a single-center cohort of 182 patients diagnosed with PSP, MSA, or CBS. A five-year subcohort with homogeneous follow-up from symptom onset ($n = 119$) was examined to estimate dystonia prevalence and spatiotemporal trajectories. Complementary time-to-event analyses were used to model the evolution of dystonia across the entire disease course. Associations between dystonia and disease-progression milestones, including dysphagia and loss of ambulation, were also explored.

Results: Within five years from symptom onset, dystonia occurred in 71% of PSP, 47% of MSA, and 86% of CBS patients. Cranial dystonia was most frequent in PSP (55.6%), whereas upper limb dystonia predominated in CBS (82.6%) (both $p < 0.001$). No significant differences were observed for cervical or truncal dystonia. Upper limb dystonia occurred earlier in CBS compared with PSP ($p = 0.025$). Dystonia-related pain was significantly more frequent in CBS than in MSA and PSP ($p < 0.001$). Dysphagia and loss of ambulation were not significantly influenced by cervical and trunk dystonia, respectively.

Conclusion: Dystonia is a common and early feature of APDs, with distinct spatial and temporal trajectories across syndromes. Systematic longitudinal assessment of dystonia may improve clinical characterization and support diagnostic and therapeutic strategies.

Disclosure: Nothing to disclose.

EPO-0281 | Recruitment barriers for Parkinson's disease research at a tertiary centre in Kenya: A TraPCAf sub-study

J. Nambafu¹; M. Pambo¹; M. Parsemei¹; J. Hooker¹; D. Sokhi¹; D. Sokhi²

¹Department of Medicine, Aga Khan University Medical College of East Africa, Nairobi, Kenya; ²Brain and Mind Institute, Aga Khan University, Nairobi, Kenya

Background and aims: Africa faces a rising burden of Parkinson's disease (PD), yet research is constrained by an unquantified failure to enrol hospital-identified patients into clinical trials, limiting data on disease phenotypes and treatment

FIGURE 1: Study site map, adapted from Step et al, Mov Disord, 2024.

FIGURE 2: Patient final enrolment outcome.

needs. We have previously described these challenges in recruiting participants to a motor neurone disease (MND) study.

Methods: As part of the ongoing multinational Transforming Parkinson's Care in Africa (TraPCAf) study, we conducted a retrospective analysis of patient recruitment challenges at our study site in Nairobi, Kenya. Participants were chosen based on coding from our hospital's electronic health records.

Results: Out of 432 potential participants, 20.8% (90/432) were recruited; of the remaining: 25.0% (108/432) had frailty including dementia; 13.7% (59/432) declined; 13.8% (60/432) were lost to follow-up; 12% (52/432) lived too far, including outside Kenya; 8.3% (36/432) were misdiagnosed; and 6.3% (27/432) were deceased.

Conclusion: Our findings underscore that patient identification from EHR does not translate to successful study enrolment. The spread of challenges is similar to those we encountered in our MND study. Our study suggests these factors should be consistently accounted for when establishing sample sizes for research studies in neurological disease in our part of the world.

Disclosure: This work was conducted as part of the TraPCAf study, funded by the UK National Institute for Health and Care Research (NIHR) via Newcastle University in partnership with Aga Khan University. The views expressed are those of the author(s) and not necessarily those of the NIHR, the UK Department of Health and Social Care, or Newcastle University. The authors have no other conflicts of interest or competing financial interests to declare relevant to this work.

EPO-0282 | Beyond motor symptoms of cervical dystonia – is cognitive deficit primary or secondary feature of the disease?

M. Dudzic¹; A. Pieczyńska²; A. Drużdż¹; A. Rajewska¹; K. Hojan²

¹Department of Neurology, Municipal Hospital in Poznań, Poland; ²Department of Occupational Therapy, Poznań University of Medical Sciences, Poznań, Poland

Background and aims: The study aimed to evaluate subtle cognitive impairment (CI) in patients with cervical dystonia (CD) and to determine whether it represents an independent non-motor feature of the disease or arises secondary to interactions between motor manifestations and other non-motor

FIGURE 1 Multivariable models of factors associated with cognitive impairment in cervical dystonia. The initial full model and the reduced final model are presented. CI denotes cognitive impairment; CD severity refers to the severity of cervical dystonia.

symptoms (NMS). Although CI is increasingly recognized in dystonia, its associations with motor severity and concomitant NMS remain insufficiently explored.

Methods: Patients with CD underwent comprehensive clinical assessment of motor symptoms (CD severity) and NMS of dystonia (cognition, depression, anxiety, sleep, pain). Matched controls underwent a single assessment (cognition, depression, anxiety, sleep).

Results: Patients with CD demonstrated significantly lower total MoCA scores compared with controls ($p < 0.001$). Relative to controls, CD patients showed poorer performance across multiple cognitive domains: executive function ($p < 0.001$), visuospatial abilities ($p = 0.004$), language ($p < 0.001$), memory ($p = 0.002$), and attention ($p = 0.022$). Patients also exhibited higher rates of depressive symptoms, anxiety, and sleep disturbances. To explore contributing factors, a multivariable model incorporating NMS and socioeconomic variables was constructed, revealing a combined influence of these factors on the severity of CI in CD.

Conclusion: The study examined CI in CD in relation to motor severity and non-motor domains, with multivariable analysis indicating a potential contribution of sleep disturbances. Although a definitive distinction between cognitive dysfunction as a core feature of dystonia or a secondary effect and overlap of other NMS cannot be made, the findings highlight interdependent mechanisms underlying cognitive deficit in CD. These results underscore the importance of comprehensive assessment of non-motor domains in this population.

Disclosure: Nothing to disclose.

EPO-0283 | Investigation of SKY-0515 in patients with Huntington's disease: Interim results of a phase 1 study

M. Miller²; M. Brault¹; J. Duffy¹; S. Paushkin¹; M. Mokhtarani¹
¹Skyhawk Therapeutics, Inc., Waltham, USA; ²Skyhawk Therapeutics Europe, Basel, Switzerland

Background and aims: Huntington's disease (HD) is a neurodegenerative disorder caused by a trinucleotide (CAG) repeat expansion in the huntingtin (HTT) gene, resulting in a toxic mutant huntingtin (mHTT) protein. Disease progression correlates with the rate of somatic CAG expansion. SKY-0515 has the potential to provide disease modifying benefits through reduction

of toxic proteins, mHTT and PMS1, a key driver of expansion. The study aims to evaluate safety, PK/PD and efficacy of SKY-0515, an orally available, brain penetrant small molecule RNA splicing modulator, in HD patients.

Methods: SKY-0515-001-C is an ongoing 15-month Phase 1 study in HD. Patients were randomized to 3mg ($N = 10$), 9mg ($N = 10$) or placebo ($N = 6$) for 84 days, after which patients rolled over onto active drug, receiving 4mg or 9mg (blinded) for an additional 12 months. Key enrollment criteria include genetic diagnosis of HD (CAG ≥ 40) and clinical baseline of TFC ≥ 10 , IS ≥ 70 , and TMS ≥ 6 , reflecting an HD-ISS disease stage 2 or mild stage 3.

Results: 9-month interim results in patients who continuously received SKY-0515 (excluding placebo) show positive trends in HD efficacy outcomes compared to expected natural history disease progression. In HD patients treated with SKY-0515, early signs of disease stabilization are observed in components of the UHDRS, including function (TFC = +0.35 points), motor (TMS = -3.69 points), and cognition (Stroop = +1.0 points). SKY-0515 has been well tolerated up to 9 months.

Conclusion: These findings support further clinical evaluation of SKY-0515 as a potential disease-modifying therapy for HD. A confirmatory Phase 2/3 study (FALCON-HD) is now enrolling.

Disclosure: The authors are full time employees of Skyhawk Therapeutics, a privately owned company, and the sponsor of the referenced study.

EPO-0284 | Objective assessment of long- and short-term levodopa effects on hypomimia and head movement

M. Novotný¹; D. Škrabal²; T. Tykalová¹; P. Dušek²; J. Ruzs¹
¹Department of Circuit Theory, Faculty of Electrical Engineering, Czech Technical University in Prague, Prague, Czech Republic;
²Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine, Charles University, Prague, Czech Republic

Background and aims: Hypomimia is a hallmark feature of Parkinson's disease (PD) that significantly impairs non-verbal communication. Although levodopa is known to improve motor symptoms, its effect on facial and head movements, particularly in the early phase of treatment, has not been objectively and quantitatively assessed.

Methods: Video recordings were obtained using a single-camera setup from 93 drug-naïve PD patients at baseline and one year later after initiation of stable pharmacological treatment. At follow-up, patients were examined in a defined OFF state (≥ 12 hours without dopaminergic medication) and in the ON state one hour after medication intake. Facial and head movements were quantified using a state-of-the-art facial landmark tracking system and derived movement markers. A control group of 50 age- and sex-matched healthy participants was also recorded.

Results: At baseline, PD patients showed significantly reduced facial and head movements compared with healthy controls ($p < 0.001$). After one year of treatment, a significant improvement was observed across all evaluated areas ($p < 0.001$) nearly matching performance of control group. However, no significant differences were found between the OFF and ON states during the short-term levodopa challenge at follow-up.

Conclusion: Levodopa treatment is associated with a significant long-term improvement of hypomimia across facial and

head movement domains in early PD. The absence of short-term OFF–ON differences suggests that a 12-hour washout period is insufficient to fully eliminate the sustained beneficial effects of stable dopaminergic treatment.

Disclosure: The authors report no disclosures. This study was supported by the Ministry of Health of the Czech Republic, grant No. NU23J-04-00042.

EPO-0285 | **Unilateral MR-guided laser interstitial thermal therapy thalamotomy for essential tremor: A 12-month follow-up study**

M. Aubignat¹; M. Tir¹; M. Ouendo²; J. Constans³; M. Lefranc⁴

FIGURE 1 Unilateral MRgLITT thalam outcomes. (A-B) Group improvements in FTM-TRS and QUEST-SI. (C-D) Longitudinal model trajectories. (E) Waterfall plot of 12-month individual responders. (F) Transition from transient (M3) to resolved (M12) adverse events.

Thermal Therapy (MRgLITT) is a minimally invasive technique allowing real-time MRI thermometry for precise thalamotomy. We evaluated the 12-month efficacy and safety of unilateral MRgLITT thalamotomy in 21 pharmacoresistant ET patients.

Methods: Patients underwent unilateral MRgLITT thalamotomy (ROSA robot, Visualase system). Assessments at baseline, 3, and 12 months used the Fahn-Tolosa-Marin Tremor Rating Scale (FTM-TRS). Primary outcome was the treated limb FTM-TRS score (rest, posture, action, drawing). Secondary outcomes included Quality of Life in Essential Tremor Questionnaire (QUEST-SI), Patient Global Impression of Change (P-CGI), Montreal Cognitive Assessment (MoCA), Mini-Mental State Examination (MMSE), and adverse events (AE). Linear mixed-effects models were used for analysis.

Results: Twenty-one patients (mean age 67.2 ± 12.8 years; 12 males; 17 right-handed) underwent unilateral thalamotomy (17 left). Treated limb FTM-TRS scores decreased by 75.1% (14.0 ± 3.1 baseline vs 3.5 ± 1.6 at 12 months; *p* < 0.001). All patients (100%) achieved > 50% improvement. QUEST-SI improved from 41.2 ± 15.7% to 18.0 ± 14.6% (*p* < 0.001). Mean satisfaction (P-CGI) was 82.0 ± 20.7%. Transient AEs (3 months: 71.4%) primarily included proprioceptive and balance disorders; only one patient (4.8%, gait ataxia) had persistent symptoms at 12 months. MoCA decreased slightly (25.4 ± 3.1 to 23.9 ± 3.5; *p* = 0.024) while MMSE remained stable (27.2 ± 2.3 vs 26.5 ± 2.6; *p* = 0.158).

Conclusion: Unilateral MRgLITT thalamotomy provides robust, sustained tremor relief and improved quality of life for

pharmacoresistant ET. Despite the small cohort, it represents a safe, promising alternative to other surgical techniques. Larger longitudinal studies are warranted to establish its long-term role.
Disclosure: Nothing to disclose.

EPO-0286 | **SWITCH-ON: Prospective, observational study of LECIG efficacy in Parkinson's disease patients previously treated with subcutaneous foslevodopa**

S. Singh; N. Smith; B. Amlani;
Britannia Pharmaceuticals Limited, Green Park, Reading, UK

Background and aims: Levodopa–entacapone–carbidopa intestinal gel (LECIG) is a device-aided therapy (DAT) for advanced Parkinson's disease (PD) patients who have severe motor fluctuations and hyperkinesia/dyskinesia that persists despite treatment with optimised oral therapy combinations (Figure 1). Subcutaneous (SC) infusion of foslevodopa/foscarbidopa (Fos) is an alternative DAT option in this setting. However, real-world data suggest patient discontinuation from SC Fos is high, so other DAT options need to be considered. The SWITCH-ON study (NCT07313176; Figure 2) will evaluate whether transition to intestinal infusion of LECIG is beneficial for those who discontinue SC Fos.

Methods: Target recruitment is ~215 adult PD patients from 30 centres in Spain, the UK, Germany, Romania and the Netherlands undergoing routine clinical care who will be followed-up for 12-months. Patients will have had prior SC Fos for ≥1 month. Data collection is planned from January 2026, with an interim analysis once 100 patients have completed ≥1 follow-up visit. Data completion is planned for January 2028.

FIGURE 1 Illustration of the placement of levodopa–entacapone–carbidopa intestinal gel (LECIG) infusion as a device-aided therapy for advanced Parkinson's disease.

FIGURE 2 SWITCH-ON Study logo.

TABLE 1 SWITCH-ON Study secondary endpoints.

Secondary endpoints and their assessment	
Off-time reduction	- At 6 months using the Movement Disorder Society Unified Parkinson's Disease Rating Scale (MDS-UPDRS) part IV - Up to 12 months using Hauser patient diaries
Treatment pattern analysis	Assessed from daily levodopa dose (mg/day) up to 12 months using total daily dose (morning bolus, continuous flow, extra boluses, and oral doses) and pump multi-rate programming usage
Other endpoints assessed	Up to 12 month change in: - Clinician Global Impression–Corrections and Patient Global Impression–Corrections - Non-motor experiences of daily living using MDS-UPDRS part I - Motor complications using MDS-UPDRS part IV - Quality of life using the Parkinson's Disease Quality of Life Questionnaire 8-item (PDQ-8) - Sleep using the Parkinson's Disease Sleep Scale 2 (PDSS-2) - Treatment satisfaction, assessed using a questionnaire - Body mass index (BMI)
Safety and tolerability	Long-term safety by reporting of adverse drug reactions and severe adverse drug reactions; gastrointestinal adverse events and severe adverse events and special situations

Results: The primary outcome is OFF time reduction with LECIG treatment at 12 months using the Movement Disorder Society Unified Parkinson's Disease Rating Scale part IV, with multiple secondary endpoints (Table 1). SWITCH-ON aims to generate valuable real-world evidence on the long-term effectiveness, safety and tolerability of LECIG in routine clinical practice for advanced PD patients transitioning from SC Fos therapy.

Conclusion: SWITCH-ON hopes to demonstrate that intrajejunal therapy can be a feasible option after Fos, and that prior SC treatment failure is not the end of the road for patients.

Disclosure: The SWITCH-ON study is sponsored by Britannia Pharmaceuticals Ltd. SS, NS and BA are employees of Britannia Pharmaceuticals Ltd.

EPO-0287 | **Patient perceptions of the Crono® LECIG pump device in advanced Parkinson's disease treatment – data from the ELEGANCE observational study**

S. Singh; N. Smith; B. Amlani;
Britannia Pharmaceuticals Limited, Green Park, Reading, UK

Background and aims: Levodopa–entacapone–carbidopa intestinal gel (LECIG) infusion is a treatment option for advanced Parkinson's disease (PD). It is delivered using the specifically designed Crono® LECIG pump (Figure 1), which aims to provide convenience and usability for patients. ELEGANCE is an international, non-interventional study (NCT05043103) capturing efficacy, safety and patient-reported outcomes data from advanced PD patients treated with LECIG in routine clinical practice.

FIGURE 1 Comparison of the Crono® LECIG pump and the Smith Medical CADD-LEGACY® 1400 pump. Silhouettes show size and weight with full cassette (references: Crono® LECIG pump user manual and Smith Medical CADD-LEGACY® 1400 pump user manual).

Methods: Here we report an analysis of interim data regarding patient perceptions of the Crono® LECIG pump for 161 patients treated with LECIG infusion for up to 24 months. Patient-reported satisfaction with the device, as well as its handling, weight, size and noise, were assessed on scale of 1 = absolutely dissatisfied to 10 = absolutely satisfied, with a total score for all parameters (possible total score: 50).

Results: Mean satisfaction scores were high (≥ 8.2 for individual parameters), giving a mean total satisfaction score of 43.5.

Table 1. Perceptions of the Crono® LECIG pump according to previous treatment at Visit 5 (up to 24 months of LECIG treatment). Total score: maximum score = 50; individual attributes: maximum score = 10.

APO, subcutaneous apomorphine infusion LECIG, levodopa-carbidopa intestinal gel infusion; SD, standard deviation.

FIGURE 2 Perceptions of the Crono® LECIG pump according to previous treatment at Visit 5. Total score: maximum score = 50; individual attributes: maximum score 10.

Scores stratified by previous treatment confirm high satisfaction, even in those who switched from another infusion therapy (Table 1; Figure 2). Levodopa infusion switch patients reported the highest satisfaction scores for most attributes, suggesting that the smaller, lighter design of the pump is meaningful. APO infusion switch patients had lower satisfaction scores which may reflect differences in device expectations.

Conclusion: Higher device satisfaction scores in those who switched from another pump therapy, suggest the Crono® LECIG pump may address some limitations of other devices. These findings highlight the critical role of patient-reported outcomes in evaluating drug-delivery developments in PD.

EPO-0288 | Eslicarbazepine acetate shows anti-tremorogenic properties in the mouse harmaline-induced tremor model

A. Coelho¹; A. Evrad²; C. Roucard²; V. di Foggia¹; P. Soares-da-Silva³; J. Holenz¹; N. Pires¹
¹BIAL – Portela & C^a, S.A, Coronado, Portugal; ²SynapCell SAS, Grenoble, France; ³Department of Biomedicine, Unit of Pharmacology and Therapeutics and MedInUp – Center for Drug Discovery and Innovative Medicines, University of Porto, Portugal

Background and aims: Essential tremor (ET) is a common movement disorder, affecting around 5% of individuals over 65.

Its hallmark feature is an 8–12 Hz kinetic tremor of upper limbs, often accompanied by head and voice tremor. Current treatment relies on pharmacological agents, yet almost 55% of patients respond inadequately. This study evaluated the anti-tremorgenic effect of eslicarbazepine acetate (ESL), an antiseizure medication approved for treatment of focal-onset epilepsy, in the harmaline-induced tremor mouse model.

Methods: Quantitative electroencephalography (EEG) was recorded for 6 hours in freely moving mice (previously implanted with electrodes on motor cortex and cerebellum) under a cross-over design. Tremor activity was assessed for 18 minutes in a tremor monitor chamber. Animals received ESL (75 and 150 mg/kg, gavage), propranolol (10–20 mg/kg, intraperitoneally) as reference, or vehicle-control, 20–30 min before harmaline (20mg/kg, intraperitoneally).

Results: In vehicle-treated ($n=10$), harmaline induced sustained EEG low gamma oscillation increase in both brain regions. Similarly to propranolol, ESL treatment significantly, and dose-dependently, prevented harmaline-induced low gamma oscillation increase vs vehicle (ESL 75mg/kg $p < 0.05$ in motor cortex, ESL 150mg/kg $p < 0.01$ in both brain regions, at 2hours time-point). In vehicle-treated, harmaline induced a generalized tremor activity ($n=12$) peaking at 12–14 Hz, whilst with ESL, similarly to propranolol, it was reduced (–18% by ESL 75mg/kg $p=0.002$, –21% by ESL 150mg/kg $p=0.0002$, vs vehicle).

Conclusion: ESL reversed harmaline-induced EEG alterations and attenuated tremor in a mouse model of ET. This effect, possibly attributed to a T-type calcium channel inhibition, suggests a therapeutic potential for this movement disorder.

EPO-0289 | Functional bowel disorders in idiopathic Parkinson's disease: A Rome IV-based controlled study

Z. Yavuz

Neurology Clinic, Etlik City Hospital, Ankara, Türkiye

Background and aims: Functional bowel disorders (FBDs) are common non-motor manifestations of idiopathic Parkinson's disease (iPD). Although constipation is well recognized, the prevalence and clinical relevance of broader Rome IV-defined FBDs in iPD remain insufficiently characterized. This study aimed to compare FBD frequency between iPD patients and controls and to examine their clinical associations within iPD.

Methods: This cross-sectional controlled study included 64 patients with idiopathic Parkinson's disease and 64 age- and sex-matched controls without neurological disease. Functional bowel disorders were assessed using the Rome IV Diagnostic Questionnaire. Non-motor symptoms, mood, and quality of life were evaluated using the Non-Motor Symptoms Questionnaire, Hamilton Depression Rating Scale, Hamilton Anxiety Rating Scale, Parkinson's Disease Questionnaire-39, and the Gastrointestinal Quality of Life Index. Multivariable logistic regression was used to assess factors associated with FBD presence, and multivariable linear regression to identify predictors of gastrointestinal quality of life.

Results: The prevalence of functional bowel disorders did not differ significantly between iPD patients and controls. Within

FIGURE 1 Prevalence of Rome IV-defined functional bowel disorders in idiopathic Parkinson's disease patients and controls ($p=1.000$).

FIGURE 2 Parkinson's Disease Questionnaire-39 total scores according to functional bowel disorder status in idiopathic Parkinson's disease patients.

FIGURE 3 Relationship between Hamilton Anxiety Scale scores and Gastrointestinal Quality of Life Index in idiopathic Parkinson's disease patients.

the iPD group, FBD positivity was associated with higher non-motor symptom burden and poorer quality of life. Cognitive and sexual domains of the Parkinson's Disease Questionnaire-39 were particularly affected. Anxiety-related measures were significant predictors of reduced gastrointestinal quality of life.

Conclusion: Functional bowel disorders do not appear to be disease-specific markers in idiopathic Parkinson's disease but rather phenotype modifiers associated with increased non-motor symptom burden. Targeting anxiety-related factors may improve gastrointestinal well-being in iPD.

Disclosure: Nothing to disclose.

MS and Related Disorders 2

EPO-0290 | Microstructural damage and disability associations of paramagnetic rim and T1-hypointense lesions in multiple sclerosis

A. Miscioscia¹; V. Mauceri²; C. Treaba³; E. Silvestri⁴; D. Landi¹; D. Centonze¹; G. Marfia¹; F. Rinaldi²; P. Perini²; A. Bertoldo⁴; C. Mainero³; P. Gallo²; M. Puthenparampil²

¹Multiple Sclerosis Clinical and Research Unit, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy; ²Multiple Sclerosis Centre of the Veneto Region (CeSMuV), Padua University Hospital, Padua, Italy; ³A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital, Boston, USA; ⁴Department of Information Engineering, University of Padua, Padua, Italy

Background and aims: Recent microglia PET studies in MS show that most white matter (WM) T1-hypointense lesions exhibit activated microglia within lesion core or at the border. Lesions with activated microglia, such as paramagnetic rim lesions (PRLs), are associated with smoldering inflammation and greater clinical disability. However, whether PRLs and non-PRL-T1-hypointense lesions share similar tissue-disrupting properties remains unclear. This diffusion MRI study investigated lesion-level microstructural damage in PRLs, non-PRL-T1-hypointense lesions, and T1-isointense lesions, and assessed the relative contribution of their lesion burden to clinical disability.

Methods: In 34 newly diagnosed, treatment-naïve patients with relapse-onset MS (mean age 38.4 years; mean disease duration 0.65 years) WM lesions were classified using FLAIR, T1-weighted and susceptibility-weighted imaging as PRLs, non-PRL-T1-hypointense lesions, or T1-isointense lesions. Fractional anisotropy (FA), mean diffusivity (MD), and neurite density index (NDI) were extracted for each lesion class. Regression models compared diffusion metrics across lesion classes and evaluated associations between lesion burden and Expanded Disability Status Scale (EDSS) scores.

Results: Among 638 lesions, 23 were PRLs (4%), 586 non-PRL-T1-hypointense (91%), and 29 T1-isointense lesions (5%). PRLs showed lower FA than non-PRL-T1-hypointense ($p=0.045$) and T1-isointense lesions ($p=0.005$). Both PRLs and non-PRL-T1-hypointense lesions had higher MD and lower NDI compared with T1-isointense lesions (all $p < 0.002$). At patient level, PRL volume was more strongly associated with clinical disability ($p < 0.001$) than non-PRL-T1-hypointense ($p=0.334$) and

T1-isointense lesion volume ($p=0.737$), independently of age and disease duration.

Conclusion: Non-PRL-T1-hypointense lesions represent over 90% of MS WM lesions and exhibit intermediate tissue disruption. Despite their low prevalence, PRL burden most strongly affects clinical disability.

Disclosure: Nothing to disclose.

FIGURE 1 Progression pattern of MRI abnormalities in MRI-driven subtype 1 identified by SuStaIn. Subtype 1 was lesion-driven, characterised by early lesion accumulation, followed by the involvement of deep grey matter structures.

FIGURE 2 Progression pattern of MRI abnormalities in MRI-driven subtype 2 identified by SuStaIn. Subtype 2 showed diffuse and early deep grey matter and brainstem damage.

FIGURE 3 Progression pattern of MRI abnormalities in MRI-driven subtype 3 identified by SuStaIn. Subtype 3 was characterised by prominent cortical grey matter damage with early deep grey matter involvement.

Background and aims: Multiple sclerosis (MS) is a heterogeneous disorder whose clinical classification does not fully capture its pathological complexity. Machine learning (ML) approaches applied to research data have identified MRI-based MS subtypes. The aim of this study is to validate this ML approach using real-world data.

Methods: We analysed cross-sectional MRI data from a multicentre MAGNIMS cohort of patients with MS (pwMS) and healthy controls (HC), including a training cohort (746 pwMS, 114 HC) and an independent validation cohort (199 pwMS). T1-weighted and T2-FLAIR MRI data were processed to extract measures of lesion burden, tissue integrity, brain and spinal cord volumes. MRI variables distinguishing pwMS from HC were normalised using Bayesian linear regression. The unsupervised ML algorithm SuStaIn was used to identify MRI-driven subtypes and stages, and their associations with clinical phenotypes and disability were assessed using appropriate regression models.

Results: Three distinct MRI-driven MS subtypes were identified and replicated across training and validation cohorts: (1) a lesion-driven subtype, (2) a subtype characterised by early deep grey matter and brainstem damage, and (3) a cortical grey matter-driven subtype. Clinical phenotype distributions were consistent across cohorts, with no significant associations between MRI-driven subtypes and standardised clinical phenotypes. ML-derived stages correlated with disease duration ($b=0.072$, $p<0.001$) and were associated with clinical phenotypes (LR $\chi^2=90.03$, $b=0.545$, $p=0.002$) and disability ($b=0.263$, $p<0.001$).

Conclusion: These findings confirm that ML applied to MRI data can identify MS subtypes and stages of progression in real-world multicentre cohorts, correlating with but extending beyond clinical phenotypes within a data-driven classification framework.

²Department of Radiology and Nuclear Medicine, MS Center Amsterdam, Amsterdam Neuroscience, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, The Netherlands;

³Department of Neurology, Amsterdam University Medical Centers, Universiteit Amsterdam, Amsterdam, The Netherlands/MS Center Amsterdam, Amsterdam, The Netherlands/Amsterdam Neuroscience, Amsterdam, The Netherlands;

⁴Department of NEUROFARBA, University of Florence, Florence, Italy

Background and aims: Cognitive impairment (CI) is a common and disabling feature of multiple sclerosis (MS), affecting

multiple domains. Understanding the biological mechanisms underlying CI in MS is key research goal. Conventional MRI measures have long been associated with cognitive deficits, reflecting the impact of white matter disconnection on large-scale brain networks. This study investigated cross-sectional and longitudinal associations between brain lesion distribution and domain-specific cognitive performance in MS.

Methods: We analyzed longitudinal data from the Amsterdam MS cohort. Cognitive performance was assessed at baseline and 5-year follow-up using the Brief Repeatable Neuropsychological Battery. Longitudinal cognitive decline was defined using a regression-based Reliable Change Index. Baseline T2-weighted lesion masks were processed and analyzed using voxel-based lesion-symptom mapping. All models were adjusted for demographic and clinical covariates, total lesion volume.

Results: Cross-sectional analyses identified lesion-symptom associations across major white matter pathways. Processing speed and attention were associated with lesions in the corpus callosum, cingulum, and internal capsule, while memory and language domains involved temporo-occipital and frontotemporal tracts. Baseline lesion distribution predicted cognitive performance at 5 years across several domains. Longitudinal decline occurred in a subset of patients and was specifically associated with lesions in the left superior temporal pole for executive

FIGURE 1 Atlas-based visualization of regions of interest across neuropsychological tests at year 0. Different colors indicate distinct anatomical regions across neuropsychological tests.

FIGURE 2 Atlas-based visualization of regions of interest across neuropsychological tests at year 5. Different colors indicate distinct anatomical regions across neuropsychological tests.

FIGURE 3 Atlas-based visualization of regions of interest associated with CST-decliners.

function. These associations were visualized using atlas-based representations of affected regions across cognitive domains.

Conclusion: Lesion location is a key determinant of current and future CI in MS. Shared involvement of major white matter tracts supports domain-general disconnection mechanism, while selective regions contribute to domain-specific vulnerability. Lesion mapping may provide prognostic information beyond global lesion measures.

Disclosure: Nothing to disclose.

Background and aims: Multiple sclerosis (MS) is a chronic immune-mediated disease of the central nervous system in which aging-related mechanisms are thought to contribute to disease activity. Telomere length is a well-established biomarker of biological aging and has been reported to be shortened in MS. However, the contribution of telomere-regulating genes such as TERF1 and TERF2 to telomere dynamics in MS remains unclear.

Methods: This case-control study included 40 patients with relapsing-remitting MS (RRMS) and 39 age- and sex-matched healthy controls aged 18–40 years. Relative leukocyte telomere length was measured by qPCR using the telomere-to-single copy gene ratio. The TERF1 polymorphisms rs10107605 and rs1545827, and the TERF2 polymorphism rs251796 were genotyped using high-resolution melting analysis.

Results: Leukocyte telomere length was significantly shorter in patients with MS compared with healthy controls ($p=0.005$). Telomere length was not associated with age, sex, smoking status, disease duration, or other clinical variables within the MS group. Receiver operating characteristic analysis demonstrated a moderate discriminatory capacity for telomere length between patients and controls (AUC=0.70). All investigated single nucleotide polymorphisms were in Hardy-Weinberg equilibrium, and no significant associations were observed between TERF1 or TERF2 variants and telomere length across any inheritance model.

Conclusion: Accelerated leukocyte telomere shortening appears to reflect biological aging in multiple sclerosis, independent of common TERF1 and TERF2 genetic variants. These findings support the relevance of cellular aging mechanisms in early MS and highlight telomere length as a potential component of multimodal biomarker strategies. Longitudinal and multi-omics studies are warranted to further clarify telomere dynamics in MS.

Disclosure: Nothing to disclose.

Background and aims: Heterogeneous registry structures limit cross-border real-world evidence generation in multiple sclerosis (MS). The European Medicines Agency calls for standardised, interoperable data approaches to support post-authorisation safety studies and rare outcome detection. We developed and validated a common data model (CDM) within the Big MS Data (BMSD) Network to enable reproducible federated analyses while preserving data sovereignty across registries.

Methods: Six MS registries (Czech, Danish, French, Italian, Swedish, MSBase) collaboratively defined 120 standardised variables covering demographics, disease history, relapses, treatments, comorbidities, disability outcomes, and paraclinical data. Registry-specific datasets were mapped to CDM format using automated transformation scripts with error logging. Validation included transformation success metrics, demographic plausibility checks, and pilot federated logistic regression analyses.

Results: The CDM successfully harmonised 348,371 patient records (ranging from 19,097 to 111,727 patients per registry). Transformation achieved 98–100% information retention across core domains (patients, visits, treatments, medical conditions). Demographic validation confirmed expected distributions:

mean age at MS onset ranged 31.8–35.4 years across registries with approximately 70% female representation. Federated logistic regression demonstrated consistent effect estimates across registries without patient-level data transfer. The framework now supports ongoing European research initiatives investigating treatment patterns and rare adverse events.

Conclusion: This CDM represents a scalable solution for privacy-preserving multi-registry MS research aligned with European regulatory requirements. By enabling federated analyses across six registries, the framework facilitates detection of rare outcomes and treatment patterns undetectable in single-registry studies, with potential applicability to other neurological conditions.

Disclosure: Supported by Ministry of Health of the Czech Republic, grant nr. NW26J-08-00103.

EPO-0295 | High levels of p-STAT1 are associated with lower brain volumes at baseline in patients with early Multiple Sclerosis

M. Manconi; R. Orlandi; S. Bartiromo; F. Gobbin; E. Butturini; A. Carcereri De Prati; S. Mariotto; A. Gajofatto
Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Italy

Background and aims: The role of oxidative stress has been suggested in Multiple Sclerosis (MS) pathogenesis. Phosphorylated Signal Transducer and Activator of Transcription 1 (pSTAT1) is a key transcription factor that promotes proinflammatory processes in response to oxidative stress. This study investigates the association of blood levels of pSTAT1 with measures of disease severity in patients with early MS.

Methods: 29 patients aged 18–40 years, recently (≤ 2 years) diagnosed with MS, were consecutively enrolled in an observational study at Verona University Hospital; a brain MRI scan performed between 6 months before and 1 month after inclusion was mandatory. A clinical and MRI follow-up was performed after 10–48 months in a subgroup of 20 of patients. We assessed the association of baseline values of pSTAT1 with clinical variables, global and regional brain volumes and their annualized variations.

Results: At inclusion, patients with medium-to-high compared to low levels of p-STAT1 showed lower median volumes of global brain (1.13×10^7 vs 1.033×10^7 mm³ $p = 0.024$), cerebellar cortex (101.7 vs 112.2 cm³, $p = 0.028$), thalamus (132.4 vs 150 cm³, $p = 0.028$), caudate (60.9 vs 69.5 cm³, $p = 0.007$) and putamen (87.56 vs 94.96 cm³, $p = 0.041$). In the longitudinal study, we didn't find any significant association between pSTAT1 and any of the imaging and clinical variables.

Conclusion: High pSTAT1 expression is associated with low brain volumes in early MS, to be confirmed in larger longitudinal studies.

Disclosure: Nothing to disclose.

EPO-0296 | Fatigue control: 24-month real-world MoOzaRt study Shows 88.8% stabilization and strong correlation with reduced MS burden

I. Penner¹; T. Wiemer²; H. Schreiber³
¹*Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Switzerland; COGITO Center for applied neurocognition and neuropsychological research, Düsseldorf, Germany;* ²*Roche Pharma AG, Grenzach-Wyhlen, Germany;* ³*Neurological Practice Center & Neuropoint Academy, Ulm, Germany*

Background and aims: Fatigue is considered the most common and one of the most debilitating symptoms in multiple sclerosis (MS). MoOzaRt assesses the impact of ocrelizumab on patient-reported persistent (trait) and transient (state) fatigue in patients with relapsing MS (RMS).

Methods: The ongoing non-interventional MoOzaRt study (ISRCTN55332718) recruited 272 RMS patients initiating ocrelizumab. The primary combined endpoint is a clinically meaningful reduction (≥ 9 points) or stabilization (± 8 points) from baseline in trait fatigue, measured by the Fatigue Scale for Motor and Cognitive Functions (FSMC) total score over 24 months. Secondary endpoints include state fatigue (Visual Analogue Scale (VAS)), Expanded Disability Status Scale (EDSS), Patient Reported Outcomes (PROs) and safety.

Results: The third interim analysis (cut-off Dec 10, 2025, snapshot) included 261 patients (Table 1 67.4% female, mean age 38.3 years, mean EDSS 2.43). Over the 24-month observation period, 88.8% of patients showed stable or reduced FSMC total scores, of which 30.1% achieved a clinically meaningful improvement. Treatment-naïve patients exhibited the highest proportion of fatigue stabilization or improvement (90.4%). Lower fatigue scores strongly correlated with reduced physical and psychological disease burden (MSIS-29, WAPI:MS, PDQ-20, HADS).

Conclusion: This analysis confirms that ocrelizumab treatment is associated with stable or even improved fatigue in a very high proportion of RMS patients, particularly in treatment-naïve patients (90.4%). Given the strong correlation between reduced fatigue scores and reduced disease burden, these findings suggest that early high-efficacy therapy (HET) is a valuable strategy for relieving and preventing disease burden.

EPO-0297 | Diagnostic guidelines for identifying and monitoring cognitive impairment in multiple sclerosis: An IMSCOGS and ECTRIMS Delphi consensus statement

I. Penner¹; S. Morrow²; L. Hancock³; F. Nonino⁴; D. Langdon⁵; M. Amato⁶; M. Schoonheim⁷

¹Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Switzerland; ²Department of Clinical Neurosciences, University of Calgary, Canada; ³Department of Neurology, Cleveland University, USA; ⁴Department of Epidemiology and Statistics, University of Bologna, Italy; ⁵Department of Health and Medicine Royal Holloway University of London UK; ⁶Department of Neurology, University of Florence Italy; ⁷Department of Neuroscience University of Amsterdam, The Netherlands

Background and aims: CI occurs frequently in MS, is a common cause of loss of employment and can have a significant impact on quality of life. The aim was to develop international guidelines to assist in the identification of cognitive impairment (CI) among adult persons with MS (PwMS) for both clinical and research applications. The three topics for these guidelines were: 1) cognitive screening, 2) cognitive measurement and diagnosis and 3) monitoring and diagnosing change over time.

Methods: The International Multiple Sclerosis Cognition Society (IMSCOGS) and European Committee for Treatment and Research in MS (ECTRIMS) partnered with Cochrane Multiple Sclerosis and Rare Diseases to conduct a scoping literature review to support the formation of guidelines. Based on this review, statements were formulated. Next, a modified Delphi approach was used to establish consensus via multiple virtual meetings and rounds of anonymous voting by a large group of clinical and research experts in this area with global representation. A minimum response and consensus of 80% was required for a statement to be accepted.

Results: Our scoping review provided an evidence gap map, identifying key inconsistencies in the assessment of CI in PwMS. Delphi voting resulted in a clear set of criteria and guidelines. Results on aims 1, 2 and 3: Cognitive screening; cognitive measurement and diagnosis; monitoring/diagnosing change over time will be presented.

Conclusion: These guidelines permit reliable diagnosis of CI and cognitive decline in MS, allowing generalizability of research findings in future studies of CI in MS and consistency across research and clinical settings.

Disclosure: IP, SM, LH, DL, MPA and MS are members of the board/steering committee of IMSCOGS. This project was financially supported by ECTRIMS.

EPO-0298 | Modifications of time-varying thalamic connectivity underpin fatigue development in multiple sclerosis

M. Margoni¹; P. Valsasina²; P. Preziosa³; D. Mistri²; M. Rocca³; M. Filippi⁴

¹Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ²Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ⁴Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and aims: Fatigue is common in multiple sclerosis (MS) and occurs independently from disease stages. Resting state (RS) functional connectivity (FC) studies showed an implication of thalamic circuits dysfunction in MS-related fatigue pathogenesis. Here, we investigated changes over time of thalamic time-varying (TV) FC and its association with fatigue development in MS.

Methods: Ninety-two right-handed MS patients and 55 healthy controls (HC) underwent clinical and 3.0T RS fMRI assessment at baseline and after 1.27-year median follow-up. The modified fatigue impact scale (MFIS) assessed fatigue at both visits; patients were considered as fatigued (F) if MFIS was >38. TVFC of left/right thalamus was analyzed using sliding-window seed-voxel correlation.

Results: At baseline, 26 patients (28%) were F and 66 not fatigued (NF). Of these, 23 (35%) developed fatigue (devF) at follow-up and 43 remained NF. At baseline, F-MS patients exhibited increased TVFC ($p < 0.001$, conjunction analysis) between the left thalamus and hippocampus, and between the right thalamus, right insula, and bilateral frontal regions. Conversely, NF-MS patients showed reduced baseline thalamic TVFC ($p < 0.001$, conjunction analysis) with temporal, occipital and cingulate regions. At follow-up, NF-MS patients showed increased thalamic TVFC with parietal, temporal and occipital regions. Conversely, devF-MS patients showed increased TVFC over time ($p < 0.001$, time-by-group interaction) between the right thalamus and bilateral cingulate, left insular, left superior frontal and left inferior temporal regions. Finally, F-MS patients presented decreased TVFC over time ($p < 0.001$, time-by-group interaction) between right thalamus and left insula.

Conclusion: Distinct patterns of thalamic TVFC changes characterized MS patients based on their fatigue status.

EPO-0299 | MRI-derived subtypes identified by sustain capture distinct clinical, cognitive, and disability profiles in Multiple Sclerosis

P. Preziosa¹; L. Storelli²; E. Pagani²; N. Tedone³; M. Margoni⁴; F. Esposito⁵; M. Filippi⁶; M. Rocca¹

¹Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy;

²Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ⁴Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neurology Unit; and Laboratory of Human Genetics of Neurological Disorders, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁶Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and aims: Clinical multiple sclerosis (MS) classifications incompletely capture disease heterogeneity. Data-driven subtyping may better reflect MS pathobiology and clinical variability. We applied SuStaIn to identify MRI-based MS subtypes.

Methods: We retrospectively analyzed 1017 MS patients and 548 healthy controls with standardized clinical, neuropsychological, and brain 3T MRI assessments. Z-scores of 21 MRI features, including white matter (WM) lesion volume major WM tract microstructural abnormalities, and global and regional normalized brain volumes, were input into SuStaIn to derive subtypes and stages. Associations with clinical phenotype (relapsing-remitting [RR] vs progressive), age at onset (AAO) (pediatric [POMS], adult [AOMS], late [LOMS]), disability

(Expanded Disability Status Scale [EDSS]), and cognition (Brief Repeatable Battery of Neuropsychological Tests) were explored.

