Disclosure: This study is funded by NIHR [National Institute for Health and Care Research] i4i award and led by Dr Laura Salisbury [CEO of KnitRegen] in collaboration with UCL [University College London].

EPO-0434 | Evolving use of botulinum toxin in neurological practice: A national audit from Malta (2013–2025)

A. Ferriggi; J. Abela; M. Mallia
Department of Neurosciences - Mater Dei Hospital, Msida, Malta

Background and aims: Botulinum toxin (BoNT) is an established treatment for neurological conditions associated with spasticity and dystonia. Since the establishment of a dedicated national BoNT service in Malta, clinical demand and service complexity have increased. This audit aimed to evaluate patient characteristics, indications, treatment patterns, clinical outcomes, and documentation practices in order to identify areas for service development and standardization.

Methods: A retrospective audit was conducted of electronic and paper records for patients attending the Neurology and Spasticity Clinic between 2013 and 2025. Data collected included demographics, neurological diagnosis, treatment status, BoNT dosing patterns, follow-up intervals, documented symptomatic and functional outcomes, adjunct pharmacological therapy, and recording of multidisciplinary team (MDT) involvement and consent. Descriptive analyses were performed.

Results: A total of 187 patients were identified, of whom 146 received BoNT therapy and 134 remained in active follow-up. Mean age was 56 years, with balanced sex distribution. Indications included post-ischemic stroke spasticity, cerebral palsy, dystonia, and traumatic brain injury. Most patients were reviewed at clinically appropriate intervals, typically every 4–6 months. Mean BoNT dose per session was 79.4 units, with higher doses used for spasticity. Symptomatic and functional improvements were commonly documented.

FIGURE 1 Results - Use of botulinum therapy in different neurological conditions.

Diagnosis	Average Dose per Session (U)	Average Time on BoTx (Years)	Average Number of Visits	Typical Follow-Up Interval
Cerebral Palsy	150	4.1	19.6	7–8 months
Ischemic Stroke	150	1.1	2.4	6–7 months
Spastic Paraparesis	180	4.9	25.3	5 months
Traumatic Brain Injury	180	6.5	19.5	4–5 months
Cervical Dystonia	75	1.8	6.1	8 months
Hemifacial Spasm	20	6.4	1.7	10 months

FIGURE 2 Results - Average doses of botulinum therapy used in different neurological conditions with follow up periods.

FIGURE 3 Results – Symptomatic and functional improvement following botulinum therapy.

Conclusion: This national audit demonstrates effective real-world use of BoNT across a heterogeneous neurological population. Variability in documentation of MDT input, dose titration, and follow-up highlights opportunities for standardization. Findings will inform the development of structured documentation tools and a local protocol, with re-audit planned to assess service improvement.

Disclosure: Nothing to disclose.

EPO-0435 | Long-term follow-up of patients with disorders of consciousness: Prognostic value of early CRS-R Improvement

B. Hakiki¹; F. Draghi²; A. De Nisco²; A. Romoli²; D. Maccanti²; C. Macchi²

¹Dipartimento di Medicina Sperimentale e Clinica, Università di Firenze, Firenze, Italy; ²IRCCS Fondazione Don Carlo Gnocchi ETS, Firenze, Italy

Background and aims: The Coma Recovery Scale–Revised (CRS-R) is the gold standard for assessing consciousness in prolonged Disorders of Consciousness (pDoC). We previously^{1,2} showed that baseline CRS-R and its 4-week increase iCRS-R predicted consciousness improvement at discharge from rehabilitation setting. This longitudinal follow-up evaluates the predictive value of baseline CRS-R and its early change for long-term survival and functional autonomy.

Methods: Using a cross-sectional approach, all patients enrolled in the previous study² were contacted. A structured telephone interview, including the Glasgow Outcome Scale–Extended (GOSE), was administered. Mortality rate, time to death were also recorded.

Results: Of 110 patients, 96 (87.3%) completed the interview and 69 patients (71.8%) died [median time from event 15 months (IQR: 52.5; 3–124)]. Lower iCRS-R (OR: 0.027; $p < 0.001$), non-traumatic aetiology (OR: 0.125; $p = 0.003$), and older age (OR: 1.049; $p = 0.020$) were significantly associated with death in the multivariate analysis. Younger age (HR: 1.038; $p = 0.001$) and greater iCRS-R (HR: 0.0284; $p = 0.007$) were associated with longer survival in the Cox-regression analysis

Conclusion: The early improvement in CRS-R during intensive rehabilitation represents a key prognostic marker of long-term survival. Longitudinal CRS-R assessment may help identify patients at higher risk of mortality and support clinical decision-making. References: 1. Portaccio et al. doi:10.1080/02699052.2018.1440420 2. EPO-0436 | Single-Session Artificial Intelligence-Assisted Gait Training Improves Spatiotemporal Parameters in Dementia and Parkinson's Disease

C. Hong

Taipei Medical University-Shuang Ho Hospital, Taiwan

Background and aims: Gait impairment in dementia and Parkinson's disease (PD) drives falls and loss of independence, yet therapist-intensive rehabilitation limits scalability. Artificial intelligence (AI)-assisted gait training may standardize delivery, reduce manpower, and provide real-time feedback. The present study aims to test whether a single session of AI-assisted gait training improves spatiotemporal gait parameters in dementia and PD.

Methods: Adults aged 60–85 years with dementia or PD who could ambulate completed one training session ($\sim 23.2 \pm 9.6$ min) comprising standardized walking tasks with real-time feedback, delivered under “Support” or “Escort” mode walking with the

FIGURE 1 Individual changes in gait parameters following the training intervention in dementia subjects.

FIGURE 2 Individual changes in gait parameters following the training intervention in Parkinson's disease subjects.

AI-assisted gait training device as needed. Primary outcomes were pre–post changes in gait speed (m/s) and the secondary outcomes included step length (cm), step count, and gait variability obtained by the device. Two-sided paired t tests were performed within four strata: Dementia–Support ($n = 67$), Dementia–Escort ($n = 43$), PD–Support ($n = 64$), and PD–Escort ($n = 43$).

Results: Gait speed increased within session across all strata. Step length increased and step count decreased in Support walking for both diagnoses, whereas Escort walking showed non-significant trends for these spatial parameters. Gait variability showed no significant changes in any stratum. Cognitive status did not affect the changing of gait parameter, supporting feasibility for targeting elders.

Conclusion: A single AI-assisted gait training produced short-term functional gains in spatiotemporal gait parameters in dementia and PD, demonstrating a therapist-sparing, scalable training model. Longer-term trials should evaluate durability, dose–response, and transfer to everyday gait and falls, and refine automation for home or remote deployment.

Disclosure: Nothing to disclose.

K. Sarhan; R. Mohamed

Faculty of Medicine, Mansoura University, Mansoura, Egypt

Background and aims: Post-stroke dysphagia is associated with aspiration, prolonged hospitalization, and poor recovery. Pharyngeal electrical stimulation (PES) is an emerging neuro-stimulation technique designed to enhance swallowing function through modulation of pharyngeal sensory pathways. This study aimed to systematically review and meta-analyze the effects of PES on swallowing outcomes and safety in patients with acute stroke.

Methods: We performed a systematic review and meta-analysis of randomized controlled trials evaluating PES in patients with post-stroke dysphagia. PubMed, Scopus, and Web of Science were searched from inception to December 2025. Outcomes included dysphagia severity, swallowing function, functional oral intake, feeding tube withdrawal, length of stay, and safety.

Results: Nine randomized controlled trials involving 448 patients were included. PES significantly improved overall swallowing function compared with control (SMD = -0.30, 95% CI: -0.50 to -0.10), with dysphagia severity scores also showing greater improvement (SMD = -0.35, 95% CI: -0.55 to -0.15). Patients receiving PES had higher rates of nasogastric tube withdrawal (RR = 2.5, 95% CI: 1.8–3.5) and improved functional oral intake. The analysis demonstrated a significant reduction in hospital length of stay, driven largely by post-extubation stroke populations (SMD = -0.5, 95% CI: -0.80 to -0.20). PES was well tolerated, with no increase in serious adverse events.

Conclusion: PES improves swallowing function and reduces dysphagia severity in patients with acute stroke. It increases the likelihood of nasogastric tube removal, improves oral intake, and shortens hospital stay, while remaining safe and well tolerated, supporting its use as an effective adjunct in stroke rehabilitation.

Disclosure: Nothing to disclose.

EPO-0438 | Abstract withdrawn

EPO-0439 | Upper-extremity functional outcomes following bilateral rTMS after stroke: Systematic review and meta-analysis

M. Kodounis¹; D. Onan²; R. Ornello³; S. Sacco³; D. Mitsikostas¹; E. Dardiotis⁴; V. Siokas⁴

¹First Neurology Department, Eginitio Hospital, School of Medicine, National & Kapodistrian University of Athens, Athens, Greece; ²Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Yozgat Bozok University, Yozgat Türkiye; ³Department of Biotechnological and Applied Clinical Sciences – University of L'Aquila, L'Aquila, Italy; ⁴Department of Neurology, University Hospital of Larissa, School of Medicine, University of Thessaly, Larissa, Greece

Background and aims: The literature largely examines unilateral high-frequency stimulation of the lesioned hemisphere or low-frequency inhibition of intact hemisphere using repetitive Transcranial Magnetic Stimulation (rTMS) on stroke patients. In contrast, bilateral protocols combining facilitative and inhibitory effects remain underexplored. This review evaluates the effects of bilateral rTMS on upper extremity function.

Methods: A systematic search was conducted in PubMed, Web of Science, and Scopus up to November 22, 2025 (Figure-1). Randomized controlled trials (RCTs) were included if stroke patients were assessed with Fugl-Meyer Assessment (FMA) and received bilateral rTMS. Bilateral rTMS and sham groups were compared. The meta-analysis was conducted in RStudio (PROSPERO: CRD420251230168).

Results: Three RCTs were included in the study and demonstrated low risk and good methodological quality (Figure-2a,2b). The bilateral rTMS intervention demonstrated a significant advantage over sham in improving upper-extremity functional outcomes. Based on the common-effect model, the post-treatment effect was substantial (SMD = 1.54, 95% CI: 1.10–1.99), while the random-effects model yielded a wider and more uncertain estimate (SMD = 3.30, 95% CI: -1.06–7.66) due to heterogeneity ($I^2 = 96.6\%$, $p < 0.0001$). At the 3-month follow-up, the improvement was sustained and even greater under the common-effect model (SMD = 2.09, 95% CI: 1.60–2.58), whereas the random-effects model again showed uncertainty (SMD = 4.23, 95% CI: -0.67–9.13) due to heterogeneity ($I^2 = 96.8\%$, $p < 0.0001$). Although the overall direction of effect consistently favors active rTMS, the heterogeneity warrants cautious interpretation of the pooled estimates (Figures-3a,3b).

Conclusion: Bilateral rTMS may provide benefits for upper-extremity functional recovery after stroke, although the limited number of included studies contributes to substantial heterogeneity. These findings indicate the need for more well-designed RCTs.

Disclosure: Nothing to disclose.

EPO-0440 | Observational gait analysis tools for neurological populations: A COSMIN meta-analysis

M. Etoom

Department of Rehabilitation Sciences, Faculty of Applied Medical Sciences, Jordan University of Science and Technology, Jordan

Background and aims: Observational gait analysis (OGA) tools are widely used due to their simplicity, low cost, and feasibility. However, the psychometric properties of OGA tools remain unclear. The aim was to conduct a systematic review and meta-analysis investigating psychometric properties of OGA tools among neurological populations.

Methods: Consensus-based Standards for the selection of health Measurement Instruments (COSMIN) guidelines were followed. COSMIN psychometric properties involve Validity (Content, Structural, Criterion, cross-cultural and Construct), Reliability (Internal Consistency, reliability and Measurement Error), and Responsiveness. The measurement Property for the will be rated as sufficient (+), insufficient (-), or indeterminate (?) using COSMIN criteria for good measurement properties. The recommendations for scales were mainly based on content validity and internal consistency.

Results: There were 26 included articles involving 8 OGA tools; Wisconsin Gait Scale (WGS), Gait Assessment and Intervention tool, Tinetti Gait Scale, Rivermead Visual Gait Assessment, Gait Abnormality Rating Scale, Malta Gait scale, Hemiplegic Gait Analysis Form, and New York Medical School Orthotic Gait Analysis. Included articles assessed through 64 studies all psychometric proprieties except structural validity. The 64 results were synthesized into 48 results in stroke, multiple sclerosis and Parkinson's disease. Thirty-one results rated as (+), 10 (-), and 8 (?). No OGA tool is currently recommended for use. All included OGA have potential for recommendation. WGS has the best potential.

Conclusion: No OGA tool is currently recommended due to absence of evidence for unidimensionality. Structural validity studies are highly required and should be prioritized to confirm unidimensionality and level of recommendations for OGA tools.

Disclosure: Nothing to disclose.

EPO-0441 | Putting family before patient: Physicians' reasons for prolonging life-sustaining treatment in chronic disorders of consciousness

W. van Erp¹; C. Span¹; J. van Gorp²; H. van Delden³; J. Lavrijsen¹; N. Kok²

¹Primary Care, Radboudumc, Nijmegen, the Netherlands; ²IQ Health, Radboudumc, Nijmegen, the Netherlands; ³Julius Center, UMC Utrecht, the Netherlands

Background and aims: The Netherlands report the lowest prevalence of prolonged disorders of consciousness (PDOC), often related to an ethical-legal context allowing the discontinuation of life-sustaining treatment (LST) when recovery is unlikely or presumed patient consent is absent. Despite this, some PDOC patients receive LST for decades. This study explores physicians' reasons for doing this.

Methods: Semi-structured interviews were conducted with physicians responsible for patients diagnosed with unresponsive wakefulness syndrome, based on repeated Coma Recovery Scale-Revised assessments. Interviews, conducted at a mean of 14 years post-injury, began with the question: "Which factors influenced your treatment decision?" Transcripts were analysed using qualitative thematic analysis supported by ATLAS.ti software.

Results: Ten elderly care physicians in nursing homes, and responsible for nine patients were interviewed. In all cases, family requests to continue treatment overruled diagnosis, prognosis, and the patient's presumed perspective. Physicians prioritized maintaining family relationships and avoided conflict, without consulting external experts. Advance care planning was often delayed, even though physicians rated the patients' quality of life as very poor (mean 1.6/10). None of the physicians would want similar treatment for themselves. When asked about their preferred treatment for the patient if they had no family, all stated they would discontinue life-sustaining treatment.

Conclusion: Even in the unique Dutch medico-ethical context, life-sustaining treatment in PDOC can continue for decades. Family preferences largely dictate these decisions, while patient

interests are often overlooked. This highlights an ethical tension in PDOC care, emphasizing the need for clear role definitions, advance care planning, and better support for physicians facing moral distress.

Disclosure: Nothing to disclose.

EPO-0442 | Introducing Disorders of Consciousness Program Accreditation Standards

P. Lucesoli de Valyi; T. Carolan
CARF International, Tucson, USA

Background and aims: Despite evidence and published guidelines demonstrating the need for specialized DoC rehabilitation, barriers to accessing these skilled programs remain. Recent evidence has provided guidance on the care for those with DoC, minimal competency recommendations for interdisciplinary teams providing care for persons with DoC, timing of withdrawal of life saving treatment, recovery and functional outcomes, and presence of consciousness in those with covert awareness. CARF International has worked with the field to create standards for transdisciplinary DoC rehabilitation programs which will focus on quality and performance improvement, advocate for individuals with DoC their family members and demonstrate the value of rehabilitation to all stakeholders including external payers and referrers.

Methods: referrers. CARF International conducted interviews with individuals with lived experience, family members, researchers, providers and payers to determine the need to create DoC Program standards. An International Standards Advisory Committee used a consensus-driven process to create draft DoC program standards, which were shared in a public field review where 133 individuals and organizations provided feedback which was then incorporated into the final DoC program standards.

Results: In July, 2026, these 24 DoC program standards will be used to provide the first DoC program accreditation, using peer-surveyors and an on-site survey process.

Conclusion: DoC Program accreditation standards will be used to establish a minimum standard for DoC programs which will allow easier identification of DoC programs for family members seeking DoC rehabilitation and create an enduring process to assess the quality of DoC rehabilitation programs.

Disclosure: I am a consultant with CARF International.