Results: SuStaIn identified four MRI subtypes: lesion-led (44%), cortex-led (23%), tract-led (23%), and deepGM-led (10%). Subtypes differed by clinical phenotype and AAO ($p < 0.001$). Cortex-led and deepGM-led were enriched in progressive forms (47% and 56%); lesion-led and tract-led were mainly RRMS (66–71%). Tract-led was overrepresented in POMS (38%) and underrepresented in AOMS (19%), lesion-led predominated in AOMS (48%), whereas deepGM-led was more frequent in LOMS (14%). Disability milestones were reached more often in cortex-led and deepGM-led patients (EDSS ≥ 4.0 : 45% and 56%; EDSS ≥ 6.0 : 28% and 29%) than in lesion-led (34% and 20%) or tract-led (32% and 19%) ($p < 0.001$). Cognitive performance did not differ across subtypes, but within each subtype higher SuStaIn stage correlated with worse global and domain-specific performance ($p \leq 0.030$).

Conclusion: SuStaIn-derived MRI subtypes capture clinically relevant heterogeneity in MS and may support personalized therapeutic strategies.

Background and aims: The long-term prognostic value of gray matter (GM) damage in multiple sclerosis (MS) is unclear; we examined MRI markers of GM and white matter (WM) damage associated with long-term outcomes in MS.

Methods: Seventy-three relapse-onset MS patients underwent clinical and brain MRI at baseline and 12 months, including WM lesion volumes, brain, GM, WM, and thalamic volume fractions, and GM, thalamic, normal-appearing (NA) WM, and WM lesions MTR. High-efficacy disease-modifying therapies (HE-DMTs) escalation was recorded. Long-term associations with Expanded Disability Status Scale (EDSS) worsening, evolution to a more severe disease stage, MS-related death, and cognitive deterioration were analyzed using LASSO-regularized logistic regression with bootstrap validation.

Results: Over a median 25.9-year follow-up, 79.5% patients experienced EDSS worsening, 72.6% evolved to a more severe disease stage, 24.7% died from MS, and 39.5% exhibited cognitive deterioration. EDSS worsening was associated with lower baseline GM and thalamic fractions, HE-DMT escalation, lower baseline NAWM MTR peak height, and higher 12-month decline in GM MTR histogram peak height (AUC=0.843). Evolution to a more severe disease stage was associated with higher 12-month EDSS score change and lower baseline GM fraction (AUC=0.793). MS-related death was associated with male sex, higher baseline EDSS score, lower baseline GMF, lower baseline GM MTR peak height, and greater 12-month thalamic MTR decline (AUC=0.887). Cognitive deterioration was associated with older age, lower baseline brain parenchymal fraction, and lower baseline mean GM MTR (AUC=0.891).

Conclusion: GM damage is associated with worse 26-year clinical outcomes in relapse-onset MS, supporting the relevance of GM-focused MRI markers.

Background and aims: Thymoma-associated Myasthenia Gravis (TAMG) represents a challenging clinical phenotype. While anti-complement therapy (C5IT) and neonatal-Fc-receptor inhibitors (aFcRn) have expanded the therapeutic landscape, comparative data regarding their efficacy in TAMG

[illegible]

Methods: We conducted a retrospective study of 93 AChR-positive TAMG patients (58 C5IT maintenance; 35 aFcRn cycles) across eight Italian centers. The primary endpoint included longitudinal changes in MG-ADL, QMG, daily CS dosage over 12 months (Table 1). LMM was performed to assess treatment-by-time interactions. aFcRn patients were stratified into “short responders” (mean cycles-intervals <8 weeks) and “long-responders” (mean cycles-intervals $\geq$ 8 weeks).

Conclusion: In TAMG patients, chronic C5IT maintenance regimen provides a greater overall clinical improvement and daily corticosteroids compared to aFcRn cycle-based treatment schedule in TAMG patients. aFcRn patients requiring frequent cycling (<8 weeks) had suboptimal responses, whereas those with sustained durability mirrored C5IT efficacy. These findings highlight the necessity of predictive factors to identify potential “short responders” and optimize personalized treatment selection and administration schedules.

Methods: Peripheral blood mononuclear cells were isolated from MuSK-MG patients ($n=36$), acetylcholine receptor myasthenia gravis patients as disease controls ($n=7$), and age- and sex-matched healthy controls ($n=12$). Genomic DNA was extracted and after sodium bisulfite conversion, DNA methylation of the promoter regions of interleukin (IL)-4, IL-10, and IL-13 was assessed using methylation-sensitive high-resolution melting (MS-HRM) analysis. Methylation levels were estimated by comparing the melting profiles of subjects' DNA samples with those obtained from DNA standards with known methylation percentages.

Conclusion: Selective hypomethylation of IL-4 and IL-13 promoters is observed in MuSK-MG, while IL-10 promoter methylation remains unaltered. This potentially facilitates increased cytokine expression, potentially favoring IgG4 subclass switching, although additional regulatory mechanisms are likely involved.

Disclosure: This project is conducted within the IgG4-TREAT consortium, a Marie Skłodowska-Curie Actions doctoral

EPO-0303 | Clinical features and outcomes of very late-onset myasthenia gravis: Insights from a greek center of reference

E. Stratakis; D. Tzavella; K. Kournis; A. Vakrakou; V. Zouvelou
1st Department of Neurology, National and Kapodistrian University of Athens, Athens, Greece, Eginition Hospital, ERN EURO-NMD

Background and aims: The demographic profile of myasthenia gravis (MG) has shifted in recent decades, with increasing prevalence among older individuals. This study investigates the clinical characteristics and outcomes of patients with very late-onset MG (VLOMG), defined as disease onset at ≥ 65 years.

Methods: We retrospectively reviewed patients with VLOMG registered in the Specialized Myasthenia Clinic database between Jan-2008 and Dec-2025.

Results: A total of 102 patients were included (72 males, 30 females), with a mean follow-up of 47.86 months. Mean age at diagnosis was 73.88 ± 6.65 years (range: 65–91), with a mean diagnostic delay of 5.1 months. Thymoma was identified in 3.92%, autoimmune disease in 11.76%, malignancies in 17.65%, and other comorbidities in 91.18%. Overall, 99% were seropositive; 94.11% AChR-Abs(+) and 4.9% MuSK-Abs(+). AChR-Abs titers ranged from 0.8 to 433 nM/L (mean 49.07 ± 76.28 nM/L). Generalized MG was present in 80.39%, most commonly with oculo-bulbar involvement. Rescue therapies were required in 63.72%; 12.74% required intensive care admission and 5.88% mechanical ventilation. Long-term immunosuppression was used in 93.13%. Advanced immunotherapies included rituximab (17.65%), FcRn antagonists (6.86%), ravulizumab (1.96%), and tocilizumab in one patient with concomitant thyroid eye disease. At last follow-up, 68.62% achieved minimal manifestations or better and 19.6% showed clinical improvement, on a mean daily prednisolone dose of 6.75 mg.

Conclusion: VLOMG represents a distinct MG subgroup characterized by male predominance, predominant bulbar phenotype, rare thymoma and high AChR positivity. Despite a significant comorbidity burden, early immunosuppression enables effective disease control with low maintenance corticosteroid doses. Novel and targeted immunotherapies may be safe and effective in elderly patients.

Disclosure: Nothing to disclose.

Background and aims: Spinal muscular atrophy (SMA) types III–IV are the most common late-onset forms and progress slowly, making sensitive biomarkers essential. The Motor Unit

FIGURE 1 ROC curves of Sum Scores (MUNIX, CMAP, MUSIX) discriminating patients with SMA from healthy controls.

FIGURE 2 MUNIX and CMAP differences between patients with SMA and healthy volunteers (HC). Upper row shows MUNIX differences and lower row CMAP differences; for MUNIX Sum Scores, CMAP Sum Scores, and MUNIX and CMAP individual muscle scores.

FIGURE 3 ROC curves of MUNIX, CMAP, and MUSIX Sum Scores discriminative performances between ambulant and non-ambulant patients with SMA.

Number Index (MUNIX) estimates motor unit loss and may complement traditional electrophysiological measures such as Compound Muscle Action Potential amplitudes (CMAP). However, their respective performances have not been directly compared in adult SMA.

Methods: In a French multicentric study (NCT04690998), 71 adults with SMA and 24 healthy controls underwent clinical and electrophysiological assessment. MUNIX, CMAP, and Motor Unit Size Index (MUSIX) were recorded in four muscles, and sum scores (SumMUNIX, SumCMAP, SumMUSIX) were computed. Test-retest reliability was evaluated using intraclass correlation coefficients (ICCs). Associations with functional outcomes and strength measures were analysed, including multivariate models.

Results: MUNIX, MUSIX and CMAP effectively distinguished SMA patients from controls. MUNIX showed the highest discriminative performance (AUC=0.92), while CMAP demonstrated the strongest and most consistent associations with clinical severity. In multivariate analyses, only CMAP remained independently associated with all functional and strength measures, whereas MUNIX and MUSIX lost significance. CMAP showed the strongest ability to discriminate between ambulant and non-ambulant SMA patients.

Conclusion: MUNIX was the most discriminative biomarker for differentiating SMA from controls, detecting motor unit loss even when CMAP remained within normal limits. CMAP better reflected overall disease burden, likely because it integrates both motor unit loss and reinnervation. These complementary profiles support the concurrent use of MUNIX and CMAP in adult SMA. Longitudinal studies are needed to determine their responsiveness and suitability as endpoints in future clinical trials.

Disclosure: This study was supported by Biogen. The funder had no role in the design, data collection, analysis, interpretation of data, or in the writing of the manuscript.

EPO-0305 | Assessment of sustained health-related quality of life in Phase 3 Vivacity-MG3 Trial of Nipocalimab versus Placebo in Generalized Myasthenia Gravis

J. Vissing¹; K. Gandhi²; S. Pease³; I. Turkoz⁴; M. Fitzgibbon³; G. Coteur⁵; W. Karmous⁶; N. Campbell²; S. Ramchandren⁴; E. Cortés-Vicente⁷

¹Department of Neurology, University of Copenhagen, Copenhagen, Denmark; ²Johnson & Johnson, Horsham, USA; ³Johnson & Johnson, Raritan, NJ, USA; ⁴Johnson & Johnson, Titusville, NJ, USA; ⁵Johnson & Johnson, Horsham, PA, USA & IPATH Solutions, Wemmel, Belgium; ⁶Johnson & Johnson, Issy-les-Moulineaux, France; ⁷Unitat Patologia Neuromuscular, Neurology Service, Hospital Santa Creu i Sant Pau, Barcelona, Spain

Background and aims: Generalized myasthenia gravis (gMG), an autoantibody-mediated disease causes fluctuating muscle symptoms and substantially impairs health-related quality-of-life (HRQoL). In Vivacity-MG3 (NCT04951622), nipocalimab+standard-of-care (SOC) demonstrated improved and sustained disease control versus placebo+SOC. HRQoL changes during the 24-week (W) double blind phase were evaluated using patient reported MGQoL-15r and EQ-5D visual analogue scale (EQ-5D-VAS).

Methods: Mean change-from-baseline (CFB) between groups in MGQoL-15r and EQ-5D-VAS over 24W were compared using ANCOVA models. Meaningful-within-person-improvement (MWPI) response was a change of one-half a standard deviation on MGQoL-15r (> = 4-points) and EQ-5D-VAS (> = 10-points). Proportion of patients achieving MWPI and time-to-MWPI over 24W were examined using Chi-square test and Kaplan-Meier analyses. Logistic regression evaluated likelihood of achieving MWPI over 24W and sustaining MWPI for > = 8, 12, 16, and 20W between groups.

Results: LS-mean (95% CI) difference in CFB on MGQoL-15r and EQ-5D-VAS was greater with nipocalimab+SOC versus placebo+SOC (-1.38 [-3.14, 0.37], not significant [ns] versus 6.86

[2.07, 11.66], $p < 0.05$, respectively) at 4W and sustained (−1.61 [−3.55, 0.33], ns; 6.47 [1.05, 11.88], $p < 0.05$) at 24W. At 24W, 67.2% (45/67) versus 56.5% (35/62) achieved MWPI on MGQoL-15r (absolute difference=10.7%[ns]) and 55.2% (37/67) versus 37.1% (23/62) patients achieved MWPI on EQ-5D-VAS (absolute difference=18.1%, [$p < 0.05$]) in nipocalimab+SOC versus placebo+SOC. For both measures, nipocalimab+SOC patients were twice more likely to achieve MWPI over 24W with median time-to-response approximately 4W versus 8W with placebo+SOC ($p < 0.05$). Similarly, nipocalimab+SOC patients were approximately twice more likely to sustain MWPI for $> 8, 12, 16, 20W$ ($p < 0.05$).

Conclusion: Nipocalimab+SOC-treated patients achieved meaningful HRQoL improvements as early as 4W and were significantly more likely to achieve and sustain these improvements over 24W versus placebo+SOC.

EPO-0306 | Safety and effectiveness of efgartigimod in Japanese patients with generalized myasthenia gravis by serostatus: Post-marketing surveillance analysis

H. Teranishi¹; R. Aoyagi¹; D. Harada¹; M. Watanabe²

¹argenx Japan K.K, Tokyo, Japan; ²Kyushu University Hospital, Fukuoka, Japan

Background and aims: Efgartigimod for intravenous infusion (efgartigimod-IV) is approved in Japan for generalized myasthenia gravis (gMG) regardless of auto-antibody profiles. Post-marketing surveillance for efgartigimod-IV in gMG was performed to assess the safety and effectiveness in real-world settings in Japan.

Methods: Patients with gMG who received efgartigimod-IV between May 2022 and September 2023 were registered. Effectiveness was evaluated by Myasthenia Gravis-Activities of Daily Living (MG-ADL) total and subdomain (ocular, bulbar, limb/gross motor, respiratory) scores. The change of oral glucocorticoid dose was also evaluated.

Results: The safety analysis set consisted of 469 patients: 57.1% ($n=268$) anti-acetylcholine receptor antibody positive (AChR-Ab+), 13.4% ($n=63$) anti-muscle-specific receptor kinase antibody positive (MuSK-Ab+), and 29.4% ($n=138$) double-seronegative. Adverse drug reaction and serious adverse drug reaction were reported in 22.6% and 4.2% of patients,

respectively. No specific safety signals were observed in any of the serological profiles. The effectiveness analysis set consisted of 307 patients with a similar composition ratio of serological profile to the safety analysis set. After three weeks from the first administration, mean MG-ADL total score improved from 7.2 to 4.2: −3.0 points (standard deviation: 2.98, $p < 0.001$). Substantial improvements were observed in all subdomain scores regardless of serological profiles. Mean dose of oral glucocorticoid (standard deviation) (mg/day) at baseline and one year later were 10.7 (7.42) and 7.7 (5.41), respectively.

Conclusion: In real-world settings, efgartigimod-IV was well tolerated and effective in patients with gMG regardless of serological profiles. Oral glucocorticoid dose reduction was observed after efgartigimod administration.

Disclosure: This surveillance was funded by argenx Japan K.K. The writing support was also funded by argenx Japan K.K. Hirofumi Teranishi, Ryohei Aoyagi, and Daisuke Harada are fulltime employees of argenx Japan K.K. EPO-0307 | Efficacy and tolerability of nipocalimab in patients with generalized myasthenia gravis: Real-world experience from an Academic Center

J. Greenberg; M. Seyam; S. Muppidi; N. Goyal

Department of Neurology and Neurological Sciences, Stanford University, Redwood City, USA

Background and aims: Nipocalimab, a neonatal Fc receptor (FcRn) inhibitor, was approved in April 2025 for treatment of antibody positive generalized myasthenia gravis (gMG). However, data from clinical practice is limited. Here we describe a single academic institution's experience with nipocalimab.

Methods: A retrospective review of 11 gMG patients who received nipocalimab between May–November 2025 was conducted. Data was collected regarding demographics, comorbidities, antibody status, treatment history, Myasthenia Gravis Activities of Daily Living (MG-ADL) scores, side effects, and corticosteroid dose.

Results: Most patients were antibody positive ($n=9$ acetylcholine receptor, $n=1$ muscle-specific tyrosine kinase, $n=1$ seronegative). Mean baseline MG-ADL was 8 (± 3.98). In all patients, nipocalimab was started due to refractory symptoms and/or intolerable side effects with prior treatments. MG-ADL scores improved by a mean of 1.9 points ($p=0.017$), and 63.6% (7/11) of patients had a clinically significant improvement (reduction ≥ 2 in MG-ADL score) at follow up 10.6 (± 4.7) weeks after treatment initiation. Nine patients previously failed one or more FcRn inhibitors ($n=6$ efgartigimod, $n=1$ rozanolixizumab, $n=2$ both) due to inefficacy ($n=2$) or wearing off between cycles ($n=7$). 77.8% (7/9) tolerated nipocalimab, and the reduction in MG-ADL score remained statistically significant ($p=0.034$). Only 1 patient reported wearing off. 100% (7/7) of patients on corticosteroids successfully lowered or discontinued dosage without symptom worsening.

Conclusion: We found nipocalimab to be effective, fast-acting, and well tolerated in patients with refractory gMG, leading to modest clinical improvement and steroid tapering in most patients. Nipocalimab was effective in patients who had previously failed other FcRn inhibitors and wearing off between doses was uncommon.

Dr. Goyal has served as a consultant for Argenx, Alexion, UCB, Janssen, Amgen, Novartis, Immunovant, Dianthus, Annexon, Seismic, Cartesian, EMD Serono, and has grant funding from Argenx.

EPO-0308 | Progression and exacerbation timing in myasthenia gravis: Real-world evidence from France (RELIEF study)

T. Gendre¹; D. Theis²; E. Guyot³; M. Nolin³; M. Belhassen³; I. Rodriguez⁴; J. Meijer⁴; L. Gautier⁴; J. Dupin⁴; J. Noury⁵

¹Département de Neurologie, APHP, CHU Henri Mondor, Créteil, France; ²Département d'information médicale, CHU de Lille, Lille, France; ³Epimentis (PELyon), Lyon, France; ⁴J&J Innovative Medicine, Issy-les-Moulineaux, France; ⁵Centre de Référence Des Maladies Neuromusculaires AOC, CHRU de Brest, Brest, France

Background and aims: Understanding the timing of progression and acute events in myasthenia gravis (MG) is critical for optimizing care. This study aimed to estimate the time-to-progression from MG to its generalized (gMG) and refractory forms, and to assess the time-to-first exacerbation or crisis.

Methods: Adults with incident MG between 2014 and 2022 were identified in the French health claims database (SNDS) using algorithms based on ICD-10 codes and treatment patterns, including first- and second-line maintenance therapies and crisis treatments (IV immunoglobulins or plasma exchange). Patients were classified as MG, gMG, or refractory gMG accordingly. Exacerbations were defined as first acute immunoglobulin/plasma exchange, hospitalization for MG or MG crisis; crises

FIGURE 1 Kaplan Meier curve for the occurrence of gMG in the incident population of MG adults with index date between 2014 and 2022 and at least one year of FU available (except in case of death).

FIGURE 2 Kaplan Meier curve for the occurrence of refractory gMG in the incident population of gMG adults with first diagnosis of gMG between 2014 and 2022 and at least one year of FU available (except in case of death).

included hospitalization with respiratory failure, intubation, ventilation, or enteral feeding. Kaplan-Meier analyses estimated progression and first exacerbation/crisis event timing.

Results: Among 10,284 MG patients (49.3% males, mean age: 61.3 ± 18.2) the probability of gMG diagnosis was 49.0% within 12 months and 60.9% within 60 months (MST: 413 days [369; 459]) (see Figure 1). Of 6,905 gMG patients, the probability of refractory disease was 19.8% at 12 months and 34.1% at 60 months (see Figure 2). In MG patients, probability of exacerbation was 55.1% [54.1; 56.1] at 12 months and 63.5% [62.5; 64.5] at 60 months (probability of crisis: 6.1% [5.6; 6.6] and 10.0% [9.4; 10.7], respectively).

Conclusion: These real-world findings demonstrate rapid progression to gMG in majority of patients, with a significant proportion of these developing refractory disease. Most also experience exacerbation (including crisis) within one year of diagnosis, underscoring the need for early and sustained disease control.

¹Centre de Référence Des Maladies Neuromusculaires AOC, CHRU de Brest, Brest, France; ²Département d'information médicale, CHU de Lille, Lille, France; ³Epimentis (PELyon), Lyon, France; ⁴J&J Innovative Medicine, Issy-les-Moulineaux, France; ⁵Département de Neurologie, APHP, CHU Henri Mondor, Créteil, France

Background and aims: Acute events drive the short-term burden in myasthenia gravis (MG). This study evaluated the one-year risk of MG crises (MGc) and exacerbations (MGe) after diagnosis of MG and its generalized form (gMG), and characterized the nature of these acute episodes.

Methods: This French health claims database (SNDS) study included patients diagnosed with MG or gMG in 2022 using algorithms based on ICD-10 codes and treatment dispensing, including first- and second-line maintenance therapies and crisis treatments (IVIg or plasma exchange). MGc were defined as hospitalization with respiratory failure, intubation, mechanical ventilation, or enteral feeding. MGe included MGc, acute IVIg/plasma exchange, or MG hospitalization. Analyses reported patients with ≥ 1 event within one year, incidence rates per 100 patient-years (100PY) [95% CI], and event components.

Results: There were 1,197 patients with MG diagnosed in 2022 (50.7% males, age: 62.4 ± 18.0), and 859 patients with gMG. MGc occurred in 76 MG (6.3%) and 89 gMG (10.4%) patients. MGe affected 685 MG (57.2%) and 619 gMG (72.1%) patients. In MG, the incidence rates were 6.8/100PY [5.4;8.5] for MGc and 117.7/100PY [109.2;126.8] for MGe, while they were 11.7/100PY [9.5;14.5] and 236.3/100PY [218.4;255.6], respectively in gMG. Of MG patients with MGc, 81.6% had mechanical ventilation, 46.1% intubation, and 44.7% respiratory failure.

Conclusion: MGe are frequent in the first year following the diagnosis, particularly in gMG patients. MGc is a life-threatening acute event whose incidence is not negligible in the first year. These results highlight the importance of early prevention and prompt therapeutic intervention in gMG patients.

Immunosuppressant, n (%)	4 (28.6)	8 (53.3)	12 (61.6)
History of thymoma	9 (64.3)	5 (33.3)	14 (48.3)

Abbreviations: QMG-quantitative myasthenia gravis; MGFA-myasthenia gravis foundation of America.

Figure 2 Changes in (A) QMG mean total score from baseline to week 24. Changes in QMG domain scores from baseline to week 24 for (B) ocular, (C) bulbar, (D) respiratory, and (E) limb domains.

Figure 3 Changes in (A) QMG mean total score from baseline to week 24 in all patients with generalised myasthenia gravis and in subgroups of patients with and without a history of thymoma. QMG response rate in (B) all patients, (C) patients treated with 160mg Telitacicept and (D) patients treated with 240mg Telitacicept from baseline to week 24. Improvement in QMG mean total score at week 24 in (E) all patients, (F) patients treated with 160mg Telitacicept and (G) patients treated with 240mg Telitacicept.

Methods: Eligible patients from a phase 2 trial (NCT04302103) were randomized to receive weekly subcutaneous telitacicept at 160 mg ($n=14$) or 240 mg ($n=15$). Key changes from baseline

to Week 24 in the total Quantitative Myasthenia Gravis (QMG) score and its bulbar, ocular, limb, and respiratory subdomain scores were analyzed. Outcomes were also assessed based on thymoma history.

Results: Both doses induced early (from Week 4) and sustained improvements across all QMG domains. The 240-mg dose resulted in a significantly greater improvement in ocular scores at Weeks 8 and 12 compared to the 160-mg dose ($p=0.037$). Patients with a history of thymoma ($n=14$) showed a numerically greater reduction in the total QMG score than those without ($n=15$). The 240-mg dose demonstrated superior efficacy regardless of thymoma status.

Conclusion: Telitacicept provides rapid and sustained improvement in muscle strength across all domains in generalised myasthenia gravis. The 240-mg dose appears particularly beneficial for ocular involvement and in patients with a history of thymoma. These promising subgroup findings warrant further investigation in larger confirmatory studies.

Disclosure: Nothing to disclose.

EPO-0311 | Efficacy of long-term rozanolixizumab treatment cycles in patients with generalised myasthenia gravis: A subgroup analysis of Phase 3 studies

Background and aims: In MycarinG (Phase 3; NCT03971422), one 6-week cycle of rozanolixizumab (7 mg/kg or 10 mg/kg) improved myasthenia gravis (MG)-specific outcomes versus placebo. Here, we evaluate the long-term efficacy of repeated rozanolixizumab treatment cycles across MycarinG and its

open-label extension studies in subgroups of patients with generalised MG (gMG).

Methods: Following MycarinG, patients could enrol in MG0004 (NCT04124965) to receive once-weekly rozanolixizumab for ≤ 52 weeks, or MG0007 (NCT04650854), which comprised an initial 6-week rozanolixizumab cycle, with further cycles administered upon symptom worsening. Final efficacy data were pooled across MycarinG, MG0004 (first 6 weeks) and MG0007 for patients with ≥ 2 symptom-driven rozanolixizumab cycles. Mean change from baseline (CFB) in MG Activities of Daily Living (MG-ADL) score to Day 43 in Cycles 1–13 was assessed. Subgroups were prespecified according to baseline characteristics.

Results: Overall, 129 patients received ≥ 2 symptom-driven cycles. Mean (standard deviation) CFB in MG-ADL score at Day 43 across Cycles 1–13 for the overall population ranged from -3.2 (3.3) in Cycle 3 ($n=113$) to -6.0 (3.9) in Cycle 12 ($n=24$). Improvements from baseline in MG-ADL scores at Day 43 were consistent in subgroups of autoantibody status (anti-muscle-specific tyrosine kinase and anti-acetylcholine receptor antibody positive), disease duration (< 5.4 and ≥ 5.4 years), age (< 65 and ≥ 65 years), MG-ADL score (< 5 and ≥ 5) and thymectomy status. Treatment-emergent adverse events occurred in 93.1% ($n=175/188$) of patients with ≥ 1 treatment cycle across MycarinG and MG0007; most were mild/moderate.

Conclusion: Repeated rozanolixizumab treatment cycles demonstrated long-term efficacy in a broad range of patients with gMG.

Disclosure: This study was funded by UCB. Full disclosure of all industry relationships will be made during congress presentation if accepted.

EPO-0312 | Aspects of molecular genetic polymorphism of the dystrophin gene in Uzbekistan

U. Omonova; I. Akhmedov
Tashkent State Medical University, Tashkent, Uzbekistan

Background and aims: To investigate the genetic polymorphism of the dystrophin gene among patients with Duchenne muscular dystrophy and to determine the frequency of dystrophin gene mutation carriage among female relatives in families affected by DMD in the population of Uzbekistan.

Methods: Molecular genetic studies were conducted MLPA diagnostics to detect deletions and duplications in patients with DMD. MLPA diagnostics was performed in 91 patients with DMD from 81 families. The analysis covered all 79 exons of the dystrophin gene.

Results: deletions were not detected in 33 patients (36.3%) from 32 families (39.5%), while deletions of the dystrophin gene of varying length—from one to nine exons—were identified in 58 patients (63.7%) from 49 families (60.5%). Extended deletions were verified in 65.3% of families, whereas single-exon deletions were observed in 34.7% of families. The main deletion spectrum was located in the distal part of the dystrophin gene at the 3' end (deletions of exons 40–60), accounting for 81.6% (40 families, 47 patients).

Conclusion: According to MLPA diagnostics in patients with Duchenne muscular dystrophy, mutations were identified in 16 of the 79 analyzed exons, which provides a basis for using the

DMD-del1 and DMD-del2 kits for the diagnosis of “major” deletions in the dystrophin gene in the population of Uzbekistan.

Disclosure: Nothing to disclose.

Neurogenetics 2

EPO-0313 | Binaural hearing in spinocerebellar ataxia type 3

A. Bazzoli¹; A. Rupp¹; H. Jacobi²

¹Sektion für Biomagnetismus, Neurologische Klinik Heidelberg, Germany; ²Neurologische Klinik, Heidelberg, Germany

Background and aims: Brainstem degeneration in spinocerebellar ataxia type 3 (SCA3) affects binaural structures such as the medial superior olive (Faber et al, 2021), potentially impairing binaural processing. Huggins Pitch (HP), a psychoacoustic phenomenon dependent on binaural synchronization, may thus serve as a marker of early dysfunction. Previously, we demonstrated that the upper limit of Huggins Pitch (HP) differed significantly between SCA3 mutation carriers and age-matched controls (Jacobi et al, 2024). Here, we investigated longitudinal HP processing in 18 SCA3 mutation carriers (pre-ataxic and ataxic) to assess its potential as a biomarker for disease progression.

Methods: HP thresholds were determined via a 3-alternative forced-choice behavioral task, and cortical N100 responses were recorded with MEG. Ataxia severity was assessed using the SARA scale.

Results: HP thresholds declined significantly from baseline to follow-up (1.8195 vs. 1.4375 kHz; $p < 0.05$), with ataxic carriers showing a stronger decline (1.6511 vs. 1.2976 kHz; $p = 0.039$) and a trend in pre-ataxic carriers (2.1983 vs. 1.7522 kHz; $p = 0.09$).

FIGURE 1.1 Boxplots show Huggins Pitch Thresholds in SCA3 carriers ($N=15$) vs healthy controls ($N=15$) at baseline and at follow-up. **FIGURE 1.2** Boxplot show HP Thresholds in SCA3 carriers at baseline vs follow-up (1.80 ± 0.67 vs 1.49 ± 0.53 kHz, $p = 0.019$).

FIGURE 2 Upper limit of Huggins Pitch frequency (kHz) vs SARA sum score in pre-ataxic ($n=7$) and ataxic ($n=9$) SCA3 mutation carriers at baseline (T1, $r = -0.44$, $p=0.105$) and at follow-up (T2, $r = -0.84$, $p < 0.001$).

FIGURE 3 LME of longitudinal development of Carriers–Controls Z-scores shows a progressive decline over time for all carriers ($\beta_1 = -0.138 \pm 0.055$, $p=0.012$), preataxic carriers ($\beta_1 = -0.054 \pm 0.079$, $p=0.499$), and ataxic carriers ($\beta_1 = -0.195 \pm 0.075$, $p=0.009$).

Thresholds correlated strongly with SARA sum score at follow-up ($r = -0.82$, $p < 0.001$) and were predicted by time to onset in linear mixed-effects models. Carriers–control Z-scores declined significantly over time, and N100 amplitude was reduced compared to controls ($p < 0.05$). Linear mixed-effects modeling showed progressive HP decline over time for all carriers ($\beta = -0.173$ kHz/year, $p=0.004$).

Conclusion: These findings indicate that HP thresholds and cortical responses reliably decline with SCA3 progression, suggesting HP as a sensitive marker for early detection and longitudinal tracking, including in pre-ataxic mutation carriers.

Disclosure: Nothing to disclose.

EPO-0314 | KMT2B-related disorders in Austria: Clinical features and long-term outcome

E. Indelicato
Center for Rare Movement Disorders Innsbruck, Department of Neurology, Medical University Innsbruck, Innsbruck, Austria

Background and aims: Since its initial description in 2016, DYT-KMT2B has emerged as one of the most common genetic causes of early-onset dystonia. Subsequent reports have expanded its phenotypic spectrum, frequently including neurodevelopmental features. Deep brain stimulation of the globus pallidus internus (Gpi DBS) has become a therapeutic mainstay; however, most published data are based on single cases or short-term observations, and long-term outcomes remain poorly characterized.

Methods: We report the clinical course and response to Gpi DBS in nine patients with KMT2B variants prospectively followed at two Austrian national reference centers for rare movement disorders. Long-term follow-up data (range: 5–20 years) were available for six patients. Clinical features and treatment outcomes were compared with previously published cohorts.

Results: Non-motor features such as developmental delay, intellectual disability, and epilepsy were more frequent in our cohort than in earlier reports. All patients developed generalized dystonia and laryngeal involvement over time, emphasizing the progressive nature of the disease. Despite secondary symptom worsening during long-term follow-up, Gpi DBS preserved ambulation in three patients and enabled sustained recovery of walking ability in two, maintaining functional independence. Surgical correction of foot deformities further supported mobility. Notably, KMT2B variants were identified upon genetic re-evaluation in two patients previously diagnosed with dyskinetic cerebral palsy.

Conclusion: Our long-term data underscore the progressive but heterogeneous course of DYT-KMT2B. Gpi DBS offers durable clinical benefits, particularly when initiated before loss of ambulation. Early surgical intervention and multidisciplinary management are essential to optimize long-term outcomes.

Disclosure: Nothing to disclose.

EPO-0315 | The first libyan patient diagnosed with POLR3B-related leukodystrophy: A case study

E. Farag¹; M. Elshukri²
¹Ankara University Faculty of Medicine, Ankara, Türkiye;
²Benghazi Medical Center, Benghazi, Libya

Background and aims: Leukodystrophies are rare inherited white matter disorders with significant clinical and genetic heterogeneity. POLR3B-related hypomyelinating leukodystrophy is typically diagnosed in childhood, while adult-onset presentations are rare and often overlooked.

Methods: We report a 19-year-old Libyan male presenting with a two-year history of progressive ataxia and tremor. Detailed neurological examination, laboratory testing, neurophysiological studies, brain magnetic resonance imaging (MRI), and genetic analysis were performed. Autoimmune, infectious, paraneoplastic, and post-COVID-19 etiologies were systematically excluded.

FIGURE 1 Left/Axial T2-weighted MRI of the brain showing confluent hyperintense lesions in the parieto-occipital deep white matter, extending through the splenium of the corpus callosum.

FIGURE 2 Right/Sagittal T2-weighted MRI of the brain demonstrating widespread hypomyelination with subtle involvement of the cerebellar peduncles, sparing the cerebellar tonsils.

FIGURE 3 POLR3B gene variant detected on genetic testing.

Results: Neurological examination demonstrated ataxia, dysarthria, tremor, nystagmus, myoclonus, and impaired coordination. Brain MRI revealed diffuse hypomyelinating white matter abnormalities involving the parieto-occipital regions, corpus callosum splenium, corticospinal tracts, and cerebellar peduncles without diffusion restriction or contrast enhancement. Genetic testing identified heterozygous variants in the POLR3B gene, confirming the diagnosis of POLR3B-related hypomyelinating leukodystrophy. The progressive clinical course, characteristic imaging findings, negative immunological and

oncological workup, and lack of response to immunotherapy unequivocally excluded post-COVID-19 neurological involvement.

Conclusion: This case highlights the diagnostic challenges of adult-onset POLR3B-related leukodystrophy and emphasizes the importance of genetic testing in young adults with progressive ataxia. To our knowledge, this represents the first reported case from Libya.

EPO-0316 | Genetic landscape of pediatric epilepsy associated with focal cortical dysplasia

F. Turdialiyeva

Center for the development of professional qualification of medical workers

Background and aims: Focal cortical dysplasia is a major structural cause of epilepsy in children and is frequently associated with drug-resistant seizures. Increasing evidence indicates that genetic factors contribute significantly to the pathogenesis of focal cortical dysplasia-related epilepsy. The objective of this study was to characterize the genetic spectrum of pediatric epilepsy associated with focal cortical dysplasia and to describe associated clinical features.

Methods: We analyzed a cohort of 36 children with epilepsy associated with focal cortical dysplasia evaluated at a national tertiary pediatric center between 2021 and 2025. All patients underwent whole-exome sequencing (WES). Available clinical data, electroencephalography (EEG), and magnetic resonance imaging (MRI) reports were reviewed. Genetic variants were interpreted according to current pathogenicity criteria. Demographic characteristics, including parental consanguinity, were assessed.

Results: Whole-exome sequencing data were available for 100 percent of patients. Pathogenic and likely pathogenic variants were identified in genes associated with epilepsy and cortical development, including SCN1A, DEPDC5, PCDH19, SCN2A, SCN8A, and TSC2. Both ion channel genes and genes related to cortical development and mammalian target of rapamycin pathway regulation were represented. Parental consanguinity was documented in 5.6 percent of cases. MRI reports were available in 77 percent of patients, EEG reports in 58 percent, and detailed clinical discharge summaries in 97 percent.

Conclusion: This study demonstrates a heterogeneous genetic landscape underlying pediatric epilepsy associated with focal cortical dysplasia. Whole-exome sequencing provides valuable diagnostic information even in settings with incomplete neuroimaging or electrophysiological data and supports its integration into routine clinical evaluation.

Disclosure: The author reports no conflicts of interest and no external funding related to this study.

Background and aims: The Cerebellar Cognitive Affective Syndrome (CCAS) scale screens for cognitive and affective impairments in cerebellar disorders, but its prevalence in real-world settings remains underexplored.

Methods: The Italian CCAS scale was administered to 68 patients from a single-center (22 Friedreich ataxia (FA), 13 SCA2, 12 RFC1-related disease, 4 SCA27B, 4 SPG7, 3 SCA8, 3 SCA42, 2 SCAR32, 2 HSD17B4, 1 each of GSS, PEX2, ATM, and SCA45) and 30 age-, sex-, and education-matched healthy controls. CCAS was classified as definite (≥ 3 failed items), and a total sum score calculated. Motor impairment was evaluated with the SARA and 9-Hole Peg Test (9HPT). Dysarthria was assessed with the PATA rate, and its correlation with verbal fluency tasks analyzed. Subtest comparisons among genotypes were adjusted for age, education, and SARA score. Neurodegenerative liquid biomarkers were also measured.

Results: Definite CCAS was present in 68% of patients. By genotype, prevalence was 100% in SPG7, 74% in FA, 62% in SCA2, 50% in SCA27B, and 20% in RFC1-related disease. CCAS total score did not correlate with SARA ($p = -0.075$, $p = 0.54$) or 9HPT ($p = -0.18$, $p = 0.14$). Patients with FA, SCA2, and SPG7 performed worse in executive function, short-term memory, and abstract reasoning than those with RFC1-related disease and SCA27B. Word-fluency subtest had the strongest discriminative ability between patients and controls.

Conclusion: Cognitive impairment is frequent in HCAs and varies by genotype. The lack of correlation with motor severity suggests cognitive deficits may occur independently of ataxia progression.

Disclosure: Nothing to disclose.

EPO-0318 | Cortical atrophy mediates the link between clinical severity and retinal neurodegeneration in spinocerebellar ataxia type three

L. Chuyi

The First Affiliated Hospital of Fujian Medical University, Fuzhou, China

Background and aims: SCA3 pathology extends beyond the cerebellum, and OCT reveals retinal thinning. We tested whether cortical atrophy mediates the association between clinical severity and retinal neurodegeneration, consistent with a cortical-retinal axis.

Methods: Ninety genetically confirmed SCA3 patients and 32 age- and sex-matched controls underwent OCT, structural MRI, and neurological assessment (SARA, ICARS). OCT metrics were compared between groups. In SCA3, correlations linked

retinal thickness with disease duration, clinical scores, and cortical volumes. Mediation analyses evaluated 20 cortical regions.

Results: SCA3 patients showed significant retinal layer thinning versus controls ($p < 0.05$). Longer disease duration and higher SARA scores correlated with reduced perifoveal thickness. Six significant indirect pathways were detected. Left calcarine atrophy mediated the link between SARA and right-eye inferior perifoveal thickness ($p = 0.04$) and mediated associations between disease duration and perifoveal thinning ($p < 0.001$). Right lingual and left precentral atrophy further mediated effects of disease duration on parafoveal thickness ($p < 0.001$).

Conclusion: Visual and motor cortical atrophy partially explains retinal thinning in SCA3, supporting OCT-derived retinal measures as noninvasive indicators of cortical integrity and disease progression.

Disclosure: Nothing to disclose.

EPO-0319 | Broadening the clinical spectrum of TGM6-related spinocerebellar ataxia: A pediatric case

S. Aloisio¹; L. Angelini²; G. Beligi¹; M. De Raggi¹; S. Grandolfo¹; D. Birreci¹; A. Spalice³; M. Bologna¹

¹Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy; ²IRCCS Neuromed, Pozzilli, Italy; ³Department of Maternal and Child Health and Urogynecological Sciences, Sapienza University of Rome, Rome, Italy

Background and aims: Spinocerebellar ataxia type 35 (SCA35), caused by pathogenic variants in the TGM6 gene encoding transglutaminase 6, is classically a late-onset cerebellar disorder characterized by progressive gait ataxia, tremor, and mild oculomotor abnormalities. Dystonia, myoclonus, and parkinsonism are less frequent, while neurodevelopmental impairment and epilepsy are rare. Although increasing evidence suggests broader phenotypic variability, early-onset presentations remain poorly characterized. Here, we describe an early-onset phenotype of SCA35 with objective kinematic characterization of associated movement disorders.

Methods: A 15-year-old boy with early developmental delay, focal epilepsy since infancy, and progressive gait impairment underwent neurological examination, longitudinal brain MRI review, and quantitative kinematic assessment of tremor and bradykinesia during repetitive finger tapping. Genetic testing was performed using a targeted next-generation sequencing panel for ataxia and movement disorders.

Results: The patient carried a heterozygous pathogenic TGM6 c.980A > G (p.Asp327Gly) variant, also detected in his mildly affected mother, supporting intrafamilial variability. Serial brain MRI (2013–2021) showed no cerebellar or brainstem atrophy. Neurological examination revealed bilateral irregular tremor at rest, posture, and action, mild cerebellar dysidiadochokinesia, and upper limb bradykinesia with stable clinical course. Quantitative kinematic analysis demonstrated a right-hand resting tremor peaking at ~8 Hz, a bilateral low-amplitude irregular postural tremor, and bradykinesia with sequence effect (Figure 1).

FIGURE 1 Quantitative kinematic characterization of tremor and bradykinesia.

Conclusion: This case expands the phenotypic spectrum of TGM6-related disease, showing that pathogenic variants may manifest in childhood with neurodevelopmental involvement, epilepsy, and complex movement disorders even in the absence of structural neuroimaging abnormalities. These findings support a network-based pathophysiological mechanism potentially involving cerebellar–basal ganglia circuits.

Disclosure: Nothing to disclose.

EPO-0320 | Long-term (30 Months) outcomes of N-Acetyl-L-leucine in adults and children with niemann-pick disease type C

T. Bremova-Ertl¹; J. Kerthi²; B. Zandrucha²; J. Raymond²; A. Hatcher²; T. Fields²; I. Billington²; M. Strupp³; M. Patterson²

¹Department of Neurology and Center for Rare Diseases, University Hospital Inselspital Bern, Bern, Switzerland;

²IntraBio Inc, Austin, USA; ³Department of Neurology, LMU University Hospital, LMU Munich, Germany

Background and aims: Niemann-Pick disease type C (NPC) is a rare lysosomal storage disorder. IB1001-301 is a Phase 3, placebo-controlled, crossover trial encompassing a Parent Study and an ongoing Extension Phase (EP) evaluating the long-term effects of N-acetyl-L-leucine (NALL) in people with NPC.

Methods: IB1001-301 enrolled participants with a genetically confirmed diagnosis of NPC. Participants received a total of 2–4 g/day orally administered NALL. The primary endpoint of the EP is the modified 5-domain NPC Clinical Severity Scale (5-D-NPC-CSS). Exploratory endpoints include the 15-D-NPC-CSS (excluding hearing), 4-D-NPC-CSS, and Scale for Assessment and Rating of Ataxia (SARA). Interim 30-month results are reported here.

Results: Forty participants completed Visit 12 (30-months) of the EP. The mean ($\pm$ SD) baseline score on the 5-D-NPC-CSS was 10.50 ($\pm$ 4.46). After 30 months, the mean ($\pm$ SD) change from baseline in the 5-D-NPC-CSS was -0.20 ($\pm$ 2.60) with NALL vs 3.75 ($\pm$ 7.9), i.e. worsening, in the historical cohort; mean difference between cohorts: -3.95 ; 95% CI -6.60 to -1.30 ; $P=0.0041$. The mean ($\pm$ SD) baseline score on the 15-D-NPC-CSS was 17.48 ($\pm$ 7.15). After 30 months, the mean ($\pm$ SD) change from baseline in the 15-D-NPC-CSS was 0.38 ($\pm$ 4.00) with NALL vs $+4.68$ ($\pm$ 2.74) in the historical cohort. The mean ($\pm$ SD) baseline scores on the 4-D-NPC-CSS and SARA were 7.65 ($\pm$ 3.32) and 15.0 ($\pm$ 7.68), respectively. After 30 months, the mean change from

baseline ($\pm$ SD) on the 4-D-NPC-CSS and SARA were -0.58 ($\pm$ 2.04) and -1.39 ($\pm$ 3.71), respectively.

Conclusion: Treatment with NALL demonstrated significant and meaningful long-term improvement, i.e. disease-modifying effects. NALL was well tolerated, and no serious adverse events occurred.

EPO-0321 | Expanding the phenotypic spectrum of FAT2-associated disorders: An Italian case series

V. Gioiosa¹; E. Cioffi¹; A. Tessa²; F. Santorelli²; C. Casali¹

¹Department of Medico-Surgical Sciences and Biotechnologies, University of Rome Sapienza; 04100 Latina, Italy; ²IRCCS Stella Maris Foundation, Calambrone, via dei Giacinti 2; 56128 Pisa, Italy

Background and aims: Spinocerebellar ataxias (SCAs) are a clinically and genetically heterogeneous group of autosomal dominant neurodegenerative disorders with more than 50 distinct subtypes described to date. Among them, SCA45, associated with FAT2 gene mutation, was first described in 2017. Reported cases are rare and typically exhibit a pure cerebellar phenotype with late onset. FAT2 is highly expressed in cerebellar granule cells and is thought to play a role in neuronal migration and cerebellar development. We describe four patients from three unrelated families, expanding the clinical spectrum of SCA45, with two cases showing additional pyramidal involvement.

Methods: Three patients were evaluated at the Neurogenetics Clinic of Polo Pontino/ICOT, Sapienza University of Rome, and one at the IRCCS Stella Maris Foundation. Genetic analyses were performed via targeted NGS panels.

Results: We identified four patients with adult-onset gait disturbances and rare heterozygous FAT2 variants. P1: Ataxic gait after age 60; cerebellar atrophy on MRI; c.8218C > T (p.Phe2740Leu). P2: Spastic-paretic gait after 50; cerebellar atrophy and axonal neuropathy; c.5240A > G (p.Asp1747Gly). P3: Sister of P2; ataxic gait after 60; same variant c.5240A > G. P4: Spastic-paretic gait, hyperreflexia; SPRS 28/52, SARA 17/40, SPATAX stage 5, FARS 4.0, FARS-ADL 15/36; c.5416G > A (p.Glu1806Lys).

Conclusion: These cases broaden the phenotypic spectrum of FAT2-related ataxia, highlighting the possible presence of spasticity and pyramidal signs in addition to cerebellar features. FAT2 variants should be considered in patients with adult-onset cerebellar ataxia, especially when common SCA repeat expansions are excluded.

Disclosure: Nothing to disclose.

V. Gioiosa¹; C. Angelini¹; C. Goizet

¹. Bordeaux University, Reference Center for Neurogenetics Disorders (BRAIN-TEAM network), Neurogenetics Unit, Bordeaux, France

Background and aims: Friedreich's Ataxia is a rare autosomal recessive neurodegenerative disease that typically presents in childhood or adolescence. It is caused by a GAA repeat expansion in the FXN gene, leading to frataxin deficiency, mitochondrial dysfunction, and progressive neurological decline. Impaired Nrf2 signaling exacerbates oxidative stress. Omaveloxolone is an oral Nrf2 activator. Following the MOXIe trials, it received FDA approval in 2023, and France initiated a national early access program in January 2024.

Methods: This study reports real life data from a French cohort treated with Omaveloxolone at CHU Bordeaux, with up to 18 months of follow up. Clinical evaluations included the Scale for the Assessment and Rating of Ataxia (SARA) and SF12. Blood samples for hepatic, lipid, and cardiac monitoring were collected at baseline and scheduled time points.

Results: The cohort initially included 32 patients, with a mean baseline SARA score of 22.8. After 18 months, 23 patients remained on treatment. The average SARA score at one year was 23. All patients received 150 mg/day of Omaveloxolone. Adverse events, particularly transient elevations in liver enzymes, were most frequent within the first 12 weeks and subsequently decreased or returned toward baseline, supporting good tolerability.

Conclusion: After 12 months, the mean change in SARA score from baseline was -0.02 SD 2.74 , indicating overall stability. This finding is consistent with a slowing of disease progression and contrasts with natural history data from the EFACTS cohort, where ambulant patients show an average annual SARA increase of $+0.82$ SD 0.05 , suggesting a potential attenuation of disease progression

Disclosure: Nothing to disclose.

EPO-0323 | Deep pheno-genotyping of NDUFV1-related mitochondrial disease

B. Pancaldi¹; R. Maroofian²; J. Raza Alvi³; I. Javed³; N. Lock-Hock⁴; P. Najarzadehh Torbati⁵; S. Sedighzadeh⁶; M. Abdel-Hamid⁷; G. Abdel-Salam⁷; M. Zaki⁷; T. Sultan⁸; K. Bhatia⁹; H. Houlden²; F. Magrinelli¹⁰

¹Department of Medicine and Surgery – University of Parma – Parma; ²Department of Neuromuscular Diseases – UCL Queen Square Institute of Neurology – London, UK; ³Department of Paediatric Neurology – The Children's Hospital and the University of Child Health Sciences – Lahore, Pakistan; ⁴Genetics Department – Hospital Kuala Lumpur – Kuala Lumpur, Malaysia; ⁵Department of Medical Genetics – Next Generation Genetic Polyclinic – Mashhad, Iran; ⁶Department of Biological Sciences, Faculty of Science, Shahid Chamran University of Ahvaz, Ahvaz, Iran; ⁷Clinical Genetics Department – Human Genetics and Genome Research Division – Cairo, Egypt; ⁸Department of Pediatric Neurology – Children's Hospital and

Institute of Child Health – Lahore, Pakistan; ⁹Sobell Department of Motor Neuroscience and Movement Disorders – UCL Queen Square Institute of Neurology – London, UK; ¹⁰Department of Clinical and Movement Neurosciences – UCL Queen Square Institute of Neurology – London, UK

Background and aims: NDUFV1 encodes a 51-kDa core subunit of mitochondrial complex I. We aim to expand the phenotypic and genotypic spectrum of NDUFV1-related mitochondrial disease.

Methods: We screened international next-generation sequencing datasets for biallelic NDUFV1 variants. Detailed phenotypic data were collected for identified individuals. Haplotype analysis was performed for recurrent variants. A PubMed search (Dec 2025, keyword “NDUFV1”) was conducted to extract published genetic and clinical data.

Results: We identified 28 new affected individuals (16 males) from 22 families of Indian, Pakistani, Iranian, Malaysian, and Egyptian ancestry and 68 previously reported cases. In our cohort age at onset ranged from birth to 10years, with gait impairment and seizures being the most common initial symptoms. Core clinical features are summarized in Figure 1. We also document orofacial dystonia and sleep disturbances as newly associated features. Oculomotor abnormalities, as well as respiratory insufficiency, frequently reported in the literature, were rare in our cohort. We identified 27 homozygotes

FIGURE 1 Clinical features of the 28 patients of our cohort.

FIGURE 2 NDUFV1 gene schematic with introns to scale; literature variants in black, known/cohort variants in blue, novel variants in red.

FIGURE 3 Haplotype analysis on exome files performed in patients carrying the NM_007103.4:c.1156C > T variant.

and 1 compound heterozygote. Among six identified variants, two were novel: NM_007103.4:c.597delC p.(Ala201LeufsTer25) and NM_007103.4:c.466A > G p.(Ile156Val). The most frequent was NM_007103.4:c.1156C > T p.(Arg386His), found in 78% of patients (Fig. 2). Although it was found recurrently in individuals from neighboring Asian regions, haplotype analysis showed distinct genetic backgrounds, supporting the view that it is not a founder effect (Fig. 3).

Conclusion: This study broadens the phenotypic spectrum of NDUFV1-related mitochondrial disease, highlighting orofacial dystonia and sleep disturbances as newly phenotypic features, and expands the genotypic landscape by identifying two novel variants.

Disclosure: Nothing to disclose.

Ageing and Dementia 3

EPO-0324 | Skin biopsy for detection of phosphorylated alpha-synuclein by indirect immunofluorescence in a cohort of patients with cognitive impairment

A. Furia¹; A. Incensi²; C. Delprete²; R. Pantieri³; G. Rizzo²; S. Capellari¹; M. Stanzani-Maserati²; G. Plazzi²; E. Antelmi⁴; F. Pizza¹; V. Vacchiano²; M. Giannoccaro¹; R. Liguori¹; W. Zou⁵; V. Donadio¹

¹Dipartimento di Scienze Biomediche e Neuromotorie, Università di Bologna, Italy; ²IRCCS Istituto delle Scienze Neurologiche di Bologna, UOC Clinica Neurologica, Ospedale Bellaria, Bologna, Italy; ³IRCCS Istituto delle Scienze Neurologiche di Bologna, UOC Neurologia, Ospedale Bellaria, Bologna, Italy; ⁴DIMI Dipartimento di Ingegneria per la Medicina di Innovazione, Università di Verona, Verona, Italy; ⁵Institute of Neurology, Jiangxi Academy of Clinical Medical Institute, The First Affiliated Hospital of Nanchang University, Nanchang, Jiangxi Province, China

Background and aims: Techniques for detection of Dementia with Lewy Bodies (DLB) and distinction from other causes of cognitive impairment are in rapid establishment. Among these are Indirect Immunofluorescence (IF) for identification of phosphorylated α -synuclein (p-syn) in skin tissue and Seeding Amplification Assays (SAAs), including Real Time Quaking-Induced Conversion (RT-QuIC).

Methods: patients referred to our Clinic for major or minor cognitive impairment were prospectively recruited from 2015 to 2025, undergoing full neurological and neuropsychological examination. Subsequent examinations were guided by the clinical presentation and the final diagnosis, serving as gold standard, was established by experienced clinicians. Skin biopsy for detection of p-syn by IF was performed in all patients at distal leg and cervical sites. Diagnostic accuracy (sensitivity, specificity) of skin IF was assessed, along with the correlation of quantitative p-syn measures with clinical measures.

Results: 50 patients with DLB (syn group) diagnosis and 74 fulfilling different diagnoses (non-syn cognitive impairment) were

recruited. Skin biopsy detected p-syn in 46 syn patients, resulting negative in all non-syn cases. Quantitative measures did not correlate with clinical measures.

Conclusion: Skin biopsy is a promising technique for detection of p-syn in patients with DLB diagnosis. The results suggest significant specificity. Current quantitative p-syn measures do not correlate with disease parameters in DLB, warranting development of more specific indexes.

Disclosure: Nothing to disclose.

EPO-0325 | Speech biomarkers derived from explainable AI reveal therapeutic effects of transcranial pulse stimulation in Alzheimer's disease

A. Günes¹; D. Wiechmann²; E. Kerz³; Y. Qiao³; M. Köhne¹; U. Sprick⁴

¹Department for Research and Development, Center for Neurostimulation, Alexius/ Josef Hospital, Neuss, Germany;

²Institute for Logic, Language & Computation, University of Amsterdam, Amsterdam, Netherlands; ³Exaia Technologies, Amsterdam, Netherlands; ⁴Faculty of Medicine, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany

Background and aims: We develop interpretable AI models using spontaneous-speech digital biomarkers to support the differential diagnosis of Alzheimer's disease (AD) and to quantify individual therapeutic effects of transcranial pulse stimulation (TPS) on disease progression. TPS is a CE-certified, non-invasive, shockwave-based neuromodulation technique. It enables neuronavigation-guided targeting and modulation of cortical gray matter as well as deep brain structures.

Methods: Automated classification models were trained on spontaneous speech from 40 AD patients and 27 socio-demographically matched healthy controls. Diagnosis followed German S3

FIGURE 1 Performance of the AD classification model. Receiver operating characteristic (ROC) curve for the final model trained on linguistic features using the full dataset. The model achieved an area under the curve (AUC) of 0.974 [95% CI: 0.927-1.000].

FIGURE 2 Speech-based biomarkers track global cognitive decline. Hierarchical clustering of Pearson correlation coefficients reveals a high-fidelity association between speech-biomarker and global cognitive measures (CERAD, $r=0.76$; MMSE, $r=0.76$).

FIGURE 3 Longitudinal trajectories of cognitive change captured by an AI-derived speech biomarker. Waterfall plot showing annualized rates of change in speech biomarker indexing cognitive functioning for a representative sub-cohort (AD group).

guidelines and was supported by CERAD Plus (including MMSE), Stroop test and structural MRI. Interpretable AI identified the most discriminative speech features. Biomarkers were then used to quantify TPS-associated modulation in 14 patients who received six sessions over 14 days, with 6000 pulses per session delivered bilaterally to the frontal and parietal lobes and the precuneus, using an energy level of 0.25 mJ/mm² and a frequency of 4 Hz.

Results: Speech biomarkers correlated with cognitive performance and captured impairment better than the Stroop test. AD versus control classification achieved F1=0.81. Group-level linguistic performance was stable or slightly improved during follow-up, contrasting with the 3.3-point annual MMSE decline expected in untreated AD. Individual t0/t1 biomarker trajectories varied markedly, indicating heterogeneous responsiveness. Discriminative speech features provided mechanistic insights into TPS-related neurophysiological effects.

Conclusion: Interpretable AI with speech-derived digital biomarkers provides a precision framework for AD diagnosis and treatment monitoring. TPS produces individualized, quantifiable effects on disease progression detectable with sensitive speech-based measures that outperform conventional cognitive assessments.

Disclosure: Nothing to disclose.

EPO-0326 | Semiquantitative neuropathologic thresholds for cerebrospinal fluid biomarker alterations in Alzheimer's disease

A. Mastrangelo¹; S. Baiardi¹; G. Bentivenga¹; E. Ruggeri²; C. Vargiu²; A. Mammana²; S. Capellari¹; P. Parchi¹

¹Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy; ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy

Background and aims: Validation of Alzheimer's disease (AD) cerebrospinal fluid (CSF) biomarkers against pathology is limited by small sample cohorts and long CSF-death intervals. Moreover, few studies assessed the burden of brain A β and tau pathologies using semiquantitative scoring. Using a large cohort, we defined the brain A β and tau burden threshold associated with significant alterations in CSF markers.

Methods: We studied 233 subjects with post-mortem neuropathology (164 prion, 69 non-prion) and antemortem CSF samples. A β and tau burden were semi-quantitatively scored across nine and six brain regions, respectively. Thal phase, Braak stage and AD neuropathologic change (ADNC) category were assigned. CSF and plasma biomarkers were measured by the Lumipulse platform. Associations between pathology and log-transformed biomarkers were tested using linear regression models. Age, sex, and CSF-death interval were considered as covariates.

Results: Median sampling-death interval was 1.5 months (IQR 0.5–5.1). CSF A β 42/A β 40 was already significantly reduced at Thal phase 2 ($p=0.019$) and low-ADNC ($p<0.001$) when compared to non-AD. The first significant reduction in CSF A β 42/A β 40 occurred at an A β density score > 15 (moderate neocortical and amygdala pathology; $p=0.047$), with increasing pathological burden associated with greater biomarker changes ($p<0.001$). Values of CSF A β 42/A β 40 ≤ 0.068 had 92% specificity and 90% sensitivity for distinguishing an A β density score > 25. In non-prion cases, A β 42/p-tau181 was earliest reduced at intermediate-ADNC and A β density-score > 35 ($p<0.001$).

Conclusion: Group-alterations of CSF A β 42/A β 40 appear at a relatively early stage of AD continuum, although initial A β deposits remain below detection. In contrast, a reduction in CSF A β 42/p-tau181 emerges only at higher levels of beta-amyloid burden.

Disclosure: Nothing to disclose.

EPO-0327 | Validation of CogniPaz: A rapid, ecologically-oriented digital biomarker for detection of mild cognitive impairment

Significance (p-value)				

FIGURE 2 Cognipaz ROC curves. MCI: mild cognitive impairment. aMCI: amnesic mild cognitive impairment. SCD: subjective cognitive decline. HC: healthy controls.

(SCD) and healthy controls (HC) is a diagnostic challenge. We developed CogniPaz, an ecologically oriented digital cognitive assessment composed of nine tasks evaluating memory and executive functions. We evaluated its diagnostic accuracy as a digital biomarker in discriminating MCI/aMCI from SCD and HC. **Methods:** We conducted a prospective observational study including participants with subjective cognitive complaints or asymptomatic controls recruited between April 2025 and December 2025. Participants were classified based on clinical evaluation and Montreal Cognitive Assessment (MoCA) scores into HC (asymptomatic; MoCA ≥ 26), SCD (cognitive complaints; MoCA ≥ 26) and MCI/aMCI (cognitive complaints without functional impairment; MoCA < 26). CogniPaz was administered after MoCA by a blinded evaluator, following a standardized protocol. We assessed correlation with MoCA score (Pearson), diagnostic accuracy (ROC analysis) and usability (satisfaction questionnaire).

Results: 80 participants were included: 39 MCI (22 aMCI), 17 SCD and 24 HC. Mean administration time was 9.65 minutes (SD 3.72). CogniPaz total scores correlated strongly with MoCA

($r=0.83$) and memory tasks correlated with MoCA memory domains ($r=0.69$). Diagnostic accuracy was excellent for distinguishing MCI from HC (AUC=0.882), MCI from SCD (AUC=0.916), aMCI from HC (AUC=0.907) and aMCI from SCD (AUC=0.937). CogniPaz also discriminated suspected neurodegenerative from non-neurodegenerative cases (AUC=0.835). Usability was rated highly (mean score 8.11 out of 9).

Conclusion: CogniPaz shows strong correlation with MoCA and excellent diagnostic accuracy. Its brevity and ease of use support its utility as an efficient digital screening tool for distinguishing MCI/aMCI from SCD and HC.

EPO-0328 | Lobar Cerebral microbleeds and white matter hyperintensities differentially associate with neuropsychiatric vulnerability in dementia with Lewy bodies

P. Stancu¹; D. Janeli¹; D. Botta²; F. Kurz²; F. Assal¹; L. Sveikata¹
¹Neurology Department, Geneva University Hospitals, Geneva, Switzerland; ²Neuroradiology Department, Geneva University Hospitals, Geneva, Switzerland

Background and aims: To explore the relationship between markers of small vessel disease (SVD)—lobar cerebral microbleeds (CMB) and white matter hyperintensities (WMH)—and neuropsychiatric symptoms (NPS) in dementia with Lewy bodies (DLB). Markers of SVD are associated with cognitive impairment in older adults, but their contribution to early neuropsychiatric manifestations in DLB remains insufficiently characterized.

Methods: Clinically diagnosed DLB cases ($n=70$) were analyzed. CMB and WMH were assessed using standardized visual rating scales. NPS, including depression, anxiety, apathy, hallucinations and delirium, was assessed retrospectively. NPS other than delirium were evaluated at the first cognitive visit. Pre-diagnostic delirium was defined via the Confusion Assessment Method scale within the year preceding diagnosis. Descriptive analyses were performed. Cross-sectional associations between SVD imaging markers and NPS were examined using regression models adjusted for age, sex, and educational level.

Results: CMB were present in 17/54 (31.5%) cases, and 45/69 (65.2%) had at least one documented delirium episode in the year preceding diagnosis. CMB were selectively associated with depression (OR=6.80, 95% CI 1.60–28.87, $p=0.009$) and pre-diagnostic delirium (OR=5.11, 95% CI 1.02–25.71, $p=0.048$). CMB were not associated with anxiety, apathy, or hallucinations. WMH showed no significant association with any NPS outcome.

Conclusion: In contrast to WMH, CMB were selectively associated with depression and pre-diagnostic delirium in clinically diagnosed DLB. These findings suggest diverging pathophysiological mechanisms of SVD comorbidity in LBD and support a differential contribution of cerebrovascular markers to prodromal neurocognitive symptoms and clinical expression in DLB.

Background and aims: To assess clinical/neuropsychological, neurophysiological, neuroimaging, genetic, and fluid biomarker profiles of individuals attending a Brain Health Service (BHS) designed for early identification of Alzheimer's disease (AD).

Methods: Fifty-two participants were referred to the BHS and underwent clinical/neurological and neuropsychological evaluations, brain MRI, electroencephalography (EEG), optical coherence tomography (OCT), APOE genotyping, and, for research purposes, blood-sampling for plasma AD-biomarker-analysis. Participants were classified as A+ ($n=22$) or A- ($n=30$) based on p-tau217, and clinically stratified into cognitively normal (CN=15; CN+ =6; CN- =9), subjective cognitive decline (SCD=18; SCD+ =3; SCD- =15), and mild cognitive impairment (MCI=19; MCI+ =13; MCI- =6). We analyzed: gray matter (GM) atrophy, white matter (WM) hyperintensities, EEG features and OCT data.

Results: A+ cases were older than A-, reported higher alcohol consumption, showed poorer cognitive performances and engaged in less physical activity. CN+ showed reduced semantic fluency compared to SCD. Compared to A-, A+ showed reduced GM volume in the left medial temporal lobe, left fusiform gyrus, right precuneus and anterior temporal gyrus, and increased WM burden in periventricular and deep regions. Compared to A-, in A+ EEG analysis revealed lower frequencies in temporal and frontal regions, and OCT revealed increased global retinal nerve fiber layer thickness.

Conclusion: Our findings support the feasibility and clinical relevance of plasma biomarkers, offered within a research framework, for the early detection of AD in individuals accessing a BHS. Early biomarker identification enables timely lifestyle interventions that may delay symptoms onset. The BHS provides a promising framework to detect at-risk individuals and guide preventive strategies.

EPO-0330 | **Greater burden of Alzheimer's co-pathology in women with Parkinson's disease**

E. Driver-Dunckley
Neurology, Mayo Clinic Arizona, Scottsdale, USA

Background and aims: Alzheimer's disease (AD) and Parkinson's disease (PD) frequently co-occur in older adults, yet the influence of sex on AD pathology in the context of PD remains unexplored. The objective of this study is to investigate sex differences in AD related pathology among autopsy-confirmed PD cases.

Methods: All subjects were enrolled in the Arizona Study of Aging and Neurodegenerative Disorders (AZSAND) and Brain and Body Donation Program (BBDP) and had annual standardized research clinical assessments by neuropsychologists, subspecialty behavioral and movement disorders neurologists, as well as comprehensive neuropathological examinations after death

Results: Among 230 autopsy-confirmed PD cases, females exhibited greater amyloid plaque pathology burden than males, regardless of a co-occurring AD diagnosis. Specifically, females with PD had significantly higher mean cortical total plaque scores (mean 6.5/15 vs. 4.9/15, $p=0.045$) and greater CERAD neuritic plaque density (mean 1.7/3 vs. 1.3/3, $p=0.035$). Females were also more likely to have a higher cortical plaque burden (plaque total ≥ 5 : 56.8% vs. 39.7%, $p=0.015$). In multivariable logistic regression models, female subjects showed greater than twice the odds of having an amyloid plaque burden ≥ 5 compared to males (OR = 2.18; 95% CI = 1.17 – 4.06; $p=0.014$), when controlling for ApoE $\epsilon 4$ status and age at death.

Conclusion: Female sex is associated with increased amyloid plaque pathology in PD, independent of ApoE ϵ 4 status. These findings highlight a sex-specific vulnerability to AD pathology in PD patients and support the need for sex-informed approaches to diagnosis and treatment in mixed neurodegenerative disease.

Disclosure: Nothing to disclose.

EPO-0331 | Cognitive improvement following transcranial pulse stimulation (TPS) in patients with dementia: A randomized, sham-controlled study

F. Pistoia¹; F. Vecchio²; C. Pappalettera²; P. Sucapane³; G. Saporito³; A. Cacciotti²; C. Carrarini²; L. Titti²; C. Decaro²; V. Socci³; N. Cimini³; P. Rossini²

¹Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy; San Salvatore Hospital L'Aquila, Italy; ²Department of Neuroscience and Neurorehabilitation IRCCS San Raffaele Roma Rome Italy; ³Department of Neurology, San Salvatore Hospital, L'Aquila, Italy

Background and aims: The burden of dementia is increasing worldwide, resulting in a substantial social and healthcare burden. Hence, the increasing interest in both pharmacological and non-pharmacological treatments, with potential to slow the clinical course of the disease. The objective of this study was to investigate whether Transcranial Pulse Stimulation (TPS) may induce cognitive improvement in patients with an early stage of dementia.

Methods: A double-blind, sham-controlled study was conducted, with patients randomly assigned to receive either TPS or sham TPS for four weeks in parallel groups. Patients received either TPS or sham treatment once daily, five days per week. TPS was applied to bilateral frontal cortex, bilateral parietal cortex and precuneus cortex via a neuronavigation system based on individual MRI spatial coordinates. Clinical assessments were performed through the Alzheimer's Disease Assessment Scale-Cognitive Subscale (ADAS-Cog) at baseline (t0), two weeks after the start of TPS (t1), one month after the start of TPS (t2), two months after the start of TPS (t3), and six months after the start of TPS (t4).

FIGURE 2 TPS device (by courtesy of Storz Medical).

Pre- vs post-stimulation ADAS-Cog score comparison.

Results: 82 patients were enrolled. Sixty (mean age $\pm$ SD 74.3 $\pm$ 8; 20 males) completed assessments at baseline and after one month of stimulation. A significant improvement in ADAS-Cog scores at one month was detected in patients receiving the active treatment ($n=34$ mean age $\pm$ SD 73.2 $\pm$ 9; 11 males) compared with those receiving sham treatment ($n=26$ mean age $\pm$ SD 75.8 $\pm$ 6.5; 9 males) ($p < 0.009$). No significant side-effects were reported.

Conclusion: Preliminary findings suggest that TPS may be a promising tool for enhancing neuroplasticity-related recovery in dementia.

Disclosure: This research was funded by the Italian Ministry of Health under the National Recovery and Resilience Plan (PNRR), Mission 6 – Component 2 – Investment 2.1 “Enhancement and strengthening of biomedical research within the National Health Service (SSN)”, Project code PNRR-MCNT2-2023-12377235 (CUP: E13C24000930001), financed by the European Union – NextGenerationEU.

EPO-0332 | EEG dynamics in Lewy body diseases is related to clinical fluctuations and degeneration of locus coeruleus

E. Výtvarová¹; K. Mitterová¹; M. Angiolelli²; A. Kovářová¹; A. Šejnoha Minsterová¹; L. Brabenec¹; M. Lamoš¹; P. Sorrentino²; I. Rektorová¹; J. Fousek¹

¹Central European Institute of Technology (CEITEC), Masaryk University, Brno, Czech Republic; ²Institute de Neuroscience des Systems (INS), Institut National de la Santé et de la Recherche Médicale (INSERM), Aix Marseille Université, Marseille, France

Background and aims: The complex relationships between the focal neurodegeneration, dynamics of the brain activity and cognitive decline are not well understood in the context of Lewy body diseases. Quantitative assessment of the transient cascades of increased brain activity (neuronal avalanches) has proven useful in capturing meaningful information across conditions. Here we examined whether the richness of brain dynamics was associated with clinical symptoms and with the microstructural integrity of catecholaminergic nuclei – the right caudal locus coeruleus (rLC) and the substantia nigra pars compacta (SNpc).

L. Yang
Zhejiang Hospital, Hangzhou, China

Group differences in flexibility. Note: Crosses (+) mark 9 outliers that were removed before statistical analysis; $n(\text{HC}) = 28$, $n(\text{CN-CCF}) = 51$, $n(\text{MCI-LB}) = 34$, $n(\text{PD}) = 28$.

Methods: The sample comprised 30 HC, 56 cognitively normal individuals with core clinical features of dementia with LB (CN-CCF), 34 individuals with mild cognitive impairment with LB (MCI-LB), and 30 advanced PD patients. Neuronal avalanches were extracted from source-reconstructed resting-state EEG and described by their count, the number of unique spatial patterns (flexibility), hemispheric symmetry of flexibility, and avalanche transition matrices. LC and SNpc integrity were assessed using neuromelanin-sensitive MRI and free-water diffusion imaging, respectively.

Results: Lewy body disease groups exhibited increased flexibility relative to HC, which was, in prodromal groups, associated with cognitive fluctuations and REM sleep behavior disorder symptoms, but not parkinsonism. Flexibility was negatively related to rLC integrity, which was lowest in MCI-LB.

Conclusion: These findings suggest that elevated flexibility reflects dysregulated brain dynamics linked to malignant non-motor features of LB diseases and to the caudal LC involvement.

Disclosure: This work has received funding from the project nr. LX22NPO5107 (MEYS): Financed by European Union – Next Generation EU; from the European Union's Horizon Europe research and innovation programme under grant agreement No 101147319 (EBRAINS 2.0); from the Ministry of Education, Youth and Sports of the CR (Joint Programme Neurodegenerative Disease), project nr. 9F25001 (TRACE-PD): Tracking the mechanisms of disease progression and functional compensation in the early phase of Parkinson's disease; from EU Joint Programme Neurodegenerative Disease (JPND) project entitled 'TACKLing the Challenges of PREsymptomatic Sporadic Dementia (TACKL-PRED),' project nr. 8F22005. This work was supported by Ministry of Health of the Czech Republic, grant nr. NNW26J04-00157; by the European Regional Development Fund project LangInLife, reg. no.: CZ.02.01.01/00/23_025/0008726.

Background and aims: Alzheimer's disease (AD) is a progressive neurodegenerative disorder posing global health challenges. Accessible, non-invasive early biomarkers are urgently needed. Plasma-derived extracellular vesicles (EVs) cross the blood-brain barrier, carrying CNS cargo and offering biomarker potential. We aim to identify, validate, and determine the cellular origins of a novel plasma EV protein panel with high diagnostic accuracy for AD.

Methods: A two-phase nested case-control study was used. Discovery: untargeted 4D-Label-free proteomics (LC-MS/MS) on plasma EVs from 25 probable AD patients and 25 matched healthy controls (HC). Bioinformatic analyses integrated public brain scRNA-seq data to infer cellular origins. Validation: candidate panel quantified by targeted mass spectrometry (SRM) in an independent multi-center cohort (30 AD, 25 MCI, 30 HC). Models adjusted for age and systolic blood pressure. Machine learning built and evaluated a multi-marker diagnostic model.

Results: Several proteins were differentially expressed; genes encoding them were enriched in brain-specific cells, notably endothelial cells and microglia. In validation, PRKCSH was upregulated in AD; ANGPT1, NCKAP1, and FLJ78516 were downregulated vs. controls (all $p < 0.001$). MCI showed intermediate levels, suggesting a disease continuum. A diagnostic model with these four biomarkers achieved AUC 0.95 (95% CI 0.91–0.99) using Random Forest, with 92% sensitivity and 91% specificity for AD vs. controls.

FIGURE 1 Volcano plot of differentially expressed EV proteins in the discovery cohort (AD vs. HC). Proteins with $\text{FC} > 2$ and $p < 0.05$ are shown in red (upregulated), while those with $\text{FC} < 0.5$ and $p < 0.05$ are in blue (downregulated).

FIGURE 2 Results of tissue origin tracing by cumulative calculation of AD exosome markers. *A: UMAP plot of cell clustering; B1-5: UMAP plots of single gene expression distribution; C: Gene bubble plot; D: Box plot of cell proportion.

TABLE 1 Diagnostic Performance of Multi-Marker Models (AD vs. HC, Validation Cohort)

Model	AUC (95% CI)	Sensitivity (%)	Specificity (%)	Accuracy (%)
Logistic Regression (LR)	0.87 (0.81–0.93)	95	98	96
Support Vector Machine (SVM)	0.87 (0.81–0.93)	95	98	96.5
Random Forest (RF)	0.88 (0.82–0.94)	96	99	97

Conclusion: A four-protein plasma EV panel (PRKCSH, ANGPT1, NCKAP1, FLJ78516) shows high diagnostic potential, likely originating from brain endothelial cells and microglia. This non-invasive panel advances toward a clinically applicable AD blood test.

Disclosure: Nothing to disclose.

EPO-0334 | Alzheimer’s disease, environment and genes – looking at the unexpected

M. Coelho¹; P. Faustino¹; C. Bernardes²; J. Durães¹; M. Lima³; D. Duro¹; M. Almeida³; I. Baldeiras³; M. Tábuas-Pereira¹; I. Santana¹
¹Neurology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; ²Neurology Department, Unidade Local de Saúde do Alto Ave, Guimarães, Portugal; ³Centre for Innovative Biomedicine and Biotechnology (CIBB), Universidade de Coimbra, Coimbra, Portugal

Background and aims: Atypical forms of Alzheimer’s disease (AD) are characterized by predominant symptoms in nonmemory cognitive domains. Apart from different clinical manifestations, these variants also have a younger age of onset, which

may suggest a higher genetic contribution. With this work we aimed to study family history in AD subtypes, as a proxy of genetic contribution to their development.
Methods: Family history and APOE status in patients with typical and atypical AD diagnosis supported by biomarkers. Non-parametric tests (χ^2) were used to verify differences between groups. Logistic regression models were performed to investigate the association between family history and APOE status and the development of an atypical variant.
Results: The study included 392 patients: 293 with typical AD and 99 with atypical AD (53 frontal, 33 logopenic, and 14 posterior variants). A positive family history was more frequent in typical AD (48.5%) than in atypical AD (33.3%; $\chi^2 = 6.775$, $p = 0.009$). Family history prevalence did not differ significantly among atypical variants ($\chi^2 = 1.107$, $p = 0.575$). APOE $\epsilon 4$ carriage was also more common in typical AD (50.5%) compared to atypical AD (38.4%; $\chi^2 = 4.852$, $p = 0.028$). In logistic regression analyses, the presence of an atypical AD variant was inversely associated with a positive family history ($\beta = -0.548$, 95% CI 0.347–0.963, $p = 0.035$) and APOE $\epsilon 4$ status ($\beta = -0.495$, 95% CI 0.371–1.000, $p = 0.050$).
Conclusion: Our results suggest that genetic factors have a lower contribution to the development of atypical variants than typical AD, suggesting the contribution of other factors, namely environmental, warranting further studies.
Disclosure: Nothing to disclose.

EPO-0335 | Effects of different exercise modalities on cognitive function in older adults: A systematic review and network meta-analysis

R. Lorandi¹; A. Rech¹; R. Radaelli²; M. Petropoulou³; H. Almeida¹; C. Silveira¹; C. Muller¹; L. Grolli¹; P. Casara¹; P. Lopez¹
¹Grupo de Pesquisa Em Exercício Para Populações Clínicas (GPCLIN), Universidade de Caxias do Sul, Caxias do Sul, Brazil; ²Egas Moniz Center for Interdisciplinary Research (CiiEM), Egas Moniz School of Health and Science, Almada, Portugal; ³Institute of Medical Biometry and Statistics, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg, Germany

Background and aims: Globally, one in four older adults experiences cognitive impairment. Physical exercise has positive cognitive effects; however, the optimal exercise modality remains to be determined. Therefore, we aimed to systematically review and analyse the effects of different exercise modalities on cognitive function domains in older adults.

Methods: We included published randomised clinical trials from seven different databases on April 8, 2025, involving older adults (≥ 60 years), with or without cognitive impairment, randomised to supervised resistance (RE), aerobic (AE) and/or combined resistance and aerobic exercise (COMB) for at least 4 weeks. Outcomes included global cognition, attention, executive function and memory. Meta-analysis was undertaken with a three-level mixed effects model, and results were expressed as standardised mean difference (SMD) and 95% confidence intervals.

Results: We included 127 randomised controlled trials ($n = 10,433$) comprising 780 cognitive outcomes. Exercise significantly improved overall cognition (0.24 [0.17–0.30], $p < 0.001$). Similar benefits were observed following COMB (0.27 [0.09–0.45], $p = 0.005$) and RE (0.26 [0.14–0.37], $p < 0.001$), with

smaller effects for AE (0.18 [0.11–0.26], $p < 0.001$). Exercise improvements were mainly for global cognition (0.42 [0.26–0.57], $p < 0.001$), followed by complex attention (0.18 [0.09–0.27], $p < 0.001$), executive function (0.14 [0.07–0.21], $p < 0.001$) and learning and memory (0.14 [0.05–0.24], $p < 0.001$). No significant effects were observed for language (0.09 [–0.03–0.21], $p = 0.130$) or perceptual-motor function (0.05 [–0.11–0.22], $p = 0.510$).

Conclusion: Our findings indicate that resistance-based exercise programs significantly improve specific cognitive domains in older adults, particularly attention, executive function, and learning/memory. These results underscore the importance of exercise to prevent cognitive decline and to support individuals presenting with cognitive impairment.

Disclosure: Nothing to disclose.

EPO-0336 | Cognitive and structural brain changes in ofatumumab-treated multiple sclerosis: A longitudinal study

E. D'Amico; P. Di Filippo; C. Robusto; M. Moretti; C. Avolio; A. Zanghi

Brand Center, Department of Medical and Surgical Sciences, University of Foggia, Italy

Background and aims: Anti-CD20 therapies control inflammatory activity in multiple sclerosis (MS), but their effects on neurodegeneration and cognition in real-world settings remain uncertain. We aimed to characterize longitudinal cognitive and regional brain structural changes in ofatumumab-treated MS patients. We also evaluated structure–cognition associations over time.

Methods: We conducted a longitudinal observational study of relapsing MS patients treated with ofatumumab. Cognitive performance was assessed using the Brief International Cognitive Assessment for Multiple Sclerosis (BICAMS), with processing speed as the primary outcome, and Magnetic Resonance Imaging (MRI) measures included thalamic volume, deep gray matter volume (DGM), and cortical thickness (Cth). Longitudinal changes and structure–cognition associations were analyzed using linear mixed-effects models.

Results: Eighty-five RMS patients treated with ofatumumab (mean age 37.9 ± 9.9 years; 69.4% female; 222 MRI scans) were included. Brain atrophy persisted but attenuated after 12 months: whole-brain volume -0.15% vs -0.09% ; DGM -1.01% to -0.36% ; thalamus -0.94% to -0.77% ; CTh -1.67% to -0.62% (all p for slope changes > 0.05). Cognitive performance improved (Symbol Digit Modalities Test, SDMT $+3.79$ points/year, 95% CI 1.35–6.23; $p = 0.003$), with improvements in verbal and visuospatial memory (all $p < 0.05$). No global longitudinal structure–cognition association was observed. In subgroups, thalamic atrophy was associated with SDMT decline in patients with Expanded Disability Status Scale ≥ 3 ($\beta = -54.31$; $p = 0.013$), and DGM atrophy with cognitive worsening in patients with baseline SDMT $z \leq -1$ ($\beta = -55.91$; $p = 0.012$).

Conclusion: In ofatumumab-treated relapsing MS, neurodegeneration persists but slows over time while cognition is preserved, and structural–functional coupling emerges only in vulnerable patients.

Disclosure: Nothing to disclose.

EPO-0337 | From intravenous to subcutaneous ocrelizumab in a high-volume infusion center: A time-and-motion-informed capacity and service-flow analysis

A. Zanghi; P. Di Filippo; C. Rutigliano; C. Avolio; E. D'Amico
University of Foggia, Italy

Background and aims: Subcutaneous (SC) ocrelizumab offers a streamlined alternative to intravenous (IV) infusion in the management of multiple sclerosis (MS). Building on time-and-motion (T&M) methodologies validated in oncology, we conducted a single-center operational study to quantify procedure-level time savings, estimate the resulting care-time dividend, and assess changes in patient flow following SC implementation.

Methods: We employed a cross-sectional observational design in a five-chair day hospital treating ~600 patients with MS treated with infusive therapies. T&M data were collected for 15 IV ocrelizumab administrations (April 2025) and 15 SC administrations (November 2025), capturing active clinical time across four phases: premedication, administration, observation, and checkout. Service-flow metrics (monthly visit volume, mean waiting time) were extracted from the electronic queue system for May 2025 (early SC implementation) and November 2025 (mature SC adoption). A deterministic operational model projected capacity gains under different SC adoption scenarios.

Results: SC ocrelizumab reduced total active clinical time from 320 to 60 minutes (-81%), driven by administration (210→10 min) and observation (60→15 min) reductions. At 15 SC administrations/month, this translated into 65 clinical hours and 50 chair-hours released—equivalent to 14 IV-equivalent infusion slots. Despite unchanged ocrelizumab volumes, monthly visits increased ($+7.9\%$) and mean waiting time decreased (-30%) from May to November 2025. Scenario modeling projected 100–133 chair-hours released at 30–40 SC administrations/month.

Conclusion: Transitioning from IV to SC ocrelizumab yields substantial procedural efficiencies and frees infusion-unit capacity. The care-time dividend enables expanded access to complex therapies without additional staff or infrastructure, positioning SC ocrelizumab as a structural efficiency tool in MS care.