EPO-0443 | Overground gait training with body-weight support in individuals with neurological disorders: A scoping review

A. Luís; R. Brandão; I. Baleia
Alcoitão School of Health Sciences, Alcabideche, Portugal

Background and aims: Neurological disorders are a major cause of disability and are frequently associated with gait impairments that reduce functional independence and quality of life. Overground body-weight supported gait training has emerged as a potential alternative to treadmill-based approaches, but its clinical application remains insufficiently explored.

Methods: A scoping review was conducted following Joanna Briggs Institute methodology and PRISMA-ScR guidelines. Searches were performed in PubMed, PEDro, CENTRAL, EBSCO, and Web of Science. Studies investigating overground gait training with body-weight support in neurological populations were included and critically appraised using JBI tools.

Results: Seven studies were included, involving individuals with stroke, cerebral palsy, spinal cord injury, and Parkinson's disease. Overground body-weight supported gait training was associated with improvements in gait independence, walking speed, endurance, gait symmetry, motor function, fall risk, and freezing of gait. Outcomes were comparable or superior to treadmill-based or conventional gait training.

Conclusion: Evidence on overground body-weight supported gait training in neurological populations is limited and heterogeneous. Although promising gait-related outcomes have been reported, methodological limitations prevent strong conclusions, highlighting the need for high-quality randomised controlled trials with standardised protocols.

EPO-0445 | Greater clinical benefit with tiomolibdate choline versus standard-of-care in neurologic WD patients in the Phase 3 FoCUS Trial

A. Poujois¹; J. Bronstein²; M. Lorincz³; P. Hedera⁴; D. Bega⁵; C. Robinson⁶; A. Cittadine⁶; D. Tuffy⁶; P. Dusek⁷; I. Mohr⁸; T. Litwin⁹

¹Department of Neurology, Adolphe de Rothschild Foundation Hospital, Paris, France; ²Department of Neurology, David Geffen School of Medicine at UCLA, Los Angeles, United States; ³Department of Neurology, University of Michigan Health Systems, Ann Arbor, United States; ⁴Department of Neurology, School of Medicine, University of Louisville, Louisville, United States; ⁵Department of Neurology, Feinberg School of Medicine, Chicago, United States; ⁶Monopar Therapeutics, Wilmette, United States; ⁷Department of Neurology and Centre of Clinical Neuroscience, Charles University and General University Hospital, Prague, Czech Republic; ⁸Department of Gastroenterology and Hepatology, Heidelberg University Hospital, Heidelberg, Germany; ⁹Second Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland

Background and aims: Wilson disease (WD) is a rare genetic disorder where excess copper (Cu) accumulation causes progressive neurologic disability. Tiomolibdate choline (TMC; ALXN1840) is an oral, once-daily, high affinity Cu-binding agent. This analysis evaluates outcomes in neurologic WD patients, a population at greater risk of symptomatic worsening on current WD therapy than asymptomatic patients.

Methods: In the open-label Phase 3 FoCUS trial (NCT03403205), 207 WD patients were randomized 2:1 to TMC or SoC for

48 weeks (W), with an optional TMC extension phase. Neurologic and clinical outcomes were analysed at 48W (primary) and 96W (extension) for patients with neurologic symptoms at baseline, defined as Unified WD Rating Scale [UWDRS] Part III score exceeding the minimum clinically important difference [MCID] of 4.668.

Results: Neurologic WD patients treated with TMC ($n=77$) demonstrated increasing clinical benefit over time, with statistically significant improvements in UWDRS Part III observed at 48W and continuing through 96W (mean change: -7.2 ; $p<0.001$). Benefit of TMC over SoC was evident by 48W, with significant UWDRS Part III improvement in the TMC arm ($p=0.002$) but not the SoC arm ($p=0.235$). Additionally, fewer TMC patients worsened by $\geq$ MCID at 48W vs. SoC (9% vs 25%). Disease improvement per Clinical Global Impression-Improvement (CGI-I) scale was statistically significantly greater for TMC vs. SoC at 48W ($p=0.003$).

Conclusion: In neurologic WD patients, 48 weeks of TMC treatment led to greater clinical benefit than SoC, with continued improvement through 96 weeks. These findings support the potential for TMC to improve neurologic outcomes in this at-risk population.

EPO-0446 | Abstract withdrawn

EPO-0447 | Clinical and kinematic assessment of the “Head snap” sign in patients with essential and dystonic tremor

D. Birreci¹; L. Angelini²; A. Grandolfo¹; M. De Ruggi¹; S. Aloisio¹; F. Santachiara¹; S. Cirinei¹; M. Bologna¹

¹Department of Human Neurosciences, Sapienza, University of Rome, Rome, Italy; ²IRCCS Neuromed, Pozzilli, IS, Italy

Background and aims: The head snap sign (HSS) is a brief, involuntary jerk of the head observed during the finger-to-nose maneuver in patients with tremor [1], [2]. Originally described in essential tremor (ET), its prevalence and clinical significance across different tremor syndromes, particularly dystonic tremor (DT), remain unclear. We aimed to assess the prevalence and reliability of HSS in ET and DT and to explore its clinical and kinematic correlates.

Methods: Seventy-five patients (55 ET, 20 DT) underwent standardized video examination and optoelectronic kinematic recordings. Five blinded raters evaluated the presence of HSS and dystonic features. Inter-rater reliability was assessed using Krippendorff's alpha. Tremor severity and cognition were assessed with standardized scales. Associations with diagnosis and dystonia were tested using Fisher's exact test. Clinical and kinematic variables were then compared between HSS-positive (HSS+) and HSS-negative (HSS-) patients.

Results: HSS was identified in 20/75 (20.0% ET, 45.0% DT). HSS was more frequent in DT than in ET (OR = 3.21, $p=0.04$)

and was significantly associated with head dystonia (OR = 3.91, $p=0.03$). HSS+ patients exhibited lower cognitive performance ($p=0.01$). Kinematic analysis revealed a more severe tremor phenotype in HSS+ patients, with higher postural, kinetic, and head tremor amplitude (all $p<0.02$).

Conclusion: HSS is more prevalent in dystonic tremor and strongly associated with head dystonia, supporting a dystonia-related origin. Although also observed in ET, HSS emerges mainly in more advanced and severe tremor phenotypes, representing a potential clinical marker of dystonic involvement within the tremor spectrum.

EPO-0448 | Exploring the phenotypic features of a large hereditary ataxia cohort: Insights from a single-center experience

E. Sahin¹; B. Samanci¹; B. Atasu²; E. Lohmann²; Z. Tufekcioglu³; E. Erzurumluoglu Gokalp⁴; S. Artan⁴; B. Bilgic¹; H. Hanagasi¹

¹Behavioral Neurology and Movement Disorders Unit, Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye; ²Department of Neurology, University of Tübingen, Tübingen, Germany; ³Department of Neurology, Faculty of Medicine, Istanbul Atlas University; ⁴Department of Medical Genetics, Faculty of Medicine, Eskisehir Osmangazi University, Eskisehir, Türkiye

Background and aims: Hereditary cerebellar ataxias (HCAs) are rare, genetically heterogeneous neurodegenerative disorders causing progressive cerebellar and multisystem involvement. Their diagnosis is challenging, particularly in populations with high consanguinity, such as Türkiye, where autosomal recessive (AR) forms are more prevalent. The aim of this study was to investigate the phenotypic features of hereditary ataxias in a large Turkish cohort.

Methods: A total of 481 individuals (207 index cases and 274 unaffected family members) were recruited from a tertiary referral center over 15 years. Clinical evaluation, pedigree analysis, and targeted genetic testing or whole-exome sequencing were performed. Variants were classified according to ACMG guidelines, and segregation analyses were completed when possible.

Results: Pathogenic variants were identified in 50 patients (24%). Of these, 83% displayed AR inheritance, reflecting the high prevalence of consanguinity. The most frequent disorder was autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS; 14%), followed by Friedreich's ataxia (6%), ANO10-related SCAR10 (8%), and CANVAS due to RFC1 expansions (8%). Less frequent variants included mutations in ATM, APTX, SETX, SYNE1, NPC1, and others. Overall, 14% of patients had late-onset disease, and several novel variants were documented.

Conclusion: This single-center study represents one of the largest hereditary ataxia cohorts reported in Türkiye. The predominance of AR inheritance highlights the impact of consanguinity on the genetic landscape. Recognition of specific phenotypic patterns, particularly treatable forms like CTX, is critical for timely diagnosis and therapeutic intervention. Advances in sequencing and emerging gene-targeted therapies emphasize the

EPO-0449 | Sex differences in non-motor symptoms and quality of life in Parkinson's disease: A systematic review and meta-analysis

S. Reis Pimenta¹; S. Moura de Sousa Brasil²; M. Carolina Soares³; M. de Medeiros Fernandes⁴; D. Leonel Boone⁵
¹Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Nordrhein-Westfalen, Germany; ²State University of Ceará, Fortaleza, Brazil; ³Federal University of São Paulo, Department of Neurology and Neurosurgery, São Paulo, Brazil; ⁴State University of Rio Grande do Norte, Medicine Department, Mossoró, Brazil; ⁵Federal University of São Paulo, Department of Neurology and Neurosurgery, São Paulo, Brazil

Background and aims: Observational studies suggests that there are sex-specific symptom profiles in Parkinson's Disease (PD), with potential differences in perceived quality of life (QoL). **Methods:** PubMed, Embase, and Cochrane were systematically searched to identify sex-related differences in the Non-Motor Symptoms Scale (NMSS) and Parkinson's Disease Questionnaire-39 (PDQ-39). Statistical heterogeneity was evaluated with I2 statistics. A random-effects model was employed for outcomes with substantial heterogeneity. **Results:** Seven reports were included (n=2,968; 1,733 men, 1,235 women). The total NMSS Mean Difference (MD) 5.00 (95% CI 2.26–7.73), p=0.0003, I2=19% shows a greater overall non-motor symptom burden in women. Similarly, the PDQ-39

Sex Differences in Non-Motor Symptoms and Quality of Life in Parkinson's Disease: A Systematic Review and Meta-Analysis

Figure 1. PRISMA flow diagram of study screening and selection

FIGURE 1 PRISMA - "Sex Differences in Non-Motor Symptoms and Quality of Life in Parkinson's Disease: A Systematic Review and Meta-Analysis".

TABLE 1 NMSS total forest plot.

TABLE 2 PDQ 39 forest plot.

MD 4.68 (95% CI 0.43 to 8.93), p=0.03, I2=88% shows a worse QoL in women. Regarding the NMSS domains, women have worse scores in the urinary domain MD 0.55 (95% CI 0.17–0.92), p=0.004, I2=65%, attention MD 0.27 (95% CI 0.02–0.51), p=0.03, I2=15%, sleep/fatigue MD 1.38 (95% CI 0.70–2.07), p<0.00001, I2=93%. **Conclusion:** Women with PD exhibit a higher non-motor symptom burden and worse QoL, particularly in sleep/fatigue and mood/cognition domains. In contrast, men tend to have higher scores in the cardiovascular domain. However, substantial

heterogeneity was observed in some analyses, indicating that the strength of these findings varies across domains.

Disclosure: Nothing to disclose.

EPO-0450 | Dynamic STN beta oscillations and fronto-subcortical connectivity track state anxiety in Parkinson's disease

L. Ricciardi

Neuromodulation and Motor Control Section, Department of Psychology and Neuroscience, School of Health and Medical Sciences, City St George's, University of London, London, UK

Background and aims: Anxiety in Parkinson's disease (PD) involves altered autonomic regulation and cortico-subcortical network dynamics. Mechanisms underlying state anxiety remain unclear.

Methods: We examined the effects of experimentally induced state anxiety and recovery via mindfulness/deep breathing on autonomic function, STN and cortical oscillations, and STN-cortical connectivity in PD, and their interaction with DBS. Thirteen PD patients with STN-DBS completed a protocol including stress induction and deep breathing/mindfulness. STN local field potentials, EEG, and ECG were recorded with DBS ON and OFF (ON medication). Oscillatory power (theta, alpha, beta), STN-cortical connectivity, and heart rate variability (HRV) were analysed using repeated-measures ANOVAs.

Results: Stress increased state anxiety ($F(1.22)=22.24$, $p<0.001$), which decreased after deep breathing ($p<0.001$), with no stimulation effect. State anxiety correlated with trait anxiety ON ($\rho=0.678$, $p=0.016$) and OFF DBS ($\rho=0.820$, $p=0.001$). STN beta power showed a stimulation $\times$ condition interaction ($F(2)=5.0$, $p=0.04$): reduced beta during deep breathing vs rest ($p=0.02$) and stress ($p=0.02$) with DBS ON, and DBS-related beta suppression during rest ($p=0.03$) and deep breathing ($p=0.01$). No theta or alpha effects were found. Root Mean Square of Successive Differences (RMSSD), a key HRV metric, showed a condition effect ($F(2)=5.5$, $p=0.01$). Stress-related anxiety changes correlated negatively with RMSSD ($\rho=-0.69$, $p=0.02$) and STN beta power ($\rho=-0.91$, $p<0.001$) with DBS ON. Recovery was associated with increased right STN-frontal beta connectivity ($\rho=-0.681$, $p=0.03$).

Conclusion: State anxiety in PD is associated with dynamic modulation of STN beta oscillations and STN-frontal connectivity. DBS enhances coupling between subjective anxiety, autonomic regulation, and STN beta activity.

Disclosure: Nothing to disclose.

EPO-0451 | Multimodal mixed-reality screening for Parkinson's disease: Accuracy and key features

M. Wójcik-Pędziwiat¹; D. Hemmerling²; B. Krawczyk³; W. Szczotka²; M. Dudek²; M. Rudzinska-Bar¹

¹Department of Neurology, Andrzej Frycz Modrzewski Cracow University, Cracow, Poland; ²AGH University of Cracow, Cracow, Poland; ³Samsung R&D Institute, Poland

Background and aims: Clinical evaluation of PD is often time-consuming and partially subjective. Objective, sensor-based

screening tools may enable scalable triage and longitudinal monitoring. The objective was to benchmark multimodal machine-learning models for Parkinson's disease (PD) detection during a mixed-reality assessment and to identify the tasks and sensor modalities most critical to diagnostic performance.

Methods: We analyzed 137 participants (66 with PD, 71 healthy controls) who performed 17 guided tasks with synchronized speech and motion capture. A total of 4,850 engineered features per participant were extracted. Data were split into training (60%) and testing (40%) sets. Missingness was substantial and group-dependent (51.8% controls; 27.6% PD). Imputation methods were compared using masked-value reconstruction RMSE; AttentionVAE achieved the lowest error (0.9481), outperforming MICE (0.9540) and mean/median imputation (1.0172/1.0424).

Results: Representation-learning approaches achieved strong classification performance. CrossModalAAVE combined with random forest reached a mean accuracy of 0.915 ± 0.060 (AUC 0.985 ± 0.019 ; F1 0.917 ± 0.059), while CrossTaskAAVE with gradient boosting achieved 0.901 ± 0.084 (AUC 0.982 ± 0.018 ; F1 0.904 ± 0.074). Speech features dominated (87.2% of informative variables). Removing head-movement features reduced accuracy from 0.873 to 0.691 and excluding both acoustic and head-movement modalities reduced accuracy to ~58%. Task-level ablations identified picture/story description and sustained vowel/a/ as most informative.

Conclusion: Mixed-reality multimodal assessment enables accurate PD screening and informs task prioritization to reduce patient burden. Larger external validation is required to establish generalizability and clinical utility.

Disclosure: Supported by the National Centre for Research and Development, Poland (LIDER/6/0049/L-12/20/NCBIR/2021).

EPO-0452 | When personality and polygenic risk scores interact to predict impulse control disorders in Parkinson's disease

M. Boussac¹; P. André Dias Bastos²; T. Wirth³; A. Lanore⁴; E. Harroch²; L. Mariani⁴; M. Anheim³; J. Corvol⁴; C. Brefel-Courbon²

¹Toulouse NeuroImaging Center (ToNIC), Inserm UMR1214, University of Toulouse III, UPS, France; ²Department of Clinical Pharmacology and Neurosciences, Parkinson Expert Center, Clinical Investigation Center, University Hospital of Toulouse, NeuroToul COEN (Center of Excellence in Neurodegeneration), Toulouse, NS-PARK/FCRIN Network, France; ³Service de Neurologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; ⁴Sorbonne Université, Institut du Cerveau - Paris Brain Institute - ICM, Inserm, CNRS, Paris, France

Background and aims: In Parkinson's disease (PD), patients may develop impulse control disorders (ICDs), as adverse effect of dopamine agonists. Some factors have already been associated with ICDs such as genetic polymorphisms (Cormier-Dequaire et al. 2018), as well as personality (Novelty Seeking/Self-Directedness dimensions) related to impulsivity in PD (Boussac et al. 2022; Meira et al. 2022). We aim to evaluate interactions effects between personality and polygenetic risk scores (PRS) on the risk of ICDs.