Disclosure: Nothing to disclose.

EPO-0338 | Serum neurofilament light chain levels are associated with increased disability and impairment of specific cognitive domains in neuro-Behçet disease

E. Tuzun¹; M. Tezel¹; H. Karpuzoglu²; A. Emekli³; T. Gunduz³; V. Yilmaz¹; M. Kurtuncu³; C. Küçükali¹

¹Department of Neuroscience, Aziz Sancar Institute of Experimental Medicine, Istanbul University, Istanbul, Türkiye;

²Department of Medical Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Istanbul Türkiye; ³Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye

Background and aims: Neurological symptoms may emerge in around 10% of Behçet disease (BD) patients. Biomarkers for

monitoring the clinical outcome of neuro-BD have not been properly investigated.

Methods: Levels of neurofilament light chain (NFL), biomarker of neuroaxonal degeneration, were measured in sera of 27 patients with parenchymal neuro-BD (16 men, 48 ± 9 -year-old, 11 ± 5 years disease duration) and age/gender-matched 30 patients with relapsing-remitting multiple sclerosis (RRMS) and 25 healthy controls by the Siemens Healthineers Atellica Analyzer. Sera of all patients were obtained during remission. Potential correlations were sought between NFL levels and clinical-cognitive aspects of neuro-BD.

Results: NFL levels of neuro-BD patients (13 ± 6 pg/mL; range, 6–31 pg/mL) were comparable with RRMS patients and significantly higher than healthy individuals ($p < 0.0001$). In neuro-BD, NFL levels were correlated with EDSS ($p = 0.019$, $R = 0.445$), 9-hole peg test ($p = 0.002$, $R = 0.603$), timed 25-foot walk ($p = 0.001$, $R = 0.612$), visual-spatial domain of Addenbrooke's cognitive examination revised (ACE-R; $p = 0.015$, $R = -0.490$), Stroop interference test ($p = 0.016$, $R = 0.506$), complex figure test ($p = 0.039$, $R = -0.422$) and Wisconsin card sorting test (WCST) scores ($p = 0.004$, $R = 0.592$). No significant correlation was found between NFL levels versus disease duration, scores of MMSE and tests assessing verbal/visual memory, language and psychiatric symptoms.

Conclusion: Neuroaxonal degeneration is intimately involved in development of somatic disability, visual-spatial and executive dysfunction in neuro-BD, whereas memory impairment and psychiatric symptoms appear to occur via divergent disease mechanisms. ACE-R, Stroop and WCST tests might potentially be used to monitor cognitive impairment in neuro-BD.

Disclosure: Nothing to disclose.

EPO-0339 | Serum galectin-3 as a biomarker in acute inflammatory polyradiculoneuropathies: A cohort study

G. Siconolfi¹; F. Vitali¹; A. Sciarrone¹; V. Guglielmino¹; G. Ciasca²; U. Basile³; G. Primiano⁴; M. Luigetti⁴

¹Dipartimento di Neuroscienze, Università Cattolica del Sacro Cuore; 00168 Rome, Italy; ²Sezione di Fisica, Dipartimento di Neuroscienze, Università Cattolica del Sacro Cuore; 00168 Rome, Italy; ³Dipartimento di Patologia Clinica, Ospedale Santa Maria Goretti, A.U.S.L. Latina, Latina, Italy; ⁴Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background and aims: Guillain-Barré Syndrome (GBS) refers to a group of acute inflammatory polyradiculopathies characterized by a diffuse inflammatory attack on the peripheral nervous system. In this study, we propose galectin-3 (Gal-3), a novel serum molecule identified expressed by Schwann cells and macrophages, as a potential biomarker in patients with GBS.

Methods: Serum levels of Gal-3 and neurofilament light chain (NfL) were measured using the Simple Plex cartridge-based immunoassay on the Ella platform in serum samples from a cohort of patients with GBS ($n = 19$) and in a validation cohort of healthy control subjects ($n = 13$). We also collected data on clinical history and patient outcomes.

FIGURE 1 Boxplot of serum levels of Gal-3 in GBS patients and in control subjects.

FIGURE 2 Discriminatory performance of Galectin-3 and Gal-3/NfL Ratio Between Axonal and AIDP GBS Patients. ROC curves demonstrating the diagnostic performance of serum Gal-3 levels (A), Gal3/NfL ratio (B), and serum NfL levels (C) in distinguishing the axonal variant.

FIGURE 3 Boxplot of serum levels of Gal-3 in subgroup based on NCS findings firstly in axonal GBS variant (AMAN or AMSAN) and AIDP patient (A) and in relation to electrophysiological findings (B).

Results: Gal-3 levels were significantly higher in patients with GBS (median: 7041 pg/mL; IQR: 5576–8561) compared to healthy controls (median: 5030 pg/mL; IQR: 3877–5998). Within the GBS cohort, Gal-3 levels were significantly elevated in patients with the axonal variant compared to those with classical AIDP variant (median: 8561 pg/mL vs. median: 5998 pg/mL, $p < 0.05$).

In multivariate logistic regression, Gal-3 remained significantly associated with the axonal variant of GBS after adjustment for age at sampling, diarrhea, GBS Disability Score at admission, and log-transformed NfL. In ROC analysis, Gal-3 demonstrated good discriminatory performance between axonal GBS and AIDP (AUC=0.84), outperforming NfL (AUC=0.76). Gal-3 threshold of 6457.5 pg/mL distinguish axonal GBS with 100% sensitivity and 61.5% specificity

Conclusion: In our cohort, Gal-3 was associated with both diagnostic and prognostic features in patients with GBS. These findings suggest that Gal-3 may serve as a potential biomarker for differentiating axonal subtypes within the GBS spectrum.

Background and aims: Detection of anti-neural autoantibodies for autoimmune epilepsy (AES) is crucial for early immunotherapy for improved outcomes. Conventional cell-based assays (CBA) test for limited panel of known autoantibodies. Immunohistochemistry (IHC) using rodent brain tissue represents a more comprehensive repertoire. Prevalence of AES and anti-neuronal antibodies in this cohort is unknown in Singapore. We describe here 1. Establishment of IHC assay and comparison to CBA sensitivity and prevalence 2. Comparing clinical characteristics between seropositive and seronegative patients 3. Clinical utility of the ACES (Antibodies Contributing to Focal Epilepsy Signs and Symptoms)score.

Methods: This is a cross-sectional, prospective, single-center study performed at the National Neuroscience Institute (NNI), Singapore. Inclusion criteria were patients with focal epilepsy of unknown etiology; able to provide informed consent; ≥18years old and had at least 1 seizure in the last 1 year prior to recruitment. Demographic data, medical history and epilepsy information were collected. ACES scores were calculated. Patients were stratified into definite/probable/possible/non-AES using IHC and CBA. Clinical characteristics, MRI, EEG and ACES scores were analyzed.

Results: 120 patients were included. Demographics and clinical data are detailed in Table 1. Figure 1 shows selected staining patterns and table showing seropositive IHC and/or CBA. Clinical characteristics of seropositive patients are detailed in Table 2A. Comparative analysis of possible AES and non-AES patients are shown in Table 2B. Diagnostic performance of ACES score is shown in Table 2C.

Table 1. Demographic and clinical characteristics of the study population (n=120)

Demographics	
Age (mean ± SD), median (IQR), range	46.0 (10.0, 11.0)
Female, n (%)	41 (34.2)
Educational level (years), median (IQR), range	12.0 (9, 16)
Race	
Chinese, n (%)	96 (80.0)
Malay, n (%)	10 (8.3)
Indians, n (%)	11 (9.2)
Others, n (%)	3 (2.5)
Past medical history	
Age of 1st seizure (years), median (IQR), range	4.0 (3, 11)
Subsequent seizures, n (%)	97 (81.7)
Current seizure, n (%)	7 (5.8)
Posterior reversible amnesia, n (%)	1 (0.8)
Epilepsy history	
Seizure frequency (per year), median (IQR), range	2.0 (0.5, 14.0)
Age of seizure onset (years), median (IQR), range	10.0 (7.0, 11.0)
Age diagnosed with epilepsy (years), median (IQR), range	12.0 (9.0, 14.0)
Frequency of seizures in the last 12 months, median (IQR), range	2.0 (0.5, 11.0)
Frequency of seizures in the last 4 months, median (IQR), range	2.0 (0.5, 5.0)
Previous status epilepticus, n (%)	9 (7.5)
Medically refractory epilepsy, n (%)	18 (15.0)
History of current antiepileptic medications, median (IQR), range	1.0 (0.5, 10.0)
Seizure semiology	
Social history without impairment of consciousness, n (%)	90 (75.0)
Social history with impairment of consciousness, n (%)	30 (25.0)
Social history resulting in behavioral modification, n (%)	10 (8.3)
Has behavioral epileptic seizure, n (%)	10 (8.3)
Others, n (%)	4 (3.3)
Other associated clinical features	
Cognitive impairment, n (%)	8 (6.7)
Depressive disorder, n (%)	9 (7.5)
Autism spectrum disorder, n (%)	6 (5.0)
Speech problems, n (%)	1 (0.8)
ADHD, n (%)	10 (8.3)
Medication findings	
Alleviated, n (%)	40 (33.3)
Medication resistant (CR), n (%)	80 (66.7)
Clinical response to AEDs, n (%)	80 (66.7)
Pharmacological enhancement, n (%)	80 (66.7)
Pharmacological enhancement, n (%)	80 (66.7)
CR, n (%)	80 (66.7)
IHC findings	
Seropositive, n (%)	9 (7.5)
Seropositive, n (%)	9 (7.5)
Seropositive, n (%)	9 (7.5)
Seropositive, n (%)	9 (7.5)

FIGURE 1 shows selected staining patterns shown and table showing seropositive IHC and/or CBA results.

Conclusion: The combination of clinical characteristics, IHC screening, and ACES scoring can improve AES detection, enabling earlier diagnosis and immunotherapy even in patients with negative CBA results.

Methods: Mechanistic studies used a dual-antigen (AQP4+MOG) EAE mouse model and SH-SY5Y cells. Interventions included GLP-1R antagonist Exendin-(9–39), agonist Exendin-4, and IL-6 inhibitor Satralizumab. Analyses comprised metabolomics, patch-clamp electrophysiology, and molecular assays.

Conclusion: GLP-1/GLP-1R-mediated glycolytic reprogramming via cAMP-PKA pathway drives AP neuronal hyperactivity in NMOSD-APS. Targeting GLP-1R signaling or IL-6-mediated

FIGURE 2 EAE mice metabolomics.

FIGURE 3 EAE mice mitochondrial dysfunction.

inflammation offers a novel therapeutic strategy by correcting both metabolic dysregulation and neuronal dysfunction. This study highlights the importance of metabolic-immune cross-talk in autoimmune neurological disorders and provides new insights into NMOSD pathophysiology.
Disclosure: Nothing to disclose.

EPO-0342 | Long-term and patient-reported outcomes (PROs) in patients with autoimmune encephalitis: A prospective cohort study

M. Borioni; A. Morano; A. Marocchi; E. Cerulli Irelli; A. Mazzeo; P. Moro; A. De Matteis; L. Fulignati; A. Giallonardo; C. Di Bonaventura
Department of Human Neurosciences, Policlinico Umberto I, Rome, Italy

Background and aims: Autoimmune encephalitis (AE) is a disorder presenting with acute neuropsychiatric manifestations and seizures. While AE may be associated with favorable recovery, prognosis can be variable. Outcomes in AE are traditionally assessed using the modified Rankin Scale (mRS) which fails to capture long-term effects on mood, sleep, and quality of life (QoL). Here, we evaluated a cohort of patients with AE using patient-reported outcomes (PROs) to provide a wider assessment of long-term prognosis.
Methods: We prospectively enrolled adult patients previously diagnosed with AE according to Graus criteria, with a minimum follow-up of two years. After collection of electroclinical data, the following validated PROs were administered: the Pittsburgh Sleep Quality Index (PSQI), Beck Depression Inventory-II (BDI-II), Hospital Anxiety and Depression Scale (HADS), and the Short Form Health Survey (SF-36).
Results: Thirty-two patients were enrolled (median age 67 years [IQR: 55–77]; 82% males), with a median follow-up of 7.5 years. At last follow-up, mRS scores ranged from 0 to 1 in 60% of patients. In contrast, the SF-36 revealed impaired quality of life in up to 80% of patients. Clinically relevant anxiety and/or depressive symptoms were observed in 71% of patients based on BDI-II and HADS scores, while 67% showed reduced sleep quality according to the PSQI. Diagnostic delay was associated with worse BDI-II ($p=0.046$) and PSQI scores ($p=0.022$).
Conclusion: Although most patients with AE show improvement on traditional mRS assessment at follow-up, a substantial proportion continues to experience mood disturbances and sleep impairment, which significantly affect their quality of life.
Disclosure: Nothing to disclose.

Background and aims: Chronic Inflammatory Demyelinating Polyradiculoneuropathy (CIDP) is a heterogeneous immune-mediated neuropathy marked by diagnostic complexity and variable treatment responses. Reliable biomarkers for diagnosis and disease stratification are lacking. Lipoproteins have emerged as regulators of neuroinflammation and potential autoimmune targets. However, their role in CIDP is unknown. We investigated the lipid profiles in serum and cerebrospinal fluid (CSF) treatment-naïve CIDP patients.

Methods: Serum and CSF samples from CIDP patients at initial diagnosis and controls were analyzed using mass spectrometry-based lipidomics targeting glycerophospholipids and sphingomyelin species ($n=26$). Patients with idiopathic intracranial hypertension and diabetic neuropathy served as control groups ($n=18$, $n=22$). Lipidomic findings were integrated with proteomic data and longitudinal clinical scores, including therapy response and disease severity, and confounders like age, gender, and total CSF protein.

Results: Preliminary proteomic data reveal a differential increase in proteins involved in lipid metabolism in the CSF of CIDP patients (including APOA2, APOA4, and APOA1). The preliminary lipidomic analysis shows a significant decrease of phosphatidylinositol 32:1 in CSF. In contrast, the sphingomyelin 18:1 CSF-to-serum-ratio is markedly elevated, with significant increases in CSF and decreases in serum ($p < 0.05$).

Conclusion: Our findings provide evidence for lipid dysregulation in CIDP patients. Especially the altered CSF-to-serum ratio of 18:1 sphingomyelin species warrants further investigation. Further correlation with clinical measures and validation in independent cohorts are required to assess the potential of lipids as mechanistic biomarkers in CIDP.

Disclosure: The authors declare no conflicts of interest.

Gemelli, IRCCS, Rome, Italy

Background and aims: To assess feasibility of a cognitive telerehabilitation protocol (CTR) in patients with autoimmune encephalitis (AE).

Methods: Patients with confirmed diagnosis of AE and neuropsychological impairment were prospectively recruited from November 2022 to November 2025. Participants were evaluated through a battery of neuropsychological testing and a comprehensive neurological evaluation at baseline (T0) and after 3 months (T1). At T0, patients and caregivers received a portable touch screen computer installed with a tailored telerehabilitation program (3 weekly, 25 min-sessions for a total of 12 weeks). User experience (UX) was assessed using the Italian-validated User Experience Questionnaire (UEQ) and the System Usability Scale (SUS). Health status was evaluated with the 12-Item Short Form Health Survey questionnaire (SF-12).

Results: Twelve subjects were included (4 LGII-AE, 2 GAD-AE, 3 CASPR2-AE, 1 seronegative-AE, 1 GABA-B-AE, 1 NMDAR-AE). A median of 100% of the sessions and 94.57% of the tasks were completed with a median SUS of 78.75. UEQ scores were above the benchmark level for all the items included in the analysis. Median MoCA scores were similar between T0 (21.5, range 14.6–30) and T1 (23, range 18–28), but cognitive performances significantly improved in attention as assessed by faster TMT-A ($p < 0.05$). In addition, patients showed an improved perception of physical health on the SF-12 questionnaire ($p < 0.05$).

Conclusion: CTR is a feasible and potentially effective approach to treat cognitive dysfunction in AE. Further prospective studies are needed to define specific protocols and timing of administration.

Disclosure: Nothing to disclose.

Background and aims: This study evaluated the impact of intravenous/subcutaneous efgartigimod (EFG) on treatment burden in Japanese patients with generalized myasthenia gravis (gMG) between heavily pre-treated (HPT) and less heavily pre-treated (LHPT) cohorts.

Methods: We conducted a retrospective cohort analysis using hospital-based claims from Medical Data Vision of adult gMG patients initiating EFG between May 2022, and April 2025. Eligible patients had 12-month baseline and follow-up observation, oral glucocorticoids (GC) or non-steroidal immunosuppressants within 90-days pre-EFG initiation, and no other biologics during follow-up (Figure 1). HPT was defined as ≥ 2 baseline fast-acting treatment (FT) cycles (intravenous immunoglobulin, plasma exchange, intravenous methylprednisolone)

FIGURE 1 Patient Selection Criteria and Study Design. Eligible patients in the study must meet all the criteria listed for both baseline and the follow-up period.

FIGURE 2 Oral GC ADD in Patients with Continuous EFG Use. ADD within 3rd, 6th, 9th, and 12th month follow-up was measured for the HPT (left) and LHPT cohorts (right), focusing on patients who continued EFG until the end of the months of measurement.

FIGURE 3: Average FT cycle count per patient in follow-up. Average FT (IVIg, PLEX, IVMP, sum of all) during 12-month follow-up was measured for the HPT (left) and LHPT cohorts (right).

or ≥ 20 mg/day prednisolone-equivalent oral GC dose within 90 days pre-EFG initiation; all others were LHPT. Outcomes were oral GC average daily dose (ADD) and FT cycles counts.

Results: Among 260 patients identified, 58% were HPT and 42% were LHPT. Mean duration from first recorded gMG diagnosis to index, and EFG treatment duration did not differ between cohorts (HPT: 5.7 years, 455 days; LHPT: 5.9 years, 447 days; $p=0.635$, $p=0.816$ respectively). Mean oral GC ADD approximately halved after EFG initiation in both cohorts (HPT: 19.1 to 9.6 mg/day, LHPT: 14.2 to 7.1 mg/day, baseline to follow-up). LHPT had higher proportion of patients achieving ≤ 5 mg/day throughout follow-up (Figure 2) and one-third as many FT cycles per patient versus HPT during follow-up (0.45 vs. 1.46, Figure 3).

Conclusion: LHPT consistently showed lower treatment burden, while effective oral GC tapering was observed in both cohorts. EFG initiation in earlier disease management may improve real-world treatment outcomes.

Background and aims: We have previously identified conformational antibodies to proteolipid protein-1 (PLP1) and its peripheral isoform DM20 in patients with combined demyelinating disorders of the peripheral and central nervous systems. However, their presence in IMN has never been investigated.

Methods: We implemented a DM20 live cell-based assay and used it to screen a retrospective exploratory cohort of defined IMN ($n=294$), a prospective validation cohort of suspect IMN ($n=324$), and controls ($n=81$). Clinical features were compared with a cohort of DM20-IgG-negative chronic inflammatory demyelinating polyneuropathy (CIDP, $n=43$).

Results: DM20-IgG were identified in 20 of 537 cases (3.7%) of IMN and in none of the controls. DM20-IgG-positive IMN fulfilled the criteria for CIDP ($n=12$) or Guillain-Barré syndrome (GBS; $n=8$). Most presented with acute onset (17/20) and had a preceding trigger (11/20, of which 5 SARS-CoV-2 vaccination). Compared with "typical CIDP", DM20-IgG positive patients showed frequent cranial nerve involvement (12/20 vs 10/43, $p=0.009$), pain (12/20 vs 11/43, $p=0.012$) and higher disability at acme (INCAT total score 4 [1–9] vs 2 [0–8], $p=0.06$). A satisfactory response to intravenous immunoglobulin was obtained in 17/18 patients (94%). DM20-IgG predominantly pertained to IgG1 (12/20) and bound myelin on rat teased nerve fibres, live oligodendrocytes and myelinated Schwann cell segments.

Conclusion: DM20-IgG defines a subgroup of IMN characterized by acute onset, cranial nerve involvement, severe disability and a favorable response to immunotherapy. Their ability to bind their target on live cultures might suggest pathogenicity, that needs to be explored in future studies.

Disclosure: Nothing to disclose.

EPO-0348 | Is selective screening safe for stroke prevention? High rates of missed severe stenosis in Pre-CABG: Validating ESVS 2023

A. Nusairat¹; M. Al-Akhras¹; A. Alanzi¹; T. Bnayan¹; Y. Al-Hushki¹; M. Abu-Nukta¹; T. Nusairat²; M. Al-Mansi¹
¹Jordan University of Science & Technology (JUST), Irbid, Jordan; ²The Hashemite University, Zarqa, Jordan

Background and aims: Perioperative stroke is a devastating complication of coronary artery bypass grafting (CABG), frequently driven by occult carotid atherosclerosis. The 2023 ESVS guidelines advise against routine carotid screening, favoring selective screening only for high-risk subsets (Age > 70, Stroke/TIA, Left Main Disease). However, the safety of this restrictive strategy in populations with high metabolic burden is unproven. We validated whether following these guidelines leaves patients at risk of undetected carotid stenosis and subsequent cerebrovascular events.

Methods: We analyzed 203 consecutive patients scheduled for CABG at King Abdullah University Hospital (Jordan). All patients underwent comprehensive neurovascular imaging (Duplex/CTA). We stratified the cohort based on ESVS selective criteria to determine the "miss rate" for hemodynamically significant internal carotid artery (ICA) stenosis ($\geq 50\%$). Multivariate logistic regression identified independent predictors of carotid disease relevant to neurological risk.

Results: The cohort had a high metabolic burden (Diabetes: 67%, Hypertension: 85%). Overall Carotid Artery Disease prevalence was 54.2%, with significant ICA stenosis ($\geq 50\%$) in 17.7% ($n=36$). Crucially, strict adherence to ESVS 2023 selective criteria would have failed to detect 11.1% ($n=4$) of patients with significant stenosis. These "missed" patients were asymptomatic and younger (< 70 years) yet possessed critical plaque burden. In multivariate analysis, Left Main Coronary Disease (OR 1.66, 95% CI 1.05–2.8) and Hypertension (OR 2.47) were independent predictors of significant carotid stenosis.

Conclusion: In a high-risk cohort, reliance on "selective screening" misses > 11% of patients with significant carotid stenosis, leaving them vulnerable to preventable perioperative stroke. To optimize neuroprotection, we propose that Left Main Disease should trigger mandatory carotid screening.

Background and aims: Acute ischemic stroke (AIS) is a time-critical emergency in which rapid diagnosis within established therapeutic windows is essential to optimize outcomes. Fluid biomarkers offer a promising adjunct to clinical and neuroimaging assessment but their temporal dynamics in the acute phases remain incompletely characterized.

Methods: We performed an umbrella review of systematic reviews and meta-analyses evaluating fluid biomarkers in AIS versus controls or stroke mimics. Quantitative synthesis of primary studies (random-effects meta-analysis of standardized mean differences) was stratified by clinically relevant time windows. Heterogeneity, small-study effects, and excess significance bias were assessed.

Results: We included 27 publications (18 biochemistry, 1 metabolomic, 10 transcriptomic, 5 cell-free-DNA [cfDNA]). Across all time-points the largest effect sizes were observed for neuron-specific enolase (NSE), ischemia-modified albumin (IMA), d-Dimer, S100B, GFAP, and IL-6. Looking at metabolites, studies revealed early accumulation of lactate, succinate, glutamate and lysophosphatidylcholines, alongside depletion of arginine, citrulline and citrate. A catalogue of 220 micro-RNAs

FIGURE 2 Forest plot of the meta-analyses for biochemistry biomarkers, comparing acute ischemic stroke (AIS) vs controls (HCs and mimics) across all time-points.

FIGURE 3 Arrow plot of the biochemistry biomarkers, comparing acute ischemic stroke (AIS) vs controls across all time-points. For each biomarker we reported the direction of the studies and the total number of patients across studies.

FIGURE 1 Prisma flowchart of the selected studies.

(132 upregulated; 108 downregulated) identified robust markers (miR-16-5p, let-7e-5p, miR-107, miR-451a, miR-126-3p). 46 circulating-RNAs, and 55 long-non-coding-RNAs were consistently dysregulated. Five studies reported elevated nuclear and mitochondrial cfDNA within 6h.

Conclusion: Fluid biomarkers exhibit a temporally evolving signature: early coagulopathy (D-dimer), glial activation (GFAP, S100B) and inflammation (IL-6), followed by neuronal necrosis (NSE) and oxidative stress (IMA) within 24 h. Multi-omic integration, including metabolomics, transcriptomics and cfDNA,

highlights convergent pathways (PI3K/Akt, NF-κB, immunometabolism) and supports the development of rapid, point-of-care panels. Standardized sampling windows and harmonized assay protocols are essential for clinical translation and prospective validation in prehospital settings.

Disclosure: Nothing to disclose.

EPO-0350 | Why genetics can't be ignored in secondary stroke prevention: The CYP2C19 challenge in Asia

A. Raheja; D. De Silva; K. Narasimhalu
Department of Neurology, National Neuroscience Institute (Singapore General Hospital Campus), Singapore

Background and aims: Stroke is a leading cause of death and disability globally, with Asia disproportionately affected. A critical barrier to effective secondary prevention is the high prevalence of CYP2C19 loss-of-function alleles, present in almost 75% of South and East Asians, which reduce clopidogrel efficacy.

Methods: Evidence from trials including CHANCE-2, shows that genotype-guided alternatives, including ticagrelor and cilostazol, substantially lower recurrent stroke risk in loss-of-function carriers. Yet, clinical adoption remains limited by insufficient genetic testing infrastructure, cost, guideline gaps, and clinician training.

Results: Despite these challenges, genotype-guided therapy is both feasible and cost-effective, with potential to reduce recurrent strokes, disability, and healthcare burden.

Conclusion: Urgent action is required to implement precision antiplatelet strategies, update guidelines, and ensure equitable access, making pharmacogenomics a central component of stroke care in Asia.

Disclosure: Nothing to disclose.

FIGURE 1 Geographic distribution of CYP2C19 intermediate (IM) and poor metabolisers (PM) rates across selected Asian countries. 3, 9, 11 Shading intensity corresponds to the combined prevalence of these phenotypes.

EPO-0351 | Cerebral small vessel disease in early- vs late-onset Alzheimer's disease in a memory clinic cohort

C. Tamba¹; A. Griffa¹; P. Michel²; P. Salvioni Chiabotti¹; S. Pistocchi³; Y. Aleman-Gomez³; V. Dunet³; O. Rouaud¹; P. Hagmann³; G. Allali¹; G. Bommarito¹

¹Leenaards Memory Center, Department of clinical neurosciences, Lausanne University Hospital and University of Lausanne (CHUV-UNIL), Lausanne, Switzerland; ²Stroke Center, Neurology Service, Department of clinical neurosciences, Lausanne University Hospital and University of Lausanne (CHUV-UNIL), Lausanne, Switzerland; ³Department of Diagnostic and Interventional Radiology, Lausanne University Hospital and University of Lausanne (CHUV-UNIL), Lausanne, Switzerland

Background and aims: Cerebral small vessel disease (CSVD) frequently co-occurs with Alzheimer's disease and increases with age. Here, we evaluated CSVD burden in early onset and late-onset Alzheimer's disease (EOAD and LOAD), distinguishing between hypertensive arteriopathy (HTNA) and cerebral amyloid angiopathy (CAA) co-pathology, as they have different underlying mechanisms.

Methods: We retrospectively included 59 EOAD and 162 LOAD (clinically-biologically diagnosed), retrieving clinical features including vascular risk factors. CSVD features were rated on MRI using established criteria, deriving HTNA and CAA prevalence. CSVD burden was compared between EOAD and LOAD, adjusting for sex and the difference between age at MRI and age at symptom onset.

Results: A probable CAA was present in 15.3% of EOAD and 29.6% of LOAD, while a moderate/severe HTNA was observed in 10.2% of EOAD and 30.2% of LOAD. LOAD present with higher rates of hypertension, diabetes, and atrial fibrillation ($p < 0.05$). LOAD showed a greater CSVD burden, driven primarily by more severe white matter hyperintensities, lacunes and perivascular spaces load ($p < 0.05$). HTNA severity and probable CAA prevalence were higher in LOAD ($p < 0.001$ and $p = 0.035$, respectively), despite the absence of significant differences in hemorrhagic features.

Conclusion: LOAD is associated with heavier vascular risk and CSVD co-pathology, in terms of both HTNA and CAA. The difference between groups seems to be mainly driven by CSVD features affecting the white matter, more severe in LOAD. However, CSVD burden in EOAD is not negligible, supporting routine vascular co-pathology assessment across age.

Disclosure: Nothing to disclose.

EPO-0352 | Medium-vessel occlusion recanalisation after medical management, and clinical outcome

¹Stroke Center, Neurology Service, Department of Clinical Neurosciences, Lausanne, Switzerland; ²Neuroradiology Unit, Service of Diagnostic and Interventional Radiology, Department of Medical Radiology, both at the Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland

Methods: From our local stroke registry we included all consecutive patients with MeVO-AIS receiving CTr or IVT. IPR was defined as complete recanalisation on 12–24-hour CTA/MRA. Clinical outcome was 24h-NIHSS and 3-month modified-Rankin-Scale (mRS). The association of treatment (CTr vs. IVT) and recanalisation (IPR vs. no IPR) with clinical outcomes was assessed using propensity-score-weighted regression models. Weighting accounted for pre-stroke mRS, baseline NIHSS, age, sex, onset-to-door time, MeVO localisation, vascular risk factors.

Results: Among 229 patients with MeVO, 52 received CTr and 177 IVT. Overall, 114 had IPR. Patients with IPR had more M3 occlusions, fewer P1-P3 occlusions, and shorter onset-to-door times. IVT was significantly associated with IPR (aOR = 16.8,

FIGURE 1 Forest plot of binary/categorical outcomes.

95% CI=5.37–48.74) but not with 3-month mRS. In the overall cohort, IPR was associated with greater 24-hour NIHSS improvement (beta-coeff=1.93, 95% CI=0.39–3.47), better 3-month mRS (pswOR=2.50, 95% CI=1.56–4.00), and higher rates of excellent outcome (mRS 0–1, pswOR=3.10, 95% CI=1.72–5.59). The same associations between IPR and clinical outcomes were observed in the cohort of IVT-treated patients

Conclusion: In MeVO-AIS treated with medical management, IPR is associated with improved functional outcome. While IVT increased the likelihood of IPR, persistent occlusion remained frequent, suggesting that more effective revascularisation strategies are needed to improve recanalisation rates and thus clinical outcomes.

EPO-0353 | Neuroanatomical correlates in stroke-related ipsilateral hemiparesis: Single center experience and review of the literature

F. Fenter¹; D. Strambo¹; A. Vicino¹; E. Dirren³; V. Dunet²; P. Michel¹
¹Stroke Center, Neurology Service, Department of Clinical Neurosciences, Lausanne, Switzerland; ²Neuroradiology Unit, Service of Diagnostic and Interventional Radiology, Department of Medical Radiology, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; ³Stroke Center, Neurology Service, Geneva University Hospital, Geneva, Switzerland

Background and aims: Ipsilateral hemiparesis (ILH) in stroke is rare and challenges the conventional understanding of motor system organization. We aim to describe ILH strokes from our academic stroke center, complemented by a literature review.

Methods: All patients with hemiparesis and an acute ischemic lesion on neuroimaging were selected from 2003–2023 in our stroke registry. ILH cases were identified, and all their investigations were reviewed, including MRI-tractography, functional MRI, and TMS (if performed). We also performed a review of the literature of ILH cases in ischemic and hemorrhagic strokes. We compared all identified cases with all patients with contralateral hemiparesis in our local registry.

Results: We found 4 ILH cases among 2,426 consecutive hemiparetic stroke patients (0.16%). MRI-tractography showed physiological corticospinal tract decussation and fMRI found bilateral motor activation in all 4. The systematic literature review

FIGURE 1 PRISMA search strategy results realized in December 2024.

FIGURE 2 fMRI (upper rows), and MR-tractography (third row) of our 4 ILH patients who all had left MCA ischemic strokes.

FIGURE 3 Multivariable binary regression model showing patients' ad stroke features independently associated with ILH. Results expressed as odds ratio (OR) and p-value. X-axis on logarithmic scale.

yielded 61 additional cases of ILH related to stroke, resulting in a total of 14 TMS, 18 fMRI, and 14 MRI-tractographic exams. In multivariable analysis, ILH was associated with younger age (beta=0.94; $p < 0.01$) and history of previous stroke (OR=7.99; $p < 0.01$). The additional investigations revealed evidence of corticospinal tract reorganization, aberrant interhemispheric connectivity, corticospinal tract anatomy variation, and involvement of secondary motor area as potential mechanisms.

Conclusion: ILH is a rare manifestation of acute stroke and seems to occur more frequently in younger patients with prior strokes. Our findings suggest that some ILH result from corticospinal reorganization and recruitment of secondary motor pathways, potentially highlighting the importance of neuroplasticity in post-stroke motor control.

Disclosure: Nothing to disclose.

EPO-0354 | **Clinical impact of systemic inflammatory response in ischaemic stroke due to atherosclerotic tandem lesions**

J. Andrada Moreno¹; M. Medina Rodríguez¹; P. Baena Palomino¹; L. Ainz Gómez¹; J. Cabezas Rodríguez¹; A. Hermosín Gómez¹; A. De Albóniga Chindurza²; M. Aguilar Pérez²; A. González García²; F. Moniche Álvarez¹; E. Zapata Arriaza²

¹Neurology, Hospital Virgen del Rocío, Seville, Spain;
²Interventional Neuroradiology, Hospital Virgen del Rocío, Seville, Spain

Background and aims: Systemic inflammatory response (SIR) is frequently elevated in patients with atherosclerotic ischaemic stroke. This study aimed to assess the clinical impact of SIR in patients with tandem lesions treated with mechanical thrombectomy (MT) and emergent carotid artery stenting (eCAS).

Methods: We analysed data from the prospective ARTISTA registry, including patients with ischaemic stroke secondary to atherosclerotic tandem lesions treated with MT and eCAS between 2019 and 2023. Baseline SIR were assessed using the neutrophil-to-lymphocyte ratio (NLR) on admission. Associations between NLR and acute carotid stent thrombosis (< 24 hours), symptomatic intracranial haemorrhage (sICH), poor functional outcome (modified Rankin Scale [mRS] > 3), and 3-month mortality were evaluated using multivariable binary logistic regression models adjusted for age, sex, and predefined covariates.

Results: 149 patients were included; 78.5% were male, with a median age of 67years (IQR 60–77). The median NLR was 1.13 (IQR 0.67–2.16). Acute stent thrombosis occurred in 9 patients (6.7%), sICH in 14 (9.4%), poor functional outcome in 63 (42.3%), and 30 patients (20.1%) died within 3 months. After adjustment for age and sex, higher baseline NLR remained independently associated with acute carotid stent thrombosis (adjusted odds ratio [aOR] 1.08, 95% CI 1.01–1.16; $p=0.02$), but not with sICH, poor functional outcome, or mortality. This association persisted after further adjustment for antiplatelet therapy.

Conclusion: Patients with tandem lesions and elevated baseline SIR are at increased risk of acute carotid stent thrombosis. These findings may guide future studies to identify patients who could benefit from intensified periprocedural antithrombotic strategies.

Disclosure: Nothing to disclose.

EPO-0355 | **Impact of liver fibrosis on stroke outcomes in patients with intracranial atherosclerotic stenosis: A swiss cohort study**

K. Mettler¹; L. Siegenthaler¹; M. Reichmuth¹; K. Antonenko¹; N. Slavova¹; W. Almiri²; A. Antonenko³; A. Hakim²; M. Heldner¹

¹Department of Neurology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; ²Institute of Diagnostic and Interventional Neuroradiology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; ³Department of Visceral Surgery and Medicine, Inselspital, University Hospital and University of Bern, Bern, Switzerland

Background and aims: Chronic liver disease (CLD) is increasingly recognized as a contributor to cardiovascular disease, but its relationship with intracranial atherosclerotic stenosis (ICAS) and stroke outcomes remains underexplored. This study aimed to investigate the association between liver fibrosis, assessed by the FIB-4 score, and outcomes in acute ischemic stroke patients with/out ICAS.

Methods: We performed a retrospective observational cohort study using data from the Bernese Stroke Registry. A total of 500 patients with acute ischemic stroke (admitted 04/2022–12/2023) were categorized into four groups based on FIB-4 score (≤ 3.25 / > 3.25) and ICAS presence (yes/no). Clinical

characteristics, vascular risk factors, ICAS location, treatment, and 3-months outcomes were compared.

Results: Patients with high FIB-4 scores were significantly older (median 82.5 vs. 71 years, $p < 0.001$) and had a higher burden of atrial fibrillation and renal insufficiency (both $p < 0.001$). Arterial hypertension was more prevalent in ICAS groups (83.6/86.7% vs. 67.3/68.2%, $p < 0.001$), while hypercholesterolemia was less frequent in high-FIB-4 groups ($p = 0.028$). No significant differences were found in acute revascularization therapies. Patients with FIB-4 > 3.25 and ICAS had significantly poorer 3-months outcomes: only 10.3% achieved an excellent outcome ($mRS \leq 1$) compared to 36.3% in the low FIB-4/no ICAS group ($p = 0.030$), recurrent ischemic stroke was more frequent (7.1% vs. 1.6%; $p = 0.041$) and mortality was significantly elevated (43.3% vs. 13.3%; $p < 0.001$).

Conclusion: High liver fibrosis (FIB-4 > 3.25) is linked to worse outcomes in acute ischemic stroke, particularly with ICAS, including more recurrent stroke, and worse 3-months functional outcome, highlighting the value of assessing liver fibrosis in stroke prognosis.

Disclosure: None.

EPO-0356 | Stroke in people living with HIV and 6-month outcomes in northwestern Tanzania

L. Mwamba¹; E. Bukelebe²; I. Paul²; J. Ngimbwa³; M. Basinda²; B. Andrew⁴; A. Paul²; A. Mawazo⁵; D. Lucas⁴; L. Rudovick⁴; B. Wajanga⁴; S. Kalluvya²; P. Olowoyo⁶; R. Peck⁷; S. Matuja²

¹Department of Neurology, First Affiliated Hospital of Jinzhou Medical University, Liaoning, China; ²Department of Internal Medicine, Catholic University of Health and Allied Sciences-Weill Bugando School of Medicine, Mwanza, Tanzania; ³Department of Internal Medicine, Aga Khan University, Dar-es-salaam, Tanzania; ⁴Department of Internal Medicine, Bugando Medical Center, Mwanza, Tanzania; ⁵Department of Microbiology and Immunology, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania; ⁶Department of Medicine, Federal Teaching Hospital Ido-Ekiti, Afe Babalola University, Ado-Ekiti, Nigeria; ⁷Center for Global Health, Department of Internal Medicine, Weill Cornell Medicine, New York, USA

Background and aims: HIV patients face a higher risk of stroke, either ischemic or hemorrhagic, which is often associated with traditional risk factors. We aimed to evaluate the current trends, characteristics, and 6-month outcomes among people living with HIV (PLWH) compared to people without HIV (PWOH).

Methods: This prospective cohort study included 463 adults with stroke registered in the Lake Zone Stroke Registry at Bugando Medical Center between November 2023 and March 2025. Baseline characteristics, stroke severity, and outcomes were assessed using the National Institutes of Health Stroke Scale (NIHSS) and the modified Rankin Scale (mRS), respectively. The Kaplan-Meier analysis was used to describe survival, and the Cox regression model to determine predictors of mortality.

Results: We analyzed 295 adults, with an HIV proportion of 8.8% (95% CI: 5.9%–12.7%) (26/295). The mean age (SD) for the overall study cohort was 66.2 ± 37.4 years, and 57.2% (164/295) were males. Among PLWH, the mean age (SD) was 53.2 ± 14.5 years,

FIGURE 1 Kaplan Meier survival probability by difficulty in breathing.

FIGURE 2 Kaplan Meier survival probability by leukocyte count.

FIGURE 3 Kaplan Meier survival probability by stroke severity based on NIHSS scores.

and females were 61.5% (16/26). The median CD4 count was 518 IQR (151.5–571) cells/ μ L, and 84.6% (22/26) were naïve to antiretroviral therapy (ART). PLWH experienced longer hospital stay, 5 days (IQR 2–7.3), $p = 0.001$. Both groups experienced poor functional outcomes, mRS 3–6, 84.7% (250/295), and a mortality rate of 38.5% (114/295) at 6 months. In the multivariate analysis, difficulty in breathing, leukocytosis, and NIHSS scores of 21–42 were independent predictors of mortality.

Conclusion: Although 6-month outcomes were comparable between both groups, targeted strategies are needed to address healthcare disparities and reduce the additional burden of stroke in PLWH.

Disclosure: Nothing to disclose.

Background and aims: Cerebral venous thrombosis (CVT) is associated with a risk of late seizures, particularly in patients with severe disease requiring decompressive surgery. The DIAS³ score was developed to predict late seizures after CVT, but its performance in surgically treated patients is unknown. We aimed to validate the DIAS³ score in a high-risk cohort of CVT patients treated by decompressive surgery.

Methods: This was a substudy of the DECOMPRESS2 – a prospective, multicentre cohort, including patients with CVT treated with decompressive surgery. Late seizures were defined as those occurring more than 7 days after CVT diagnosis, up to

1 year follow-up. DIAS3 score was calculated for all included patients. Predictive performance was assessed only for the 1-year risk of late seizures. Discrimination was evaluated using receiver operating characteristic analysis, and calibration by comparing predicted and observed seizure risks. Diagnostic performance was assessed across multiple probability thresholds.

Results: Eighty-nine patients were included (mean age 37.3 years; 69.7% female). Late seizures occurred in 22 patients (24.7%). The mean predicted 1-year seizure risk according to the DIAS³ score was 28.4%. The DIAS³ score showed poor discrimination (area under the curve 0.44, 95% confidence interval

FIGURE 1 ROC curve for late seizure prediction using the DIAS3 score in the DECOMPRESS2 cohort (AUC=0.44, 95% CI 0.30–0.59). The dashed diagonal line represents the reference line of no discrimination.

FIGURE 2 Calibration plot for late seizure prediction using the DIAS3 score in the DECOMPRESS2 validation cohort (n = 89).

0.30–0.59) and poor calibration. Across all tested thresholds, sensitivity and specificity showed an expected trade-off, but overall predictive accuracy was limited.

Conclusion: The DIAS³ score demonstrated poor discrimination and calibration in CVT patients treated by decompressive surgery. These findings suggest that the DIAS³ score should not be used to predict late seizures in this high-risk surgical subgroup.

Disclosure: Nothing to disclose.

EPO-0358 | Impact of ambient temperatures on ischemic stroke characteristics and in-hospital recurrence in a swiss cohort

I. Rizzo¹; F. Huber¹; C. Bouverat¹; M. Costa¹; L. Siegenthaler¹; K. Antonenko¹; T. Dobrocky²; E. Piechowiak²; T. Bremova-Ertl¹; M. Heldner¹

¹Department of Neurology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; ²Institute of Diagnostic and Interventional Neuroradiology, Inselspital, University Hospital and University of Bern, Bern, Switzerland

Background and aims: The association between ambient temperatures and ischemic stroke remains poorly characterized in Europe. This study aimed to examine the influence of acute heat and cold exposure on stroke characteristics.

Methods: We conducted a retrospective cohort study of 500 patients experiencing a first ischemic stroke, using data from the Bernese Stroke Registry (09/2018–12/2020). Patients were categorized based on the temperature on the day of stroke: normal (0–30°C; $n=365$), hot ($>30^{\circ}\text{C}$; $n=22$), and cold ($<0^{\circ}\text{C}$; $n=113$). Stroke etiology, vascular risk factors, and in-hospital stroke recurrence were compared across temperature groups.

Results: Cardioembolism was the most prevalent stroke etiology across all temperature groups, with the highest proportion observed in the cold group on the day prior to stroke (43.9%). Coronary heart disease prevalence was significantly higher in the hot group (41.7%) compared with the normal temperature group (20.1%; $p=0.039$). The incidence of new in-hospital ischemic strokes was markedly elevated in the extreme temperature groups: 36.4% in the hot group and 18.0% in the cold group, versus 8.9% in the normal temperature group ($p<0.001$). Temperature on the stroke day was also associated with significant differences in stroke etiology ($p=0.014$), with cardioembolism observed in 38.9% of patients in the cold group. No significant differences were noted for other vascular risk factors, occlusion location, or acute interventions.

Conclusion: Extreme temperatures influence ischemic stroke profiles and in-hospital recurrence. Heat is associated with increased cardiovascular comorbidity and recurrence risk, while cold exposure favors cardioembolic strokes, suggesting delayed cardiovascular effects. These findings underscore ambient temperature as a clinically relevant, modifiable stroke risk factor.

Disclosure: None.

EPO-0359 | Association of admission LDL cholesterol with clinical profile and 3 months outcomes after ischaemic stroke

M. Costa¹; C. Berger¹; K. Antoneko¹; M. Peycheva²; M. Krasteva³; A. Scutelnic¹; A. Hakim⁴; M. Kielkopf¹; H. Sarikaya¹; M. Heldner¹

¹Department of Neurology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; ²Department of Neurology, Medical University Plovdiv, Plovdiv, Bulgaria; ³Department of Neurology, Inselspital, University Hospital and University of Bern, Bern, Switzerland and Department of Neurology, University Hospital Queen Giovanna, Sofia, Bulgaria; ⁴Institute of Diagnostic and Interventional Neuroradiology, Inselspital, University Hospital and University of Bern, Bern, Switzerland

Background and aims: While low-density lipoprotein cholesterol (LDL-C) is a well-established modifiable risk factor for stroke, recent evidence suggests a “lipid paradox,” where low LDL-C levels may be associated with worse outcomes.

Methods: In this retrospective cohort study, we analyzed 1634 patients aged ≥ 18 years admitted to the Bernese Stroke Centre (02/2015–03/2023). We investigated the association between admission LDL-C levels and clinical characteristics after first-ever acute ischaemic stroke. Patients were stratified into five LDL-C groups: >3.0 mmol/L ($n=493$), 2.6–3.0 mmol/L ($n=225$), 1.8–2.6 mmol/L ($n=490$), 1.4–1.8 mmol/L ($n=254$), and <1.4 mmol/L ($n=172$). Functional outcome was assessed at 3 months.

Results: Patients with LDL-C <1.4 mmol/L were older (median 78 vs. 73 years; $p<0.001$), more often male (59% vs. 44%; $p<0.001$), and had a higher burden of comorbidities, including arterial hypertension, coronary heart disease, atrial fibrillation, heart failure, and renal impairment (all $p<0.001$). Over 70% of patients in the lowest LDL-C group were already receiving lipid-lowering therapy at admission, versus $<10\%$ in the highest group ($p<0.001$). Laboratory markers associated with frailty showed significant differences: haemoglobin levels were lower (124 vs. 139 g/L; $p<0.001$) and creatinine levels higher (92 vs. 79–83 $\mu\text{mol/L}$; $p<0.001$) in the lowest versus highest LDL-C group. Favourable (mRS 0–2) and excellent (mRS 0–1) functional outcomes at 3 months declined across groups (42% to 29% and 36% to 23%, respectively), as did survival (80% to 61%; all $p<0.05$).

Conclusion: Low LDL-C at stroke onset identifies older, multimorbid, and frail patients with poorer 3 months outcomes, likely reflecting underlying vulnerability and comorbidities rather than independently causing poor prognosis.

Disclosure: None.

EPO-0360 | CLadribine tablets level of respOnse preDICTors in cliNical practice: Interim analysis of CLODINA

R. Hupperts¹; A. Kalinowska-Lyszczarz²; T. Reynders³; J. Sequeira⁴; M. Vachová⁵; S. Deftereos⁶; A. Antonakopoulou⁶; P. Vandenberk⁷; P. Rane⁸; N. Grigoriadis⁹

Background and aims: CLODINA is a multicenter, Phase IV ambispective, non-interventional study in patients diagnosed with RMS who have received cladribine tablets, aiming to identify baseline patient characteristics predicting the time to treatment discontinuation in real-world. Secondary objectives are to assess relapses, disability progression and improvement, MRI activity, and safety.

Methods: This interim analysis, conducted after 50% of patients completed the 2-year follow-up, reports Annualized Relapse Rate (ARR), disability progression and improvement, and MRI data descriptively. A predictive model for discontinuations was not created, as it would be superseded by the final analysis.

Results: The Full Analysis Set included 365 patients (33.7% prospective, 66.3% retrospective); median age was 38 years. 72.1% were female, and 73.4% (268) had received a DMT prior to cladribine tablets, with 79.4% (213) switching from platform therapies and 20.6% (55) from high-efficacy therapies. The main reason for switching was inadequate response to prior DMT; psychiatric disorders were the most common comorbidities (15.3%). MRI assessment within 12 months before the index date was available for 98.9% of patients. At year 2, relapse data were available for 87.1% of patients, and ARR was 0.08 (0.03, 0.08). 298 patients (81.6%) were relapse-free. 6-month confirmed disability progression/improvement was seen in 4.1% and 3.3%. 233 patients had available MRI data at year 2, of whom 189 (81%) were free from MRI activity. 19.7% reported adverse events.

Conclusion: Cladribine tablets are highly effective, showing low ARR over a 2-year follow-up, with a generally safe and well-tolerated profile.

EPO-0361 | Post-hoc analysis of the OPTIMUM long-term extension study: Preservation of independent ambulation in patients treated with Ponesimod

M. Martínez Gines¹; M. Heubl²; S. de Guitaut²; A. Sarfati²; A. Atallah²

¹Neurology Department, Hospital Gregorio Marañón, Madrid, Spain; ²Medical Affairs Department, Juvise Pharmaceuticals, Paris, France

Background and aims: Disability accumulation in relapsing multiple sclerosis (RMS) is commonly quantified using the Expanded Disability Status Scale (EDSS). Reaching EDSS 6 marks the need for an ambulatory aid, while EDSS 7 reflects loss of independent ambulation and wheelchair dependence, representing major milestones in long-term disease burden.

Methods: Following 108 weeks of double-blind treatment with ponesimod 20 mg or teriflunomide 14 mg in the core OPTIMUM study, participants could enter the long-term extension (LTE) and receive open-label ponesimod 20 mg. This post hoc analysis confirmed EDSS 6 and EDSS 7 over a follow-up of up to 7 years. Kaplan–Meier estimated the cumulative incidence of reaching these disability milestones.

Results: Overall, 1133 patients were randomized in the core study, and 877 entered the LTE. At core baseline, mean EDSS was 2.56 ± 1.20. Median cumulative exposure to ponesimod during the combined core plus LTE period was 6.3 years (IQR

FIGURE 1 EDSS superior or equal to 6 free probability, Kaplan-Meier curve, combined analysis period.

FIGURE 2 EDSS superior or equal to 7 free probability, Kaplan-Meier curve, combined analysis period.

FIGURE 3 EDSS superior or equal to 6 free probability, Kaplan-Meier curve, extension period.

2.8–6.7). Among patients treated continuously with ponesimod ($n=567$), 86.8% had not reached EDSS 6 (Figure 1) and 98.7% had not reached EDSS 7 by week 360 (Figure 2). During the LTE period, 90.5% of patients remained free from EDSS 6 (Figure 3) (92.3% in those initially randomized to ponesimod and 88.8% in those initially randomized to teriflunomide), and 99.3% remained free from EDSS 7 (99.1% and 99.5%, respectively).

Conclusion: This post-hoc analysis of OPTIMUM-LTE shows a sustained preservation of mobility and functional independence with ponesimod over up to 7 years of follow-up, supporting its durable efficacy in patients with RMS.

EPO-0362 | The effect of cladribine tablets on retinal microglial activity in relapsing multiple sclerosis: Optical coherence tomography findings from MAGNIFY-MS

D. Jakimovski¹; J. Havla²; L. Leocani³; M. Danten⁴; L. Gardner⁵; N. De Stefano⁶

¹Buffalo Neuroimaging Analysis Center, Department of Neurology, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, State University of New York, Buffalo, USA; ²Institute of Clinical Neuroimmunology, LMU University Hospital, LMU Munich, Munich, Germany; ³University Vita-Salute San Raffaele, Milan, Italy; ⁴Global Biostatistics, Merck Santé S.A.S, Lyon, France, an affiliate of Merck KGaA; ⁵EMD Serono Research & Development Institute Inc, Billerica, USA, an affiliate of Merck KGaA; ⁶Department of Medicine, Surgery and Neuroscience, University of Siena, Siena, Italy

Background and aims: Hyperreflective foci (HRF) are retinal punctate structures, observable with optical coherence tomography (OCT), and are potential neuroinflammatory biomarkers. Pathological correlates of HRF may be microglial accumulation. We evaluated the presence and change of HRF in cladribine tablets (CladT)-treated people with highly-active relapsing multiple sclerosis (pwRMS) over 24 months and determined relationships with clinical and magnetic resonance imaging (MRI) outcomes. **Methods:** Overall, 36 pwRMS enrolled in the OCT sub-study in MAGNIFY-MS (NCT03364036). Clinical (progression independent of relapse activity [PIRA]) and MRI (lesions and brain volume) outcomes were analysed. Total HRF (sum of HRF in the ganglion cell inner plexiform layer [GCIPL] and inner nuclear layer [INL]), GCIPL-HRF, and INL-HRF were determined by OCT. All outcomes measured at baseline, month (M) 12, and M24. Linear regression models were used; data are presented as mean and standard deviation. HRF analysis was performed by an experienced rater (D.J.).

Results: From baseline to M24, CladT significantly decreased the total number of HRF ($p=0.007$) and GCIPL-HRF ($p=0.002$; Table 1). Compared to MRI-stable pwRMS, those with in-trial MRI activity had higher baseline GCIPL-HRF (5.6 vs. 3.0, $p=0.032$), and a larger decrease in GCIPL-HRF over 24 months (-2.6 vs. -0.6 , $p=0.013$; Table 2). PIRA activity was associated with baseline INL-HRF ($p=0.034$). Total baseline HRF was the only predictor of 12-month brain volume loss ($R^2=0.323$, $p=0.038$).

Conclusion: In our exploratory analysis, CladT treatment reduced overall HRF burden in pwRMS. Baseline GCIPL-HRF was associated with early inflammatory activity, whereas INL-HRF was associated with chronic neurodegenerative changes.

FIGURE 1 ATE-weighted risk of new T2 lesions at 18 months in patients treated with ocrelizumab (OCR) or siponimod (SIP). Error bars represent 95% confidence intervals derived from stabilized inverse probability weighting.

FIGURE 2 IPW-weighted Kaplan–Meier curves for confirmed disability progression over 18 months in patients treated with ocrelizumab or siponimod. Shaded areas indicate 95% confidence intervals.

Background and aims: We compared the effectiveness and safety of siponimod (SIP) versus ocrelizumab (OCR) in real-world cohort of patients with secondary progressive multiple sclerosis (SPMS).

Methods: We retrospectively included SPMS patients from five Italian centers initiating SIP or OCR and followed-up for 18 months. Outcomes included time to first relapse, annualized relapse rate (ARR), confirmed disability progression (CDP), progression independent of relapse activity (PIRA), MRI activity at 18 months (new T2 lesion or Gd+ lesion), and safety. Baseline differences were addressed using stabilized inverse probability of treatment weighting and overlap weighting. Weighted Cox and negative binomial models were applied.

Results: Among 182 patients (98 OCR; 84 SIP; mean age 50.9 years), clinical outcomes were similar: time to first relapse SIP vs OCR (HR 1.41; 95% CI 0.58–3.45; $p=0.451$); recurrent relapses (HR 1.20; 0.52–2.76; $p=0.667$); CDP (HR 0.83; 0.38–1.82; $p=0.643$); PIRA (HR 0.86; 0.38–1.94; $p=0.708$); ARR (IRR 1.78; 0.83–3.81; $p=0.136$). MRI activity at 18 months differed between groups, with new lesions occurring more frequently under SIP (OR 9.12; 1.26–66.34; $p=0.029$), confirmed in overlap-weighted analysis (OR 7.14; 1.09–46.63; $p=0.040$). SIP was associated

with lower white blood cells/lymphocytes/neutrophils (all $p < = 0.0037$) and higher liver enzymes ($p < = 0.049$); infection and adverse-event rates were similar.

Conclusion: In SPMS, short-term clinical outcomes were comparable between SIP and OCR, whereas MRI activity at 18 months differed, with higher odds of new lesions under SIP. When disability endpoints fail to discriminate over short follow-up, suppression of subclinical inflammatory MRI activity may represent the key differentiator guiding treatment choice, particularly in patients with residual inflammatory activity.

EPO-0364 | Evaluating the value of serum neurofilament light chain after DMT initiation for monitoring early treatment response

F. Föttinger; J. Nolte; N. Krajnc; M. Ponleitner; F. Leutmezer; T. Monschein; P. Rommer; C. Schmied; B. Kornek; T. Zrzavy; G. Zulehner; T. Berger; G. Bsteh
Medical University of Vienna, Department of Neurology, Vienna, Austria

Background and aims: Serum neurofilament light chain (sNfL) is an established biomarker of axonal injury in multiple sclerosis (MS). While sNfL typically decreases with effective disease-modifying therapy (DMT), it remains unclear whether early post-initiation sNfL levels or their change predict treatment response. We evaluated sNfL as an early biomarker of DMT response in relapsing MS (RMS).

Methods: Within an ongoing prospective observational cohort at the Medical University of Vienna, we included patients with RMS newly initiating any DMT. Serum NfL was measured at treatment start (baseline) and at 6 months and expressed as age- and BMI-adjusted z-scores. Minimum follow-up was 24 months. Treatment failure (EDA-3) was defined by relapse, MRI activity, and/or confirmed disability progression.

Results: Ninety-two patients were analyzed (mean age 35 ± 8 years; 71% on high-efficacy DMT); 22 (24%) developed EDA-3 during follow-up. Baseline sNfL was not significantly associated with subsequent EDA-3 (aOR 1.36, 95% CI 0.90–1.99; $p = 0.20$). At 6 months, median sNfL z-scores were lower in those remaining relapse-free (0.03 in NEDA-3 vs 1.94 in EDA-3; $p < 0.001$; change of Δz -0.94 vs 0.01; $p = 0.014$). Discrimination for future EDA-3 was moderate for both absolute 6-month z-scores (AUC 0.752; optimal cut-off 0.935) and Δz -scores (AUC 0.733; cut-off -0.811), with high negative predictive values (95.6% and 97.8%). In multivariable analysis, 6-month absolute z-scores predicted future EDA-3 (aOR 3.40, 95% CI 1.91–7.07; $p = 0.017$).

Conclusion: Six-month sNfL z-scores, particularly their normalization after DMT initiation, may early identify patients with favorable treatment response in RMS.

EPO-0365 | CAR T-cell therapy in neuroimmunological diseases – The vienna model (Neuro CAR-T Vienna)

G. Bsteh¹; P. Rommer¹; T. Zrzavy¹; L. Haider²; N. Worel³; E. Han³; K. Phan³; W. Rabitsch⁴; N. Dominik⁴; H. Lechner-Radner⁵; J. Marschalek⁶; T. Berger¹; A. Müller³

¹Department of Neurology, Medical University of Vienna, Vienna, Austria; ²Department of Neuroradiology, Medical University of Vienna, Vienna, Austria; ³Department of Transfusion Medicine and Cell Therapy, Medical University of Vienna, Vienna, Austria; ⁴Department of Internal Medicine I, Bone Marrow Transplantation Unit, Medical University of Vienna, Vienna, Austria; ⁵Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; ⁶Department of Obstetrics and Gynaecology, Medical University of Vienna, Vienna, Austria

Background and aims: Chimeric antigen receptor (CAR) T-cell therapies have undergone rapid development in recent years, with increasing evidence supporting their efficacy and safety in severe, treatment-refractory autoimmune diseases of the nervous system. In response, the Medical University of Vienna has established Austria's first center dedicated to the application of CAR T-cell therapy in neuroimmunological disorders.

Methods: The Neuro CAR-T Vienna model is based on a structured, interdisciplinary collaboration between Neurology, Transfusion Medicine & Cell Therapy, and Hemato-Oncology, with additional involvement of Rheumatology, Neuroradiology, and Gynecology. Central to the model is an interdisciplinary CAR T-cell board, where patients are systematically evaluated and indications reviewed. Referrals are accepted for patients with neuroimmunological diseases that are insufficiently controlled by conventional therapies and carry a high risk of a deleterious disease course. Evaluation requires comprehensive documentation of disease and treatment history, current imaging and laboratory findings, and confirmation of the patient's willingness and psychological suitability for an invasive therapy.

Results: CAR T-cell therapy may be administered either as an individual compassionate-use treatment using in-house manufactured CAR T cells or within clinical trials. Patients receive comprehensive interdisciplinary counseling, including potential effects on fertility and family planning, with fertility preservation options discussed when appropriate. For pharmacovigilance purposes, treated patients commit to a structured

FIGURE 1 Neuro CAR-T Vienna.

long-term follow-up with at least annual assessments for a minimum of five years.

Conclusion: The Neuro CAR-T Vienna model represents Austria's first standardized interdisciplinary framework for CAR T-cell therapy in neuroimmunological diseases, enabling safe, transparent, and patient-centered implementation and serving as a reference model for future national expansion.

Disclosure: Nothing to disclose.

EPO-0366 | Efficacy and safety of fenebrutinib vs teriflunomide in relapsing multiple sclerosis: Results of the FENhance 1 and 2 studies

Hoffmann-La Roche Ltd, Basel, Switzerland; ⁹Genentech, Inc, South San Francisco, USA; ¹⁰University Hospital and University Basel, Research Center for Clinical Neuroimmunology and Neuroscience (RC2NB), Basel, Switzerland; ¹¹University of California San Francisco, San Francisco, USA

Background and aims: Bruton's tyrosine kinase inhibitors (BTKis) may address both relapsing and progressive disease biologies in multiple sclerosis (MS) via a dual mechanism of action. Phase III trials in patients with relapsing MS (RMS) have not met their primary endpoint in showing that covalent, irreversible BTKis reduce annualized relapse rate (ARR) vs teriflunomide. The objective of the FENhance Phase III studies was to evaluate the efficacy and safety of fenebrutinib—a noncovalent, reversible, highly selective BTKi—vs teriflunomide in adults with RMS.

Methods: FENhance 1 (NCT04586010) and FENhance 2 (NCT04586023) are two identical Phase III, multicenter, randomized, double-blind, double-dummy, parallel-group studies enrolling adults aged 18–55 years with RMS (2017 revised McDonald criteria; Expanded Disability Status Scale [EDSS] score 0–5.5). Patients were randomized 1:1 to oral fenebrutinib 200 mg twice daily or teriflunomide 14 mg once daily for a minimum of 96 weeks. The primary endpoint was ARR.

Results: In total, 1497 patients were enrolled globally. The mean (SD) age at baseline was 35.8 (9.4) years, mean (SD) EDSS score was 2.5 (1.3) and 66.5% were female. The mean (SD) duration since MS symptom onset was 5.5 (5.9), and mean (SD) duration since diagnosis was 3.6 (5.1) years. Primary efficacy and safety data from both FENhance studies will be presented.

Conclusion: While other BTKis have not shown superiority to teriflunomide in suppressing disease activity, the FENhance trials will determine whether fenebrutinib's unique molecular

design, optimized CNS exposure and promising Phase II results translate into significant benefits in RMS.

EPO-0367 | Anti-CD20 drugs and Natalizumab confer equal protection against progression independent of relapse activity (PIRA) in people with multiple sclerosis

L. Palazzo¹; F. Clarelli²; M. Surano¹; A. Giordano¹; L. Moiola¹; M. Rocca¹; M. Filippi¹; F. Esposito¹

¹Neurology Unit and MS Center, IRCCS Ospedale San Raffaele, Milan, Italy; ²Laboratory of Human Genetics of Neurological Disorders, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background and aims: Highly effective (HE) disease-modifying therapies (DMTs) reduce relapse-associated worsening (RAW) and progression independent of relapse activity (PIRA). Natalizumab (NTZ) and anti-CD20 agents show similar efficacy on relapse suppression, but long-term comparative data on PIRA are limited. We aimed to compare PIRA accrual in relapsing-remitting MS (RRMS) patients treated with NTZ and anti-CD20 drugs over a long follow-up.

Methods: We included RRMS patients followed at our centre and recorded in the Italian MS and Related Disorders Register with at least 5 years of continuous treatment with NTZ or anti-CD20 agents (Ocrelizumab, Rituximab, Ofatumumab), at least 3 Expanded Disability Status Scale (EDSS) assessments, and complete demographic and clinical data. Patients were matched for sex, age at treatment initiation, and disease duration. Logistic regression and Cox proportional hazard models were applied.

Results: Of 267 eligible patients (178 NTZ, 89 anti-CD20), optimal matching yielded 89 balanced pairs. A first PIRA event was observed in 37.1% of NTZ-treated and 32.6% of anti-CD20-treated patients. Although the absolute number of PIRA events was higher in the NTZ group (47 vs 30; $p=0.015$), adjusted analyses revealed no significant differences in cumulative risk (RR: 1.15; 95% CI: 0.57–2.37; $p=0.692$) or time to first PIRA event (HR: 1.21; 95% CI 0.47–1.39; $p=0.446$).

Conclusion: In this real-world cohort with long-term follow-up, NTZ and anti-CD20 therapies conferred comparable protection in controlling disability progression beyond relapse, leaving space for further survey, desirably in a larger cohort, to confirm and refine these observations.

Disclosure: Nothing to disclose.

Background and aims: Ocrelizumab has been approved for both relapsing and primary progressive multiple sclerosis (MS), but the impact of this treatment on brain innate immune cell neuro-inflammation remains unknown.

Methods: People with MS (PwMS) aged 18–60 years with relapsing–remitting (RRMS), active secondary progressive (SPMS), or primary progressive MS (PPMS) underwent neurological evaluation and a 90-min dynamic PET–MR using the [18F] DPA714 TSPO tracer at baseline and at months 6 and 24 after ocrelizumab initiation. Ocrelizumab was administered as 600-mg infusions every 24 weeks. Age-, sex-, and TSPO-genotype-matched healthy controls underwent a single PET–MR scan. The primary outcome was the change in active voxels in total white matter (TWM) between baseline and month 24, defined using [18F] DPA714 thresholds derived from comparisons with controls. Secondary analyses assessed longitudinal changes at months 6 and 24 and within MS subgroups.

Results: Thirty-seven PwMS completed all evaluations. The proportion of DPA-active voxels in TWM was not significantly reduced between month-24 and baseline (median relative change: +3.58% [–43.32%,+23.98%]; $p=0.86$), but decreased significantly between baseline and month 6 (–26.75% [–39.86%,–10.61%]; $p=0.017$), with a subsequent increase trend between month-6 and -24. Significant reductions between baseline and month 6 were observed in TWM and normal-appearing WM in RRMS patients ($p=0.027$, 0.037) and in lesions in RRMS and SPMS subjects ($p=0.005$, 0.035). No significant longitudinal changes were detected in PPMS subjects.

Conclusion: Ocrelizumab initiation was associated with reduced white matter neuroinflammation at month 6, an effect that was no longer detectable at month 24.

EPO-0369 | Characterizing patient profiles linked to treatment persistence in multiple sclerosis: Federated analysis of clinical real-world data in different healthcare systems

V. Illiano¹; M. Elze¹; G. Zilborri¹; A. Morgan²; T. Görbing³; N. Orr⁴; E. Longbrake²; T. Ziemssen³; L. Steinman⁴; B. Tackenberg¹; M. Antonin¹

¹F. Hoffmann-La Roche AG, Basel, Switzerland; ²Department of Neurology, Yale University, New Haven, Connecticut, USA; ³Department of Neurology, Dresden University of Technology, Dresden, Germany; ⁴Department of Neurology and Neurological Sciences, Stanford University, Stanford, California, USA

Background and aims: The therapeutic landscape of Multiple Sclerosis (MS) has evolved significantly in recent years and the treatment strategy has become a contentious debate. It has been shown that persistence is critical to treatment effectiveness. However, more real-world evidence is needed to understand correlates of persistence among people with MS (pwMS). In this study, we applied Federated Analysis (FA) to simplify data analysis across three sites in two countries, investigating covariates of treatment persistence and its effects on clinical and socioeconomic outcomes in MS across different healthcare systems.

Methods: The study cohorts included people with MS (pwMS) initiating a Disease Modifying Treatment (DMT) between 2018 and 2021 with at least 2 years of follow-up data. Persisters were defined as pwMS having continuous records of a certain class of DMT within the 2-year follow-up period. Outcomes were collected retrospectively, harmonized, and made available for FA. This approach keeps data localized at the institutions and transmits only aggregated data.

Results: We analyzed data of 2528 pwMS across three clinical sites (Dresden University of Technology, Stanford University and Yale University). 76.5% of pwMS were persisters. The likelihood of persistence was positively associated with treatment efficacy, age, and conversely with a lower risk of hospitalization or need for walking aids or wheelchairs.

Conclusion: We explored covariates of persistence and their association with clinical outcomes in different healthcare systems. The results will foster an understanding of the influence of different treatment approaches in the real-world and the benefits of leveraging FA spanning multiple healthcare systems.

EPO-0370 | Real-world short-term outcomes of ofatumumab and ocrelizumab in RR-MS

N. Cavalli¹; G. Boffa¹; E. Cipriano¹; S. Al Qudsi¹; F. Baldisseri¹; E. Capello²; A. Laroni¹; M. Inglese¹; C. Lapucci²

¹Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics and Maternal and child sciences, University of Genoa, Genoa, Italy; ²Neurology Unit, San Martino Hospital, Genoa, Italy

Background and aims: Real-world comparative data about ofatumumab (OFA) and ocrelizumab (OCR) efficacy and safety in multiple sclerosis (MS) are still scarce.

Methods: We compared efficacy and safety of our 103 relapsing–remitting (RR) MS OFA-treated patients with those of the first consecutive 103 RR-MS OCR-treated patients. Only OFA-treated patients with at least 6 months FU were included.

Results: OFA and OCR patients exhibited similar demographic and clinical features at baseline [OFA: 64.1% females, mean (SD) age 40.6 (10.4) years, disease duration (DD) mean 10.9 (9.7) years, median EDSS 1.5, 30.8% naïve; OCR: 59.2% females, mean age 39.5 (11) years, DD mean 11.5 (11.3) years, median EDSS 2.5, 15% naïve]. No patients showed relapses at 1-year and 2-year FU. At 1-year, comparing OFA and OCR no significant differences in terms of MRI activity [12/85 (14.1%) vs 19/103 (18.4%)] and PIRA events [3/85 (3.5%) vs 3/103 (2.9%)] were observed. 1-year No Evidence of Disease Activity-3 (NEDA-3) was achieved by 70/85 (82.4%) and 84/103 (81.6%) respectively. At 2-year, no significant differences in terms of MRI activity [8/38 (21.1%) vs 18/99 (18.2%)] and PIRA events [3/38 (7.9%) vs 9/99 (9.1%)] were observed. MRI activity occurred within the first 6 months of treatment (median 2.8 and 4 months respectively). At 2-year FU only one new cortical lesion (CL) was observed in the OCR cohort. At 2-year FU, severe infections were reported in 1 and 4 patients respectively (OFA: 1 urosepsis; OCR: 4 pneumonias, 2 during COVID-19 pandemic).

Conclusion: OFA and OCR showed similar short-term efficacy and safety. Our data demonstrated the efficacy of both therapies also in preventing CLs development.

Disclosure: GB received personal fees from Novartis and Roche. AL received fees for consultation, public speaking or both from Roche, Genzyme, Merck, Biogen, Novartis and Bristol-Myers Squibb. MI received grants from NIH, NMSS, FISM, and Ministero dell'Università e ricerca (MUR) and received fees for consultation from BMS, Janssen, Roche, Genzyme, Merck, Biogen and Novartis. CL has received honoraria for speaking, travel grants and participating in advisory boards from Merck, Sanofi, Novartis, Roche and Alexion. NC, EC, SAQ, FB and EC have nothing to disclose.

EPO-0371 | Real-world effectiveness of ocrelizumab: Altering the six-year disease trajectory in multiple sclerosis

O. Mammadov¹; U. Samadzade²; S. Alizada¹; C. Caliskan²; S. Ozakbas²

¹Department of Neurology, Dokuz Eylul University, Izmir, Türkiye; ²Department of Neurology, Izmir University of Economics, Izmir, Türkiye

Background and aims: Ocrelizumab is highly effective for relapsing and progressive multiple sclerosis (MS). We evaluated clinical trajectories during the three years preceding and six years following treatment initiation.

Methods: This retrospective study analyzed 268 patients (158 RRMS, 110 SPMS). Clinical outcomes were compared across three-year intervals: pre-treatment, Years 0–3, and Years 3–6. Effectiveness was assessed using annualized relapse rates (ARR), EDSS progression, and MRI activity. NEDA-3 (no relapses, no disability progression, and no new MRI lesions) was the primary endpoint. Regression models identified predictors for long-term NEDA-3 achievement.

Results: Patients showed dramatic improvement, particularly in Years 3–6 versus Years 0–3. Mean ARR fell from 1.00 to 0.03, MRI activity dropped from 31.5% to 1.5%, and disability progression slowed from 42.9% to 13.4%. By the second period, 84% of patients achieved NEDA-3. Notably, 76.5% of patients who lacked NEDA-3 in the first three years reached stability during the second period. For SPMS, early NEDA-3 achievement was the strongest predictor of long-term success (OR = 4.30, $p = 0.019$).

Conclusion: Ocrelizumab almost completely stops MS activity over a six-year period. The treatment's benefits increase over time, with the best results seen after the third year. Achieving stability early in treatment is key to long-term success, particularly for those with progressive MS.

Disclosure: Nothing to disclose.

Neuroimaging 1

EPO-0372 | Bayesian predictive validation of a multimodal Alzheimer disease modeling framework

B. Haji; Q. Zhang; A. Tahami Monfared
Eisai Inc., Tokyo, Japan

Background and aims: Disease-progression models inform cost-effectiveness analyses, payer decisions, and simulation studies of Alzheimer therapies. Multimodal latent models may improve biological fidelity, but their value for health-economic modeling depends on predictive validation. We evaluated calibration, accuracy, and decision relevance of a Bayesian latent trajectory model.

Methods: We analyzed 932 β -amyloid-positive participants from the Alzheimer's Disease Neuroimaging Initiative (ADNI) with repeated multimodal measures spanning neurodegeneration, amyloid/tau pathology, metabolism, neuroaxonal injury, and cognition. Probabilistic principal component analysis generated a harmonized latent severity score (PPC1). Hierarchical Bayesian regression estimated participant-specific trajectories.

Predictive validity was assessed using posterior predictive checks, cross-validated predictive error, predictive-interval coverage, widely applicable information criterion (WAIC), expected log predictive density, and Pareto-smoothed importance sampling leave-one-out cross-validation (PSIS-LOO).

Results: Posterior predictive distributions closely matched observed latent trajectories. Adding apolipoprotein E (APOE) genotype improved predictive accuracy while preserving calibrated uncertainty. Predictive-interval coverage was ~98%, supporting probabilistic sensitivity analysis. WAIC and expected log predictive density favored the genotype-augmented model by 16–22 points. PSIS diagnostics were stable with fewer influential observations, and conclusions were consistent across sensitivity analyses.

Conclusion: This validated multimodal Bayesian framework provides accurate, well-calibrated forward projections of Alzheimer progression with uncertainty suitable for decision modeling, supporting cost-effectiveness analyses, payer simulations, and trial-enrichment forecasting.

EPO-0373 | A multimodal latent severity axis for Alzheimer disease progression modeling

B. Haji; Q. Zhang; A. Tahami Monfared
Eisai Inc., Tokyo, Japan

Background and aims: Reliable quantitative severity scales are essential for disease-progression, value-based modeling, and simulation studies. Single-modality measures can misrepresent the interconnected biology of Alzheimer disease. We developed a multimodal latent disease-severity metric using probabilistic principal component analysis (PPCA) to integrate structural, molecular, metabolic, and cognitive signals into a biologically anchored index related to—but distinct from—clinical and biological staging.

Methods: Thirteen biomarkers from an amyloid-positive baseline cohort ($N=1,058$)—MRI atrophy, CSF tau and A β species, plasma neurofilament light, amyloid PET, FDG-PET, and cognitive scores—were harmonized, sign-aligned, and z-scaled after age and intracranial-volume adjustment where appropriate. PPCA was fit to the baseline matrix to define a latent coordinate system. Follow-up visits were projected using the PPCA conditional distribution to accommodate missing modalities, yielding a continuous severity axis (PPC1) robust to missingness. Structural stability was assessed by bootstrap resampling (100 replicates).

Results: PPC1 explained 38.7% of multimodal variance and was highly stable (loading correlations ≈ 0.997 ; score correlations ≈ 0.999). Loadings reflected coherent neurobiology spanning neurodegeneration, tau/amyloid dysregulation, metabolic decline, neuroaxonal injury, and cognitive impairment. Diagnostic groups aligned along an ordered continuum. PPC1 captures latent continuous severity inferred from multimodal patterns rather than a clinical stage, although its distribution tracked standard staging categories. Residual age effects were minimal after adjustment, and the multimodal score reduced noise relative to individual biomarkers.

Conclusion: PPCA yields a robust, biologically grounded severity index enabling cleaner longitudinal modeling, uncertainty propagation, and simulation inputs for value assessment.

Disclosure: All authors are employees of Eisai Inc.

EPO-0375 | Magnetic resonance neurography in neuralgic amyotrophy: Clinical and electrodiagnostic correlations

F. Greloni¹; J. Pastor Rueda²; E. Garat³; P. Totah⁴; F. Varela⁵; C. Cejas⁶; F. Barroso⁷

¹FLENI (Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia), Ciudad Autónoma de Buenos Aires, Argentina; ²FLENI (Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia), Ciudad Autónoma de Buenos Aires, Argentina; ³FLENI (Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia), Ciudad Autónoma de Buenos Aires, Argentina; ⁴FLENI (Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia), Ciudad Autónoma de Buenos Aires, Argentina; ⁵FLENI (Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia), Ciudad Autónoma de Buenos Aires, Argentina; ⁶FLENI (Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia), Ciudad Autónoma de Buenos Aires, Argentina; ⁷FLENI (Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia), Ciudad Autónoma de Buenos Aires, Argentina

Background and aims: Neuralgic amyotrophy (NA) is a non-traumatic peripheral nervous system disorder predominantly affecting the brachial plexus, typically presenting with unilateral involvement of the upper and middle trunks. Diagnosis is primarily clinical, while complementary studies mainly exclude alternative diagnoses. Advances in magnetic resonance neurography (MRN) allow detailed assessment of roots, trunks, and denervated muscles, revealing anatomical involvement in NA beyond clinical and electrodiagnostic evaluation. The objective is to describe MRN findings in patients with clinically diagnosed NA and assess concordance with clinical and electrodiagnostic features.

Methods: We retrospectively reviewed adult patients with NA undergoing MRN 2012–2025. Demographic and clinical variables, including symptom laterality and topography, were collected. Electrodiagnostic (EMG/NCS) and MRN findings were analyzed, focusing on root, trunk, and muscle involvement.

Results: Twenty-four patients were included (79% male; mean age 45.7 years). Mean time from symptom onset to evaluation was 2.3 months. Pain and weakness were present in 95.8%, and muscle atrophy in 75%. Proximal upper limb involvement in 87.5%. Electrodiagnostic studies ($n=21$) were abnormal in 85.7%, mainly involving the upper trunk (55.6%). MRN showed abnormal findings in all patients, predominantly affecting roots and trunks of the upper trunk territory (91.7%). Muscle denervation most commonly involved the supra- and infraspinatus muscles (41.7%). Concordance between clinical and electrodiagnostic topography was high, but MRN identified additional nerve and muscle involvement, including subtle or subclinical abnormalities.

Conclusion: MRN identified a broader extent of nerve and muscle involvement than clinical examination and electrodiagnostic studies. These findings support that NA may represent a more extensive, potentially bilateral and asymmetric radiculoplexopathy, usually unilateral clinically.

Disclosure: Nothing to disclose.

FIGURE 1 (A) MR neurography showing C5–C6 nerve enlargement and hyperintensity (arrow). (B) Sagittal T2 images revealing hyperintensity in the supraspinatus (white arrow) and infraspinatus (blue arrow). (C) Focal constrictions of upper trunk nerves (ast).

TABLE 1 Concordance between clinical presentation, electrodiagnostic (EDX), and MR neurography (MRN) topography in patients with neuralgic amyotrophy.

	Clinical (N=23)	EDX (N=23)	MRN (N=23)
			Neurography
Upper trunk (C5–C6)	23 (100%)	10 (50%)	21 (91.3%)
Middle trunk (C7)	12 (52.2%)	4 (25%)	10 (43.5%)
Lower trunk (L5–S1)	10 (43.5%)	3 (25%)	7 (30.4%)

EPO-0376 | Spatial covariance of cortical metabolism with multiple metrics of nigrostriatal degeneration in Dementia with Lewy bodies (DLB)

G. Tomassini²; L. Sofia¹; L. Lombardo²; F. D'Amico¹; T. Di Raimondo¹; F. Massa²; D. Arnaldi²; B. Orso²; F. Lanfranchi¹; S. Raffa¹; N. Epis²; E. Sentieri²; G. Bozzo²; W. Kreshpa²; F. De Cesari²; M. Losa²; M. Pulze²; G. Sambuceti¹; A. Uccelli¹; M. Bauckneht¹; S. Morbelli³; M. Pardini²

¹Department of health sciences (DISSAL), University of Genoa, Genoa, Italy; ²Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOEMI), University of Genoa, Genoa, Italy; ³Nuclear Medicine, University of Turin, Turin, Italy

Background and aims: From a biomarker perspective, Dementia with Lewy bodies (DLB) is characterised by striatal dopamine transporter (DaT) deficits and by specific patterns of cortical hypometabolism, assessable through DaT-SPECT and FDG-PET, respectively. However, the relationship between dopaminergic and metabolic imaging features remains unclear. This study aimed to

investigate the association between dopaminergic deafferentation in different striatal regions (caudate, anterior and posterior putamen) and cortical metabolic patterns in DLB.

Methods: 76 DLB patients (27 females, 49 males) who underwent both DaT-SPECT and FDG-PET were included. DaT-SPECT scans were analysed using DaTQUANT 2.0 to obtain striatal binding ratios (SBR). FDG-PET images were flipped to align the most affected hemisphere to the right. Correlations between SBR values and FDG-PET metabolic patterns were assessed using SPM12, correcting for age, sex and MMSE. Family-wise error-corrected p values <0.05 at the cluster level were considered significant.

Results: Caudate SBR reduction correlated with hypometabolism in parietal, occipital and lateral temporal cortices, with the most significant cluster in the lateral temporal cortex (p[FWE] <0.001). Anterior putamen SBR reduction was associated with a smaller hypometabolic cluster in similar regions, mainly in the angular gyrus (p[FWE] <0.005). Posterior putamen SBR reduction correlated predominantly with occipital hypometabolism, particularly in the inferior occipital gyrus (p[FWE] <0.001).

Conclusion: In DLB, progressive dopaminergic deafferentation from the posterior putamen to the caudate is associated with increasingly widespread cortical hypometabolism, with region-specific striatal deficits linked to distinct cortical metabolic patterns.

Disclosure: Nothing to disclose.

EPO-0377 | Intranasal esketamine expands key frontal and hippocampal regions and reduces serum neurofilament levels in patients with major depressive disorder

J. Garcia-Carmona¹; A. Rodriguez-Lorente²; P. Campos-Navarro²; P. Almela Rojo³; J. Navarro-Zaragoza³; J. Martinez-Riquelme³; D. López Segura¹; F. Salazar Hernandez¹; M. Ruiz Perello¹; B. Gomez Gozalvez¹; A. Lara Fernandez⁴; S. Benavente López⁴

¹Neurology, Santa Lucia University Hospital, Cartagena; Spain;

²Psychiatry, Santa Lucia University Hospital, Cartagena; Spain;

³Pharmacology, University of Murcia; Spain; ⁴Psychiatry,

Infanta Elena University Hospital, Madrid

Background and aims: We investigated the effects of intranasal esketamine (ESK-IN) on brain structural volumes and serum neurofilament light chain (sNfL) levels over a six-month period in patients with treatment-resistant depression (TRD).