Methods: PD patients with ($n=139$) and without ($n=111$) ICDs were included in the BADGE-PD study (NCT02319395).

Personality dimensions were assessed using the Temperament and Character Inventory-Revised (TCI-R) (Cloninger et al. 1994), while 18 PRS associated with psychiatric or behavioral phenotypes were calculated. Logistic regression models were done to evaluate main and interaction effects between TCI-R dimensions and PRS on ICD risk by calculating odds ratios (OR).

Results: Main significant effects were found for the Self-Directedness personality dimension, for the attention deficit hyperactivity disorder (ADHD, PGS003753) and the major depressive disorder (MDD, PGS000907) PRS: higher scores being associated with higher risk to develop ICDs (ORs between 1.31 and 1.54). Moreover, some personality*PRS interactions significantly modulated this risk either amplifying or attenuating it. Highest ICD risk was found from the interaction between Self-Directedness and MDD PRS (global OR of 2.78) corresponding to a 278% increased risk of ICD for each increase of one standard deviation in both variables.

Conclusion: This study highlights some important interactions between genetic and personality to consider in personalized risk assessment for ICDs in PD.

Disclosure: I declare no conflict of interest for this study. This study was funded by a grant of the French Ministry of Health (PHRC AOM 1008), with the support of the Mutuelles AXA health sponsorship program for the ancillary part of this study.

EPO-0453 | A Bayesian reappraisal of disease-modifying drug candidates for Parkinson's disease

M. Russo¹; T. Costa²; G. Polito¹; D. Calisi¹; N. Spano¹; E. Cammarano¹; L. Miccoli¹; S. Sensi¹

¹Department of Neuroscience, Imaging and Clinical Sciences, G. d'Annunzio University of Chieti-Pescara, Chieti, Italy;

²GCS-fMRI, Koelliker Hospital and Department of Psychology, University of Turin, Turin, Italy

Background and aims: Parkinson's disease (PD) remains without a confirmed disease-modifying therapy (DMT). Numerous clinical trials have investigated candidate compounds, yet conclusions often rely on frequentist analyses that may obscure the strength or weakness of the evidence.

Methods: We performed a Bayesian reappraisal of major DMT trials—covering cinpanemab, deferiprone, CoQ10, amroxol, NLY01, liraglutide, lixisenatide, and exenatide—focusing on motor and non-motor outcomes, with standardized effect sizes, Bayes Factors (BF₁₀), and posterior probabilities.

Results: Deferiprone (FAIRPARK-II) showed extreme evidence for a detrimental effect on 36-week MDS-UPDRS total scores (BF₁₀ = 5.03 × 10⁶; P(H₁) = 0.993). Liraglutide demonstrated strong evidence for improvement in Non-Motor Symptoms Scale scores (BF₁₀ = 41.7; P(H₁) = 0.977). Lixisenatide showed moderate evidence for a small motor improvement on MDS-UPDRS-III at 12 months (BF₁₀ = 4.75; P(H₁) = 0.826). CoQ10, cinpanemab, amroxol, NLY01, and exenatide (2025) all showed BF₁₀ < 1, indicating no support for efficacy.

Conclusion: Bayesian analysis aligns with the strongest frequentist signals while clarifying ambiguous or inconsistent results, underscoring that the magnitude of the effect and

evidential strength vary substantially across compounds. GLP-1R agonists show promising efficacy as DMT candidates for PD treatment. Pharmacokinetic and pharmacodynamic differences among the compounds could underlie the different efficacy profiles concerning the disease stage and different symptoms (i.e., motor or non-motor).

Disclosure: Nothing to disclose.

EPO-0454 | The longitudinal Progression of Gait Symptoms in Early Parkinson's Disease: A 7-year study from the PPMI dataset

R. Iredale¹; V. Foster¹; S. Sahana Sathyanarayana¹; D. Galley¹; C. Stewart¹; J. Pasquini²; D. Ledingham¹; N. Pavese¹

¹Clinical Ageing Research Unit, Newcastle University, Campus for Ageing and Vitality, Newcastle upon Tyne, UK; ²Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Clinical Ageing Research Unit, Newcastle University, Campus for Ageing and Vitality, Newcastle upon Tyne, UK

Background and aims: Gait disturbances are cardinal symptoms of Parkinson's disease (PD). Existing studies in early PD focused on aggregate scores, lacking sensitivity to sub-item level changes. Correlations between gait and cognitive impairment were demonstrated but findings remain inconsistent. This study longitudinally tracked the progression of early gait disturbances along with cognitive impairment to understand their impact on Activities of Daily Living (ADL) over 7-years.

Methods: Data was obtained from 150 PD participants in the Parkinson's Progression Markers Initiative (PPMI) database. Motor symptoms, cognition and ADL were measured using the Movement Disorder Society- Unified Parkinson's Disease Rating Scale (MDS-UPDRS), the Montreal Cognitive Assessment (MoCA) and the Modified-Schwab England (ADL- SE) scale respectively from PPMI annual visits.

Results: Patient reported outcomes (PROs) identified walking and balance dysfunction in 32% of the cohort at baseline, 53% by year 3 and 69% at year 7. Whereas, clinicians identified gait disturbances in 55% at baseline, 60% at year 3 and 74% at year 7 with a significant impact on ADLs. Freezing of gait (FOG) presented between year 4 (3%) and 5 (5%) in clinician scores, but 5% of patients already reported FOG at baseline that increased to 17% by year 5 and 35% at year 7 on PROs. At year 7, FOG, gait, and postural stability scores correlated negatively with MoCA scores ($p < 0.012$).

Conclusion: This study shows that gait disturbances are widely prevalent in early PD with a fast rate of progression, highlighting the importance of appropriate physiotherapy and management early in the disease course.

Disclosure: Nothing to disclose.

U. Lazic¹; A. Milovanovic¹; R. Damjanovic²; M. Svetel¹; V. Kostic¹; N. Dragasevic Miskovic¹; I. Stankovic¹

¹Neurology Clinic, University Clinical Center of Serbia, Belgrade, Serbia; ²University Clinical Center Nis, Neurology Clinic, Nis, Serbia

Background and aims: Adult-onset genetic movement disorders can present with autonomic failure alongside parkinsonism, ataxia, and other movement disorders. Autonomic dysfunction, a frequent cause of misdiagnosis of multiple system atrophy (MSA), has not been systematically evaluated across these disorders. This study aimed to comprehensively characterize dysautonomia in adult-onset genetic movement disorders.

Methods: A systematic PubMed search using predefined terms identified original English-language research articles. Of 313 papers retrieved on September 8, 2025, 82 were included (61 original studies, 5 case series, and 16 case reports). Exclusions comprised 7 review articles, 12 chapters, 206 unrelated publications, and 6 non-English papers. Extracted data included study population, age at onset, inheritance pattern and genetic mutation, presence of control groups, clinical phenotype, autonomic assessment methodology, and key findings related to autonomic dysfunction. Results were summarized in a table of evidence.

Results: Thirty-four adult-onset genetic movement disorders caused by mutations in 52 genes were identified as manifesting autonomic failure in association with ataxia, parkinsonism, dystonia, spastic paraplegia, chorea, or complex phenotypes. Several conditions—including spinocerebellar ataxias, hereditary spastic paraplegias, certain genetic parkinsonian syndromes, fragile X tremor–ataxia syndrome, LMNB1-related autosomal dominant leukodystrophy, and RFC1-related disease—emerge as MSA mimics. The phenotype and severity of dysautonomia varied considerably across disorders.

Conclusion: Many adult-onset genetic movement disorders can closely resemble MSA, creating significant diagnostic challenges. Autonomic dysfunction is an important but often overlooked feature in these conditions and should be considered in the differential diagnosis of MSA. Comprehensive clinical history, autonomic testing, and targeted genetic testing in selected cases may improve diagnostic accuracy and reduce misdiagnosis.

Disclosure: Nothing to disclose.

EPO-0456 | Epigenetic modifications of cerebrospinal fluid cell-free DNA as a marker of neuronal damage

C. Starvaggi Cucuzza^{1,2,3}; C. Rao Prakash^{1,2}; C. Nolan⁴; A. Simeone⁴; L. Sarre⁴; T. Charlesworth⁴; F. Puddu⁴; Y. Han^{1,2}; M. Khademi^{1,2}; B. Evertsson^{1,5}; K. Fink^{1,2,3,5}; P. Svenningsson^{1,3}; C. Ingre^{1,5}; C. Seitz⁶; F. Fang⁶; E. Thelin^{1,5}; L. Kular^{1,2}; F. Piehl^{1,2,3,5}; M. Needhamsen^{1,2}; M. Jagodic^{1,2,3}

¹Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden; ²Center for Molecular Medicine, Karolinska University Hospital, Stockholm, Sweden; ³Center for Neurology, Academic Specialist Center, Stockholm, Sweden; ⁴biomodal Limited, Chesterford Research Park, Cambridge, UK; ⁵Department of Neurology, Karolinska University Hospital, Stockholm, Sweden; ⁶Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Background and aims: Degenerative processes during Multiple Sclerosis (MS) progression are scarcely captured by currently available biomarkers. Cell-free DNA (cfDNA) are fragments of DNA shed into biological fluids by dying cells and retain the cell-of-origin DNA methylation. Our aim is to utilize DNA methylation signatures in cfDNA from cerebrospinal fluid (CSF) to detect ongoing neuronal death in MS and other neurological diseases.

Methods: We profiled bulk methylation (mC) using enzymatic methylation sequencing (EMSeq) and/or true methylation (5mC) and hydroxymethylation (5hmC) using 6-base sequencing in cfDNA extracted from CSF of healthy controls and people with MS, amyotrophic lateral sclerosis (ALS), narcolepsy type 1, movement disorders, or traumatic brain injury (TBI).

Results: While cfDNA extraction from CSF yielded a low amount of DNA for all but TBI samples, EMSeq and 6-base sequencing successfully generated sequencing libraries, although with low genome coverage. To overcome the latter, we aggregated EMSeq reads and calculated methylation scores for neuronal or glial damage. TBI samples showed significantly higher scores than HC, followed by increased scores in ALS, suggesting more extensive neural cell death in these conditions. To increase sensitivity for neuronal damage, we quantified the neuron-enriched hmC with 6-base sequencing, and we confirmed higher neuronal DNA content in CSF cfDNA from TBI. Clustering of samples based on regions enriched for hmC successfully separated HC from neurological conditions, including MS.

Conclusion: Analysis of DNA methylation modifications of cfDNA has the capacity of capturing a neuronal signature in cell-free CSF. Further studies are needed to implement cfDNA epigenetic analysis as real-time biomarker of neurodegeneration.

EPO-0457 | Smelling and tasting neurodegeneration: Chemosensory dysfunction and retinal changes in multiple sclerosis: A pilot study

E. Idini¹; G. Sollai³; M. Melis²; G. Coghe³; J. Frau³; I. Tomassini Barbarossa²; E. Cocco³

¹Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy; ²Department of Biomedical Sciences, University of Cagliari, Cagliari, Italy; ³Multiple Sclerosis Center, Binaghi Hospital, Cagliari, Italy

Background and aims: To characterize gustatory and olfactory function in relapsing-remitting multiple sclerosis (RRMS) and explore associations with clinical variables and optical coherence tomography (OCT) retinal measures.

Methods: Single-centre cross-sectional pilot study (Cagliari, Italy; February to April 2025), 78 adults with RRMS completed Taste Strips (Total Taste score 0–16; hypogeusia defined as less than 9). A subgroup ($n=60$) completed Sniffin Sticks battery (Threshold, Discrimination, Identification; TDI score 1–48). Spectral-domain OCT measured peripapillary retinal nerve fibre layer (pRNFL) and ganglion cell-inner plexiform layer (GCIPL) thickness in eyes without prior optic neuritis. Correlations analyses and multivariable linear regression assessed associations between chemosensory measures, clinical variables and pRNFL thickness.

Results: Mean Total Taste score was 11.5 (standard deviation 2.85) and 13 (16.7%) had hypogeusia; sour required higher concentrations for correct identification than sweet, salty and bitter ($p<0.05$). Higher body mass index was associated with lower taste scores ($r=-0.30$; $p=0.033$) and smoking with hypogeusia ($p=0.023$); taste performance was not associated with Expanded Disability Status Scale (EDSS), disease duration, pRNFL or GCIPL. Mean TDI was 29.5 (3.38) and 23 (38%) were hyposmic. TDI correlated with disease duration ($r=-0.56$; $p<0.001$) and pRNFL thickness ($r=0.28$; $p=0.038$). In multivariable models for pRNFL thickness, only disease duration remained independently associated ($p=0.029$).

Conclusion: Chemosensory dysfunction is common in RRMS and should be recognized clinically. Taste impairment appears mainly linked to modifiable factors (BMI, smoking), whereas olfactory performance reflects cumulative disease burden; the olfaction-pRNFL association was not independent of disease duration. Larger longitudinal, multimodal studies including magnetic resonance imaging and cognition are needed.

Disclosure: Nothing to disclose.

EPO-0458 | Enhancing clinical assessment in multiple sclerosis: The role of patient-reported outcomes and the PDDS scale

E. Idini¹; I. Schiavetti²; G. Mura³; G. Coghe³; E. Carta³; E. Cocco³; J. Frau³

¹Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy; ²University of Genoa, Department of Health Sciences, Genoa, Italy; ³Multiple Sclerosis Center, Binaghi Hospital, ASL Cagliari

Background and aims: The multiple sclerosis (MS) management increasingly integrates traditional clinical measures with Patient-Reported Outcomes (PROs) to capture dimensions like fatigue and psychological well-being often missed by physician-led scales. Aim of the Study: To evaluate the efficacy of the “Patient Determined Disease Steps” PDDS as a simplified self-assessment tool, equivalent to the Expanded Disability Status Scale (EDSS), for monitoring functional status.

Methods: MS patients were assessed using PDDS and various PROs. Clinical and demographic data have been collected for each participant. Agreement between PDDS and EDSS was evaluated via quadratically weighted Cohen's kappa (κ) and Spearman's rho. Potential effect modifiers (demographics, clinical data, and PROs) were analyzed to assess stability of the agreement.

Results: 221 participants (71.9% female; mean age 48.4) were enrolled, predominantly RRMS (94.6%). Median EDSS and PDDS were 2.0 and 1.0, respectively. High prevalence of depression (38.5%), fatigue (37.6%), and anxiety (26.7%) was observed. A substantial agreement was found between EDSS and PDDS ($\kappa=0.84$, 95% CI:0.783–0.879; $\rho=0.73$; $p<0.001$). Subgroup analysis revealed higher concordance in RRMS ($\kappa=0.831$) than in progressive form ($\kappa=0.600$; $\Delta\kappa=0.231$, $p<0.05$). No other factors significantly influenced the agreement.

Conclusion: The robust agreement between EDSS and PDDS confirms its validity as an accessible tool for disability monitoring. Its stability across most variables supports PDDS use in remote monitoring and research. The lower concordance in progressive forms suggests differing disability perceptions in advanced stages. Integrating PDDS into clinical follow-up promotes a more personalized, patient-centered approach to MS care.

Disclosure: Nothing to disclose.

EPO-0459 | Sensor-based gait and balance testing can detect subclinical sensorimotor dysfunction in radiologically isolated syndrome

K. Akar¹; S. Bünül²; F. Akkoç²; H. Efendi²; A. Vural³

¹Graduate School of Health Sciences, Koç University, Istanbul, Türkiye; ²Faculty of Neurology, Kocaeli University, Kocaeli/Izmit, Türkiye; ³School of Medicine, Koç University, Istanbul, Türkiye

Background and aims: Radiologically isolated syndrome (RIS) presents with MRI features suggestive of multiple sclerosis (MS) without overt clinical signs or symptoms. We hypothesized

L. Azzarone¹; H. Abreu²; C. Muschitiello¹; M. Cerina³; E. Gallo³; D. Raineri²; R. Di Martino³; T. Pirali³; A. Chiochetti²; D. Vecchio⁴; G. Cappellano²; B. Riva¹
¹ChemiCare srl, Novara, Italy; ²Department of Health Sciences, Interdisciplinary Research Center of Autoimmune Diseases-IRCAD, University of Eastern Piedmont, Novara, Italy; ³Department of Pharmaceutical Sciences, University of Eastern Piedmont, Novara; ⁴Department of Translational Medicine, Neurology Unit, Maggiore Della Carità Hospital, University of Eastern Piedmont, Novara, Italy

Background and aims: Multiple Sclerosis (MS) is an autoimmune demyelinating disease of the CNS for which current high-efficacy disease-modifying therapies often cause severe immunosuppression. Dysregulated Ca^{2+} -calcineurin-NFAT signalling, driven by overactivated Store-Operated Ca^{2+} entry (SOCE), promotes immune activation and pro-inflammatory cytokine release (Fig1). This study evaluates SOCE as a therapeutic target using CIC-39, a novel SOCE inhibitor in preclinical development, to restore immune homeostasis. Targeting SOCE may provide a safer, immune-preserving strategy for MS, reducing immunosuppressive side effects (Fig2).

Methods: Peripheral blood mononuclear cells from MS patients and healthy controls were collected (Ethical Committee CE152/2024). CD4^{+} T cells were isolated, activated, and differentiated. CIC-39 (1–3 μM) was tested in vitro for SOCE, proliferation, and cytokine release. In vivo, EAE mice were treated with CIC-39 60 mg/kg via minipumps for 15 days (prot. 503/2024-PR).

Results: SOCE was overactivated in PBMCs from MS patients, and CIC-39 effectively restored Ca^{2+} homeostasis. Unlike the immunosuppressant teriflunomide, CIC-39 did not impair CD4^{+} T-cell proliferation but significantly reduced Th1/Th17-associated cytokines (IL-17A, TNF- α , IFN- γ , GM-CSF) while preserving iTreg differentiation and regulatory function. In vitro and preliminary EAE studies demonstrated that CIC-39 attenuated pro-inflammatory responses, decreased circulating cytokines, and

FIGURE 2 Role of SOCE in Th1 and Th17 pro-inflammatory cytokine release.

effectively arrested disease progression, highlighting its potential as an immune-preserving therapeutic strategy for MS.

Conclusion: Our findings demonstrate that CIC-39 selectively modulates overactive SOCE in MS, restoring physiological Ca^{2+} levels and preserving lymphocyte proliferation. It reduces Th1/Th17 cytokines, and preliminary studies in EAE mice confirmed rapid disease arrest with decreased IFN- γ and IL-17A, supporting CIC-39 as a promising safer and immune-preserving disease-modifying therapy for MS.

Disclosure: Beatrice Riva owns stocks of ChemiCare srl. Luigi Azzarone and Carlotta Muschitiello are at present employees of ChemiCare srl.

EPO-0462 | Preliminary results from the brain-age MS study: NAWM CEST and T1 show no association with paramagnetic rim lesion count

L. Pirpamer¹; S. Navarrete²; M. Capiglioni³; S. Marti⁴; R. McKinley¹; R. Wiest¹; R. Hoepner⁴; A. Betancourt⁴; P. Radojewski⁵

¹Institute for Diagnostic and Interventional Neuroradiology, Support Center for Advanced Neuroimaging, University of Bern, Bern, Switzerland; ²Faculty of Engineering, Universidad de Concepción, Chile; ³High Field Magnetic Resonance Center, Max Planck Institute for Biological Cybernetics, Tübingen, Germany; ⁴Department of Neurology, Inselspital, Bern University Hospital and University of Bern, Switzerland; ⁵Translational Imaging Center (TIC), Sitem-insel, Bern, Switzerland

Background and aims: Paramagnetic rim lesions (PRLs) are established imaging markers of chronic active multiple sclerosis (MS), reflecting focal inflammatory pathology. While PRLs are well characterised at the lesion level, it remains unclear whether PRL-count is associated with diffuse alterations in normal-appearing white matter (NAWM). Chemical exchange saturation transfer (CEST) imaging is sensitive to metabolic tissue properties beyond conventional MRI. In this preliminary

FIGURE 1 SOCE-Calcineurin-NFAT pathway in B and T lymphocytes.

FIGURE 1 NAWM CEST metrics and quantitative T1 stratified by PRL count. Boxplots show distributions across PRL categories with overlaid individual values; red lines indicate medians. *p*-values derive from linear regression trend tests between PRL count and NAWM met.

analysis of the brain-age MS study (NCT06221631), we investigated whether PRL-count is associated with CEST-metrics and T1 relaxation in clinically stable MS.

Methods: Clinically stable MS patients underwent 7T MRI including CEST imaging (amide, amine, rNOE, MT) and MP2RAGE-based T1 mapping. PRLs were identified on susceptibility-weighted imaging, and PRL-count was determined per subject. NAWM regions of interest were conservatively defined by excluding T2-FLAIR-visible lesions. Linear associations between PRL-count and median NAWM quantitative metrics were assessed.

Results: No significant linear associations were observed between PRL-count and NAWM CEST or T1. Substantial inter-individual variability was present, but no consistent monotonic trends were observed with increasing PRL-count.

Conclusion: In this preliminary analysis of clinically stable MS patients from the brain-age MS study, PRL count was not associated with metabolically sensitive NAWM CEST metrics or quantitative T1. These findings suggest that PRL-related pathology remains spatially focal and is not reflected by diffuse NAWM alterations at this stage. Larger longitudinal studies are needed to determine whether NAWM metabolic changes emerge with disease progression.

Disclosure: Nothing to disclose.

EPO-0463 | OCT and OCT angiography in differential diagnosis of MS: The retina as a window on the CNS

M. Di Cristinzi¹; L. Alonzo¹; C. Lenzetti²; F. Azzolini³; A. Mariottini¹; A. Poggesi¹; L. Massacesi¹; G. Virgili¹; A. Repice⁴

¹Department of Neurofarba, University of Florence, Florence, Italy; ²Department of Ophthalmology, AOU Careggi; ³Department of Neurology, IRCCS Neuromed; ⁴Department of Neurology, AOU Careggi, Florence, Italy

Background and aims: MS is an inflammatory demyelinating disease of the CNS characterized by immune-mediated perivenular inflammation, reflected by the perivenular distribution of white matter lesions (PVL) on MRI by the central vein sign (CVS). In contrast, several MS-like and atypical MS disorders share overlapping clinical and radiological features but show a lower prevalence of PVL, suggesting alternative pathogenic mechanisms in which vascular dysfunction may play a prominent role. Optical coherence tomography (OCT) and OCTangiography (OCTA) enable non-invasive assessment of retinal neuroaxonal integrity and microvascular perfusion, providing insights into CNS vascular involvement.

Methods: 56 patients underwent OCT-OCTA and 19 received 3T MRI with CVS assessment (CVS+ if PVL>50%). OCT measured retinal nerve fiber layer (RNFL) and ganglion cell complex (GCC) thickness, while OCTA assessed optic nerve head vessel density and superficial (SCP) and deep (DCP) capillary plexus density.

Results: Patients were classified as MS (*n*=34), atypical-MS (*n*=8), and not-MS (nMS;*n*=15), including other inflammatory, vascular, and neoplastic CNS disorders. Previous optic neuritis was associated with RNFL and GCC thinning, without significant changes in vessel density. MS showed significant temporal RNFL thinning compared with atypical-MS and nMS (*p*<0.001). Conversely, atypical-MS and not-MS exhibited a marked reduction in SCP and DCP density, in the absence of major structural retinal damage. In the CVS subgroup, CVS-eyes demonstrated significantly lower vessel density than CVS+eyes, with high concordance between CVS+ and SCP status.

Conclusion: Atypical-MS and not-MS are characterized by predominant retinal microvascular impairment with minimal neuroaxonal loss, supporting a primary vascular pathogenic

EPO-0464 | Exploring the impact of multiple sclerosis on social determinants of health: Results from the SocialMS study

M. Ponzano¹; A. Signori²; D. Landi³; A. Bellavia⁴; I. Schiavetti²; L. Lavorgna⁵; A. Di Sapio⁶; R. Fantozzi⁷; F. Marinelli⁸; M. Sormani²

¹Department of Life Sciences, Health and Health Professions, Link Campus University, Rome, Italy; ²Department of Health Sciences, University of Genoa, Genoa, Italy; ³Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy; ⁴Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA; ⁵Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli, Naples, Italy; ⁶Department of Neurology & Regional referral Multiple Sclerosis Centre (CRESM), University Hospital San Luigi Gonzaga, Orbassano, Italy; ⁷Department of Neurology, IRCCS Neuromed, Pozzilli (IS), Italy; ⁸MS Center, Neurology Unit, F. Spaziani Hospital, Frosinone, Italy

Background and aims: Multiple Sclerosis (MS) can affect several social determinants of health (SDH), but research remains limited and fragmented, with no studies exploring multiple SDH simultaneously. We examined four SDH (education, work, financial resources and social life) to assess the impact of MS and interrelationships, to identify risk factors, and to study associations with social support.

Methods: SocialMS is a cross-sectional Italian questionnaire-based study including adults with MS. The number of SDH affected was the primary endpoint, while secondary outcomes included impact on at least one domain and on individual domains. Risk factors were identified using Poisson and logistic regression.

Results: We included 1,039 participants followed at 68 MS centers (mean age: 43.82years (standard deviation: 11.53); 68.82% females; 86.53% relapsing remitting, median Patient Determined Disease Steps (PDDS): 1.00 (interquartile range (IQR): 0.00–3.00)). Median number of SDH affected was 1 (IQR: 0–3), with social life (51%) and work (48%) most impacted; high interrelationships among domains were observed (Figure 1). Relevant risk factors included socioeconomic factors (education incomplete at diagnosis: incidence-rate ratio (IRR)=1.19, $p=0.004$; non-working or early retired: IRR=1.18, $p=0.007$; hardly making ends meet: IRR=1.47, $p<0.001$); comorbidities (IRR=1.23, $p<0.001$) and PDDS (IRR=1.17, $p<0.001$) (Table 1). Economic strain and disability were associated with all secondary outcomes ($p<0.05$). Almost 90% received tangible (64.29%) or intangible (85.18%) social support, and number of impacted SDH was positively associated with both (odds ratios=1.88 and 1.25, $p<0.05$, Figure 2).

Conclusion: MS substantially affects multiple SDH, with greater impact in individuals with socioeconomic and MS-related vulnerabilities.

EPO-0465 | Microglial activation in MS brain contributes significantly to brain age gap between MS patients and controls

O. Hartiala; J. Tuomaala; M. Saraste; M. Matilainen; L. Airas
Neurocenter, Turku PET Centre, Clinical Neurosciences and InFLAMES Research Flagship, Turku University Hospital, and University of Turku, Finland

Background and aims: Disease- and aging-related factors impair brain health in people with MS. Aging MS patients typically experience gradual disease progression without relapses due to glial activation causing neuroaxonal damage. Aging-, MS-CNS pathology- and autoimmunity-related factors may exacerbate detrimental glial activation and neuroaxonal damage in MS brain. We sought to investigate how aging associates with microglial activation and white matter damage and evaluate differences in brain age gap among healthy controls (HCs) and people with MS. **Methods:** 128 MS patients and 69 age- and sex-matched HCs underwent 18-kDa translocator protein (TSPO)-binding radioligand 11C-PK11195 positron emission tomography for assessment of glial activation using distribution volume ratio (DVR) and concomitant magnetic resonance imaging (MRI) including diffusion tensor imaging (DTI). Brain age gap was calculated as difference between chronological and biological age estimated using data on 1) MRI-measured atrophy, 2) atrophy and DTI and 3) the machine-learning tool Braineager.

Results: Normal-appearing white matter (NAWM) DVR values increased ($p=0.001$) and DTI metrics worsened ($p<0.01$ for all

measures) with increasing age among MS patients but not HCs. Brain age gap was significantly elevated in MS patients vs. HCs and this gap increased further when NAWM DVR was included in the model.

Conclusion: Higher age associated with increased glial activation among MS patients but not among HCs and co-occurred with loss of white matter structural integrity in the NAWM and increases in biological brain age in MS. Increased TSPO signal in aging MS patients likely represents increasing compartmentalized inflammation, which can be accelerated by general inflammation leading to premature brain neurodegeneration.

Disclosure: Olli Hartiala has received support for congress participation and travel from Novartis, Merck and Roche. Maija Saraste has received support for attending meetings and/or travel from Turku University Foundation, the InFLAMES Flagship Programme of the Academy of Finland and Merck. Joel Tuomaala: nothing to disclose. Markus Matilainen: nothing to disclose. Laura Airas has received honoraria and institutional research grant support from Sanofi and Merck Serono. This work was funded by the Research Council of Finland (decision number: 330902), the InFLAMES Flagship Programme

Background and aims: Disability progression in multiple sclerosis (MS) is dominantly driven by chronic compartmentalized rather than acute focal inflammation, emphasizing the need for biomarkers to capture this biology. Evidence supporting the prognostic value of common genetic variants, serum neurofilament light chain (sNfL) and glial fibrillary acidic protein (sGFAP) in progressive MS is limited. We assessed whether sNfL and sGFAP predict disability progression in a cohort of people diagnosed with primary progressive MS (pwPPMS) and evaluated the interaction with relevant common genetic variants.

Methods: Baseline sNfL and sGFAP Z-scores were acquired. Risk-carriership of rs10191329 and HLA-DRB1*15:01 were collected from SNP-array data and MS severity and susceptibility weighted genomic risk scores were calculated. Logistic regression models including age and immunomodulatory treatment (IMT) assessed prediction of disability progression at 1, 2, and 3 years.

Results: 173 pwPPMS (median age 60 years, 51% female) were included. sNfL Z-scores correlated positively with disability severity, as measured by Expanded Disability Status Scale (EDSS) ($p=0.19$, $p=0.014$) and Age-Related Multiple Sclerosis Severity Score (ARMSS) ($p=0.25$, $p<0.001$). Higher sNfL Z-scores predicted EDSS progression at 1 year (OR 1.83 [95% CI 1.03–3.26], $p=0.04$) and 2 years (OR 1.67 [95% CI 1.02–2.67], $p=0.04$), but not at 3 years. Results of GFAP and genetic analyses will be presented.

Conclusion: Elevated sNfL predicted early disability progression. These findings support sNfL as a clinically relevant biomarker in progressive MS, with potential implications for prognostication and personalised treatment.

Disclosure: This work was funded by Stichting BeterKeten, the Dutch National MS Foundation (OZ2021-019 and 2019-019), and Siemens Healthineers. Joost S received research support from Biogen, Roche, Siemens Healthineers and Hansa Biopharma, and lecture and/or consultancy fee from Biogen, Merck, Novartis, Roche, and Sanofi. Muscle and neuromuscular junction disorder 3

EPO-0467 | Risk of myasthenia gravis exacerbation during pregnancy and postpartum: A nationwide cohort study

L. O'Connor¹; K. Gabrysch²; A. Wikström³; A. Rostedt Punga¹

¹Department of Medical Sciences, Clinical Neurophysiology, Uppsala University, Uppsala, Sweden; ²Uppsala Clinical Research Center, Uppsala University, Uppsala, Sweden;

³Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden

Background and aims: Pregnancy and postpartum represent unique physiological states that may influence autoimmune diseases such as myasthenia gravis (MG). Evidence on MG exacerbations during these periods is scarce and often based on small case series. We aimed to assess the risk of MG exacerbation during pregnancy and up to one year postpartum using nationwide longitudinal register data.

Methods: We conducted a population-based cohort study including women with MG and their pregnancies in Sweden

between 1987 and 2019. Data were obtained through linkage of the Swedish MG Register with national health and sociodemographic registers. The primary outcome was hospital admissions for MG during pregnancy and up to one year postpartum, compared with the year preceding pregnancy. Cox regression models estimated hazard ratios (HR), adjusting for disease duration and thymectomy. Secondary outcomes included changes in immunosuppressive MG medications and whether women conceived during periods of relative disease stability.