Methods: 22 patients with TRD received ESK-IN in addition to ongoing oral antidepressant therapy. Clinical assessments were performed at baseline and after 1, 3, and 6 months of treatment. Structural brain MRI and blood sampling were conducted at baseline and at the six-month follow-up. MRI data from 44 matched healthy controls were also analyzed to enable comparisons of basal brain volume measures. Brain volumetric analyses were performed using VolBrain2 and DSI Studio software.

Results: At baseline, TRD patients showed significantly reduced volumes compared to healthy controls in the insula, frontal cortex, superior parietal cortex, and both superior and inferior temporal cortices. Reduced volumes were also observed in subcortical structures, such as the nucleus accumbens, putamen,

thalamus, and hippocampus. Following six months of ESK-IN treatment, significant volumetric increases were detected in the frontal cortex, superior frontal gyrus, frontal operculum, and anterior cingulate cortex, as well as in the hippocampus. Additionally, increases were observed in the volume and integrity of white-matter tracts involved in emotional regulation and cognitive control, including the frontoparahippocampal, frontoparietal, and frontal aslant tracts. Concomitantly, sNfL concentrations decreased after treatment, suggesting a reduction in ongoing neuronal damage.

Conclusion: Altogether, these findings indicate that ESK-IN may induce neuroplastic structural changes in brain regions critical for mood regulation while exerting potential neuroprotective effects in patients with TRD.

Disclosure: Nothing to disclose.

EPO-0378 | Molecular changes induced by anti-CGRP monoclonal antibodies for chronic migraine prophylaxis: A brain magnetic resonance spectroscopy study

M. Pengo¹; C. Manfredi¹; C. Gambini²; J. Bottini¹; M. Stroppi³; V. Patisso⁴; M. Olivero⁵; V. Marinato⁶; S. Sbaraini⁷; C. Uggetti⁶; S. Marceglia⁶; A. Priori⁸; M. Secchi¹

¹Neurology Unit, ASST Santi Paolo e Carlo, San Paolo University Hospital, Milan, Italy; ²Neurology and Stroke Unit, ASST Rhodense, Garbagnate M.se Hospital, Milan, Italy; ³Medical Physics Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ⁴Department of Neurology, IRCCS Istituto Auxologico Italiano, Milan, Italy; ⁵Department of Neurology, Maggiore della Carità Hospital, University of Piemonte Orientale, Novara, Italy; ⁶Aldo Ravelli Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, University of Milan, Milan, Italy; ⁷Neuroradiology Unit, Department of Radiology, San Carlo Borromeo Hospital, ASST Santi Paolo e Carlo, San Carlo Borromeo Hospital, Milan, Italy; ⁸Aldo Ravelli Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, University of Milan, Milan, Italy. Neurology Unit, ASST Santi Paolo e Carlo, San Paolo University Hospital, Milan, Italy

Background and aims: Calcitonin gene-related peptide monoclonal antibodies (CGRP-mAb) are effective treatments for preventing chronic migraine (CM). However, the molecular basis of indirect effects on the central nervous system (CNS) is still to be explored. We applied Brain Magnetic Resonance Spectroscopy (MRS) to investigate the neurochemical changes in the CNS induced by CGRP-mAb in CM.

Methods: This longitudinal study included 9 patients with CM without aura, evaluated before and six months after CGRP-mAb treatment initiation. At baseline, subjects underwent brain MRS (3T scanner, voxel 8 cm³, TE 135 ms) and comprehensive clinical evaluation including headache frequency, headache intensity (HIT-6), disability (MIDAS), cognitive assessment (MOCA) and mood (BDI). At 6-month follow-up, patients were re-evaluated with clinical assessment and MRS. All patients were scanned interictally. Linear mixed models were applied to evaluate changes in metabolite concentrations before and after treatment.

Results: After treatment neurochemical changes were observed: phosphocreatine (PCr) increased ($p=0.02$) and glutathione

FIGURE 1

(GSH) decreased ($p=0.02$) in occipital cortex (OCC), whereas glycerophosphocholine (GPC) increased ($p=0.03$) in anterior cingulate cortex (ACC). Trends suggested positive correlations between baseline migraine intensity and changes in PCr and GPC concentration in OCC and ACC, respectively.

Conclusion: The main finding of this study is the increase of PCr concentration in OCC, in line with previous evidence of the key role of brain energetics in CM. Whether this represents a central correlate of treatment or an epiphenomenon related to the reduction in migraine frequency requires further investigation.

Disclosure: Nothing to disclose.

EPO-0379 | Multispiral computed tomographic angiography in diagnosing neurovascular conflict in classical trigeminal neuralgia: A 15-year study

O. Zykova; B. Elena; A. Anastasia
Rostov State Medical University, Rostov-on-Don, Russian Federation

Background and aims: The aim of the study was to compare the accuracy of magnetic resonance imaging (MRI) and 3D multispiral computed tomographic angiography (MSCTA) in differentiating neurovascular conflict in patients with classical trigeminal neuralgia (CTN).

Methods: The study included 500 patients diagnosed with CTN based on the actual ICHD and the ICOP classification. Each patient underwent MRI scans and MSCTA in 3D mode with bolus contrast. The study focused on identifying neurovascular conflict (NVC) by examining the superior cerebellar artery loop's apex as it transitions from the anterior pontomesencephalic segment to the lateral segment, relative to the Meckel cave and the trigeminal nerve root. Microvascular decompression (MVD) was performed on patients who did not respond to conservative treatment. Intraoperative assessments were conducted to verify the MRI and MSCTA findings.

Results: The MRI performed on patients effectively excluded secondary causes of CTN, but it could not determine the type of NVC or distinguish between NVC and contact. MSCTA revealed NVC type 1 in 320 patients (64%), type 2 in 180 patients (36%). Intraoperative assessments in 412 patients indicated that MRI misdiagnosed neurovascular conflict in 64 cases (15.5%). Notably, 78 patients (18.9%) with MRI-confirmed neurovascular conflict who underwent microvascular decompression did not experience pain relief.

Conclusion: MRI has limitations in differentiating between NVC and contact, leading to concerns about overdiagnosis and misinterpretation in CTN patients and healthy individuals. This reliance on MRI may reduce favorable surgical outcomes.

MSCTA demonstrates higher accuracy in identifying the neuro-vascular relationship and indicating the need for MVD.

Disclosure: Nothing to disclose.

FIGURE 1 Magnetic resonance imaging: a) there is no conflict between the trigeminal nerve root (TNR) and the superior cerebellar artery (SCA); b) neurovascular conflict between the trigeminal nerve root and the superior cerebellar nerve on the left.

EPO-0380 | A progressive lesional mantle adjacent to the frontal cortices disclosing a CSF1R leukoencephalopathy in presymptomatic stage

E. Peczenik¹; P. Alegria²

¹Neurology, CHU Tivoli, La Louvière, Belgium; ²Neurology, CHU Charleroi-Chimay, Charleroi, Belgium

Background and aims: Colony-stimulating factor-1 receptor (CSF1R) related leukoencephalopathy usually presents around the 4th decade of life and frequently progresses to death in a few years. Transmission is autosomal dominant but de novo mutations and incomplete penetrance may account for a negative family history. Allogenic bone marrow transplantation has been reported to stabilize patients and a therapeutic trial with a receptor agonist is ongoing. Early diagnosis will be essential to allow treatment before neurologic damage installs.

Methods: We report the evolution of a presymptomatic patient and describe a particular MRI pattern that could help to identify other patients.

Results: A 35-year-old woman with no relevant personal medical history, underwent a brain MRI for tension-type headaches. Besides a few unspecific deep white matter point lesions, a

FIGURE 1 30years-old. FLAIR. Small lesions adjacent to the left frontal cortex.

FIGURE 2 40 years-old. FLAIR. This unusual pattern raised the hypothesis of a leukodystrophy.

few unusual small lesions adjacent to both prefrontal cortices (but sparing the U-fibers) were present. A subsequent MRI at 39 years-old showed a degree of coalescence of the frontal lesions

FIGURE 3 40years-old. Lesions elsewhere in the brain are sparse and unspecific and wouldn't disclose the diagnosis by themselves.

adjacent to the cortex, starting to form a “mantle”. One year later this mantle started to appear also in the right temporal lobe and 2 small lesions showed restriction on diffusion. She remained asymptomatic but a first neurological examination by that time noted some mild attention deficits and a bilateral ankle clonus. She reported that her mother had died of an obscure neurological disease by the age of 44. Genetic testing disclosed a c.2625G > A mutation. At 41 years-old she remains stable.

Conclusion: A patchy mantle of small frontal juxtacortical lesions can disclose this disease in a very early phase.

Disclosure: Nothing to disclose.

EPO-0381 | Substantia nigra neuromelanin magnetic resonance imaging in LRRK2 asymptomatic carriers

¹Department of Neurosciences and Mental Health, Neurology, Santa Maria Local Health Unit, Lisbon, Portugal; ²Department of Neurological Imaging, Santa Maria Local Health Unit, Lisboa, Portugal; ³Department of Medical Genetics, Department of Pediatrics, Santa Maria Hospital, Santa Maria Local Health Unit, Lisbon, Portugal; ⁴Department of Neurology, Garcia de Orta Hospital – Almada-Seixal Local Health Unit, Almada, Portugal; ⁵Neurology Department, Beatriz Ângelo Hospital, Loures, Portugal; ⁶Department of Neurology, Santo António Hospital, Porto University Hospital Centre, Porto, Portugal; ⁷CNS – Campus Neurológico, Torres Vedras, Portugal

Background and aims: Parkinson's disease (PD) is a progressive neurodegenerative disorder, with long pre-clinical and prodromal stages. The development of non-invasive biomarkers for pre-diagnostic stages is of utmost importance. Neuromelanin (NM)-sensitive magnetic resonance imaging (MRI) of the substantia nigra (SN) is an established biomarker of neurodegeneration in PD, which is expected to begin years before motor symptoms emerge, and for which LRRK2 mutation asymptomatic carriers are at higher risk. We aim to investigate NM MRI in asymptomatic LRRK2 carriers

Methods: Asymptomatic at-risk first-degree relatives of LRRK2-PD patients were sequentially recruited. An extensive clinical evaluation, including motor and non-motor symptoms, as well as a study of neuromelanin, using a specific T1-weighted MRI sequence, was performed. Targeted genetic testing for LRRK2 variants was performed after clinical evaluation and imaging studies.

Results: Nineteen asymptomatic participants were included, of which 12 LRRK2 non-carriers (NC) and 7 carriers (AC). Baseline demographics did not differ between groups (median age AC 46years (IQR 35–53) vs NC 51.5 (39–59) $p=0.379$). Motor scores did not differ between groups (MDS-UPDRS III median 2 (2–4) in AC vs 2.5 (1.5–5.4) in NC, $p=0.863$). NM area was significantly smaller in AC when compared to NC, (16 mm^2 (14.9–19.1) vs 20.6 mm^2 (19.3–24.0), $p=0.025$).

Conclusion: NM-MRI can be significantly decreased in LRRK2-G2019S AC. This technique may be a promising biomarker of neurodegeneration in pre-diagnostic stages of PD.

Disclosure: Nothing to disclose.

EPO-0382 | Association of glymphatic imaging markers with functional independence and white matter hyperintensity burden after intracerebral hemorrhage

X. Hu; Z. Wang; Q. Li
Department of Neurology, The Second Affiliated Hospital of Anhui Medical University, Hefei, China

Background and aims: Glymphatic system plays a critical role in cerebral metabolite clearance and white matter injury. However, its clinical relevance and underlying mechanisms in intracerebral hemorrhage (ICH) remain poorly understood. This study aimed to investigate imaging-based glymphatic markers in relation to functional outcomes and white matter hyperintensity (WMH) burden in patients with ICH.

Methods: We included 70 patients with acute supratentorial ICH who underwent diffusion tensor imaging (DTI). Glymphatic-related imaging parameters were derived using DTI and T1-weighted MRI, including the contralateral DTI-ALPS index, free water (FW) ratio in contralateral deep white matter (WM), and relative perivascular space (PVS) volume. Relative WMH volume was defined as absolute WMH normalized to intracranial volume and log-transformed. Functional independence was defined as a 3-month modified Rankin Scale score of 0–2. Associations were examined using multivariable logistic and linear regression models.

Results: In fully adjusted logistic regression models, higher FW in deep WM was independently associated with a lower likelihood of functional independence at 3 months (OR=0.59; 95% CI, 0.36–0.98; $P=0.041$), with consistent findings across sequential

FIGURE 1 Flowchart of imaging processing. (A) Diffusion tensor imaging preprocessing. (B) Generation of contralateral deep white matter (WM) and PVS masks. (C) Calculation of the DTI-ALPS. (D) Free water ratio in contralateral deep WM excluding PVS.

TABLE 2 Linear regression analyses between relative WMH volume and glymphatic parameters. Model 1: Unadjusted. Model 2: Adjusted for age, NIHSS, and baseline hematoma volume. Model 3: Adjusted for variables in model 2, mean diffusivity and scanner.

	FW in deep WM	Contralateral ALPS	Relative PVS volume
Model 1	0.002 (0.001 to 0.003)	-0.001 (-0.002 to 0.001)	-0.002 (-0.003 to -0.001)
Model 2	0.001 (0.000 to 0.002)	-0.001 (-0.002 to 0.001)	-0.001 (-0.002 to 0.001)
Model 3	0.143 (0.008 to 0.277)	0.008 (0.000 to 0.016)	-0.001 (-0.002 to 0.001)

models. Linear regression analyses further demonstrated that greater relative WMH burden was significantly associated with increased FW in deep WM ($\beta=0.143$; 95% CI, 0.008–0.277; $P=0.038$) and with smaller relative PVS volume in fully adjusted models.

Conclusion: These findings suggest that white matter injury may influence functional recovery after ICH through glymphatic system dysfunction, with FW emerging as the most sensitive imaging marker linking WMH burden to adverse functional outcomes.

Disclosure: We declare no conflict of interests.

EPO-0383 | Peri-nidal hypoperfusion on multi-delay ASL is associated with epilepsy in unruptured brain arteriovenous malformation

X. Li¹; C. Wu¹; Y. Yin¹; B. Xu²; T. Wu²; J. Lu¹; Q. Qin³
¹Department of Radiology and Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, China; ²MR Research China, GE Healthcare, Beijing, China; ³Diagnostic Imaging Sciences Center (DISC), University of Washington School of Medicine, Seattle, USA

Background and aims: The hemodynamics of epilepsy in unruptured brain AVM remains unclear. This study aims to investigate the perfusion characteristics of the whole brain and peri-nidal tissues and explore their relationships with AVM-related epilepsy.

Methods: This study enrolled patients with unruptured brain AVMs. Time-encoding multi-delay ASL was performed to obtain corrected cerebral blood flow (cCBF), arterial transit time (ATT), and arterial cerebral blood volume (aCBV). After excluding draining veins, five concentric perinidal zones were delineated, each 2mm thick. Within each zone, perfusion parameters were specifically quantified for the entire brain tissue, gray matter, and white matter separately. Independent samples t-tests were applied to compare these parameters between AVM patients with and without epilepsy.

Results: A total of 40 AVM patients (20 with epilepsy, 20 without) were included. While no global perfusion differences were found, patients with epilepsy showed significantly lower cCBF and aCBV in the tissue closest to the nidus (≤ 2 mm), particularly in gray matter, compared to non-epilepsy patients. This difference diminished with increasing distance from the nidus, with the most severe impairment found in the peri-nidal gray matter.

Conclusion: The findings of a pronounced and distance-dependent steal effect in epilepsy patients support the hemodynamic steal hypothesis. This suggests that an AVM's high-flow shunt critically diverts blood, causing chronic ischemia in the adjacent cortex. Such ischemia may contribute to neuronal

FIGURE 3 Imaging comparison and the peri-nidal steal phenomenon.

dysfunction, selective loss, and gliosis, which collectively lower the seizure threshold and create an epileptogenic focus, revealing a potential hemodynamic mechanism for epilepsy.

EPO-0384 | Augmenting clinical reasoning: Integrating artificial intelligence into neuropsychological and mental health assessment

A. Desmarais; A. Hudon

Département de psychiatrie et d'addictologie, Université de Montréal, Montréal, Canada

Background and aims: Artificial intelligence (AI) is increasingly entering neuropsychological and mental health practice, yet its adoption remains limited by ethical concerns, professional responsibility, and clinician acceptability. Beyond technical performance, effective integration of AI in neurology and neuropsychology depends on alignment with clinical reasoning, ethical standards, and professional identities. This presentation reflects on these challenges through the design of Flow, an AI-enabled clinical platform developed in collaboration with mental health professionals.

Methods: This presentation adopts a conceptual, practice-informed approach grounded in participatory and ethical-by-design principles. Flow was developed through iterative exchanges with neuropsychologists and clinicians, focusing on real-world workflows. The platform functions as a supervisory tool that supports clinical reasoning without generating autonomous diagnoses. Transparency, clinician control, and clear boundaries of responsibility guide its design.

Results: Drawing on clinical feedback and field experience, this presentation synthesizes key themes related to clinician expectations, perceived risks, and conditions for acceptability of AI tools. Tensions between efficiency and clinical nuance, automation and professional judgment, and innovation and regulation are highlighted.

Conclusion: Overall, the future of AI in neuropsychology and mental health depends less on algorithmic sophistication than on ethical design, clinician trust, and alignment with professional values.

Disclosure: Annie Desmarais is the founder and CEO of Flow Factor, the company developing the Flow clinical AI platform. Her postdoctoral research is conducted on and in relation to the Flow platform.

FIGURE 2 Comparison of perinidal cCBF, ATT, and aCBV between AVM patients with and without epilepsy.

M. Favaro; A. Panzavolta; C. Cerami
IUSS Cognitive Neuroscience ICoN Center, Scuola Universitaria Superiore IUSS, Pavia, Italy

Background and aims: Growing evidence reported social cognition impairments in patients following stroke, with converging findings highlighting a higher prevalence in individuals with right-hemisphere lesions. Despite increasing recognition of socio-cognitive deficits after stroke, substantial variability remains across studies with respect to prevalence rates, affected sub-domains, and underlying neural correlates. This systematic review therefore aimed to synthesize current evidence on post-stroke social cognition impairments, with a specific focus on domain-specific performance and hemispheric lesion patterns, to define the post-stroke socio-cognitive profile.

Methods: A systematic literature search was conducted in PubMed, Scopus, and Web of Science databases following PRISMA guidelines. The risk of bias assessment was assessed with the AXIS and the NIH Quality Assessment tools.

Results: Among the 1293 papers initially retrieved, 33 studies met eligibility criteria. Quality assessment showed a middle-high overall quality of evidence. Emotion recognition is the most frequently investigated socio-cognitive sub-domain, with impairments reported in about 25–35% of post-stroke patients without any consistent emotion-specific pattern. Theory of Mind deficits are reported in both cognitive and affective components, especially following right hemisphere strokes. Findings on empathy are more heterogenous, with studies reporting reduced cognitive empathy alongside relatively preserved affective empathy.

Conclusion: Despite consistent evidence across studies, heterogeneity in assessment methods, timing and samples strongly prevents a clear profiling of social cognition impairments in post-stroke patients. Standardization of cognitive assessment protocols and harmonization of neuropsychological procedures is needed to overcome current literature gaps and improve diagnostic precision, support targeted rehabilitation, and enhance functional and interpersonal outcomes in stroke survivors.

Disclosure: None.

EPO-0386 | Early-life multidomain engagement relates to semantic fluency and episodic learning in aging and mild cognitive impairment

F. Cieri¹; J. Caldwell²; D. Cordes¹; C. Cross³
¹Department of Neurology, Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, USA; ²University of Wisconsin–Madison, Madison, USA; ³School of Veterinary Medicine, Texas Tech University, Amarillo, USA

Background and aims: Engagement in cognitively, physically, creatively, and socially stimulating activities is recognized as a modifiable protective factor against cognitive decline and dementia. However, whether early-life periods represent sensitive windows for later-life neuropsychological resilience remains insufficiently characterized, particularly across the continuum

TABLE 1 Significant HMR results — dNA → Cognitive.

dNA	It	Cog Test	N	β	95%-CI	p	FDR p	AK Block	p (F-change)
COG1	All	Vegetables	58	0.410	[0.239, 0.543]	.001	.003	0.154	0.000
COG1	CN	Vegetables	19	0.521	[0.239, 0.811]	.001	.003	0.245	0.000
COG1	All	Animals	58	0.487	[0.283, 0.771]	.002	.005	0.162	0.011
PHY1	All	RAVLT— Learn	55	0.417	[0.154, 0.681]	.001	.006	0.233	0.007

Note: Block 1 = age, sex, edu, diagnosis; Block 2 = dNA domains from the same time windows (TW). dNA = dynamic Neurocognitive Adaptation; CN = cognitively normal; MCI = mild cognitive impairment; FDR = False Discovery Rate adjusted p-value (Benjamini-Hochberg procedure). Time windows: TW1 = 0–10 years, TW2 = 11–20 years, TW3 = 21–30 years, TW4 = 31–40 years, TW5 = 41–50 years, TW6 = 51–60 years.

dNA- Cognitive RESULTS

Fig. 1. dNA COG1 and PHY1 associations with cognitive scores
Panels show partial regressions with adjusted fits (solid line) and 95% confidence intervals (shaded bands); axes are z-scores. Covariates: age, sex, education, and diagnosis. The CN-only panel excludes participants with MCI.

Notes: Models are adjusted as above; no influential outliers; quadratic terms non-significant unless indicated in the text.

from cognitively unimpaired (CU) aging to mild cognitive impairment (MCI).

Methods: Fifty-eight participants, including CU older adults and individuals with MCI, completed the dynamic Neurocognitive Adaptation (dNA) scale, assessing engagement across four domains (cognitive, physical, creative, social) over seven life-course time windows. Neuropsychological outcomes included semantic fluency (vegetables, animals) and episodic learning (RAVLT). Participants also underwent amyloid PET assessment. Hierarchical regression analyses examined associations between domain- and time-specific dNA scores and cognitive performance, controlling for age, sex, education, and amyloid status.

Results: Childhood emerged as a sensitive period for neuropsychological outcomes. Higher childhood cognitive engagement (COG1) was associated with better semantic fluency (vegetables: $\beta=0.410$, $p=0.003$; animals: $\beta=0.487$, $p=0.005$), while higher childhood physical engagement (PHY1) was associated with stronger episodic learning ($\beta=0.417$, $p=0.006$). No dNA domain predicted delayed recall. All associations survived false discovery rate correction and were not moderated by sex, education, or diagnosis.

Conclusion: Early-life multidomain engagement, particularly cognitive and physical activity during childhood, is associated with preserved semantic and episodic memory performance in CU and MCI. These findings support early-life engagement as a protective factor for neuropsychological resilience and highlight the value of time-resolved tools such as the dNA for prevention research.

EPO-0387 | Alzheimer's disease in stroke: Prevalence in 3 cohorts and links with clinical, imaging, and cognitive status

J. Neel¹; J. Morris²; V. Mok³; P. Cervellera¹; M. Roussel¹; T. Benzinger⁴; B. Lam³; C. Lamy¹; B. Gordon⁴; S. Canaple¹; B. Grant⁵; A. Courselle-Arnoux¹; A. Wong³; C. Leclercq¹; M. Streitz²; O. Godefroy¹

¹Department of Neurology Amiens University Hospital and Laboratory of Functional Neurosciences (UR 4559) University of Picardie Jules Verne, Amiens, France; ²Department of Neurology, Washington University School of Medicine, St. Louis, USA; ³Division of Neurology, Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong; ⁴Department of Radiology, Washington University School of Medicine, St. Louis, USA; ⁵The Institute for Informatics, Data Science and Biostatistics, Washington University School of Medicine, St. Louis, USA

Background and aims: Amyloidopathy is reported in stroke populations with varying prevalence and cognitive impact. To address this limitation, the present study pooled data from the 3 largest stroke cohorts assessing cognitive status and amyloid burden using PET (IDEA3, ref 1, St Louis, 2 and STRIDE, 3). Our primary objective was to estimate the prevalence of amyloidopathy in stroke. Secondary objectives included associations between amyloidopathy and clinical characteristics, Mini-Mental State Examination (MMSE) score, cognitive status and brain imaging markers.

Methods: A cross-sectional analysis was performed on 218 patients (age 70.8 ± 10.8 years; 59% male; education 9.5 ± 4.4 years), including infarct, TIA, and hemorrhage. Cognitive status was categorized as dementia, mild cognitive impairment, or normal. Data were analyzed using mixed models adjusted for age, education, stroke subtype, stroke severity, and prestroke dementia.

Results: Amyloidopathy prevalence was 19.7% and increased with age ($p=0.001$), with no effect of stroke-PET time interval ($p=0.1$). Amyloidopathy was associated ($p=0.012$) with lower MMSE score but not with cognitive status. Regarding imaging amyloidopathy was associated with lobar microbleeds ($p=0.04$) but not with deep microbleeds, white matter hyperintensities and hippocampal volume.

Conclusion: Amyloidopathy affects about one fifth of stroke patients, increasing with age. It worsens cognitive performance as measured by MMSE but does not influence overall cognitive status, highlighting the role of vascular lesions in post-stroke impairment. The presence of lobar microbleeds should prompt the search for amyloidopathy, even in ischemic stroke. References 1. Godefroy O et al. Stroke 2025;56:74–83 2. Koenig L.N et al. EPO-0388 | Sex-specific cognitive divergence in Parkinson's disease

J. Saltyte Benth¹; G. Sanchez Nido²; O. Tysnes²; G. Alves³; C. Tzoulis²; G. Skeie²

¹Department of Clinical Medicine, University of Bergen, Bergen, Norway; ²Neuro-SysMed, Department of Neurology, Haukeland University Hospital, Bergen, Norway; ³Department of Neurology and Center for Movement Disorders, Stavanger University Hospital, Stavanger, Norway

Background and aims: Sex differences in cognitive impairment in Parkinson's disease (PD) have been reported, with several studies suggesting greater cognitive decline in males. However, evidence on long-term trajectories across specific cognitive domains is limited, as most prior work is cross-sectional. Thus, we aim to investigate sex-specific longitudinal changes across multiple cognitive domains over 9 years in idiopathic PD, compared to demographically matched controls.

Methods: We analyzed data from the prospective ParkWest study, including $n=190$ persons with PD (PwPs) and $n=202$ age- and sex-matched controls, followed for 9 years. Regularly assessed cognitive domains included semantic fluency, processing speed, cognitive control, memory, and visuospatial ability. Linear mixed-effect models were used, including a three-way interaction between time, disease status and sex, to test whether sex-specific cognitive change in PD differed from that observed in controls. Models were adjusted for age, years of education, baseline depression, and UPDRS part II.

Results: Male PwPs showed faster decline than female PwPs across most cognitive measures, resulting in gradually increasing sex-differences over 9 years. However, compared with controls, the differential sex-specific decline was statistically significant only for semantic fluency ($p=0.013$) and processing speed ($p=0.027$ and $p=0.035$). These findings remained significant after covariate adjustment.

Conclusion: Over 9 years, PD was associated with increasing sex-differences in semantic fluency and processing speed, driven by faster decline in males. These findings confirm the male susceptibility to cognitive decline in PD and suggest that sex-specific vulnerabilities in cognitive trajectories in PD are domain-specific.

Disclosure: Nothing to disclose.

K. Chompalov¹; G. Spray²; D. Georgieva¹; P. Atanasova¹
¹Department of Neurology, St. George Hospital, Medical University of Plovdiv, Plovdiv, Bulgaria; ²Department of Speech, Language, and Hearing Sciences, Auburn University, Auburn, USA

Background and aims: Early identification of mild cognitive impairment due to Alzheimer's disease (MCI) is essential for timely intervention. Although episodic memory deficits are central to MCI, language performance may also be affected early. This study examined cognitive and language performance differences between individuals with MCI and cognitively healthy older adults using the Bulgarian version of the Scales of Cognitive and Communicative Ability for Neurorehabilitation (SCCAN).

Methods: Thirty individuals with MCI and 30 cognitively healthy controls were assessed with the Bulgarian SCCAN. Group differences were examined using independent samples t-tests for the total SCCAN score and selected domains, including episodic memory, attention, problem solving, and oral expression.

Results: Participants with MCI showed significantly lower total SCCAN scores than healthy controls (mean 75.7, SD 8.0 vs. mean 85.2, SD 8.8; $p < 0.001$), with a large effect size (Cohen's $d = 1.13$). Episodic memory demonstrated the largest group difference ($p < 0.001$, Cohen's $d = 1.75$). Oral expression was also significantly reduced in the MCI group ($p = 0.006$, Cohen's $d = 0.73$). Differences in attention and problem solving were smaller and did not reach statistical significance, although moderate effect sizes were observed.

Conclusion: Beyond memory impairment, individuals with MCI exhibit clinically meaningful deficits in oral language performance. These findings highlight the importance of incorporating language performance measures into early cognitive assessment and support the clinical utility of the Bulgarian SCCAN for identifying cognitive-communicative profiles in MCI.

Disclosure: The authors report no conflicts of interest.

EPO-0390 | Sustained cognitive and mood benefits of a prismatic adaptation-based digital therapy in stroke rehabilitation

M. Oliveri
Department of Biomedicine, Neurosciences and Advanced Diagnostics (BiND), University of Palermo, Palermo, Italy

Background and aims: Stroke survivors often experience persistent cognitive deficits and mood disturbances, which can hinder functional recovery. Non-invasive neuromodulation combined with game-based digital therapies has been proposed as a novel approach to enhance cognitive and emotional rehabilitation. This study investigated whether a prismatic adaptation-based digital therapy could provide sustained cognitive and mood benefits compared with standard pen-and-paper rehabilitation.

Methods: Patients with a first-ever ischemic or hemorrhagic stroke affecting either hemisphere were recruited at the Santa

Table 1: Demographic and baseline characteristics of study participants. Continuous variables are reported as mean ± standard deviation (SD), and categorical variables as number and percentage (%). VIS = visual perception; HHG = spatial attention/hemineglect; LAN = language; MEM = memory; EXF = executive functions.

	Experimental (N=28)	Control (N=29)	Group differences (p-value)
Age, mean (SD)	60.86 (14.67)	61.85 (11.48)	$p=0.628$
Sex, Female, No (%)	14 (50%)	17 (58.6%)	$p=0.514$
Education, years, mean (SD)	13.39 (4.46)	13.51 (3.97)	$p=0.918^*$
Stroke location, Left, No (%)	13 (46.4%)	10 (34.5%)	$p=0.389$
VIS, mean (SD)	201.96 (54.81)	176.12 (73.31)	$p=0.367$
HHG, mean (SD)	32.11 (15.83)	32.33 (13.94)	$p=0.962$
LAN, mean (SD)	86.07 (29.24)	86.83 (25.48)	$p=0.941$
MEM, mean (SD)	88.11 (28.13)	88.89 (29.24)	$p=0.978$

FIGURE 1 Longitudinal changes in cognitive domain scores over time.

Lucia Foundation IRCCS, Rome, Italy. Participants were randomly assigned to an experimental group ($n = 28$) receiving the digital therapy or a control group ($n = 29$) receiving standard cognitive rehabilitation. Cognitive outcomes were measured across five domains: visual perception, spatial attention/hemineglect, language, memory, and executive functions. Depressive symptoms were assessed using the Hamilton Depression Rating Scale (HAM-D) at baseline, 3 months, and 6 months.

Results: Significant Group $\times$ Time interactions were observed for all cognitive domains. Participants in the experimental group demonstrated progressive improvements over time, whereas the control group showed no significant changes. Cognitive gains were most pronounced at the 3- and 6-month follow-ups. Additionally, depressive symptoms were significantly reduced in the experimental group at 3 months compared with baseline.

Conclusion: Prismatic adaptation-based digital therapy resulted in sustained cognitive improvements and reduced depressive symptoms post-stroke. Combining non-invasive neuromodulation with game-based cognitive training may enhance rehabilitation outcomes by addressing both cognitive and emotional recovery in stroke survivors.

Disclosure: None.

M. Rijntjes¹; A. Dressing¹; M. Reisert²; E. Van den hoven¹; V. Glauche¹; H. Urbach³; K. Willmes⁴; C. Weiller¹
¹Department of Neurology and Clinical Neuroscience, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany; ²Department of Radiology, Medical Physics, Medical Center, University of Freiburg, Faculty of Medicine, University of Freiburg, Germany; ³Department of Neuroradiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany; ⁴Department of Neurology, RWTH Aachen University, Aachen, Germany

Background and aims: The Dual Loop Model with hubs in inferior frontal and parieto-temporal cortex, combining the dorsal pathway for processing sequences and the ventral pathway for hierarchical-structural categorisation, was suggested as the anatomical substrate for syntax in all modalities. The caudal pathway, from multimodal associations in the angular gyrus to abstract concept formation in anterior temporal lobe (ATL), was suggested as essential for semantics. In stroke patients, we searched for the common anatomical substrate for syntactic and semantic deficits in apraxia, aphasia and neglect.

Methods: 165 patients with a single left medial cerebral artery infarction were tested for apraxia, the Token Test and spatial attention. We used the new method of streamline-based lesion-symptom mapping (SLSM, FDR 0.001) to detect white matter disconnections related to common behavioural deficits.

Results: Two Principal components (PC) explained 60% of variance across domains. PC1 (50% of variance) was associated with progressive loading for more complex apraxia tests, the Token Test and neglect. PC2 (an additional 10%) related to easier apraxia tests and extinction (Figure 1). Affected streamlines associated with PC1 included the dorsal and ventral pathway of the dual loop, additionally the Middle longitudinal Fascicle (MdIF) as the caudal pathway. PC2 was only associated with the dorsal pathway and MdIF. The interaction analysis showed that the ventral pathway, predominantly connecting inferior frontal cortex with ATL, was selectively involved in PC1 (Figure 2).

Conclusion: A lesion of the ventral pathway leads to multimodal deficits when syntax and semantics have to be combined.

EPO-0392 | From eye clinic to neurology: Diagnostic clues in Heidenhain-variant Creutzfeldt–Jakob disease

N. Bocero Hanan; S. Sánchez Gamino; A. Sarmiento Pita; P. Dodu; J. Pérez Ceballos
Neurology, Hospital Regional Universitario Malaga, Malaga, Spain

Background and aims: Creutzfeldt–Jakob disease (CJD) is a rare and invariably fatal prion-related neurodegenerative disorder, typically presenting with rapidly progressive dementia. The Heidenhain variant (HvCJD), however, manifests predominantly with isolated visual symptoms at onset, frequently leading to misdiagnosis and delayed neurological assessment. This report describes two cases of HvCJD initially attributed to ophthalmological pathology, highlighting key diagnostic challenges.

Methods: We retrospectively analyzed two patients who presented with isolated visual disturbances and underwent cataract surgery before a neurological diagnosis was established. Clinical course, neuroimaging findings, cerebrospinal fluid (CSF) biomarkers (14-3-3 protein and RT-QUIC), and electroencephalographic (EEG) data were reviewed. Findings were contextualized through a focused review of the literature on HvCJD to identify common diagnostic pitfalls.

Results: An 80-year-old man presented with persistent visual impairment and hemianopia refractory to cataract surgery; brain MRI revealed posterior cortical hyperintensities consistent with prion disease. A second patient, a 60-year-old man, developed progressive visual symptoms followed by gait instability after cataract surgery, with MRI and EEG findings suggestive of CJD. CSF analysis was positive for both 14-3-3 protein and RT-QUIC in both cases. Published series confirm that isolated visual symptoms frequently result in misdiagnosis, delayed referral to neurology, and exposure to unnecessary invasive procedures.

Conclusion: HvCJD should be considered in patients with unexplained or rapidly progressive visual disturbances, particularly when symptoms are inconsistent with primary ocular disease.

FIGURE 1 MRI and EEG of the first patient explained.

FIGURE 2 MRI with restriction on diffusion (second patient).

FIGURE 3 EEG showing triphasic waves (second patient).

Visual manifestations reflect cortical involvement rather than ophthalmological pathology. Increased awareness among ophthalmologists and neurologists, together with early neuroimaging and CSF biomarker assessment, is essential to reduce diagnostic delay and avoid iatrogenic risks.

Disclosure: Nothing to disclose.

EPO-0393 | Impact of a structured neurocognitive and psychosocial intervention on quality of life and psychosocial morbidity in drug-resistant epilepsy: An RCT

N. Choudhary¹; P. Kharbanda¹; D. Rana²; K. Chakravarty¹; A. Sharma²; J. Baishya¹

¹Department of Neurology, Post Graduate Institute of Medical Education and Research, Chandigarh, India; ²Department of Psychiatry, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background and aims: Patients with drug-resistant epilepsy (DRE) experience substantial psychosocial morbidity, including depression, anxiety, stigma, and functional disability, which contribute significantly to reduced quality of life (QOL). Despite optimal medical management, these challenges remain under-addressed in routine clinical practice. We assessed the effectiveness of a structured neuro-cognitive and psychosocial intervention module in improving psychosocial outcomes and QOL in individuals with drug-resistant epilepsy.

Methods: A randomized controlled trial was conducted on 60 adults with DRE, allocated to an intervention group ($n=30$) and a control group ($n=30$). The intervention consisted of psycho-education, cognitive-behavioral strategies, cognitive retraining, and family counseling, delivered over 8 weeks, in addition to standard medical treatment. Psychosocial outcomes were evaluated using QOLIE-31, BDI, HARS, Stigma Scale for Epilepsy (SSE), WHODAS, and Dysfunctional Analysis Questionnaire (DAQ). Per-protocol and intention-to-treat analyses were performed.

Results: Patients receiving the intervention showed a clinically meaningful improvement in quality of life, with QOLIE-31 scores improving from 52.4 ± 8.5 at baseline to 67.8 ± 7.2 post-intervention ($p < 0.001$). Significant reductions were observed in anxiety (HARS: 21.3 ± 5.8 to 12.1 ± 4.7 , $p < 0.001$), depressive symptoms, perceived stigma ($p=0.03$), psychosocial dysfunction, and disability scores. The control group showed no statistically significant changes over the same period. Seizure frequency remained stable, indicating that improvements were independent of seizure control.

Conclusion: The integrated neuro-cognitive and psychosocial intervention is effective in reducing psychosocial morbidity and improving quality of life in patients with drug-resistant epilepsy. Incorporating such structured interventions into routine epilepsy care may substantially enhance holistic patient outcomes.

Disclosure: Nothing to disclose.

EPO-0394 | Wernicke encephalopathy with normal imaging and labs in a severely malnourished elderly patient: A case report

S. Mouddeen; O. Cherkaoui Ghazouani
Neurology Department, Military Hospital of Avicenna, Marrakech, Morocco

Background and aims: Wernicke's encephalopathy is a neurological emergency secondary to thiamine deficiency, with a frequently atypical clinical presentation. The absence of the classic triad and normal complementary investigations may delay

diagnosis. We report a case of probable Wernicke's encephalopathy revealed by a progressive neuropsychiatric syndrome.

Methods: We report the case of a 65-year-old female patient with a history of recent untreated hyperthyroidism, laryngeal carcinoma treated with radiotherapy, and hypertension. She was admitted for behavioral disturbances including psychomotor agitation, opposition to care, aggressiveness, and irritability, associated with memory impairment and visual hallucinations, with progression over 20 days. Investigations included blood tests, thyroid function assessment, brain imaging, electroencephalography, and lumbar puncture with cerebrospinal fluid analysis.

Results: On admission, the patient was fully conscious with a Glasgow Coma Scale score of 15/15, but severely malnourished with a low body mass index, dehydrated, and uncooperative, with no focal neurological deficits. Biological investigations were unremarkable. Brain computed tomography showed mild ventricular enlargement, while brain magnetic resonance imaging and electroencephalography were normal. Cerebrospinal fluid analysis revealed no abnormalities. Given the strong clinical suspicion of thiamine deficiency, vitamin B1 therapy was initiated, along with nutritional and hydration support. This resulted in a marked and rapid improvement in behavioral symptoms, cognitive functions, and general condition. Visual hallucinations partially persisted. The patient was discharged on chlorpromazine 25 mg nightly, with follow-up scheduled one month later.

Conclusion: This case highlights the importance of considering Wernicke's encephalopathy in malnourished elderly patients with acute or progressive neuropsychiatric syndromes. Early thiamine administration should not be delayed when suspected.

Disclosure: Nothing to disclose.

EPO-0395 | When the past catches up: Iatrogenic Creutzfeldt–Jakob Disease with a 39-year incubation period

S. Chowdhury¹; M. NG²; S. Mead³; S. Oghuvwu⁴; S. Lim¹; S. Sedehizadeh¹

¹Neurology, Nottingham University Hospitals NHS Foundation Trust, Nottingham, UK; ²National Prion Clinic; ³University College London Hospitals NHS Foundation Trust, London, UK; ⁴Sherwood Forest Hospitals NHS Foundation Trust, Sutton-in-Ashfield, UK

Background and aims: Creutzfeldt–Jakob disease (CJD) is a rare, fatal prion disease, most commonly occurring sporadically but occasionally transmitted through medical procedures, resulting in iatrogenic CJD (iCJD).

Methods: A 39-year-old man presented to Queen's Medical Centre, Nottingham, UK with a four-week history of rapidly progressive cognitive and behavioural decline. His family reported impaired executive function, including leaving dirty cookware in cupboards, difficulty following instructions at work, misplacing personal items, and gait disturbance with leftward leaning. At six weeks of age, he developed meningitis complicated by seizures and bilateral subdural empyema. On 7 January 1986, he underwent craniotomy with dural repair using a cadaveric dura mater graft (Lyodura). He had lifelong learning difficulties, dyslexia, and communication and social difficulties.

Results: During admission, he deteriorated rapidly, becoming bedbound, non-verbal, and doubly incontinent. He developed

FIGURE 1 MRI brain demonstrated diffusion restriction in the bilateral basal ganglia with multifocal cortical ribboning, more prominent on the left.

FIGURE 2 MRI brain demonstrated diffusion restriction in the bilateral basal ganglia with multifocal cortical ribboning, more prominent on the left.

FIGURE 3 MRI brain demonstrated diffusion restriction in the bilateral basal ganglia with multifocal cortical ribboning, more prominent on the left.

stimulus-induced myoclonus, initially treated with levetiracetam but switched to clonazepam due to rash. MRI brain demonstrated diffusion restriction in the bilateral basal ganglia with multifocal cortical ribboning, more prominent on the left. EEG showed non-specific encephalopathy. Cerebrospinal fluid was acellular with normal protein, and RT-QuIC was positive. He was referred to palliative care and died in a hospice within two weeks of discharge.

Conclusion: The case highlights the diagnostic value of a detailed lifetime surgical history, particularly childhood neurosurgical interventions that may otherwise be overlooked. Incubation periods in iCJD can exceed 30–40 years, making careful lifetime surgical history essential. Continued vigilance, prompt recognition, and systematic reporting are essential to support surveillance efforts and improve understanding of iatrogenic prion disease in neurological practice.

Disclosure: Nothing to disclose.

EPO-0396 | Transient epileptic amnesia as an underdiagnosed form of late-onset temporal lobe epilepsy

A. Atrous¹; O. Sakli¹; A. Ghatbi¹; I. Abdelkafi²; M. Kabbage¹; Y. Abida¹; A. Souissi¹; I. Kacem¹; A. Gargouri¹; R. Gouider¹

¹Neurological department, Center of clinical investigation on neuroscience and mental health LR18 SP03, Razi Hospital, Manouba, Tunisia; ²Hospital of interior security forces, Marsa, Tunisia

Background and aims: Late-onset epilepsy is defined as epilepsy with first seizure onset from the age of 50 years onward. Within this spectrum, temporal lobe epilepsy in older adults (TLE-OA) is increasingly recognized. Among its clinical phenotypes, transient epileptic amnesia (TEA) represents a distinctive but frequently underdiagnosed form.

Methods: We conducted a retrospective analysis of patients followed for TLE-OA at the Neurology Department of Razi Hospital. Clinical features, interictal electroencephalography (EEG) and brain magnetic resonance imaging (MRI) were reviewed. Diagnostic criteria included the presence of recurrent episodes of transient amnesia with preservation of other cognitive functions, associated with ictal features, EEG abnormalities, or a clear response to antiseizure medication.

Results: Ten out of fourteen patients fulfilled diagnostic criteria for TEA. The mean age was 65.2 years (range 51–74), with equal sex distribution. The median time to diagnosis was 16.5 months. Two patients reported persistent cognitive/behavioral symptoms. EEG revealed epileptiform abnormalities involving the frontal and/or temporal regions in 50% of cases. MRI revealed focal abnormalities in one case. Anti-seizure therapy, most often with a single agent, resulted in improvement in all eight cases with available follow-up.

Conclusion: TEA represents a frequent yet underrecognized presentation of TLE-OA rather than a separate diagnostic entity. Because routine EEG and MRI findings may be normal, TEA is particularly prone to diagnostic delay and misclassification. Improved awareness of TEA as a form of epilepsy in older adults is essential, as early clinical recognition enables appropriate anti-seizure treatment and may limit long-term cognitive impact.

Disclosure: Nothing to disclose.

EPO-0397 | Long-term outcomes and predictors of response to vagus nerve stimulation in drug-resistant epilepsy

C. Dönmez¹; Y. Sele¹; A. Akkan Suzan¹; B. Türk¹; M. Delil¹; C. İşler²; T. Tanriverdi²; M. Uzan²; S. Yeni¹; Ç. Özkara¹

¹Department of Neurology, Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Istanbul, Türkiye; ²Department of Neurosurgery, Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Istanbul, Türkiye

Background and aims: Vagus nerve stimulation (VNS) is an established neuromodulatory treatment for drug-resistant epilepsy. Long-term studies suggest that its efficacy may increase over time. This study evaluate long-term clinical outcomes and potential predictors of treatment response in patients who underwent VNS implantation at a tertiary epilepsy center.

Methods: We retrospectively reviewed patients who received VNS therapy between 2005 and 2025. Potential predictors of VNS response included epilepsy classification (focal vs. generalized), underlying etiology (structural vs. non-structural), age at seizure onset, duration of epilepsy prior to VNS therapy, previous epilepsy surgery, maximum stimulation voltage, and duration of VNS therapy.

Results: A total of 122 patients were included. At the last follow-up, 30% of patients achieved a $\geq 50\%$ reduction in seizure frequency and were classified as responders. Patients with structural epilepsy ($n=64$) demonstrated a significantly higher responder rate compared to those with non-structural etiologies ($p=0.006$). The duration of VNS therapy was significantly longer in responders compared to non-responders (8.02 ± 4.73 years vs. 4.89 ± 4.02 years, $p=0.001$), supporting a time-dependent treatment effect. No significant associations were observed between treatment response and age at seizure onset ($p=0.373$), age at VNS implantation ($p=0.195$), duration of epilepsy prior to VNS therapy ($p=0.592$), or maximum stimulation voltage ($p=0.202$). Furthermore, maximum stimulation voltage was not associated with the occurrence of adverse effects.

Conclusion: VNS therapy demonstrates greater efficacy in patients with structural epilepsy and in those with longer treatment duration, supporting a cumulative and time-dependent therapeutic effect.

Disclosure: Nothing to disclose.

EPO-0398 | Clinical and demographic correlates of multifocal epileptiform activity in hospitalized adults

D. Carapinha; J. Silva; P. Neves; A. Martins; J. Peres
Neurology Department, ULS Amadora/Sintra, Portugal

Background and aims: Multifocal epileptiform activity, defined as the presence of at least three independent epileptiform foci involving both cerebral hemispheres on EEG, is poorly characterized clinically. Clinical observations suggest an association with advanced age, comorbidities, and systemic illness; however, these relationships have not been studied. We aimed to evaluate the clinical and demographic correlates of multifocal epileptiform activity in hospitalized adults.

Methods: Methods: We conducted a retrospective observational study including 80 hospitalized patients selected in reverse

chronological order from our institutional EEG database (accessed 30 November 2024): 40 with multifocal epileptiform activity and 40 with non-multifocal activity. Demographic data, medical history, EEG indication, metabolic disturbances defined by the ILAE as causes of acute symptomatic seizures, and neuroimaging findings were collected. Statistical significance was set at $p < 0.05$.

Results: Patients with multifocal epileptiform activity were older than those with non-multifocal activity ($p=0.003$). EEG indications differed between groups ($p=0.002$), with altered consciousness more frequent in the multifocal group and convulsive seizures in the non-multifocal group. Cognitive decline (OR 2.9; 95% CI 1.1–7.2; $p=0.024$) and sepsis (OR 9.8; 95% CI 1.2–82.1; $p=0.029$) were more frequent in the multifocal group. In a multivariable logistic regression, explaining approximately 25% of the variability ($p < 0.001$), only age remained independently associated with multifocal activity (OR 1.04; 95% CI 1.01–1.08; $p=0.020$).

Conclusion: Multifocal epileptiform activity in hospitalized adults occurs predominantly in older patients and is associated with altered consciousness and sepsis, suggesting that it reflects global disease severity rather than a specific epileptic etiology.

Disclosure: Nothing to disclose.

EPO-0399 | Efficacy and adverse event profile of pharmacological and non-pharmacological therapies in Dravet Syndrome: A systematic review

C. Michel¹; L. Pimentel¹; C. Quant¹; P. Miranda¹; M. Read¹; D. Vásquez¹; A. Tejada¹; K. Yorro¹; C. Pérez Lizardo¹; A. Reyes¹; M. Rodríguez²

¹Synaptic Research League, Santo Domingo, Dominican Republic; ²Hospital Universitario Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic

Background and aims: Dravet Syndrome (DS) is a severe epileptic encephalopathy with onset in early infancy that requires long-term pharmacological management [1]. Increasing evidence has highlighted significant treatment-related adverse effects, including cognitive, behavioral, and systemic complications [2]. This study aims to analyze and summarize treatment-associated complications in patients with Dravet Syndrome.

Methods: We conducted a systematic literature review following PRISMA guidelines. Of 74 studies, 7 were included. PubMed was searched using the keywords Dravet syndrome, treatment regimens, adverse effects, and treatment complications. Treatment regimens, outcomes, and adverse effects were evaluated.

Results: We analyzed 275 patients with Dravet syndrome. The mean age was 14.3 years. The most frequent treatments were fenfluramine, valproate, clobazam, and stiripentol, see Figure 1 Adjuvant therapies included cannabidiol/THC (19 patients) and a ketogenic diet (60 patients). A $\geq 50\%$ reduction in seizures was achieved in 58–83% of patients, with seizure freedom in 7.6–25%. Adverse effects were common (up to 59.1% somnolence, 31.5% total events) but generally manageable, leading to discontinuation in $< 21\%$ of cases.

Conclusion: Available evidence suggests that fenfluramine and ketogenic diet can reduce crisis in Dravet, with a minority achieving freedom from disease, while cannabinoids show variable answers. However, design heterogeneity, co-interventions and incomplete security report limit comparisons and robust

FIGURE 1 Prisma-P flowchart of the process of inclusion of studies in the systematic review.

FIGURE 2 Frequency of Pharmacological Regimens and Their Adverse Events of Dravet Syndrome.

meta-analysis. Studies with standardized structures are required and systematic follow-up of adverse events to better define risk-benefits.

Disclosure: Nothing to disclose.

	Inadequate sample	2 (3.3)

M – median, MTLE – mesial temporal lobe epilepsy, ASM – antiseizure medication, N – number, HS – hippocampal sclerosis, ILAE – International League Against Epilepsy

Background and aims: Ictal rhythms ≥ 5 Hz are well described as important predictors of favourable outcome after mesial temporal lobe epilepsy (MTLE) surgery. However, the precise anatomical structures involved in generation and propagation of these activities have not been fully understood. Aim of our study was to analyze structural brain alterations of anatomical regions typically involved in seizures in MTLE to determine associations with these rhythms.

Methods: This retrospective study included MRIs of 60 patients who underwent successful MTLE surgery and had at least one seizure documented during video-EEG monitoring (Table 1). Patients were classified based on observed rhythmic ictal activity ≥ 5 Hz in alpha and fast theta frequency. Volumes of 25 brain structures were analyzed. Univariate and multivariate logistic regression models were used to determine structures associated with temporal alpha (TA) and fast temporal theta (FTT).

Results: We observed TA in 20 seizures in seven patients and FTT in 219 seizures in 39 patients. Demographic and clinical variables (age, sex, and age at epilepsy onset) did not differ significantly between patients groups based on presence of TA and FTT. Univariate logistic regression analysis identified significant association between TT and three corpus callosum regions: mid-posterior, central and mid-anterior, while TA showed an association with ipsilateral thalamus and isthmus gyri cinguli. Multivariate analysis revealed that only the mid-anterior corpus callosum was an independent predictor of TT, while ipsilateral thalamus and isthmus gyri cinguli were both independent predictors of TA.

Conclusion: Mid-anterior corpus callosum, thalamus, and isthmus gyri cinguli are significantly associated with TT and TA in MTLE.

Disclosure: Nothing to disclose.

EPO-0402 | Cenobamate for refractory epilepsy secondary to primary CNS tumours: Real-world outcomes across WHO classifications

M. Elbadri; S. Bose; S. Samarasekera

Department of Neurology, Queen Elizabeth Hospital, Mindelsohn Way, Edgbaston, Birmingham, UK

Background and aims: Epilepsy is the commonest chronic and life-limiting neurological co-morbidity associated with primary central nervous system (CNS) tumours. Cenobamate

(CNB), a third generation antiseizure medication (ASM), has demonstrated high efficacy in focal epilepsy. Evidence for its efficacy in brain tumour-related epilepsy (BTRE) remains limited. We evaluated the real-world tolerability and effectiveness of CNB in BTRE.

Methods: Patients with BTRE attending the Queen Elizabeth hospital Birmingham who were prescribed CNB between 2022 and 2025 were observed. Tumours were classified according to the 2021 WHO CNS tumour classification. Data including tumour histology and grade, baseline seizure frequency and adverse events were recorded. The primary outcome was significant ($\geq 50\%$) seizure reduction. Additional outcomes included $\geq 90\%$ seizure reduction, change in ASM burden and tolerability.

Results: 25 Patients representing a broad spectrum of WHO tumour entities (grades I–IV) were included. Median duration of follow up was 19 months. Mean number of concomitant ASMs decreased from 2.75 at baseline to 1.79 following CNB initiation. 11/25 patients (44%) achieved a $\geq 50\%$ reduction in seizure frequency. 6 patients (24%) achieved $\geq 90\%$ seizure reduction. Response was observed across multiple tumour subtypes and WHO grades. CNB was generally well tolerated. Treatment discontinuation due to adverse effects (commonly somnolence and sedation) occurred in 3/25 patients (12%).

Conclusion: This is the largest real-world cohort of patients with refractory BTRE treated with CNB. CNB was associated with significant seizure reduction in over 40%. These findings support Cenobamate as a valuable therapeutic option in BTRE, irrespective of tumour type.

Disclosure: Dr Shanika Samarasekera has received speaker honoraria from Angelini Pharma. QEHB has been supported by Angelini Pharma with a grant for an epilepsy pharmacist.

EPO-0403 | IPCEF1-mediated NMDA receptor trafficking: A novel IL-1 β -driven mechanism linking inflammation to epileptogenesis and NREM sleep desynchrony

P. Yi¹; S. Huang²; F. Chang²

¹Department of Sport Management, Aletheia University, New Taipei City, Taiwan; ²Department of Veterinary Medicine, National Taiwan University, Taipei, Taiwan

Background and aims: Epilepsy often co-occurs with sleep disturbances, but molecular links between inflammation, excitatory plasticity, and these comorbidities are unclear. We hypothesised that IL-1 β signalling activates the PIP3–AKT–NF- κ B cascade to upregulate IPCEF1, promoting NMDA receptor (NMDAR) trafficking and hippocampal hyperexcitability, thereby driving seizures and non-rapid eye movement (NREM) sleep desynchrony.

Methods: Pentylentetrazol (PTZ) kindling (35 mg/kg i.p., every 48 h for 14 days) was induced in wild-type and IL-1R1 knockout mice. Interventions included IL-1 receptor antagonist (IL-1ra) and inhibitors of PIP3–AKT–NF- κ B signalling (PIT-7, HS-173, BMS-345541). Continuous EEG/EMG monitored seizures and sleep architecture. Hippocampal inflammation (IL-1 β , microglia, astrocytes) and NMDAR subunit expression/trafficking were assessed by Western blotting and immunofluorescence. IPCEF1 was specifically silenced to isolate its role.

IL-1 β -driven IPCEF1-mediated NMDAR trafficking links inflammation to epileptogenesis and cortical desynchrony in NREM sleep.

Results: PTZ kindling elevated hippocampal IL-1 β , glial activation, synaptic NMDAR enrichment, seizure frequency, and disrupted NREM slow-wave synchrony. Blocking IL-1R1 or downstream cascade prevented inflammation, reduced NMDAR trafficking, suppressed seizures, and normalised sleep. Notably, IPCEF1 silencing selectively reduced seizures and restored NREM synchrony without affecting total sleep–wake distribution.

Conclusion: IL-1 β -driven IPCEF1-mediated NMDAR trafficking links inflammation to epileptogenesis and cortical desynchrony in NREM sleep. The IL-1-IPCEF1-NMDAR axis represents a precise therapeutic target for controlling seizures and sleep comorbidities in epilepsy.

Disclosure: Nothing to disclose.

EPO-0404 | From seizures to vascular risk: Carotid ultrasound markers in epilepsy

F. Dono; R. Agosto; M. Russo; M. Di Pietro; S. Sensi
Department of Neuroscience, Imaging and Clinical Science,
“G. d’Annunzio” University of Chieti-Pescara, Chieti, Italy

Background and aims: Cardiovascular risk may be increased in epilepsy, potentially influenced by chronic anti-seizure medication (ASM) exposure. Carotid intima-media thickness (IMT) is a validated surrogate marker of subclinical atherosclerosis. We investigated whether carotid IMT differs according to drug-resistant epilepsy (DRE) and exposure to enzyme-inducing ASMs.

Methods: We consecutively enrolled patients attending a tertiary epilepsy center between January 2025 and January 2026. Seventy-one subjects underwent carotid ultrasound assessment. Right, left, mean, maximal IMT and side-to-side IMT difference were recorded, along with carotid stenosis. Participants were stratified by DRE status and by enzyme-inducing ASM exposure.

Results: No demographic or lifestyle differences were observed between DRE and non-DRE groups, nor between participants with vs without exposure to enzyme-inducing ASMs. Carotid IMT measures were not significantly different between DRE vs non-DRE (right IMT $p=0.673$; left IMT $p=0.173$; mean IMT $p=0.223$; maximal IMT $p=0.143$). A non-significant trend toward higher left and maximal IMT was observed in DRE. No significant differences were found according to enzyme-inducing ASM exposure (right IMT $p=0.813$; left IMT $p=0.503$; mean

IMT $p=0.673$; maximal IMT $p=0.513$). Carotid stenosis prevalence was comparable between exposure groups ($p=0.972$).

Conclusion: In this cohort, DRE and enzyme-inducing ASM exposure were not associated with increased carotid IMT. Larger samples may clarify whether the observed DRE trend reflects a true biological effect.

Disclosure: Nothing to disclose.

EPO-0405 | Plasma NfL and phosphorylated tau as emerging biomarkers of neuronal injury in pediatric drug-resistant epilepsy: A preliminary study

S. Drago¹; A. Butera¹; F. Polito²; G. Irene²; L. Licitri²; V. Macaione²; G. Di Rosa³; M. Aguenouz²

¹Department of Chemical, Biological, Pharmaceutical and Environmental Sciences, University of Messina, Messina, Italy;

²Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; ³Dipartimento di Scienze biomediche, odontoiatriche e delle immagini morfologiche e funzionali, University of Messina, Messina, Italy

Background and aims: Pediatric drug-resistant epilepsies represent a significant clinical challenge, profoundly affecting neurocognitive development, quality of life, and long-term prognosis. The identification of novel neurodegenerative biomarkers could improve patient stratification, clinical management, and support the development of therapies.

Methods: A prospective study was conducted analyzing blood samples from patients with drug-resistant epilepsy followed at the Pediatric Neuropsychiatry Unit of Messina. Biomarker levels were measured. Descriptive analyses were performed, while Spearman's rank correlation analyses were conducted to evaluate the relationships between biomarker levels and clinical variables.

Results: The study included 14 pediatric patients with drug-resistant epilepsy (mean age 8.5 years), and 8 (57.1%) were male. Plasma biomarker showed a mean neurofilament light chain (NfL) level of 31.997 pg/mL, pTau181 mean value of 1.172 pg/mL, pTau217 showed a mean of 0.179 pg/mL. Compared with age matched reference values, 10 patients (71.4%) exhibited elevated NfL levels, and 7 (50%) showed increased pTau217. The most frequent diagnosis was epileptic encephalopathy (42.9%), including Lennox-Gastaut (21.4%) and Dravet syndrome (7.1%). EEG abnormalities were mainly diffuse fronto-centro-temporal (28.6%), parieto-temporal/post-central (28.6%), or non-localized (21.4%). Overall, patients with early onset complex encephalopathies showed the most severe biochemical profiles, whereas those with Lennox-Gastaut syndrome exhibited consistently lower NfL levels.

Conclusion: Correlation analyses showed NfL positively associated with pTau217 ($p=0.55$, $p=0.041$) and pTau181 with pTau217 ($p=0.70$, $p=0.005$). These results suggest NfL and pTau217 are sensitive, complementary biomarkers of neuronal injury in children with drug-resistant epilepsy, with potential for disease stratification and clinical decision.

Disclosure: Nothing to disclose.

EPO-0406 | Evaluating gender related outcomes with adjunctive cenobamate in focal-onset seizures

S. Lattanzi¹; B. Steinhoff²; E. Alvarez-Baron³; J. Leach³; P. Perez-Domper³; V. Villanueva⁵; Thangavelu⁴

¹Department of Experimental and Clinical Medicine, Neurological Clinic, Marche Polytechnic University, Ancona, Italy; ²Department for Adults, Kork Epilepsy Center, Kehl-Kork, Germany Clinic for Neurology and Neurophysiology, University of Freiburg, Germany; ³Global Medical Department, Angelini Pharma S.p.A, Rome, Italy; ⁴MeDaStats LLC, Tampa, USA; ⁵Refractory Epilepsy Unit, Neurology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain, Member of ERN Epicare

Background and aims: Sex differences are observed in neurological disorders and may be apparent in prevalence, clinical presentation, and treatment outcomes. In epilepsy, sex related factors can influence the selection and dosing of antiseizure medications (ASMs), yet little is known about variations in treatment response. This analysis explored potential differences in the efficacy and safety of adjunctive cenobamate (CNB).

Methods: This post-hoc analysis of the C017 placebo-controlled double-blind trial evaluated efficacy and safety of CNB in adults with uncontrolled focal-onset seizures despite 1–3 prior ASMs at stable doses. Outcomes were assessed by sex across CNB dose groups (100, 200, and 400 mg) and placebo.

Results: Females represented 49.5% of the randomized population. They had a median age of 40 years, 25 years since epilepsy diagnosis, and a baseline seizure frequency of 10 seizures/28 days. Males had a median age of 37 years, 21.4 years since diagnosis, and a baseline seizure frequency of 8.65 seizures/28 days. Seizure freedom rates during maintenance-phase in males were 3.6%, 10.2%, and 25.0% for CNB 100, 200, and 400 mg, respectively, versus 1.8% for placebo. In females, rates were 4.3%, 12.2%, and 17.6% for the same CNB doses, with 0% for placebo. The incidence and nature of adverse events were similar between sexes across CNB groups.

Conclusion: Cenobamate demonstrated consistent efficacy and a similar tolerability profile in both females and males. Although small numerical differences were observed, no clear meaningful sex related differences emerged. These findings suggest that treatment-benefit from CNB is not sex dependent.

FIGURE 1 Seizure Freedom Rates during the Maintenance Phase.

EPO-0407 | Time to pre-randomization monthly seizure frequency for patients with uncontrolled focal onset seizures treated with cenobamate

S. Lattanzi¹; V. Villanueva²; E. Alvarez-Baron³; J. Leach³; P. Perez-Domper³; K. Thangavelu⁴; B. Steinhoff⁵

¹Department of Experimental and Clinical Medicine, Neurological Clinic, Marche Polytechnic University, Ancona, Italy; ²Refractory Epilepsy Unit, Neurology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain, Member of ERN Epicar; ³Global Medical Department, Angelini Pharma S.p.A, Rome, Italy; ⁴MeDaStats LLC, Tampa, USA; ⁵Department for Adults, Kork Epilepsy Center, Kehl-Kork, Germany Clinic for Neurology and Neurophysiology, University of Freiburg, Germany

Background and aims: The updated EMA guideline on clinical investigation in epileptic disorders (September 2025) recognizes time to event endpoints as a potential approach for primary analyses, with the aim of reducing exposure to placebo. This post hoc analysis evaluated the time required to reach pre randomization monthly seizure frequency as a measure of cenobamate (CNB) efficacy.

Methods: Data were derived from the C017 randomized, placebo-controlled trial in adults with uncontrolled focal onset seizures receiving 1–3 concomitant ASMs at stable doses. Time to achieving the individual 28-day baseline seizure rate was compared between placebo and CNB treatment groups (100, 200, and 400 mg/day). Analyses included the proportion of patients reaching baseline seizure frequency and the median time to event during the maintenance phase.

Results: The proportion of patients reaching baseline seizure rate was 89.1% with placebo versus 76.4% ($p=0.0161$), 66.9% ($p<0.001$), and 51.7% ($p<0.001$) with CNB 100, 200, and 400 mg, respectively. Median (95% CI) time to baseline seizure frequency was 5.34 (4.71–6.29) weeks for placebo, compared with 6.00 (5.57–8.14) weeks for CNB 100 mg, 8.71 (7.43–11.57) weeks for CNB 200 mg, and 10.86 (8.43–NA) weeks for CNB 400 mg.

Conclusion: Cenobamate significantly prolonged the time to pre randomization monthly seizure rate and reduced the proportion of patients reaching it compared with placebo in a dose-dependent manner. Consistent with previously reported outcomes, higher CNB doses resulted in greater effects. These findings support time to baseline seizure rate as a promising endpoint for future epilepsy trials.

Headache 3

EPO-0408 | Migraine without vascular risk factors versus controls: White matter hyperintensities align with systemic inflammation and atherogenic lipid ratios

A. Kale; N. Tepe; G. Ertürk Kale

Neurology, Balıkesir University Health Practice and Research Hospital, Balıkesir/Türkiye

Background and aims: To compare white matter hyperintensities (WMH) between a control group and migraine patients classified according to the Fazekas score, and to evaluate their relationships with disease burden, inflammatory and lipid indices.

Methods: Retrospective cross-sectional analysis of 320 adults: controls ($n=90$), migraine with Fazekas-0 ($n=112$), and migraine with Fazekas 1–3 ($n=118$). Participants had no vascular comorbidities. WMH were graded on brain magnetic resonance imaging (MRI). We analyzed C-reactive protein (CRP), systemic immune-inflammation index (SII), total-cholesterol to high-density lipoprotein ratio (TC/HDL) and atherogenic index of plasma (AIP). Group comparisons used Welch or Kruskal-Wallis tests with Holm correction. In migraine, Spearman correlations and logistic regression assessed associations with WMH.

Results: CRP increased across groups (median 1.22 in controls, 1.12 in Fazekas-0, 2.19 in Fazekas 1–3; $p=1.1e-8$). TC/HDL also

FIGURE 1 Relationship between Fazekas score and TC/HDL in migraine group.

FIGURE 2 CRP – Comparison of 3 groups; found to be statistically significant.

FIGURE 3 TC/HDL – Comparison of 3 groups; found to be statistically significant.

increased (mean 3.00, 3.70, 5.15; $p=1.4e-30$), and AIP was higher in Fazekas 1–3 (mean 0.14, 0.15, 0.17; $p=0.0011$). SII did not differ ($p=0.256$). In migraine, Fazekas score correlated with TC/HDL (Spearman $r=0.53$, $p=5.6e-18$) and CRP ($r=0.30$, $p=4.3e-6$). After adjustment for age, migraine duration, and monthly attack frequency, TC/HDL (odds ratio (OR) 3.84 per-unit, $p=5.1e-8$) and CRP (OR 1.47 per-unit, $p=0.0019$) remained associated with

WMH. In the Fazekas 1–3 migraine group, disease duration and monthly attack frequency were significantly higher than in the Fazekas-0 group ($p<0.001$). Among aura patients, right-to-left shunt rates were higher in Fazekas 0 than Fazekas 1–3, but not statistically significant (38.7% vs 33.3%).

Conclusion: In migraine without vascular comorbidities, higher WMH burden is linked to higher CRP and more atherogenic lipid profile (TC/HDL and AIP), while SII was not discriminative. Longitudinal studies are needed.

Disclosure: Nothing to disclose.

EPO-0409 | Most bothersome non-pain symptoms in migraine and their response to CGRP monoclonal antibodies: A service evaluation

P. Amaraseena; A. Gimson; F. Greenwood; S. Maniataki; U. Ashraf; M. Villar-Martinez; N. Karsan; P. Goadsby
Headache Group, Wolfson Sensory, Pain and Regeneration Centre, King's College London, London, UK

Background and aims: Monoclonal antibodies targeting calcitonin gene-related peptide (CGRP-mAbs) have been in wide use as migraine preventives for five years. They have potential efficacy in improving the most bothersome non-pain symptoms (MBS).

Methods: Patients currently on mAbs at King's College Hospital, London completed a questionnaire, and clinical and efficacy data were collected from patient records as part of a service evaluation. Associations between categorical variables were assessed using Pearson Chi-Square tests.

Results: A total of 223 patients responded (median age 48 years; 82% female): chronic migraine (62%), episodic migraine (29%), and new daily persistent headache with migraine phenotype (9%). Fatigue was the most frequent MBS ($n=44$, 20%), followed by brain fog ($n=38$, 17%), neck stiffness ($n=31$, 14%), nausea ($n=26$, 12%) and photophobia ($n=21$, 9%). Overall, 191 (88%) reported >30% improvement in headache with their current CGRP-mAb; however, only 107 (56%) of responders reported improvement in their MBS. Improvement of the MBS had a statistically significant positive effect on headache improvement ($\chi^2=7.77$, $P=0.005$). Of those who reported headache improvement with mAbs, majority of those who identified fatigue (56%), brain fog (58%), photophobia (67%) and nausea (77%) as the MBS reported improvement and only 46% of those who identified neck stiffness as the MBS reported improvement.

Conclusion: Fatigue, brain fog and neck stiffness are the most common non-pain symptoms among migraine patients. Despite headache improvement with CGRP-mAbs, many patients continue to experience their most bothersome non-pain symptoms, particularly neck stiffness.

Disclosure: PA, AG, FG, SM, UA, MV and NK have nothing to declare. PJG reports, over the last 36 months, personal fees from Aeon Biopharma, Abbvie, Aurene, CoolTech LLC, Dr Reddy's, Eli-Lilly and Company, Kallyope, Linpharma, Lundbeck, Pfizer, PureTech Health LLC, Satsuma, Seaport Therapeutics, Shiratronics, and Teva Pharmaceuticals.

EPO-0410 | CGRP monoclonal antibodies in migraine: Persistence of premonitory symptoms in the absence of headache — A service evaluation

P. Amarasekera; A. Gimson; F. Greenwood; G. Sebastianelli; S. Maniataki; U. Ashraf; M. Villar-Martinez; D. Moreno-Ajona; N. Karsan; P. Goadsby
Headache Group, Wolfson Sensory, Pain and Regeneration Centre, King's College London, London, UK

Background and aims: Monoclonal antibodies targeting calcitonin gene-related peptide (CGRP-mAbs) have been in wide use for migraine prevention for five years. They have efficacy on headache and potential effects on premonitory symptoms (PreS).

Methods: Patients currently receiving CGRP-mAbs at King's College Hospital, London completed a questionnaire, including data on PreS as part of a service evaluation. Clinical data were extracted from patient records. Associations between categorical variables were assessed using McNemar's tests.

Results: A total of 223 patients responded (median age 48 years; 82% female); chronic migraine (62%), episodic migraine (29%), and new daily persistent headache with migraine phenotype (9%). Overall, 188 patients (84%) recognised PreS, with a median of 6 symptoms (IQR 2–9). Most common PreS were fatigue (67%), neck stiffness (58%) and brain fog (58%). Yawning (McNemar's $\chi^2 = 4.985$, $P = 0.026$) and euphoria (exact McNemar test, $P < 0.001$) were more likely to occur in the premonitory phase than the headache phase. Food cravings were more common in the premonitory phase without statistical significance. Build-up of PreS without headache was reported by 114 (53%), which included 54% ($n = 104$) of patients with $> 30\%$ improvement in headache and 38% ($n = 10$) of those with $< 30\%$ improvement. Median number of PreS in this group was 5 (IQR 3–7). Brain fog (60%), fatigue (54%), and neck stiffness (51%) were most common and the duration of PreS was 1–24 hours in most (67%).

Conclusion: PreS are recognised by a significant majority of migraine patients. Over half of those responding to mAbs continue to experience PreS without headache.

Disclosure: PA, AG, FG, SM, UA, MV and NK have nothing to declare. PJG reports, over the last 36 months, personal fees from Aeon Biopharma, Abbvie, Aurene, CoolTech LLC, Dr Reddy's, Eli-Lilly and Company, Kallyope, Linpharma, Lundbeck, Pfizer, PureTech Health LLC, Satsuma, Seaport Therapeutics, Shiratronics, and Teva Pharmaceuticals.

EPO-0411 | Persistent headache attributed to ischemic stroke: Impact on health-related quality of life

H. Weber¹; M. Naumann¹; D. Freuer²; C. Meisinger²; J. Linseisen²; M. Ertl³; L. Braadt¹

¹Department of Neurology and Clinical Neurophysiology, University Hospital Augsburg, Augsburg, Germany;

²Epidemiology, Faculty of Medicine, University of Augsburg, Augsburg, Germany; ³Department of Neurology and Neurological Rehabilitation, BKH Günzburg, Günzburg, Germany

Background and aims: Persistent headache attributed to ischemic stroke (PHAIS) is a chronic headache disorder developing

after ischemic stroke. While demographic and clinical characteristics have already been described, impairment of the health-related quality of life (QoL) in patients suffering from PHAIS has not yet been demonstrated. This study aims to investigate whether PHAIS impairs the QoL at 12 months after stroke using the Stroke Impact Scale (SIS).

Methods: Data was derived from the Prospective Stroke Cohort Augsburg (SCHANA I & II). After baseline assessment, patients completed a 3- and 12-month follow-up regarding headache characteristics (Rostock Headache Questionnaire) and QoL (SIS). PHAIS was defined as new onset headache since stroke persisting at 12 months. Statistical analyses comprised Kruskal-Wallis-Tests including post-hoc tests and median regression adjusted for age, sex and history of migraine. Bonferroni-correction was applied to account for multiple testing.

Results: Of 973 valid responses at 12-month follow-up, 35 (3.6%) met PHAIS criteria. Patients classified with PHAIS had significantly reduced scores in SIS Domain Memory compared to patients without headaches ($p = 0.015$). In multivariable median regression, SIS Domain Memory remained impaired (estimate: -5.03 , 95% confidence interval: -7.02 to -3.05 , $p < 0.001$). Phenotype of PHAIS was heterogeneous with 15% of patients having migraine-like, 12% tension-like and 15% unspecific symptoms.

Conclusion: PHAIS significantly impairs SIS Domain Memory at 12 months after stabilisation of stroke, independently of age, sex and history of migraine. Our findings support the consideration of routine headache assessment in poststroke follow-ups and may indicate the necessity of future adaptations of PHAIS in poststroke guidelines.

Disclosure: Nothing to disclose.

FIGURE 1: Multivariable median regression for all SIS outcomes.

J. Versijpt¹; K. Fanning²; P. Gandhi³; N. Chalermphananupap³; E. Leroux⁴; P. Jacob³; K. Carr³; D. Buse⁵; R. Gil-Gouveia⁶
¹Department of Neurology, Universitair Ziekenhuis Brussel, Brussels, Belgium; ²MIST Research, Wilmington, USA; ³AbbVie, North Chicago, USA; ⁴Montreal Neurological Clinic, Montreal, Canada; ⁵Department of Neurology, Albert Einstein College of Medicine, Bronx, USA; ⁶Neurology Department, Hospital da Luz, Lisbon, Portugal; Center for Interdisciplinary Research in Health, Universidade Católica Portuguesa, Lisbon, Portugal

Background and aims: Individuals with migraine may experience suboptimal efficacy or adverse events with triptans, potentially contributing further to disease burden, particularly among working populations. CaMEQ-I, a multi-country, cross-sectional, observational survey study, assessed the burden of migraine internationally. This analysis evaluates the impact of the number of triptans trialed on work productivity loss and annual indirect costs, among employed individuals with migraine.

Methods: This post hoc analysis included employed adults with complete Work Productivity and Activity Impairment (WPAI) data from CaMEQ-I, stratified by number of triptans trialed: current user (0), 1, 2, and ≥ 3 . Median work impairment and indirect costs were measured via WPAI. Indirect costs were estimated in respondents' local currency, scaled using country-specific working weeks, and adjusted for inflation to October 2025 values.

Results: Here, data from US ($n=565$), UK ($n=506$), and Germany ($n=571$) are reported; results for all six countries are in the complete analysis. Median WPAI: overall work productivity impairment ranged from 50.0–85.8%, increasing with the number of triptans trialed (Figure 1). Parallel trends were observed in median annual indirect costs. Those who trialed ≥ 3 triptans generally demonstrated the highest indirect costs: \$32,927 (US), £18,964 (UK), and €24,716 (Germany). Across all countries, indirect cost generally increased across response strata, with most countries showing the greatest cost burden among individuals who trialed ≥ 3 triptans (Figure 2).

Conclusion: Insights from the CaMEQ-I study suggest that among employed individuals with migraine, trialing multiple triptans is associated with increases in both work productivity loss and indirect costs, across multiple countries.

EPO-0413 | Familial hemiplegic migraine and treatment with CGRP-mabs – A swiss cohort study

L. Krenger; F. Riederer; N. Slavova; A. Scutelnic; A. Maurer; L. Weichsel; C. Schankin
 Neurology, Inselspital, Bern, Switzerland

Background and aims: Familial Hemiplegic Migraine (FHM) is a rare hereditary migraine subtype characterized by motor aura with potentially severe neurological manifestations. Treatment is mostly based on standard migraine therapies, as FHM is usually excluded from clinical trials and existing evidence mainly consists of case reports and series. We present a single-center cohort study to evaluate disease course and treatment, focusing on calcitonin gene-related peptide (CGRP)-based therapies.

Methods: We retrospectively analyzed a cohort of 13 patients with FHM ($N=11$) or probable FHM ($N=2$) treated at

Inselspital Bern, based on medical records and headache diaries. Two patients received the anti-CGRP monoclonal antibody (mab) erenumab.

Results: Eight women and five men were followed for a median of 2, 35 years (range 0–11). Three patients had genetically confirmed FHM type 1 and two had type 2. Clinical course varied, ranging from infrequent mild attacks to severe migraines with prolonged neurological symptoms. Patients requiring prophylaxis, showed favorable responses to lamotrigine, flunarizine, or propranolol. Several patients used triptans acutely without reported adverse events. Two patients (one with FHM1, one with FHM2) with frequent, severe attacks refractory to multiple prophylactic therapies were treated with erenumab. In combination with other medications, antibody therapy reduced attack frequency and severity, although efficacy declined over time in one patient.

Conclusion: This case series highlights the heterogeneity of FHM and the need for individualized treatment strategies. While evidence remains limited, mabs, and combination therapies may represent effective and well-tolerated prophylactic options in selected patients. Further data collection on CGRP mabs in FHM is warranted.

Disclosure: FR: Speaker and consultancy honoraria from Lundbeck, Teva, Abbvie, Merz The authors declare no potential conflicts of interest.

EPO-0414 | Lasmiditan efficacy and cardiovascular safety in high-risk patients: A systematic review and meta-analysis

S. Biswas¹; S. Vasireddy²; Y. Srivastava¹; S. Arora³; J. Rajamani⁴; F. GOHIL⁵; K. Jindal⁶

¹Department of Internal Medicine, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine; ²Department of Neurology, NMC Specialty Hospital, Abu Dhabi, United Arab Emirates; ³Department of Internal Medicine, University of Debrecen, Hungary; ⁴Department of Internal Medicine Medical College, Caucasus University, Tbilisi, Georgia; ⁵Department of Internal Medicine, Università Cattolica del Sacro Cuore, Rome; ⁶Department of Internal Medicine Government Medical College, Patiala

Background and aims: Approximately 20% of migraine patients have cardiovascular contraindications to triptans. Lasmiditan, a selective 5-HT_{1F} receptor agonist without vasoconstrictive properties, may offer a safer alternative, though systematic evidence in cardiovascular-risk populations remains limited.

Methods: We systematically searched MEDLINE, Embase, Scopus, and Cochrane CENTRAL from inception to June 2025. Primary outcomes were pain freedom at 2 hours and major adverse cardiovascular events (MACE). We performed random-effects meta-analyses and assessed bias using Cochrane RoB 2 and ROBINS-I tools.

Results: Sixteen studies were included (5 lasmiditan efficacy trials with 5,555 participants, 10 triptan safety studies). Lasmiditan significantly increased pain freedom versus placebo (OR 2.28, 95% CI 1.94–2.67, $p < 0.001$; NNT 4.2–15.4) with clear dose-response relationships (50 mg: OR 1.29; 100 mg: OR 1.72; 200 mg: OR 2.10). Treatment effects remained consistent

across cardiovascular risk categories ($p = 0.56$ for interaction). Cardiovascular adverse events occurred in $< 1\%$ of patients with no increase in highest-risk patients (OR 1.48, $p = 0.56$). Zero vasoconstriction events occurred across $> 19,000$ treatment occasions. Central nervous system effects were common (dizziness 8.6–18.1% vs 2.5% placebo; NNH 6.4–16.4) but predominantly mild-to-moderate. Observational triptan data showed apparent MACE protection (HR 0.82, 95% CI 0.73–0.92), likely reflecting confounding.

Conclusion: Lasmiditan demonstrates robust efficacy and favorable cardiovascular safety with complete absence of vasoconstriction events. Given tolerability profiles, gepants may represent preferred first-line cardiovascular-safe alternatives, with lasmiditan reserved for gepant non-responders.

Disclosure: Nothing to disclose.

EPO-0415 | Impact of atogepant on functional outcomes for the preventive treatment of migraine: A Phase 3, open-label, 156-week, long-term safety extension study

M. Ashina¹; P. Gandhi²; S. Ashina³; C. Tassorelli⁴; S. Cho⁵; R. Man²; J. Smith²; J. Stokes²; K. Nagy²; P. Goadsby⁶

¹Danish Headache Center, Department of Neurology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; ²University of Copenhagen, Copenhagen, Denmark; ³AbbVie, North Chicago, USA; ⁴Harvard Medical School, Boston, USA; ⁵University of Pavia, Pavia, Italy; ⁶IRCCS Mondino Foundation, Pavia, Italy; ⁷Hallym University College of Medicine, Hwaseong, Korea; ⁸King Abdullah University of Science and Technology, Thuwal, Saudi Arabia; ⁹King's College London, UK

Background and aims: Evaluate the long-term impact of atogepant on functional outcomes for the preventive treatment of migraine.

Methods: An open-label, 156-week, long-term safety extension study enrolled adult participants with chronic or episodic migraine who had an inadequate response to 2–4 classes of conventional oral preventive treatment, and completed the lead-in studies PROGRESS or ELEVATE, respectively. The primary outcome was safety. Clinical efficacy and functional outcomes were prespecified exploratory analyses. Functional outcomes included change from baseline (CFB) in performance of daily activities (PDA) and physical impairment (PI) domain scores of the Activity Impairment in Migraine-Diary (AIM-D) and Migraine-Specific Quality of Life Questionnaire v2.1 (MSQv2.1) Role-Function Restrictive (RFR) domain score during 156 weeks.

Results: A total of 529 participants were included in the modified intent-to-treat population (PROGRESS, $n=285$; ELEVATE, $n=244$). Overall safety results were consistent with the known safety profile of atogepant. The mean (SD) change from lead-in study baseline in PDA domain score at weeks 13–16 was -16.0 (14.1), and this reduction (improvement) was consistent at 153–156 weeks [CFB = -16.0 (14.1)] (Figure 1a). The mean (SD) change from lead-in study baseline in PI domain score at weeks 13–16 was -13.2 (13.1), and this reduction was consistent through 153–156 weeks [CFB = -13.4 (13.6)] (Figure 1b). An improvement in MSQv2.1 RFR scores was demonstrated at week 12 and was consistent at week 156 (Figure 2).