Results: Our findings indicate that pregnancy is generally associated with clinical stability, whereas the postpartum period may carry an increased risk of exacerbation in a subset of women. Patterns of immunosuppressive therapy appear to reflect these trends. These results provide population-level evidence on MG risk dynamics surrounding pregnancy.

Conclusion: This nationwide cohort study offers novel insights into MG risk dynamics during pregnancy and postpartum. These insights will inform clinical counselling and management strategies for women with MG planning pregnancy.

Disclosure: Nothing to disclose.

EPO-0468 | Effect of exercise on functional decline in Inclusion body myositis based on the Yale IBM registry

A. Ozonoff¹; G. Cutter²; E. Chakraborty¹; K. Petschke³; A. Paltiel³; B. Roy¹

¹Department of Neurology, Yale University, New Haven, USA;

²Department of Biostatistics, UAB School of Public Health, Birmingham, USA; ³Health Policy and Management, Yale School of Public Health, New Haven, USA

Background and aims: Inclusion body myositis (IBM) is a rare, progressive muscle disease with preferential involvement of quadriceps and long finger flexors, leading to muscle weakness and atrophy, gait impairment, and loss of hand function. The potential beneficial role of exercise has been implicated, but the impact of exercise in IBM, including the safety of exercise in IBM, is not well established.

Methods: In this study, we leveraged IBM functional rating scale (IBM-FRS) scores, longitudinally collected by the Yale IBM registry (IBMR). A linear mixed-effects model was used to examine the role of exercise on functional decline in IBM.

Results: We included 401 patients (age 68.4 ± 8.4 years), of whom 139 were women (34.7%). The baseline mean IBM-FRS score was 26.9 ± 6.8 . All patients showed a decline in IBM-FRS over time. We did not notice any major differences in disease progression by gender or age. The habit of exercise was associated with a slower rate of decline (p -value < 0.01), with a graded benefit for more active patients (p -value < 0.001). Patients actively engaged in physical therapy and walking showed slower deterioration than those with no exercise (p -values of 0.003 and 0.04, respectively). Analyses of within-person changes emphasized the role of exercise continuity.

Conclusion: These findings, based on patients' self-reports, suggest safety and the potential benefit of remaining physically active in IBM. Large and long-duration clinical trial with a structured exercise regimen to delineate the true impact of exercise on IBM disease progression is warranted.

EPO-0469 | Continuing medical education improves competence in implementing new therapies for myasthenia gravis

S. Rohani-Montez¹; M. Calle¹; F. David¹; E. Santos²; N. Gilhus³
¹Medscape Education Global, London, UK; ²Biomedical Sciences School of University of Porto, Santo Antonio University Hospital, Porto, Portugal; ³University of Bergen, Haukeland University Hospital, Bergen, Norway

Background and aims: Treatments for myasthenia gravis (MG) are evolving, requiring physicians to consider new mechanisms including FcRN or complement inhibition. We sought to improve knowledge of these new therapies and their application in today's clinical practice.

Methods: Physicians participated in a 3-part video-based, online CME activity (available at www.medscape.org/view-article/1002773). The education effects were assessed using a 3-question, repeated pairs, pre-assessment/post-assessment study design. One question assessed confidence. Pre- to post-assessment differences were evaluated using the McNemar's test. $p \leq 0.05$ is the significance level. The activity launched in 08-2025 and data were collected through 10-2025.

Results: 53 neurologists and 80 primary care physicians (PCPs) completed all pre- and post-assessment questions. Overall significant improvements were seen after participation for neurologists (correct pre-assessment response rate of 47% vs 73% at post-assessment; $p < 0.001$, Cohen's $d = 0.9$), and PCPs (correct pre-assessment response rate of 31% vs 54% at post-assessment; $p < 0.001$, Cohen's $d = 0.98$). Improvements were observed in clinicians' understanding of the rationale for FcRN inhibition in MG, and how best to tailor new therapies in different clinical scenarios (Figure 1). After participating, 38% of neurologists and 26% of PCPs had measurable improved confidence in determining which patients with MG may benefit from a targeted therapy.

FIGURE 1 Changes in Knowledge and Competence Pre- vs Post-Education.

FIGURE 2 Intended practice changes post-education.

Post-education, 52% of neurologists and 42% of PCPs said they intend to consider targeted therapies earlier for patients with severe or rapidly progressive MG (other responses in Figure 2).

Conclusion: This study demonstrates the success of online, multi-component, video-based education in improving competence in implementing new targeted therapies for MG in practice.

Disclosure: Nothing to disclose.

EPO-0470 | Effect of subcutaneous self-administered Gefurulimab on ocular muscle function in myasthenia gravis in the PREVAIL Trial

F. Saccà¹; D. Annane²; M. Mäurer³; M. Takahashi⁴; S. Rakhade⁵; J. Scholz⁵; S. Shang⁵; T. Vu⁶

¹NSRO Department, University of Naples Federico II, Napoli, Italy; ²General ICU, Hôpital Raymond Poincaré, Garches, France; ³Clinic for Neurology and Neurological Early Rehabilitation, Würzburg-Mitte Hospital, Würzburg, Germany; ⁴Department of Clinical Laboratory and Biomedical, The University of Osaka Graduate School of Medicine Sciences, Osaka, Japan; ⁵Alexion, AstraZeneca Rare Disease, Boston, USA; ⁶Department of Neurology and Neuromuscular Medicine, University of South Florida Morsani College of Medicine, Tampa, FL

Background and aims: Gefurulimab, a novel dual-binding nanobody, blocks complement component 5 activation. The phase 3 PREVAIL trial, assessing the efficacy and safety of gefurulimab in adults with anti-acetylcholine receptor antibody-positive (AChR-Ab+) generalised myasthenia gravis (gMG) (NCT05556096), met all primary and secondary endpoints and demonstrated clinically meaningful improvement from baseline in Myasthenia Gravis Activities of Daily Living (MG-ADL) total score at week 26 compared with placebo. Here, we present the effect of gefurulimab on ocular symptoms.

Methods: Adults with AChR-Ab+ gMG were randomised 1:1 to weekly subcutaneous self-administration of gefurulimab or placebo. The primary endpoint was change from baseline

in MG-ADL total score at wk26. MG-ADL and Quantitative Myasthenia Gravis (QMG) subdomain scores were also assessed. **Results:** 260 patients were randomized (gefurulimab: $n=131$; placebo: $n=129$). Mean $\pm$ SD baseline MG-ADL and QMG total scores were 9.0 ± 2.16 and 14.8 ± 4.37 , respectively. Improvements in ocular subdomain scores were observed at first assessment after treatment initiation (MG-ADL, wk1; QMG, wk4) and sustained through wk26. Least squares mean $\pm$ SEM change from baseline at wk26 in MG-ADL and QMG ocular subdomain scores for gefurulimab versus placebo were -1.2 ± 0.14 versus -0.6 ± 0.13 (treatment difference, -0.6 ± 0.19 ; 95% CI: $-1.0, -0.2$; $p=0.0016$) and -1.7 ± 0.14 versus -0.9 ± 0.14 (treatment difference, -0.7 ± 0.19 ; 95% CI: $-1.1, -0.4$, $p=0.0002$), respectively. Improvements were also observed in other MG-ADL and QMG subdomains. Adverse events were similar between groups; no meningococcal infections were reported.

Conclusion: Gefurulimab, self-administered once weekly via subcutaneous injection, showed early and sustained improvements in MG-ADL and QMG ocular subdomain scores, demonstrating benefits for patients with gMG experiencing ocular symptoms.

EPO-0471 | Expanded phenotypic and ultrasound characterization of the p.Ser55Phe myotilinopathy variant: The MYOT MUR study

G. Zmork Martínez¹; L. Pulido Fraiz¹; Ó. Camejo Mas¹; M. Aledo Serrano¹; A. Mena Bravo¹; M. Lorenzo Diéguez¹; A. García Leal¹; J. Pérez Lucas²; A. Terry Sanz-Pastor³; E. Pérez García³; R. Martínez Marín¹

¹Neurology, La Paz University Hospital and Stroke Center, Madrid, Spain; ²Neurology, El Tajo University Hospital, Madrid, Spain; ³Neurosurgery, La Paz University Hospital and Stroke Center, Madrid, Spain

Background and aims: Myotilinopathies are the most frequent myofibrillar myopathy in Spain, mainly the p.Ser55Phe MYOT variant. We characterized the phenotype and disease progression in the largest known cohort of this variant from Murcia, Spain.

Methods: We conducted an ambispective observational study (2022–2025) on 46 p.Ser55Phe carriers. Annual evaluations included history, pedigree analysis, neuromuscular ultrasound (NMUS) and neurological examination including North Star Ambulatory Assessment (NSAA), Medical Research Council (MRC) scale, and 6-minute walk test (6mWT). Sex differences were analyzed using non-parametric tests.

Results: The cohort ($n=46$; 44% female) had a mean onset age of 47.4 years. 71.7% were symptomatic. Weakness was asymmetric (89.7%). Lower limb weakness (67.4%) typically had distal onset ($n=15$) with frequent foot drop (60.6%), progressing proximally. Upper limb weakness (54.3%) was mostly proximal at onset (68.8%), progressing distally. Pain (60.9%) and dyspnea (37%) were frequent. Males were more symptomatic (84% vs 55%, $p=0.049$) with earlier onset than females (45.3 vs 51.5 years, $p=0.013$). Males exhibited lower limb predominance ($p=0.006$), more foot drop ($p<0.001$), atrophy ($p<0.001$), and lower NSAA, MRC, and 6mWT scores across most visits. Females showed axial predominance. NMUS revealed increased echogenicity initially in the tibialis anterior and extensor digitorum brevis, progressing to the vastus intermedius and brachialis.

Conclusion: We describe the largest p.Ser55Phe myotilinopathy cohort to date, an expanded clinical phenotype, and a characteristic ultrasound pattern. Weakness is asymmetric and distal-predominant. We highlight a significant sex difference, with males experiencing a more severe course and worse functional prognosis.

Disclosure: Nothing to disclose.

EPO-0472 | Immediate FcRn inhibitor initiation following fast-acting treatment in generalised myasthenia gravis: A single-centre retrospective cohort study

K. Yanagisawa; T. Ishii; T. Saito; M. Zenko; T. Aoki; A. Sugie; H. Myojin; T. Saito; Y. Kondo; K. Sato; T. Uchiyama
Department of Neurology, Seirei Hamamatsu General Hospital, Shizuoka, Japan

Background and aims: Early initiation of fast-acting treatment (FT; intravenous immunoglobulin, plasma exchange, or intravenous methylprednisolone) improves long-term outcomes

FIGURE 1 Kaplan–Meier curves of treatment escalation–free probability since FcRn-i initiation in gMG (immediate $n=8$ vs delayed $n=30$). Tick marks indicate censoring; numbers at risk are shown below. Log-rank $p=0.019$.

in patients with generalised myasthenia gravis (gMG). However, the optimal approach to achieve durable disease control after FT remains unclear. We hypothesised that the timely initiation of an FcRn inhibitor (FcRn-i) as a "consolidation therapy" following FT may promote sustained benefit, particularly in patients with shorter disease duration.

Methods: This retrospective single-centre cohort study included adults with gMG treated with FcRn-i between January 2022 and September 2025. Immediate initiation was defined as FcRn-i administration within 60 days after the last FT and disease duration ≤ 2 years; all others were classified as deferred. The primary outcome was the time to treatment escalation to additional FT or C5 inhibitor therapy. Group differences were analysed using Kaplan–Meier curves with log-rank tests and Firth's penalised Cox models adjusted for age and MGFA classification.

Results: Thirty-eight patients were included (immediate, $n=8$; deferred, $n=30$). Median follow-up was 355 days (IQR 190–572). Treatment escalation occurred in 0/8 immediate patients and 15/30 deferred patients. Kaplan–Meier analysis showed a significant difference (log-rank $p=0.02$). In Firth's Cox model, immediate initiation was associated with a markedly lower hazard of treatment escalation (HR 0.09, 95% CI 0.001–0.70).

Conclusion: Immediate post-FT initiation of FcRn-i was associated with a reduced hazard of treatment escalation to additional FT or C5 inhibitor therapy. This consolidation-type strategy may support more stable disease control in patients early in the disease course and will be further evaluated in larger cohorts.

Disclosure: Nothing to disclose.

EPO-0473 | Measuring daily living ambulation of patients with high accuracy to derive meaningful clinical conclusions

M. Poleur¹; N. Noblot²; O. Piquet²; N. Benmhammed¹; M. Duclos¹; L. Médard¹; A. Tricot²; D. Eggenspieler²; L. Servais³

TABLE 1 Stride detection results by pathology. Precision is defined as the ratio of well-detected strides among all strides detected by the wDHT. Recall is defined as the ratio of well-detected strides among all existing strides.

Pathology	Number of participants	Precision	Recall
Amyotrophic lateral sclerosis	10	99.4%	97.8%
Charcot-Marie-Tooth disease	10	99.9%	99.8%
Myotonic dystrophy type 1	9	99.8%	99.6%
Limb girdle muscular dystrophy	8	99.9%	97.7%
Pompe disease	3	99.8%	99.7%
Myasthenia gravis	3	99.7%	99.1%
Huntington disease	4	99.7%	99.5%
Parkinson's disease	3	100%	97.7%
Chronic inflammatory demyelinating polyneuropathy	5	99.8%	99.7%
Spinal muscular atrophy	9	98.0%	88.9%
Duchenne muscular dystrophy	16	99.3%	97.7%
Healthy volunteers	20	98.7%	98.6%

Background and aims: Wearable devices are increasingly used in clinical trials in neurology. However, their actual capacity to precisely identify and measure movements in different conditions is never reported. The qualification of a digital measure, stride velocity 95th centile, as a primary endpoint in Duchenne muscular dystrophy (DMD) showed that suitable wearable digital health technologies (wDHT) can be reliable tools to measure disease progression and efficacy of therapeutic interventions in diseases impacting ambulation. It is crucial to establish in various populations the wDHT accuracy to detect strides and to precisely measure gait features.

Methods: This study enrolled 100 participants, including patients with amyotrophic lateral sclerosis, Charcot-Marie-Tooth disease, myotonic dystrophy type 1, limb girdle muscular dystrophy, Pompe disease, myasthenia gravis, spinal muscular atrophy, Huntington disease, Parkinson's disease, chronic inflammatory demyelinating polyneuropathy, DMD and healthy volunteers. Participants wore Syde ankle sensors and walked at different paces on path with turns, in a room equipped with a motion capture system (reference).

Results: Individual strides were correctly detected with an average precision of 99.5% and average recall of 97.8% (Table 1). The mean difference between the wDHT and the reference on stride length and stride velocity were −0.8 to 4.8 cm and −0.9 to 4.3 cm/s, respectively. Standard deviations of the absolute errors were between 1.5–4.1 cm for stride length and 1.5–3.5 cm/s for stride velocity.

Conclusion: We demonstrated Syde excellent precision to detect individual strides and similar performance in measuring gait parameters in several pathologies affecting ambulation, supporting its application to develop digital endpoints.

Disclosure: This study was funded by Sysnav. NN, OP, AT and DE are employees of Sysnav. LS has given consultancy for Sysnav.

EPO-0474 | Anti-Titin antibodies and thymoma in myasthenia gravis: A 10-year age-adjusted portuguese cohort study

M. Almeida¹; I. Carvalho¹; A. Geraldo¹; R. Cunha²; L. Negrão¹; A. Matos¹; L. Almendra¹

¹Neuromuscular and Neurophysiology Unit, Department of Neurology – Unidade Local de Saúde de Coimbra, Coimbra, Portugal; ²Clinical Pathology Laboratory – Unidade Local de Saúde de Coimbra, Coimbra, Portugal

Background and aims: Anti-titin antibodies are detected in approximately one-third of patients with myasthenia gravis (MG) and are considered a sensitive biomarker for thymoma in patients aged ≤50years. However, their high prevalence in late-onset MG reduces specificity, limiting their clinical utility in older patients. We aimed to assess the predictive value of anti-titin antibodies for thymoma in a Portuguese MG cohort.

Methods: We conducted a retrospective study of all patients newly diagnosed with MG between January 1, 2015, and August 1, 2025. Anti-titin antibody status was assessed by immunoblotting, and thymoma was evaluated using chest CT, PET-CT, or histopathology. Associations between anti-titin positivity, age, and thymoma were analyzed.

Results: Among 114 MG patients (mean age 66.6years), 34 had thymoma and 81 were anti-titin–positive. In patients <50years, anti-titin positivity showed a non-significant trend toward association with thymoma (OR 4.44, *p*=0.181). In patients ≥50years, anti-titin positivity was not predictive of thymoma (OR 0.44, *p*=0.171) and was inversely associated with thymoma in those aged 50–75 years (OR 0.23, *p*=0.042). Age significantly modified the predictive value of anti-titin antibodies (*p*=0.039). Anti-titin positivity was markedly more frequent in older non-thymoma patients (≥50: 81.2% vs <50: 27.3%, *p*<0.001), while sensitivity among thymoma patients was similar across age groups.

Conclusion: In MG patients over 50years, anti-titin antibodies show reduced specificity for thymoma due to high positivity among non-thymoma cases. In patients aged 50–75years, anti-titin positivity may favor the absence of thymoma. These findings highlight the age-dependent limitations of anti-titin antibodies in thymoma prediction.

Disclosure: The authors have nothing to disclosure.

EPO-0475 | Clinical and immunological features of thymoma patients with and without myasthenia gravis: A pilot study

M. Corbo¹; F. Beretta¹; R. Taliani¹; S. Bongiolatti²; L. Voltolini²; L. Massacesi¹; V. Damato¹; G. Spagni¹

¹Department of Neurosciences, Psychology, Drug Research and Child Health (NEUROFARBA), University of Florence, Italy; ²Thoracic Surgery Unit, Careggi University Hospital, Florence, Italy

Background and aims: Thymoma-associated myasthenia gravis (TAMG) is nearly invariably associated with acetylcholine receptor antibodies (AChRAb). However, approximately 15% of thymoma patients have AChRAb in the absence of MG and rarely may develop post-thymectomy MG (PTMG). This study evaluates the clinical and immunological features of thymoma

patients with and without MG to identify predictive biomarkers of PTMG.

Methods: Patients with thymoma treated in our Centre between 2011 and 2025 were included in the study. Demographic and clinical data were collected, and available serum samples were evaluated for in vitro complement activation using a flow cytometry live cell-based assay.

Results: Fifty thymoma patients were included in the study: 17/50 (34%) TAMG, 27/50 (54%) thymoma patients with no MG and AChRab negative (AChRab-MG-), 6/50 (12%) AChRab positive thymoma patients without MG (AChRab+MG-), of whom 2/6 (33%) developed PTMG. Types AB/B thymomas predominated across groups ($n=40/50,80\%$) without statistically significant difference between MG and non-MG patients (with/without AChRab). Most had a Masaoka stage I–II ($n=43/50,86\%$). The majority of patients had maximum MGFA>II (13/19, 68%). Sixteen serum samples were available for further analyses (10 TAMG, 2 PTMG, 4 AChRab+MG-). Complement activation was significantly lower in AChRab+MG- thymoma patients compared to TAMG and PTMG patients ($p=0.0332$, Mann-Whitney U test). In one PTMG patient with available serial serum samples, level of complement activation increased significantly from thymoma diagnosis to MG onset.

Conclusion: In vitro assessment of complement activation could represent a novel biomarker of PTMG. Future studies are warranted to investigate in-depth antibody as well as thymic and B-cells properties in PTMG patients.

EPO-0476 | Omaveloxolone for Friedreich ataxia: What does 'Cochrane' have to say about it?

S. Lyons
Department of Neurology, University Hospital Waterford,
Waterford, Ireland

Background and aims: Omaveloxolone (RTA 408) is thought to activate the nuclear factor erythroid-derived 2-related factor (Nrf2) signalling which is grossly impaired in Friedreich ataxia (FRDA) which is a rare autosomal recessive, progressive disease, typically presents around puberty. Approximately one third of people with FRDA are diagnosed after the age of 20. It usually presents with unsteadiness, followed by progressive limb and gait ataxia. It can be associated with scoliosis, pes cavus, cardiomyopathy and diabetes mellitus. Cochrane Reviews are systematic reviews and preform meta-analyses, where possible. They are a key resource in evidence-based medicine.

Methods: The aim of the review was to assess the effects of pharmacological treatments in Friedreich ataxia after one year's treatment. We found 7 randomised controlled trials of 1 year duration. We synthesised results for each outcome using meta-analysis, used GRADE to assess the certainty of evidence.

Results: Pharmacological treatments probably make little or no difference to change in ataxia rating scale (ARS) but improved upper limb dexterity (ULD) There was variation in that omaveloxolone helped ARS and leriglitazone helped ULD. The evidence for both outcomes was moderate and was an unexpected finding given that both outcomes share similar competencies.

FIGURE 1 Forest plot- change in ataxia rating score after 12 months treatment.

FIGURE 2 Forest plot - change in upper limb dexterity after 12 months treatment.

Background and aims: The classical complement pathway plays a significant role in the pathogenesis of generalized myasthenia gravis (gMG). Claseprubart is a monoclonal antibody that targets the classical pathway by inhibiting active C1s. The MaGic trial assessed the safety and efficacy of claseprubart in adults with acetylcholine receptor antibody positive (AChR+) gMG.

Methods: MaGic (NCT06282159) is a randomized, double-blind, placebo-controlled Phase 2 study. 65 participants with AChR+ gMG were randomized 1:1:1 to receive: claseprubart 300 mg (Q2W), claseprubart 600 mg (Q2W), or placebo for 13 weeks, followed by a 52-week open-label extension and 40-week safety follow-up. Endpoints at 13 weeks included safety, tolerability, efficacy (MG activities of daily living (MG-ADL), Quantitative MG score (QMG), Minimal Symptom Expression (MSE) and MG Composite scale (MGC).

Results: Claseprubart was well tolerated with no serious adverse events, no serious bacterial infections, and no autoimmune activation. Injection site reactions were infrequent and mild to moderate. At Week 13, claseprubart improved MG-ADL by 4.6 ($p=0.0113$) for 300 mg, 5.4 ($p=0.0006$) for 600 mg, and 2.8 for placebo (no significant difference between active treatment arms). Significant improvement in MG-ADL was observed as early as Week 1. At Week 13, claseprubart 300 mg improved QMG by 4.4 ($p=0.0144$), claseprubart 600 mg by 4.5 ($p=0.0111$), and 2.0 for placebo. MSE was achieved by 37% (300 mg) and 27% (600 mg) versus 14% for placebo. MGC for 300 mg was 8.7 ($p=0.0008$), 8.6 ($p=0.0008$) for 600 mg versus 3.1 for placebo.

Conclusion: With a favorable safety profile, claseprubart demonstrated rapid, statistically significant, and clinically meaningful improvements in MG-ADL, QMG, MGC.

Background and aims: Patients with myasthenia gravis (MG) still require consolidation therapy after acute exacerbation to control symptoms and prevent relapse. This interim analysis aims to explore whether efgartigimod in addition to standard of care (SOC) provides added benefit as consolidation therapy.

Methods: Adult patients with Acetylcholine Receptor (AChR) antibody-positive generalized MG who achieved clinically meaningful improvement after one treatment cycle of efgartigimod for acute exacerbation were enrolled in the study (NCT07079020). Patients were allocated to either efgartigimod plus SOC (EFG) group or SOC alone (SOCA) group based on real-world clinical

FIGURE 1 Proportion of patients achieving MSE at the interim analysis.

FIGURE 2 Proportion of patients with MG worsening compared with the previous visit.

FIGURE 3 Proportion of patients with MG worsening compared with the baseline.

decision-making, with a 6-month follow-up period. The primary endpoint was achievement of minimal symptom expression (MSE) within the second month of the consolidation phase and sustained MSE for more than four consecutive months.

Results: A total of 112 patients with ≥ 2 months of follow-up by October 2025 were included (48 in SOCA group, 64 in EFG group). MSE was achieved in 64.58% of patients in the SOCA group and in 75% of patients in the EFG group ($p=0.010$)

(Figure 1). MG worsening was less frequently observed in the EFG group compared with the SOCA group, either relative to the previous visit (37.50% vs 50.00%, $p=0.013$) or to the baseline (18.75% vs 35.42%, $p=0.016$) (Figures 2 and 3).

Conclusion: In this interim analysis, efgartigimod was associated with higher rates of achieving MSE, and reduced risk of MG worsening in consolidation therapy. These findings support the role of efgartigimod as a therapeutic strategy in post-exacerbation MG management.

EPO-0479 | Intrathecal AAV-based gene therapy for metachromatic leukodystrophy: Preclinical efficacy and safety in a large animal model

A. Ayupova; A. Ibrahim; A. Fattakhova; A. Sharshakova; V. Solovyeva; Y. Mukhamedshina; A. Yakubova; A. Rizvanov
Institute of Fundamental Medicine and Biology, Kazan Federal University, Kazan, Russian Federation

Background and aims: Metachromatic leukodystrophy (MLD) is an autosomal recessive neurodegenerative lysosomal storage disorder caused by deficiency of arylsulfatase A (ARSA), leading to progressive motor dysfunction, spastic tetraparesis, ataxia, seizures, optic atrophy, and cognitive decline. The aim of this study was to develop and evaluate a gene therapy product based on recombinant adeno-associated virus serotype Olig001 (AAVOlig001) carrying a codon-optimized human ARSA gene. **Methods:** AAVOlig001-ARSA containing a unique codon-optimized ARSA sequence was generated. Following intravenous administration of mannitol (1 g/kg), pigs received an intrathecal injection of AAVOlig001-ARSA at a dose of 2×10^{13} gc/kg. ARSA enzymatic activity was dynamically assessed in cerebrospinal fluid (CSF) and plasma using pNCS. One month after administration, central nervous system (CNS) tissues were collected for analysis of ARSA activity, gene expression (qPCR), and protein expression by immunohistochemistry (IHC). Safety was evaluated using biochemical and hematological blood analyses.

Results: No significant differences in plasma ARSA activity were observed between experimental and control animals, while ARSA activity in CSF was detectable on day 28. In contrast, CNS tissue homogenates showed a marked increase in ARSA activity, most prominently in the cerebellum, cervical, thoracic, and lumbar spinal cord, and brainstem. Overexpression of the codon-optimized ARSA gene and ARSA protein expression in the CNS were confirmed by qPCR and IHC. Blood biochemical parameters remained within physiological ranges; however, hematological changes observed on day 28 suggested systemic exposure to the vector and a potential immune response (Figure 1).

Conclusion: In summary, intrathecal administration of AAVOlig001-ARSA enabled efficient CNS delivery and induced ARSA overexpression.

Disclosure: This work was supported by the Kazan Federal University Strategic Academic Leadership Program (PRIORITY-2030).

FIGURE 1 ARSA enzymatic activity analysis in homogenates of various CNS regions on day 28 after AAV-Olig001-ARSA administration. Data represent the mean of five biological replicates $\pm$ SD. * — $p < 0.001$.

EPO-0480 | Giant axonal neuropathy: A homogeneous phenotype, a diverse genetic landscape, and the emergence of gene therapy

P. Tejada¹; G. Fernández¹; L. Jiménez¹; S. Campusano¹; Y. Rodríguez¹; C. Pérez Lizardo¹; K. Yorro¹; A. Tejada¹; A. Reyes¹; M. Rodríguez²
¹Synaptic Research League, Santo Domingo, Dominican Republic; ²Neurology Department, Hospital Universitario Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic

Background and aims: Giant Axonal Neuropathy (GAN) is a genetic autosomal disorder caused by mutations in the GAN gene, patients usually develop a progressive degeneration of the central and peripheral nervous systems [1]. This study aims to investigate the correlation between specific genetic variants and clinical profiles to better define the disease spectrum.
Methods: We conducted a systematic literature review following PRISMA protocols, emphasizing abnormal presentations. PubMed and Google Scholar databases were searched using keywords "Giant Axonal Neuropathy". We evaluated age, genotype, CNS signs, cranial nerve involvement and physical signs.
Results: We included 29 studies, reporting 128 patients with Giant Axonal Neuropathy (GAN) revealed a uniform and severe

FIGURE 2 Distribution of Pathogenic Giant Axonal Neuropathy Gene Variants by Type.

clinical presentation. The mean age of onset was 2.8 years, with diagnosis at 9.3 years. Motor (100%) and sensory (99%) neuropathy were nearly universal, accompanied by cerebellar ataxia (93%) and curly hair (93%). Scoliosis was present in (52%) of patients. Autonomic dysfunction was less common (<10%). More than 20 pathogenic variants were identified in the GAN gene, see Figure 1 Intrathecal gene therapy (NCT02362438) in 14 patients showed stabilization of motor function (MFM-32) and neurophysiological improvements, offering the first disease-modifying intervention.
Conclusion: Despite the various genetic variants, GAN presents a remarkably uniform clinical profile, dominated by early-onset neuropathy, ataxia, and characteristic capillary changes. This phenotypic consistency, along with new gene therapy data, provides a clear framework for diagnosis and highlights a promising intervention for disease modification.

EPO-0481 | Multiple systemic lipomatosis associated with the 8344A>G tRNA^{Lys} mtDNA variant in a large Italian family: Searching for a threshold effect

V. Gioiosa¹; E. Cioffi¹; A. Tessa²; F. Santorelli²; C. Casali¹
¹Department of Medico-Surgical Sciences and Biotechnologies, University of Rome Sapienza, 04100 Latina, Italy; ²IRCCS Stella Maris Foundation, Calambrone, via dei Giacinti 2, 56128 Pisa, Italy

Background and aims: Myoclonic epilepsy with ragged red fibers (MERRF) is a rare mitochondrial DNA (mtDNA) disorder commonly caused by the 8344A>G mutation in the MT-TK gene encoding tRNA^{Lys}. Clinical expression is highly variable due to tissue-specific heteroplasmy and threshold effects. In addition to the classic neurological and systemic features, multiple systemic lipomatosis (MSL) has been described. The aim of this study was to investigate a large Italian family carrying the 8344A>G variant and to explore a possible threshold effect for the development of MSL.
Methods: The proband was a 28-year-old woman presenting with myoclonic epilepsy, cerebellar ataxia, peripheral neuropathy, and a large cervical lipoma. Following molecular confirmation of the 8344A>G variant, 14 maternally related family members were evaluated. Clinical assessment focused on

FIGURE 1 Prisma-P flowchart of the process of inclusion of studies in the systematic review.

neurological features and the presence of MSL. Molecular analysis was performed on peripheral blood leukocytes (PBLs) and urinary epithelial cells to determine heteroplasmy levels.

Results: Ten out of 14 family members presented isolated MSL with variable extension. All affected individuals carried the 8344A>G variant. Mean mutation load was higher in affected subjects. In the proband, heteroplasmy exceeded 84% in both tissues. Individuals without MSL showed lower mutation loads. Overall, variant levels were higher in urinary epithelial cells than in PBLs.

Conclusion: This study describes a large family in which MSL was often an isolated manifestation. Differences in heteroplasmy between tissues and between affected and unaffected individuals suggest an apparent threshold effect for the development of MSL. These findings support considering MERRF in families with maternally inherited MSL and warrant further investigation.

Disclosure: Nothing to disclose.

EPO-0482 | Breaking the age barrier: Adult-onset GM2A gangliosidosis with reclassification of two likely pathogenic variants

C. Guerreiro¹; F. Godinho²

¹Neurology department, Unidade Local de Saúde São José, Lisbon, Portugal; ²Centro Neurológico Sénior, Torres Vedras, Portugal

Background and aims: GM2 gangliosidosis are rare autosomal recessive lysosomal storage disorders, with a classically fatal infantile onset. GM2 activator protein deficiency (GM2, AB variant), caused by variants in GM2A, is the rarest subtype, with adult-onset cases being exceptionally rare. To date, only one adult-onset case has been reported. We describe two adult siblings with late-onset disease and provide genetic and functional evidence supporting reclassification of two GM2A variants as likely pathogenic.

Methods: Two affected siblings underwent clinical, neurophysiological, imaging, enzymatic, genetic, and functional evaluation, including plasma ganglioside quantification.