Conclusion: Atogepant demonstrated improvements in functional outcomes at Week 12 and was consistent at 156 (MSQv2.1 RFR), and at Weeks 13–16 and was consistent at 153–156 (PDA and PI).

EPO-0416 | Workplace productivity improvements following preventive treatment with eptinezumab: Region-based analyses from the phase 3 SUNRISE trial

T. Takeshima¹; P. Pozo-Rosich²; Y. Matsumori³; B. Kim⁴; D. Danno⁵; M. Chu⁵; K. Ranc⁶; A. Ettrup⁶; B. Sperling⁶; A. Mittoux⁶; S. Yu⁷

¹Tominaga Hospital, Osaka, Japan; ²Headache Unit, Neurology Department, Vall d'Hebron University Hospital; Headache and Neurological Pain Research Group, VHIR, Barcelona, Spain; ³Sendai Headache and Neurology Clinic, Sendai, Japan; ⁴Eulji University School of Medicine, Seoul, Republic of Korea; ⁵Neurology Department, Severance Hospital, Yonsei University, Seoul, Republic of Korea; ⁶H. Lundbeck A/S, Copenhagen, Denmark; ⁷Department of Neurology, The First Medical Center, Chinese PLA General Hospital, Beijing, China

Background and aims: To evaluate migraine-related impairments in productivity and impact of eptinezumab versus placebo in the SUNRISE trial in chronic migraine, and to explore regional differences.

Methods: SUNRISE (NCT04921384) confirmed the migraine-preventive efficacy and safety of eptinezumab in participants with chronic migraine, predominantly from Asian countries. Adults (18–75y) diagnosed with chronic migraine were randomized 1:1:1 to 12-week double-blind treatment with IV eptinezumab 100mg, 300mg, or placebo. The patient-reported Migraine-specific Work Productivity and Activity Impairment questionnaire (WPAI:M), captured at baseline and at Weeks 4, 8, and 12, includes sub-scores for absenteeism, presenteeism, work productivity loss, and activity impairment. Region-based subgroup analyses were conducted post hoc for Asia and Europe. *p*-values are descriptive.

Results: Of 978 participants treated, 63%/37% were from Asia/Europe. Mean WPAI:M baseline sub-scores (total population) were absenteeism: 7–10%; presenteeism: 53–57%; work productivity loss: 55–60%; and activity impairment: 58–60% (Europe > Asia across sub-scores). In the full population, both eptinezumab

doses were associated with greater improvements from baseline versus placebo ($p < 0.05$) in presenteeism, productivity loss, and activity impairment at Weeks 4, 8, and 12. Smaller changes from baseline in absenteeism may reflect lower baseline scores, which could suggest participants working despite migraine burden.

Conclusion: In a predominantly Asian population with chronic migraine, eptinezumab provided greater improvements than placebo in workplace productivity and activity from Week 4 through Week 12. Participants from Asia reported less absenteeism (at baseline and improvement) than participants from Europe, reflecting a more pronounced pattern of work attendance despite a similar high level of migraine burden.

EPO-0417 | Hormonal migraine across the life course: European migraine in women survey results (EMHA), H2 2025

P. Pozo-Rosich¹; E. Ruiz de la Torre²; Goadsby³; D. Watson⁴; E. Couturier⁵; A. MacGregor⁶; R. Nappi⁷; E. Merki⁸; D. Hurtado⁹; C. Fairley¹⁰

¹Headache Clinic, Neurology Department, Vall d'Hebron University Hospital, Barcelona, Spain; ²European Migraine & Headache Alliance (EMHA); ³Division of Biomedical Sciences, King Abdullah University of Science and Technology, Saudi Arabia; and King's College London, London, UK; ⁴GPwER headache, Department of Neurology, Aberdeen Royal Infirmary, Aberdeen, Scotland; ⁵MD, Consultant Neurologist, Head of Department of Neurology, Neurologie Centrum Amsterdam, Amsterdam, The Netherlands; ⁶Centre for Neuroscience, Surgery and Trauma, Barts and the London School of Medicine and Dentistry, London, UK; and Centre for Reproductive Medicine, St Bartholomew's Hospital, London, UK; ⁷Department of Clinical, Surgical, Diagnostic and Pediatric Sciences, University of Pavia, Pavia, Italy; and Research Center for Reproductive Medicine, Gynecological Endocrinology and Menopause, IRCCS S. Matteo Foundation, Pavia, Italy; ⁸University of Zürich, Zürich, Switzerland; ⁹Prescient Healthcare Group; ¹⁰Prescient Healthcare Group.

Background and aims: Migraine attack improvement or worsening has been attributed to hormonal life stages, yet prospective, longitudinal data is limited and tailored management remains inconsistent. EMHA, with oversight from an interdisciplinary Scientific Committee, launched the Migraine in Women Survey to generate patient-reported evidence to inform education and care pathway improvements.

Methods: A cross-sectional online survey was conducted across 13 European countries. Recruitment used GAD3 and dissemination via EMHA national patient associations. Women (18–70) were screened using the validated 3-item ID Migraine tool (positive screen $\geq 2/3$), yielding 5,410 screened-positive respondents for analysis. Questions assessed headache patterns and care experiences across menstruation/perimenopause, pregnancy/postpartum, and menopause, with a separate path for transgender participants using hormone therapy.

Results: Overall, 42% reported no formal migraine diagnosis and 76% reported having discussed their attacks with a healthcare professional. Among menstruating/perimenopausal respondents ($n = 3,783$), 66% linked attacks to their period (38% most/every period; 28% some periods) and 47% reported attacks a few days before bleeding. Period-related attacks were more painful (36%), longer-lasting (28%), and more medication-resistant (20%) than non-menstrual attacks, yet only 23% reported being offered specific treatment options. 16% rated current treatments “very effective,” and 72% wanted more education on hormone-headache links.

Conclusion: Hormonal influences on migraine are commonly reported across Europe, but substantial gaps persist in diagnosis, healthcare engagement, and tailored management, supporting targeted clinician/patient education and improved hormonal migraine pathways.

¹Harvard Medical School, Boston, USA; ²AZ Sint-Jan Brugge, Brugge, Belgium; ³Pfizer Inc, Princeton, USA; ⁴Pfizer Inc, Groton, USA; ⁵Pfizer NV/SA, Brussels, Belgium

Background and aims: A previous phase 4 trial (NCT05518123) conducted in 14 countries evaluated the efficacy and tolerability of rimegepant for the prevention of episodic migraine in participants with a documented history of inadequate response to 2 to 4 categories of non-migraine-specific oral preventive medications (OPMs). This exploratory analysis evaluated rimegepant efficacy in participants with inadequate response to 3 or 4 prior non-migraine-specific OPM categories.

Methods: Following a 28-day observation phase (OP), adults not using preventive therapy with 4–14 monthly migraine days (MMDs) and <15 monthly headache days were stratified by OPMs with prior inadequate response and migraine days in the OP then randomized to double-blind treatment (DBT) with rimegepant 75 mg orally disintegrating tablet (ODT) or placebo every other day (EOD) for 12 weeks.

Results: 114 participants with documented prior inadequate response to 3 or 4 OPM categories were enrolled into the rimegepant group and 109 into the placebo group. In both DBT groups, most participants had 3 prior OPMs (81.6% and 84.4%) and ≥8 migraine days in the OP (64.9% and 66.1%). The primary endpoint analysis favored rimegepant vs. placebo: mean change from the OP in MMDs over the entire DBT phase was -2.1 vs. -0.6 (difference = -1.5; 95% CI = -2.4, -0.6; nominal $p = 0.0016$; Figure). Key secondary endpoint analyses also favored rimegepant (all nominal $p < 0.05$; Figure).

Conclusion: Rimegepant 75 mg ODT EOD demonstrated efficacy for the prevention of episodic migraine in participants with a documented history of inadequate response to 3 or 4 categories of non-migraine-specific OPM.

Disclosure: This study was sponsored by Pfizer. In the past 24 months, Paul G Mathew has served as a consultant for Pfizer, Abbvie, Axsome, Lilly, Theranica, and Tonix. For this abstract, he served as an uncompensated consultant and not in his capacity as a member of the HMS/MGB Faculty. Annelies Van Dycke has served on advisory/scientific boards and/or given lectures

Figure. Efficacy endpoint analyses in participants with a documented history of inadequate response to 3 or 4 categories of non-migraine-specific OPM

A shows the primary endpoint analysis in the subgroup of participants with a documented history of inadequate response to 3 or 4 categories of non-migraine-specific OPMs. B-F show key secondary endpoint analyses in the subgroup of participants with a documented history of inadequate response to 3 or 4 categories of non-migraine-specific OPMs. In these analyses, participants who had a ≥8% reduction from OP to MMDs over the entire DBT phase (A, C, D, and F) were analyzed using a modified effect size of 0.5 (0.5 = 0.50). The modified effect size was used for the primary endpoint analysis (A) and for the secondary endpoint analyses (B, C, D, E, and F) because the effect size of 0.5 is a more conservative estimate of the effect size. The modified effect size was used for the primary endpoint analysis (A) and for the secondary endpoint analyses (B, C, D, E, and F) because the effect size of 0.5 is a more conservative estimate of the effect size. The modified effect size was used for the primary endpoint analysis (A) and for the secondary endpoint analyses (B, C, D, E, and F) because the effect size of 0.5 is a more conservative estimate of the effect size.

EPO-0419 | Effectiveness And Safety of Monthly Versus Quarterly Fremanezumab for migraine prevention: A 12-Month Italian multicenter real-world study

R. Messina¹; A. Visentini¹; E. Ratto²; I. Cetta¹; F. Genovese¹; L. Zanandrea¹; C. Lovati³; S. Cevoli⁴; V. Favoni⁴; F. Vernieri⁵; C. Altamura⁵; B. Colombo²; M. Filippi¹

¹Neuroimaging Research Unit and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; ²Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³L. Sacco Department of Biomedical and Clinical Sciences, University of Milan, Milan, Italy; ⁴IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; ⁵Unit of Headache and Neurosonology, Department of Medicine and Surgery, University Campus Bio-Medico di Roma, and Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy

Background and aims: Fremanezumab, an anti-calcitonin gene-related peptide (CGRP) monoclonal antibody approved for migraine prevention, can be administered monthly (225 mg) or quarterly (675 mg). In clinical practice, regimen selection is mainly based on patient preference, while real-world evidence comparing the effectiveness of the two dosing strategies remains limited. We aimed to compare monthly versus quarterly fremanezumab in a real-life setting over 12 months.

Methods: This prospective, multicenter, real-world study involved four Italian headache centers. Patients received monthly or quarterly fremanezumab according to preference. Primary endpoints were changes in monthly migraine days (MMD) and monthly headache days (MHD) at 3, 6, and 12 months, and the occurrence of adverse events (AEs). Secondary endpoints included $\geq 30\%$, $\geq 50\%$, and $\geq 75\%$ responder rates in migraine frequency, reductions in monthly acute medication days (AMD) and pills (AMP), changes in disability and clinical scores (MIDAS, HIT-6, NRS, ASC-12), and medication-overuse headache (MOH) cessation.

Results: A total of 294 patients were enrolled (152 monthly; 142 quarterly). At 6 months, 138 and 133 patients, and at 12 months, 98 and 102 patients completed follow-up in the monthly and quarterly groups, respectively. Baseline characteristics were comparable. Both regimens showed similar reductions in MMD and MHD across all time points, with no significant differences in AEs. Improvements in AMP, AMD, MIDAS, HIT-6, NRS, and ASC-12 scores were comparable, as were responder rates and MOH cessation.

Conclusion: Monthly and quarterly fremanezumab demonstrated comparable effectiveness and safety for migraine prevention over 12 months in a real-world setting.

Disclosure: Nothing to disclose.

EPO-0420 | [18F]- FDG-PET metabolic patterns in idiopathic normal pressure hydrocephalus and neurodegenerative disorders: A voxel-wise analysis

C. Espinoza-Vinces¹; E. Prieto²; I. Avilés-Olmos¹; J. Núñez-Córdoba³; G. Martí-Andrés⁴; J. Arbizu²; M. Luquin¹
¹Department of Nuclear Medicine, Clínica Universidad de Navarra, Pamplona, Spain; ²Department of Nuclear Medicine, Clínica Universidad de Navarra, Pamplona, Spain; ³Research Support Service-Central Clinical Trials Unit, Clínica Universidad de Navarra, Pamplona, Spain; ⁴Department of Neurology, University Hospital of Navarra, Pamplona, Spain

Background and aims: Idiopathic normal pressure hydrocephalus (iNPH) is a potentially treatable cause of gait impairment that frequently overlaps clinically and radiologically with neurodegenerative disorders (ND). We aimed to identify [18F]-FDG-PET metabolic patterns associated with iNPH in comparison with ND in patients presenting with ventriculomegaly.

Methods: We retrospectively analysed 50 adults (mean age 72.0 $\pm$ 7.5 years) with gait impairment and ventriculomegaly, characterised by disproportionately enlarged subarachnoid-space hydrocephalus, with supportive features including Evans Index >0.30 and callosal angle $<90^\circ$. Diagnostic classification integrated neurological and cognitive assessments, brain MRI, CSF biomarkers when available, and dopaminergic imaging when required. Final diagnoses and key characteristics are summarised in Tables 1 and 2. FDG-PET scans underwent blinded visual interpretation at baseline by an experienced nuclear medicine specialist. Voxel-wise analyses were performed in SPM on spatially and intensity-normalised images. Group comparisons used

TABLE 1 Demographic and clinical characteristics of patients with ventriculomegaly classified by predominant clinical phenotype.

Characteristic	Predominant ND phenotype (n= 24)	Predominant iNPH phenotype (n=26)
Sex M/F ^a	9/15	10/16

¹Dublin Neurological Institute at the Mater Misericordiae University Hospital, Dublin, Ireland; ²University Hospital Limerick, Limerick, Ireland; ³Children's Health Ireland at Temple Street, Dublin, Ireland; ⁴James J and Joan A Gardner Center for Parkinson's disease at the University of Cincinnati, Ohio, USA

Background and aims: PRKRA-related dystonia-parkinsonism (DYT-PRKRA) is a rare autosomal recessive disorder typically presenting with childhood-onset progressive generalised dystonia. We report a case with an acute encephalopathic presentation triggered by febrile illness, a phenotype that remains poorly characterised.

Methods: We describe the longitudinal clinical, neuroimaging, and genetic findings of a patient with an acute encephalopathic onset followed by progressive dystonia. Clinical data were obtained from serial neurological assessments. Brain MRI studies were reviewed longitudinally, with particular focus on basal ganglia involvement. Genetic investigations included metabolic testing, mitochondrial studies, and whole-exome sequencing.

Results: A previously healthy child developed an acute encephalopathy at 3 years of age following a viral febrile illness, characterised by somnolence, loss of ambulation, axial hypotonia, ataxia, dysarthria, and pyramidal signs. Cerebrospinal fluid, metabolic, and infectious investigations were unremarkable. Brain MRI demonstrated bilateral putaminal T2 hyperintensities, subsequently evolving into progressive putaminal atrophy (Figure 1). Mitochondrial genetic testing and muscle biopsy were normal. Partial neurological recovery occurred, followed by progressive generalised dystonia with prominent oromandibular involvement during adolescence. Treatment with levodopa, biotin, and thiamine was ineffective. Whole-exome sequencing identified a homozygous likely pathogenic variant in PRKRA (c.665C>T; p.Pro222Leu), confirming the diagnosis of DYT-PRKRA.

Conclusion: This case demonstrates that DYT-PRKRA may present with an acute encephalopathic phenotype triggered by febrile illness, mimicking ATP1A3-related rapid-onset dystonia-parkinsonism, but distinguished by striatal necrosis on MRI. These findings support a shared clinicopathological spectrum among PRKRA-, ATP1A3-, and SLC19A3-related

FIGURE 1 Voxel-wise FDG-PET metabolic patterns across major neurodegenerative disorders in patients with ventriculomegaly.

independent-sample t-tests and ANOVA at a voxel-level threshold of $p < 0.005$. Statistical parametric maps were projected onto a T1-weighted MRI template.

Results: Voxel-wise comparisons demonstrated metabolic differences between iNPH and ND subgroups. Relative to progressive supranuclear palsy, iNPH showed higher metabolism in ventromedial frontal regions and basal ganglia. Compared with Alzheimer's disease, iNPH displayed increased metabolism in bilateral medial temporal cortices. Compared with Lewy body disease, iNPH demonstrated greater metabolism in bilateral posterior cortical regions. Relative to frontotemporal dementia and Parkinson's disease, iNPH showed higher metabolism in the cerebellar vermis ($p < 0.005$) (Figure 1).

Conclusion: Voxel-wise FDG-PET reveals regionally distributed metabolic differences in iNPH, supporting its role in early clinical characterisation within a spectrum of neurodegenerative disorders.

Disclosure: Nothing to disclose.

EPO-0422 | Lower urinary tract symptoms in functional neurological disorder: A prospective cohort study

E. Louis¹; C. Hentzen²; M. Teng²; R. Assaraj³; S. Baltassis³; M. Houot⁴; B. Garcin³

¹Frontlab team, Paris Brain Institute (ICM), Paris, France;

²Department of Neuro-urology, AP-HP, Pitié-Salpêtrière Hospital, Paris, France; ³Department of Neurology, AP-HP, Avicenne Hospital, Bobigny, France; ⁴Clinical Investigation Centre, Paris Brain Institute (ICM), Paris, France

Background and aims: Lower urinary tract symptoms (LUTS) are common in neurological disorders but unexpected in functional neurological disorder (FND) in which neural pathways are structurally intact. Evidence on this association is scarce. The primary objective was to describe the prevalence and pattern of LUTS in FND, and the secondary objective was to identify associated factors.

Methods: In a two-year prospective cohort study, we enrolled consecutive patients assessed for FND, with a diagnosis confirmed by positive clinical signs. Conditions causing LUTS were excluded. LUTS, pelvic symptoms, psychiatric comorbidity, pain, and quality of life were assessed using validated questionnaires; anticholinergic load was quantified by the Anticholinergic Drug Scale. The presence of LUTS was defined by cutoffs on the Urinary Symptom Profile or on a visual analog scale of pelvi-perineal discomfort. Factors independently associated with LUTS were identified using stepwise multivariable logistic regression.

Results: Of 145 participants (mean [SD] age 43 [13.7] years; 81% women), 64 (44%) reported LUTS, predominantly storage-type (30/64, 47%), frequently associated with coexisting bowel and sexual dysfunction (46/61, 72%). Independent factors associated with LUTS were (OR [95% CI] per 1-SD increase): higher symptom count (1.98 [1.31–3.12]; $p=0.002$), anticholinergic load (1.86 [1.23–2.93]; $p=0.005$), pain intensity (1.81 [1.19–2.90]; $p=0.008$), and childhood adversity (1.61 [1.09–2.43]; $p=0.019$).

Conclusion: Prospective systematic assessment revealed frequent LUTS in FND (44%), mainly storage symptoms, exceeding previous prevalence estimates. The combination of multiple associated factors suggests multifactorial mechanisms. These findings support systematic screening and targeted management, including medication review and multimodal pain management.

Disclosure: Nothing to disclose.

EPO-0423 | Unique challenges and barriers to increasing equitable access to neuropalliative care in Parkinson's disease: A scoping review

F. Connolly¹; B. Kluger²; S. Seshadri²

¹Department of Neurology, University of Rochester, Rochester, USA; ²Department of Medicine, Palliative Care, University of Rochester, Rochester, USA

Background and aims: Persons with Parkinson's disease (PD) have significant palliative care needs that can be addressed through Neuropalliative care (NPC). NPC aims to improve quality of life through non-motor symptom and pain management, caregiver support, emotional/spiritual support, advanced care planning and specialist/hospice referral. However, NPC is underutilized by individuals with PD from underserved communities and the reasons for this inequity are not fully understood.

Methods: We conducted a scoping review of the literature with the primary research question, "What are the barriers to equitable access to neuropalliative care in Parkinson's disease?" A literature search was completed on PubMed and Covidence was utilized to review the search results.

Results: Of the 383 articles identified and 27 were included in the final review. Four Themes were identified: a) Lack of knowledge of characteristics of normal aging as distinct from PD symptoms; b) Systemic barriers such as skewed geographic distribution of neurologists, lack of inclusive research, insurance coverage for specialist care etc. can impede access to NPC; c) Sociocultural misunderstanding and resistance to palliative care; d) Underutilization of innovative and culturally responsive models such as telehealth, and partnerships with community partners.

Conclusion: Multifactorial barriers impede underserved persons with PD from accessing NPC. Future research is needed to further understand and address the barriers identified. Future directions for improving access to NPC among those from underserved communities could include increasing community outreach, improving awareness about resources provided by NPC, demystifying the term "palliative care" through community based programs, and increasing appropriate referrals from primary care to neurology.

Disclosure: Nothing to disclose.

¹Department of Neurology, Military Institute of Aviation Medicine, Warsaw, Poland; ²Department of Public Health and Epidemiology, Poznan University of Medical Sciences, Poznan, Poland; ³Maria Skłodowska-Curie Medical Academy, Warsaw, Poland

Background and aims: Huntington's disease (HD) is an incurable neurodegenerative disorder. Therefore, identifying lifestyle factors that influence its progression is of particular interest. This study aimed to evaluate the impact of smoking tobacco on the onset and progression of HD symptoms.

Methods: The study is based on the Enroll-HD database. A cohort of 2,438 HD subjects (799 of whom were presymptomatic) who had four consecutive annual visits was extracted. Logistic regression models were used to evaluate the impact of lifetime smoking on progression to the symptomatic phase. For the premanifest group, a Cox proportional hazards model was applied to estimate the hazard ratio of HD diagnosis for smokers versus nonsmokers during the three-year observation period. Multivariate linear regression models were used to investigate the relationship between smoking and the progression of HD clinical measures.

Results: Among presymptomatic HD females, but not males, we found that lifetime smoking was associated with a higher risk of transitioning to the symptomatic phase (odds ratio: 1.26, $p=0.026$). Current female smokers were at a higher risk of progressing to the symptomatic phase than nonsmokers (hazard ratio: 1.35, $p=0.023$). For the symptomatic HD cohort, regardless of sex, smoking was associated with faster progression of motor symptoms (Total Motor Score, $p=0.038$; 95% confidence interval [CI], 0.03–0.9) and cognitive impairment (Stroop Word Reading Test, $p=0.04$; 95% CI, 0.1–0.9).

Conclusion: Lifetime and current smoking may be associated with an earlier age of onset and faster progression of HD.

Disclosure: Nothing to disclose.

Background and aims: Sex differences in the treatment of people with Parkinson's disease (PwP) with a device-aided therapy (DAT) have been poorly investigated. Our aim was to analyze sex differences in the management and response to a DAT in PwP in daily clinical practice (DCP).

Methods: Data collected in the DATs-PD GETM Spanish Registry until October 30, 2025, were used. This is a descriptive, observational, prospective, multicenter clinical registry with progressive inclusion of PwP treated with a DAT in DCP conditions in more than 30 centers from Spain (Santos-García. PLoS One 2025). Sex differences in the DAT received and changes in quality of life (QoL), motor symptoms (MS), non-motor symptoms (NMS), and autonomy for activities of daily living (AADL) after 6 months of treatment were analyzed.

Results: A total of 618 PD patients (66.9 ± 9.5 years old; 57.6% males) were treated with a DAT. A significant difference was observed in the DAT type according to sex ($p=0.006$), with 73.1% of PwP who were treated with deep brain stimulation being males (Figure-1). At the time of DAT indication, females were older, received a higher levodopa equivalent daily dose, and had a worse health-related QoL and AADL (Table-1). OFF time decreased, whereas MS and NMS burden and health-related QoL improved at 6 months follow-up in both groups, males and females (Table-2). AADL improved only in males during the OFF state (Table-2).

Conclusion: Sex differences were detected in the use of DATs in PwP. Improvement in OFF time, MS, NMS, and QoL were detected in both groups.

Disclosure: There are no financial disclosures.

Background and aims: Friedreich's Ataxia (FRDA) is a rare neurodegenerative disorder characterized by progressive ataxia. Clinical assessment relies on observer-based scales such as the Scale for the Assessment and Rating of Ataxia (SARA) and the modified Friedreich's Ataxia Rating Scale (mFARS), which may be insensitive to subtle motor changes. This study applies video-based analysis and unsupervised anomaly detection to quantify upper-limb coordination.

Methods: 778 video recordings of the finger-nose (SARA, mFARS), finger-tapping (mFARS) and pronation-supination tasks (SARA, mFARS) of 64 individuals with FRDA (48% female), and 58 controls (47% female) acquired during routine clinical visits were analyzed. Features describing movement speed, frequency, smoothness, entropy, and variability were extracted. Group- and severity-related differences were assessed using Mann-Whitney U Test. To capture multivariate deviations in movement patterns not detectable by univariate testing, unsupervised anomaly detection models trained exclusively on controls were used. Here, subject-specific anomaly scores and assess their relevance to disease status were extracted.

Results: Most features differed significantly between patients and controls and across increasing SARA and mFARS severity. Greater severity was associated with prolonged task execution, slower and less frequent movements, increased variability, and higher spectral entropy. Anomaly scores increased with severity, showing strong associations in finger fapping (Spearman's $\rho \approx 0.64$ – 0.65) and pronation–supination ($\rho \approx 0.71$ – 0.72), with moderate associations in nose–finger task ($\rho \approx 0.33$ – 0.36).

Conclusion: Video-based upper-limb kinematic analysis combined with anomaly scoring provides an objective, feature-driven measure of motor impairment with potential utility for quantifying disease severity and tracking progression in FRDA.

Background and aims: Spinal cord stimulation (SCS) has recently been suggested to improve gait impairment in Parkinson's disease (PD). However, it remains unclear whether any specific stimulation paradigm is superior. Here, we aimed to compare different paradigms of SCS in PD patients with gait impairment.

Methods: Eight gait-impaired PD patients who had previously received SCS were included. Four stimulation paradigms (Fast Acting Sub-perception Therapy [FAST], MicroBurst, low frequency/high pulse width, and high frequency/low pulse width) were administered in a randomised order, each for two months. The Postural Instability and Gait Disorder (PIGD) score was assessed before initiation of SCS (approximately two years prior) and during each stimulation paradigm. A linear mixed model was used to compare the stimulation paradigms. In addition, the individually optimal paradigm was compared with a natural cohort of gait-matched PD patients ($n=8$) without SCS.

Results: Seven participants completed follow-up for at least two settings (four completed all settings, one completed three, and two completed two). One participant was excluded due to non-compliance. No stimulation paradigm was found to be overall superior to the others. After two years, participants receiving SCS demonstrated an improvement in PIGD when using their individually optimal paradigm, which was significantly better compared with the two-year PIGD deterioration observed in a natural cohort of PD patients without SCS ($p=0.001$).

Conclusion: Our findings suggest that the SCS paradigm should be individualised rather than based on a “one-size-fits-all” approach. Furthermore, long-term SCS may mitigate the natural progression of gait deterioration in PD.

Disclosure: This work was funded by the Independent Research Fund Denmark and the Danish Parkinson's Association. Funders had not impact on trial design, execution or analysis.

P. Oikonomou

Department of Neurosciences, UC San Diego Health System, University of California, San Diego, La Jolla, USA

Background and aims: Parkinson's disease psychosis (PDP) is a disabling non-motor feature of PD. Treatment options are limited, with clozapine constrained by safety concerns, quetiapine demonstrating variable efficacy, and pimavanserin approved specifically for PDP but unavailable outside of the U.S. Long-term real-world data on treatment effects are scarce. This study examined whether initiation of PDP pharmacotherapy alters the longitudinal trajectory of psychosis and subjective cognitive symptoms.

Methods: We performed a retrospective longitudinal observational study using electronic medical records from University of California San Diego movement disorders clinics from 2015–2025. Eligible patients had PD and a Movement Disorder Society–Unified Parkinson's Disease Rating Scale Part I item 1.2 score of at least one. Patients were categorized by treatment (pimavanserin, quetiapine, combination (pimavanserin and quetiapine), or no treatment). Ordinal psychosis and cognitive symptom scores were analyzed using cumulative link mixed-effects models. Treated groups were modeled with pre- and post-treatment trajectories.

Results: 100 patients were included (pimavanserin $n=14$; quetiapine $n=12$; combination $n=16$; untreated $n=58$), followed for a mean of 4.3 years (SD 2.7; range 0–12.8). After adjustment for demographics and disease duration, only pimavanserin was associated with a statistically significant attenuation of psychosis progression after treatment initiation (Δ slope = -0.498 ; $p=0.045$). Quetiapine and combination therapy showed non-significant reductions. Cognitive symptoms worsened prior to treatment in all groups, with significant post-treatment attenuation observed for pimavanserin and combination therapy, but not quetiapine.

Conclusion: Pimavanserin was associated with long-term attenuation of psychosis and cognitive symptom progression in this real-world cohort, exceeding effects observed with other treatments.

Disclosure: This research was funded by Acadia Pharmaceuticals. The authors report no other disclosures.

EPO-0429 | Effects of proprioceptive–visual and vestibular–visual integration training on balance and gait in Parkinson's disease: A randomized controlled trial

Q. Zhao; X. Luo; L. Jin
Department of Movement Disorders, Neurorehabilitation Center, Shanghai Yangzhi Rehabilitation Hospital (Shanghai Sunshine Rehabilitation Center), Tongji University School of Medicine, Shanghai, China

Background and aims: Postural instability and impaired sensory integration are major contributors to falls and disability in Parkinson's disease (PD), yet the optimal sensory integration training strategy remains unclear.

Methods: 184 individuals with PD were allocated randomly to the control group, proprioceptive–visual integration group A and vestibular–visual integration group B. All participants received 4 weeks of conventional rehabilitation, while group A and B additionally performed 30-minute sensory integration training with center-of-mass visual feedback, with or without

Figure 2. Changes in balance and sensory integration outcomes after intervention. A–E: Changes in SOT composite score, endpoint excursion, ankle strategy, vestibular ratio, and sensory preference ratio after intervention. Group B showed greater improvements than the control group across all outcomes.

FIGURE 2 Results.

an unstable surface. The primary outcome was the Sensory Organization Test (SOT) composite score. Secondary outcomes included clinical balance, motor symptoms, sensory integration parameters, gait measures, and quality of life.

Results: Vestibular–visual integration training combined with conventional rehabilitation can better improve balance control, motor symptoms and gait symmetry in patients with PD.

Conclusion: Vestibular–visual integration training combined with conventional rehabilitation can better improve balance control, motor symptoms, and gait symmetry in patients with PD. This approach may be particularly beneficial for patients with prominent postural instability and elevated fall risk.

EPO-0430 | Echinacoside Attenuates Pathogenic α -Synuclein Aggregation by Inhibiting the PERK–eIF2 α –ATF3/CHOP Pathway in the PFFs Models of Parkinson's Disease

Q. Zhao; Z. Wang; L. Jin
Department of Movement Disorders, Neurorehabilitation Center, Shanghai Yangzhi Rehabilitation Hospital (Shanghai Sunshine Rehabilitation Center), Tongji University School of Medicine

Background and aims: Abnormal aggregation of α -synuclein (α -Syn) is a core pathological hallmark of Parkinson's disease (PD), and the α -Syn pre-formed fibrils (PFFs) model closely mimics this process. Our previous work showed that echinacoside (ECH) protects against MPTP-induced injury by suppressing endoplasmic reticulum (ER) stress. Here, we asked whether ECH ameliorates α -Syn mediated dopaminergic damage in PFFs-based models and whether this effect involves ER-stress related ATF3 signaling.

Methods: In vivo, mice received unilateral striatal PFFs injections followed by intragastric ECH (40 or 20 mg/kg) for 1 month. Motor function was assessed by standard behavioral tests, and substantia nigra pathology was evaluated by

Figure 1. CONSORT flow diagram of participant enrollment, randomization, and analysis. This figure illustrates participant flow through the study.

FIGURE 1 CONSORT flow diagram.

tyrosine hydroxylase (TH) immunofluorescence and Western blot of phosphorylated α -syn (p- α -syn), GRP78 and PERK-eIF2 α -ATF3-CHOP proteins. In vitro, PFFs-treated SH-SY5Y cells were exposed to the ER-stress inducer thapsigargin (Tg) or to ECH. Cell viability, TH, p- α -syn and the same ER-stress markers were quantified.

Results: PFFs induced motor deficits, TH loss, p- α -syn accumulation and up-regulation of GRP78 and PERK-eIF2 α -ATF3-CHOP in mouse substantia nigra. ECH improved motor behavior, increased TH expression and significantly decreased p- α -syn and ER-stress marker levels ($p < 0.05$; Figure 1). In SH-SY5Y cells, Tg further enhanced PFFs-induced GRP78, p-PERK, p-eIF2 α , ATF3, CHOP and p- α -syn, whereas ECH reduced p- α -syn and down-regulated these ER-stress proteins ($p < 0.05$; Figure 2).

Conclusion: ECH protects nigrostriatal dopaminergic neurons and reduces pathological α -Syn aggregation in PFFs-induced cellular and mouse models of PD, an effect closely associated with inhibition of PERK-eIF2 α -ATF3-CHOP-mediated ER stress.

EPO-0431 | Significant elevation of serum pro-inflammatory cytokines in GBA1-associated Parkinson's disease: Implications for immune-mediated pathogenesis

V. Busco¹; G. Di Lazzaro²; A. Cimmino¹; J. Gambelli¹; M. Petracca²; D. Genovese²; A. De Biase²; F. Musso¹; P. Calabresi²; A. Bentivoglio²

¹Università Cattolica del Sacro Cuore, Rome, Italy; ²Neurology Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background and aims: Parkinson's disease (PD) associated with GBA1 mutations (GBA-PD) is increasingly recognized as a clinically and biologically heterogeneous subtype[1]. This study aimed to investigate differences in serum inflammatory and neurodegeneration markers between Parkinson's disease (PD) patients carrying GBA1 variants (mPD) and patients with idiopathic sporadic PD (sPD), focusing on the potential role of interferon-gamma (IFN- γ), a key Th1 cytokine[2].

Methods: We enrolled 12 patients with GBA1-associated PD and 12 with sporadic PD, matched for age, sex, and disease duration. Clinical data and serum samples were collected. PD diagnosis followed Movement Disorder Society criteria. Serum cytokines (IL-1 β , IL-17A, IFN- γ , IL-4, TNF- α , IL-10, IL-6) were measured by ELISA. Neurodegeneration markers included neurofilament light chain (NfL) and brain-derived neurotrophic

TABLE 1 Demographics and clinical characteristics of mPD and sPD patients. Continuous variables are mean $\pm$ SD, categorical as counts. Groups were matched; no statistically significant differences were observed.

Mean	mPD(n=12)	sPD(n=12)	P value
Age (years)	62.3 $\pm$ 7.5	63.4 $\pm$ 8.0	0.732
Disease Duration	4.2 $\pm$ 2.5 years	4.4 $\pm$ 2.1 years	0.834
Men/women	10/2	10/2	1.0

factor (BDNF). Group differences were analyzed with Mann-Whitney U test ($p < 0.05$).

Results: IFN- γ levels were significantly elevated in GBA-PD compared to sPD ($p = 0.0078$), along with IL-1 β ($p < 0.05$), while other cytokines, NfL, and BDNF showed no differences. Comorbidities in GBA-PD included depression (66%) and melanoma (25%). The selective IFN- γ elevation suggests a Th1-skewed systemic immune activation in GBA1 mutation carriers.

Conclusion: GBA-PD patients exhibit a distinct peripheral immune-inflammatory profile characterized by Th1-associated IFN- γ and IL-1 β elevation, supporting the concept of a biologically unique PD subgroup. This Th1-skewed signature may contribute to both neurodegeneration and comorbid autoimmune or psychiatric manifestations[3]. IFN- γ represents a potential biomarker and therapeutic target, and modulation of Th1 pathways could offer novel strategies to personalize treatment in this PD subgroup. Validation in larger cohorts is warranted.

Neurorehabilitation 1

EPO-0432 | Temporal precision requirements for neuroplasticity-based neurorehabilitation: A meta-regression analysis

A. Oza

Science Department, Northern Highlands Regional High School, Allendale, USA

Background and aims: Brain-computer interface (BCI) systems combined with functional electrical stimulation (FES) demonstrate efficacy in research settings (pooled effect size $d = 0.72$), yet clinical adoption remains limited. This translation gap suggests that available systems fail to meet neurophysiological requirements, particularly temporal precision within the neuroplasticity window required for Hebbian learning.

Methods: Following PRISMA guidelines, a systematic review examined randomized controlled trials evaluating timing-sensitive neurorehabilitation interventions for post-stroke upper limb recovery. Interventions were classified as research prototypes or commercial systems. The primary outcome was change in the Fugl-Meyer Upper Extremity score. Meta-regression assessed associations between neural-to-stimulation latency and efficacy while adjusting for intervention duration, stroke chronicity, and study quality. Segmented regression identified latency thresholds, and mediation analysis evaluated whether latency explained performance differences.

Results: Across 28 studies including 1,247 participants, a critical latency threshold of 300 ms (95% CI: 250–350 ms) was identified. Systems operating below this threshold achieved larger effects ($d = 0.89$) than those exceeding it ($d = 0.38$; $p < 0.001$). Research prototypes demonstrated lower latencies (median 220 ms) and greater efficacy ($d = 0.85$) than commercial systems (median 1,150 ms; $d = 0.34$). Mediation analysis indicated that 73% of the efficacy gap was attributable to latency, with each additional 100 ms associated with a 0.042 reduction in effect size ($p < 0.001$).

Conclusion: Clinical translation failure is therefore attributable to latency-mediated loss of efficacy operating beyond the

TABLE 1 Systems with latency below 300ms achieve 3.6x better outcomes ($d = 1.02$ vs 0.28) than high-latency systems, demonstrating temporal precision as the primary driver of neuroplasticity-based recovery in stroke rehabilitation.

Table 1. Clinical Outcomes Stratified by System Latency Categories				
Latency Category	Studies (n)	Effect Size SMD (95% CI)	FIM-UE Points (95% CI)	p-value
Ultra-low (<200ms)	5	0.82 (0.61, 1.23)	10.2 (8.5, 12.5)	<0.001
Low (200-300ms)	7	0.81 (0.63, 0.99)	8.1 (6.3, 9.9)	<0.001
Medium (300-500ms)	9	0.52 (0.34, 0.70)	5.2 (3.4, 7.0)	<0.001
High (>500ms)	7	0.28 (0.09, 0.47)	2.8 (0.9, 4.7)	0.004

TABLE 2 Commercial systems operate 5x slower than research prototypes (1150ms vs 220ms) which explains why marketed BCI devices fail clinically despite promising research trials.

Table 2. Comparative Performance: Research Prototypes vs. Commercial Systems			
Metric	Research Prototypes (n=15)	Commercial Systems (n=10)	p-value
Median latency (FIM), ms	220 (180-250)	1150 (880-1600)	<0.001
Pooled effect size, SMD (95% CI)	0.85 (0.68-1.01)	0.35 (0.17-0.51)	<0.001
FIM-UE improvement, points (95% CI)	9.2 (7.4-10.0)	1.6 (1.3-5.4)	<0.001
Heterogeneity (I ²)	58%	31%	—
Studies achieving <300ms threshold, %	80% (12/15)	0% (0/10)	<0.001

TABLE 3 Low-latency systems are cost-effective (\$38K/QALY) despite higher costs, while cheaper high-latency systems exceed thresholds (\$94K/QALY) due to poor outcomes.

Table 3. Cost-Effectiveness Analysis by System Latency Category					
System Type	Total Cost (£)	FIM-UE Gain	QALY Gain	ICER (£/QALY)	CEA
Low latency (<300ms)	15,000	9.1	0.10	38,400	Yes
Medium latency (300-500ms)	11,000	8.2	0.18	54,300	No
High latency (>500ms)	12,000	3.6	0.13	94,200	No
Commercial therapy (comparison)	1,200	0	0	—	—

identified 300 ms threshold. Enforcing engineering standards based on segmented and mediation analyses, including sub-300 ms latency targets linked to superior cost-effectiveness, is essential for improving therapeutic and economic outcomes.

EPO-0433 | **Evaluation of reticulospinal plasticity using a novel wearable (PowerBead) for post-stroke finger extension recovery**

A. Das¹; Y. Wang¹; L. Salisbury¹; N. Ward²; S. Baker³
¹KnitRegen, London, UK; ²Clinical Neuroscience Centre, Institute of Neurology, UCLH, Queens Square, London, UK; ³Henry Wellcome Building, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK

Background and aims: Loss of finger extension excludes ~50% stroke survivors from rehabilitation. Strengthening the reticulospinal tract (RST) may aid recovery when the corticospinal tract (CST) is damaged. The RST, activated via muscle spindle afferents (MSA), can be stimulated by mechanical ‘taps’. Pairing these with timed auditory ‘clicks’ may induce neuroplastic

FIGURE 1 Depicts the device ‘The PowerBead’.

FIGURE 2 The blue box in the graph denotes a sample MSA response generated by the PowerBead.

changes through convergent input [Salisbury, Wang & Baker, n.d.]. The objective of this study is to evaluate the feasibility and physiological efficacy of a wearable tap-click neuromodulation approach in inducing reticulospinal plasticity relevant to post-stroke finger extension.

Methods: The PowerBead is a wearable delivering a ‘tap’ to the affected forearm and an earpiece providing a synchronised contralateral ‘click’. Co-designed with clinicians and therapists, it provides 4-hour treatment cycles to 20 healthy participants and 20 stroke survivors, guided by PPI feedback. Efficacy is assessed pre- and post-cycle using TMS-evoked EMG at the extensor digitorum, the Modified Ashworth Scale, grip/pinch strength, and Box & Block tests.

Results: Previous studies confirmed PowerBead induced MSA activation [Salisbury, Wang & Baker, n.d.]. Building on work by Baker et al (2021), which showed MSA-auditory pairing supports recovery, our device integrates this ‘tap-click’ loop to promote passive finger extension. Early data demonstrated RST plasticity after 4 hours of treatment, with increased cortical excitability and suppressed brainstem activity.

Conclusion: Early PowerBead findings indicate promising engagement of the RST through the ‘tap-click’ loop, highlighting its novelty in translating lab-based neuroplasticity into accessible home-based therapy. Data collection is ongoing, with plans for clinical trials and public availability.