Results: A 57-year-old man developed progressive lower limb weakness from age 30. His 53-year-old brother had presented with symmetric areflexic paraparesis, thigh muscle atrophy, gait impairment and Gowers' sign, from age 20. distal sensory involvement was present in one sibling. Electromyography revealed a chronic, long-standing motor neuronopathy associated with a milder sensory neuronopathy. Muscle MRI was significant for quadriceps atrophy, and muscle biopsy showed angular fiber atrophy. β -hexosaminidase activity was normal. Genetic testing identified compound heterozygosity for GM2A variants c.428G>A and c.496G>A, both initially classified as variants of uncertain significance. Plasma ganglioside analysis showed increased GM2 levels compared to controls in both siblings, with a profile comparable to patients with confirmed GM2A pathogenic variants and Tay–Sachs disease, supporting reclassification of both variants as likely pathogenic.

Conclusion: These cases represent an exceptionally rare adult-onset GM2 AB variant, expanding the phenotypic and molecular spectrum of GM2A-related disease and highlighting the diagnostic value of functional studies for variant reclassification in late-onset neuromuscular phenotypes.

Disclosure: Nothing to report.

EPO-0483 | Genotype–phenotype patterns in genetic Parkinson's disease in a tertiary center from Türkiye

F. Bayır; D. Tezen; H. Apaydın; A. Gündüz
Department of Neurology, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Türkiye

Background and aims: Genetic forms of Parkinson's disease (PD) are clinically heterogeneous and increasingly recognized, particularly in regions with elevated consanguinity such as Türkiye. Despite growing international data, national evidence remains limited. This study evaluates the clinical and genetic characteristics of patients with confirmed pathogenic variants to explore genotype–phenotype relationships.

Methods: In this retrospective cohort, medical records of 1812 patients diagnosed with PD between 2010 and 2024 were reviewed. Thirty-one individuals with confirmed pathogenic or likely pathogenic variants were included and stratified into three groups: PRKN, GBA, and other genetic causes. Demographic, motor, and non-motor features were compared. Logistic regression with correction was used to mitigate small-sample bias, with cognitive involvement as the outcome.

Results: Homozygous or compound heterozygous PRKN variants were the most frequent variations and were associated with earlier onset and a relatively homogeneous, motor-predominant phenotype. Heterozygous GBA variants demonstrated a more heterogeneous profile, with higher frequencies of cognitive impairment and postural instability; exploratory regression indicated increased odds of cognitive impairment (OR $\approx$ 5.7). Rare variants—including ATP13A2, FBXO7, HTRA1, and GCH1—occurred as single cases and were linked to atypical or complex presentations.

Conclusion: This cohort highlights the substantial genotypic and phenotypic diversity of PD in Türkiye. PRKN and GBA predominate, while rare variants contribute to atypical disease profiles.

Disclosure: Nothing to disclose.

EPO-0484 | Genetic contributions in Parkinson's disease and Parkinsonism from the PADUA-CESNE cohort

G. Bonato¹; M. Carecchio²; A. Guerra²; M. Campagnolo²; V. Misentini²; R. Biundo²; M. Ginevrino²; L. Salviati³; A. Antonini¹

¹Neurodegenerative Disease Unit, Department of Neuroscience, University of Padova, Padova, Italy; ²Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, University of Milan, Milan, Italy; ³Neurodegenerative Disease Unit, Department of Neuroscience, University of Padova, Padova, Italy; ³Clinical Genetics Unit, Department of Women and Children's Health, Azienda Ospedale Università Padova, University of Padova, Padova, Italy

Background and aims: In Parkinson's disease (PD), monogenic causes account for 5–10% of cases and are rarer in atypical parkinsonism. In our previous study of 218 selected patients, genetic causes were identified in 20%. The PADUA-CESNE cohort as a biocollection program has now doubled these data, so we aim at further investigating genetic contributions to parkinsonism in our Italian population.

K. Kukumägi¹; E. Õiglane-Šlik²; K. Õunap³

FIGURE 1 Gene panel diagnostic yield in Padua-CESNE cohort.

FIGURE 2 Main genetic findings in positive cases.

Methods: NGS multigene panel analysis, MLPA, 409 patients with PD/parkinsonism (377 PD, 32 atypical parkinsonism or DLB).

Results: Overall, 266 genetic variants in genes associated with movement disorders and/or cognitive decline were identified in 204/409 patients; 40 carried multiple variants. According to ACMG-AMP criteria, 98/266 variants were classified as likely pathogenic. Most variants were missense (212/266), followed by frameshift/nonsense variants (23/266); splice-site and copy number variants were less frequent. A diagnosis of monogenic parkinsonism was established in 67 patients (25% of the cohort), all but four with PD. GBA1 mutations were the most frequent finding (39 patients, 58.2% of positive cases), with N370S accounting for 41% of GBA1-PD cases, followed by LRRK2 pathogenic variants (13 patients, 19.4%, half G2019S) and biallelic PRKN variants (9 patients). Rare genetic etiologies (GRN, OPTN) were also identified. Variants of uncertain significance were found in 137 patients, mainly in recessive PD-related genes or other movement disorder genes.

Conclusion: NGS analysis revealed a substantial proportion of monogenic parkinsonism, confirming the central role of GBA1 and LRRK2 and supporting the clinical utility of genetics in movement disorders.

Disclosure: Data partially submitted for 2026 Italian movement disorders congress as abstract/poster Nothing to disclose

Background and aims: Biallelic pathogenic variants in the C19orf12 gene have been shown to cause neurodegeneration with brain iron accumulation 4 (NBIA4), and the same variants have now been identified in Estonia. This study aimed to characterize the phenotype of Estonian NBIA4 patients.

Methods: This retrospective study included eight patients from Tartu University Hospital, born between 1981 and 2010. All patients had radiological and clinical features consistent with NBIA and a homozygous 11-base-pair C19orf12 deletion c.171_181del (p.Gly58Argfs*10). Clinical data were collected from medical records.

Results: In a cohort of eight patients, six were male and two female. At the time of the study, two patients were alive and six were deceased. All patients presented with their first symptoms in early childhood; the mean ($\pm$ SD) age at symptom onset was 4.6 ± 2.1 years. Initial symptoms included vision loss (50%), spasticity of the lower limbs (50%) and gait impairment (37.5%). Optic nerve atrophy was diagnosed in seven of eight patients at a mean age of 9.1 ± 3.1 years. All patients attended school up to the 9th grade and developed movement disorders and neuropsychiatric abnormalities during the disease course. The mean life expectancy of the six deceased patients was 30 ± 4.7 years (range 23–35 years).

Conclusion: The Estonian NBIA4 patients with homozygous C19orf12 deletion c.171_181del exhibited similar clinical features, including pyramidal signs and optic nerve atrophy from early childhood, with survival extending into early adulthood.

Disclosure: An author reports research funding from Estonian Research Council (grant PRG2040).

FIGURE 1 Clinical milestones of NBIA4 patients..

L. Furnica³; S. Bandrivska¹; W. Sun⁴; Popescu⁶; A. Zirra⁵; M. Ostrožovičová¹

¹Department of Neuromuscular Disorders, UCL Queen Square Institute of Neurology, University College London, London, UK; ³Department of Neurology, Colentina Clinical Hospital, Bucharest, Romania; ⁴Department of Neurodegenerative Diseases, Hertie Institute for Clinical Brain Research, University of Tuebingen and German Center for Neurodegenerative Diseases (DZNE), Tuebingen, Germany; ⁵Centre for Preventive Neurology, Wolfson Institute of Population Health, Queen Mary University of London, UK; ⁶"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background and aims: Nuclear factor kappa B1 (NFκB1), a key transcription factor in inflammatory signalling, has been linked to Parkinson's disease (PD) and neurodegeneration. This study intends to clarify the effect of NFκB1 variants in the pathogenesis of PD through a systematic review, and by investigating variants in this gene in the Global Parkinson's Disease (GP2) genotyping data.

Methods: For the systematic review, out of 51 identified records, 11 studies met the inclusion criteria, encompassing a wide methodological spectrum. We also conducted an analysis on genotyping imputed data from GP2 release 10 (33,813 PD cases and 18,714 controls across 11 different ancestries). The NFκB1 gene region was extracted with PLINK2, variants were annotated using ANNOVAR. Fisher's exact test was applied to examine differences between allele frequencies for common variants. Single-nucleotide polymorphism (SNP) associations were also evaluated using logistic regression, with Bonferroni correction applied within each ancestry. To assess the cumulative effect of low-frequency variants we ran burden analyses using RV tests.

Results: Evidence across all studies indicates that NF-κB1 is consistently upregulated in Parkinson's disease and plays a key role in neuroinflammation and dopaminergic neuronal injury. In the large GP2 genotyping data 167 nominal associations with PD risk were observed across multiple ancestries. None remained significant after Bonferroni correction. Burden analyses showed no statistical significance.

Conclusion: While existing literature supports a pathogenic role for NF-κB1 pathway in PD, our large-scale multi-ancestry genetic analysis finds no significant association between NFκB1 variants and PD risk, highlighting the need for future whole-genome sequencing studies to further clarify this relationship.

Disclosure: Nothing to disclose

M. Marconi¹; S. Diamant²; S. Petrucci³; L. Travaglini⁴; M. Piane³; M. Salvetti²; S. Romano²; G. Ristori²

¹Department of Neurology, Sant'Andrea University Hospital, Rome, Italy; ²Department of Neurosciences, Mental Health and Sensory Organs, Sapienza University of Rome, Rome, Italy; ³Department of Clinical and Molecular Medicine, Sapienza University of Rome, Rome, Italy; ⁴Laboratory of Molecular Genetics, Bambino Gesù Children's Hospital, Rome, Italy

Background and aims: The nuclear gene AARS2 encodes the mitochondrial alanyl-tRNA synthetase. Pathogenic biallelic AARS2 variants cause mitochondrial disease, presenting as early-onset cardiomyopathy or leukoencephalopathy, progressive, with ovarian failure (LKENP). LKENP is an autosomal recessive neurodegenerative disorder characterized by gait impairment, ataxia, spasticity, cognitive decline, and premature ovarian failure, usually beginning in young adulthood. Muscle biopsy may show ragged-red fibers and brain MRI typically reveals progressive white-matter abnormalities. We report a patient with LKENP carrying a previously unreported pathogenic AARS2 variant.

Methods: Clinical and neurological data were collected at Sant'Andrea Hospital (Rome). Brain MRI and genetic testing were performed as part of routine diagnostic evaluation.

Results: The patient is a 34-year-old woman with a history of cardiac arrest at birth, early menopause, clumsiness, and

FIGURE 1 Brain MRI (axial FLAIR) obtained at age 34 showing diffuse white matter hyperintensity involving both cerebral hemispheres, mainly in periventricular regions, corpus callosum, and posterior hippocampal areas.

FIGURE 2 Brain MRI (sagittal T1) obtained at age 34 demonstrating thinning of the corpus callosum, bilateral enlargement of frontal pericortical spaces, and mild widening of pericerebellar cisterns.

corrected bilateral strabismus, and a family history of cerebrovascular disease and autism. Karyotype and FMR1 testing at age 24 were normal. At 28, she had a transient loss of consciousness; brain MRI showed small bilateral frontal subcortical lesions, progressing to diffuse white-matter abnormalities five years later. She subsequently developed cognitive decline, dysmetria, and gait impairment. Next-generation sequencing identified two AARS2 variants: a previously unreported frameshift variant c.2821_2832dupTG, p.(Ala945fs*33), classified as pathogenic by ACMG criteria, and the known pathogenic variant c.595C>T, p.(Arg199Cys). Parental testing confirmed compound heterozygosity.

Conclusion: Genetic findings and clinical presentation confirm LKENP diagnosis. No effective therapies are currently available; the patient is receiving symptomatic management, including oral coenzyme Q10 supplementation, which has shown potential benefit in recent reports.

Disclosure: Nothing to disclose

EPO-0488 | Leukoencephalopathy and cerebral venous thrombosis secondary to autosomal recessive MTHFR deficiency: A case report

N. MacAlevey¹; K. Lau¹; K. Teo Soon Hwee¹; H. Chin²; Y. Chan¹

¹Division of Neurology, Department of Medicine, National University Hospital, Singapore; ²Department of Paediatrics, National University of Singapore, Singapore, Singapore

Background and aims: Methylenetetrahydrofolate reductase (MTHFR) is an enzyme catalysing the conversion of homocysteine to methionine. Genetic variants that result in MTHFR deficiency may cause hyperhomocysteinemia and its associated complications.

Methods: A middle-aged female presented with progressive unsteady gait and cognitive decline occurring over several years. Clinically, the patient had spastic paraparesis with brisk lower limb reflexes and a scissoring gait. She had a significant background of dietary folate and B12 deficiency which was treated with maintenance B12 and folate supplementation. MRI brain showed confluent periventricular T2-weighted hyperintensities suggestive of an underlying leukodystrophy and identified an incidental venous sinus thrombosis in the junction between the left sigmoid sinus and left internal jugular vein. MRI Whole Spine showed no abnormal cord signal or enhancement, and cerebrospinal fluid analysis was unremarkable. A workup for her venous sinus thrombosis identified a high serum homocysteine (>50.0umol/L) with normal B12, folate levels and low-normal serum methionine levels.

Results: Expanded Exome Proband Analysis confirmed homozygosity for a pathogenic variant c.971A>G in the MTHFR gene. She was diagnosed with autosomal recessive MTHFR deficiency and managed with betaine and B12/folate replacement. Betaine contributes an alternative methyl donor for remethylation of homocysteine to methionine, treating her hyperhomocysteinemia. Apixaban was started to treat her venous sinus thrombosis in the presence of a prothrombotic state.

Conclusion: MTHFR deficiency is a rare but treatable genetic metabolic disorder that may predispose patients to leukoencephalopathy, cognitive decline, spastic paraparesis, spinal cord atrophy, or thrombosis due to hyperhomocysteinemia. It should be suspected in patients with severe hyperhomocysteinemia and hypomethioninemia without folate/B12 deficiency.

Disclosure: Nothing to disclose.

EPO-0489 | Late-onset RANBP2-associated acute necrotizing encephalopathy (ANE1) in two siblings from an Italian family

V. Ciampagna¹; L. Paciolla¹; G. Filisetti¹; S. Asaro¹; F. Caushi²; L. Corrado²; C. Comi¹; S. D'Alfonso²; D. Vecchio¹

¹Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, University-Hospital Maggiore della Carita', Novara, Italy; ²Laboratory of Human Genetics, Department of Health Sciences, University of Piemonte Orientale, Novara, Italy

Background and aims: Acute Necrotizing Encephalopathy (ANE) is a rare para-infectious encephalopathy of childhood, characterized by symmetric bilateral thalamic brain magnetic resonance imaging (MRI) lesions. Adolescent or adult onset is exceptional. Familial or recurrent forms are linked to heterozygous pathogenic RANBP2 variants (ANE1). We report two siblings with late-onset ANE1, diagnosed after the second presentation.

Methods: Both underwent neurological evaluation, MRI, cerebrospinal fluid analysis, and infectious, autoimmune, and metabolic testing. Genetic investigations included whole-exome sequencing in the second sibling and targeted Sanger sequencing in the first.

Results: The male developed fulminant post-febrile encephalopathy at age 15, rapidly progressing to coma. MRI showed bilateral thalamic, pontine, and external capsule involvement. He recovered with motor and cognitive sequelae. He remained undiagnosed for over 20years. His sister presented at age 20

with milder post-infectious encephalopathy and visual-sensory symptoms. MRI revealed bilateral thalamic lesions involving the external capsules, optic tracts, and mammillary bodies. She received high-dose corticosteroids followed by intravenous immunoglobulin, achieving recovery. Extensive investigations were non-diagnostic in both. In the second sibling, whole-exome sequencing revealed a heterozygous missense RANBP2 variant (c.1754C>T; p.Thr585Met) confirmed by Sanger sequencing in her brother.

Conclusion: A concordant phenotype with variable severity supports a familial ANE1. These cases confirm RANBP2-associated ANE1 as a cause of late-onset encephalopathy and expand the phenotypic spectrum, highlighting intrafamilial variability. Our family is the third reported in Italy and the first with delayed onset and relatively favorable prognosis. Early recognition and immunomodulatory therapy may improve outcomes. Awareness of late-onset ANE1 and RANBP2 testing in adults is warranted.

Disclosure: Nothing to disclose.

EPO-0490 | Genetic insights into somatic symptoms and related disorders versus psychiatric phenotypes

V. Fominykh; P. Jaholkowski; A. Shadrin; O. Andreassen
Institute of Clinical Medicine, University of Oslo, Oslo, Norway

Background and aims: The genetic mechanisms underlying somatic symptoms and related disorders (SSRD) are poorly known, even though they have a significant impact on health-care. We aimed to identify additional significant loci using statistical genetics methods and first large-scale SSRD GWAS meta-analysis including functional neurological (FND) and somatoform disorders (SomD), and to examine genetic overlap with psychiatric disorders.

Methods: We performed the cross-sectional analysis of SSRD GWAS [Fominykh et al, 2025, 22,203 and 1,831,107 controls] and three psychiatric disorders: anxiety [ANX, N 175,163], major depression [MDD, N 250215] and post-traumatic symptoms disorder [PTSD, N 146,660] from Million Veterans Projects. Genetic correlations were assessed using LDSC. The conditional/conjunctional false discovery rate framework (cond/conjFDR) was used to identify new and shared loci for SSRD. FUMA and Open Targets were used for functional annotations.

Results: LDSC analysis shows significant genetic correlation between SSRD and MDD ($rg=0.8$), ANX ($rg=0.75$) and PTSD ($rg=0.7$) in range with previous publication. We revealed 9 new loci for SSRD using condFDR. ConjFDR analysis identified 2 loci jointly associated with SSRD and MDD, 2 loci – with SSRD and PTSD. The lead SNP common for all three phenotypes was mapped to EXD3 gene. The remaining lead SNPs mapped to BPTF and GPM6A, which is linked to psychiatric and neurological conditions.

Conclusion: This study explores the genetic aspects of the SSRD. We reveal new SNPs associated with SSRD, as well as common SNPs involved in SSRD development and most comorbid psychiatric disorders.

Ageing and dementia 4

EPO-0491 | Abstract withdrawn

EPO-0492 | Investigating synaptic and neuroinflammation biomarkers in the Alzheimer's disease continuum

F. Roveta¹; L. Bonino¹; S. Boschi¹; A. Chiarandoni¹; G. Brodini¹; E. Piella¹; A. Cermelli¹; M. Zotta²; G. Rovera²; S. Morbelli²; E. Rubino¹; I. Rainero¹

¹Department of Neuroscience “Rita Levi-Montalcini”, University of Turin, Turin, Italy; ²Nuclear Medicine Unit, University Hospital “Città della Salute e della Scienza di Torino”, Turin, Italy

Background and aims: Synaptic dysfunction and neuroinflammation are key mechanisms in Alzheimer's disease (AD), potentially preceding neurodegeneration. Synaptosome-associated protein 25 (SNAP-25) reflects synaptic damage, whereas glial fibrillary acidic protein (GFAP) and soluble TREM2 (sTREM2) index glial activation. Human data on their interplay across the AD continuum remain limited.

Methods: We prospectively enrolled 69 patients with AD (age 70.9 ± 7.0 ; 59% female). Based on Clinical Dementia Rating (CDR), participants were classified as mild cognitive impairment (MCI; CDR=0.5; $n=34$) or dementia (CDR ≥ 1 ; $n=35$). All underwent standardized neuropsychological assessment including MMSE. Cerebrospinal fluid (CSF) levels of GFAP, sTREM2, SNAP-25, and neurofilament light chain (NfL) were measured using Simoa. Associations with AD biomarkers were assessed using Spearman correlations. Longitudinal cognition over two years was analyzed with linear mixed-effects models. Voxel-wise analyses explored relationships with FDG-PET metabolism.

Results: CSF NfL and GFAP were higher in dementia than MCI ($p=0.029$ and $p=0.030$), while sTREM2 and SNAP-25 did not differ. GFAP correlated with p-Tau181 ($\rho=0.41$, $p=0.001$). sTREM2 correlated positively with p-Tau181 ($\rho=0.32$, $p=0.012$) and negatively with the A β 42/40 ratio ($\rho=-0.38$, $p=0.003$). SNAP-25 correlated with t-Tau ($\rho=0.30$, $p=0.019$). Baseline biomarkers were not associated with cognition. Higher NfL predicted faster MMSE decline ($\beta=-0.16$, $p<0.001$). Higher GFAP was associated with reduced FDG uptake in the right medial and orbitofrontal prefrontal cortex ($p<0.001$).

Conclusion: GFAP differentiated clinical stages and was linked to frontal hypometabolism, highlighting the contribution of astrocytic activation to AD-related neurodegeneration. These findings support the relevance of neuroinflammatory biomarkers for staging and monitoring disease progression across the AD continuum.

Background and aims: To refine the diagnostic performance of plasma pTau217 for Alzheimer's disease (AD) in a real-world setting, we evaluated double-cutoff strategies and the added discriminative value of GFAP within the pTau217 "gray zone".

Methods: We analyzed 441 consecutive patients from the San Raffaele Memory Center, including 181 with cerebrospinal fluid (CSF) A/T classification. Plasma pTau217, pTau181, GFAP, NFL, and A β 42/40 were measured using automated immunoassays (Lumipulse G600II). The CSF-defined subgroup was used to derive optimal pTau217 double cutoffs across all sensitivity-specificity pairs ≥ 0.90 , quantifying the proportion of indeterminate ("gray") cases. GFAP discriminative ability (AUC) was assessed within each gray zone. Associations between GFAP, age, APOE- ϵ 4, sex, and cognition were explored using generalized additive and linear models.

Results: No pTau217 cutoff combination achieved $\geq 95\%$ sensitivity/specificity while limiting gray cases to $\leq 20\%$. The optimal balanced pair (90% sensitivity, 91% specificity) resulted in 28% indeterminate subjects. Within this gray zone, GFAP discriminated A+ from A- individuals (AUC=0.83), reducing indeterminate cases by 37% when used as a triage marker. GFAP increased with age, particularly in A+ individuals, and remained independently associated with A-positivity after adjustment for APOE and sex ($p < 0.001$). Adding GFAP to pTau217 modestly improved explained MMSE variance ($\Delta R^2 = 0.04$).

Conclusion: Systematic sensitivity-specificity mapping shows that plasma GFAP provides robust complementary value in resolving intermediate pTau217 results. Integrating GFAP into multimarker workflows may enhance diagnostic certainty and support the clinical implementation of blood-based biomarkers for AD.

EPO-0494 | Integrating retinal OCT and blood biomarkers to characterize cognitive decline across the Alzheimer's disease spectrum

G. Rugarli¹; G. Cecchetti²; R. Santangelo³; F. Coraglia¹; E. Spinelli¹; A. Ghirelli¹; S. Pisano⁴; E. Canu⁴; F. Caso⁵; G. Magnani⁵; F. Agosta¹; M. Filippi⁶

¹Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ²Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Neurology Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁴Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁶Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and aims: To investigate the relationship between retinal structural alterations, assessed by optical coherence tomography (OCT), and plasma biomarkers of neurodegeneration across the Alzheimer's disease (AD) continuum, from cognitively unimpaired individuals to patients with dementia.

Methods: A total of 205 participants were recruited at the Neurology Unit, IRCCS San Raffaele Scientific Institute, including subjects with subjective cognitive decline (SCD), mild cognitive impairment (MCI), dementia (DEM), and healthy controls (HC). Plasma levels of A β 42, A β 40, pTau-181, pTau-217, and neurofilament light chain (NfL) were quantified using automated CLEIA technology. OCT was used to measure peripapillary

retinal nerve fiber layer (RNFL), ganglion cell layer (GCL), and inner plexiform layer (IPL) thickness. Correlations between retinal parameters, plasma biomarkers, cognitive performance (MMSE), and carotid ultrasound findings were analyzed, with a one-year longitudinal follow-up in a subsample.

Results: Inner retinal layer thinning—particularly in the GCL and IPL—showed significant associations with plasma NfL and pTau-217 levels, suggesting that retinal structural loss parallels systemic markers of neuroaxonal damage. These correlations were strongest in early disease stages (SCD and SCD_AD) and diminished with advanced cognitive decline. Longitudinal data demonstrated a significant reduction in GCL thickness over one year, reinforcing its sensitivity as an early indicator of neurodegeneration.

Conclusion: Retinal OCT may serve as a non-invasive biomarker for early detection and monitoring of AD-related neurodegeneration. Combining retinal imaging with plasma biomarkers could improve diagnostic accuracy, disease staging, and patient stratification in clinical trials, ultimately advancing personalized therapeutic approaches in Alzheimer's disease.

EPO-0495 | Early-onset dementia: Etiological and clinical insights from a 10-year cohort

G. Yılmaz Çakan¹; B. Samancı¹; M. Alaylıoğlu²; E. Şahin¹; H. Gürvit¹; E. Dursun²; H. Hanağası¹; D. Gezen Ak²; B. Bilgiç¹
¹*Istanbul University, Istanbul Faculty of Medicine, Behavioral Neurology and Movement Disorders Unit, Istanbul, Türkiye;*
²*Brain and Neurodegenerative Disorders Research Laboratories, Department of Neuroscience, Institute of Neurological Sciences, Istanbul University-Cerrahpasa, Istanbul, Türkiye*

Background and aims: Early-onset dementia (EOD) represents 5–9% of all dementia cases and differs clinically from late-onset dementia (LOD), often delaying recognition and complicating management. Despite its clinical relevance, large cohort data remain limited, particularly in Türkiye. This study presents a decade-long EOD cohort from a tertiary referral center.

Methods: A total of 1,656 patients were evaluated between 2015–2025. After excluding LODs and secondary dementias, 656 patients with complete CSF assessments were included. Clinical and demographic features were analyzed.

Results: The cohort included 52.1% female. Mean age at onset was similar across groups except for atypical Alzheimer's disease (AD) versus mixed dementia ($p=0.017$). The most common diagnoses were typical AD (24.5%), atypical AD (18.1%), and frontotemporal dementia (FTD) (15.6%). Posterior cortical atrophy (PCA) was the leading atypical AD subtype (30.3%), while behavioral-variant FTD (bvFTD) predominated within FTD (47.1%). When staged at the time of biomarker assessment, dementia was more frequent in typical AD than atypical AD, and in atypical AD than FTD ($p=0.001$), whereas no difference between FTD and typical AD ($p=0.759$).

Conclusion: This cohort resembles previous EOD populations but differs in etiological distribution and clinical stage at diagnosis. Findings underscore the importance of early symptom recognition and timely diagnostic evaluation, given that EOD follows a distinct clinical course compared to LOD. As a decade-long cohort from a high-volume tertiary center, this study may reflect the broader population, addressing gaps in epidemiological and etiological data on EOD globally and within Türkiye.

Disclosure: Nothing to disclose.

EPO-0496 | GFPaint: A novel technique for visualizing alpha-synuclein strains across synucleinopathies

N. Graves; E. Sierecki
Department of Molecular Medicine, School of Biomedical Sciences, University of New South Wales, Sydney, Australia

Background and aims: Misfolded alpha-synuclein aggregates are a defining feature of Parkinson's disease, dementia with Lewy bodies, and multiple system atrophy. However, distinguishing disease-relevant alpha-synuclein strains remains a major challenge. The objective of this study was to develop a single-molecule approach to discriminate alpha-synuclein strain polymorphs derived from different synucleinopathies and defined synthetic conditions based on selective protein interactions.

Methods: We developed GFPaint, a single-molecule fluorescence assay combining cell-free expression of green fluorescent

FIGURE 1 Conceptual schematic of alpha-synuclein fibrillation and strain diversity. Chaperone-mediated proteostasis maintains soluble alpha-synuclein, whereas pathogenic conditions promote formation of distinct fibril strains with differential chaperone engagement.

FIGURE 2 Overview of the GFPaint workflow. Green fluorescent protein tagged heat shock proteins are expressed in a cell-free system and incubated with defined alpha-synuclein fibril strains. Dual-channel single-molecule data produced.

protein tagged heat shock proteins with dual-channel coincidence spectroscopy. A panel of chaperones spanning HSP40, HSP70, HSP90, and small heat shock protein families was incubated with alpha-synuclein fibrils generated under traditional, metal ion, and saccharide conditions, as well as with brain-derived samples from Parkinson's disease, dementia with

FIGURE 3 Strain-dependent protein interaction profiles across alpha-synuclein fibril classes. Heat maps, quadrant analyses, and radar plots reveal distinct peak and integral binding specificity patterns for standard, metal ion, and saccharide induced aSyn strains.

Lewy bodies, and multiple system atrophy. Binding interactions were quantified using coincidence, binding affinity, and binding specificity metrics, including peak- and integral-based analyses. **Results:** GFPaint revealed pronounced strain-dependent differences in chaperone engagement. HSP40 family members, particularly DNAJB1 and DNAJB6, showed strong and selective binding to specific alpha-synuclein polymorphs, whereas HSP70 and HSP90 family members displayed weak or nonspecific interactions. Distinct binding fingerprints differentiated Parkinson's disease, dementia with Lewy bodies, and multiple system atrophy brain samples and aligned with defined synthetic strain profiles.

Conclusion: GFPaint enables single-molecule strainotyping of alpha-synuclein based on selective protein interactions, providing a scalable platform to distinguish disease-specific alpha-synuclein conformations across synucleinopathies.

Disclosure: Nothing to disclose.

EPO-0497 | Relationship between cortical neurotransmitter target impairment and core features of behavioural variant frontotemporal dementia

N. Epis; M. Losa; E. Sentieri; S. Garbarino; F. Massa; L. Lorenzini; S. Raffa; L. Sofia; S. Morbelli; L. Roccatagliata; D. Arnaldi; B. Orso; M. Pardini
Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child 3 IRCCS Ospedale Policlinico San Martino, Genoa, Italy

Background and aims: Behavioural variant frontotemporal dementia (bvFTD) is characterized by distinct patterns of neurodegeneration and neurotransmitter deficits, but the relationship between specific neurotransmitter vulnerability and core symptoms of bvFTD is poorly explored. We aimed to investigate the spatial colocalization between hypometabolism and normative distribution of neurotransmitter receptors, assessing their association with the main neuropsychiatric and cognitive symptoms of bvFTD.

Methods: We analysed [18F]FDG-PET scans from bvFTD patients compared to healthy controls to derive relative hypometabolism maps. Using the JuSpace toolbox, we computed spatial correlations between hypometabolism and normative density maps of the neurotransmitter systems target known to be impaired in bvFTD, such as serotonergic (5HT), dopaminergic (D), GABAergic (GABA), and glutamatergic (mGluR) receptors.

Multivariate logistic or linear regression models were applied to evaluate the association between the receptor-specific spatial colocalization coefficients, bvFTD-related subitems of the Neuropsychiatric Inventory (NPI), and executive performance.

Results: In bvFTD patients ($n = 86$; age 73 ± 7 years), the hypometabolism distribution significantly colocalized with the distribution of 5HT1a ($r = -0.24$), 5HT2a ($r = -0.15$), 5HT4 ($r = -0.21$), D1 ($r = -0.29$), D2 ($r = -0.21$), and mGluR5 ($r = -0.21$) receptors (all $p < 0.001$). In multivariate models, apathy presence was associated with 5HT2a vulnerability (OR = 0.029; $p = 0.040$), while disinhibition with D1 (OR = 0.058; $p = 0.038$) and D2 (OR = 0.098; $p = 0.049$) vulnerability. mGluR5 impairment was associated with Trail Making Test A (TMT-A; $B = -0.060$; $p = 0.033$), TMT-B ($B = -0.075$; $p = 0.023$), Corsi test (OR:3.56; $p = 0.03$) and phonemic fluency ($B = 0.76$; $p = 0.042$), while D1 was associated with TMT-B ($B = -0.06$; $p = 0.040$).

Conclusion: Our findings highlighted a distinct receptor vulnerability in bvTFD patients, which correlated with disease-specific symptoms, suggesting possible pharmacological targets. Further studies should evaluate the implications at the individual-patient level, potentially guiding therapeutic strategies.

Disclosure: The authors declare no conflicts of interest.

EPO-0498 | 3D convolutional neural network predicts MCI-to-AD conversion: Systematic review and meta-analysis

R. Mohamed¹; Z. Hasan²; A. Kertam³; N. A. Mohammed⁴; E. M. Soliman⁵; A. Wael Moftah⁶; A. Essam El-dain Said⁷; S. Ali⁸; A. Ahmed Radi⁹; B. Ayoub¹⁰

¹Faculty of Medicine, Alexandria University, Egypt; ²Jordan University of Science and Technology, Irbid, Jordan; ³Tu Lab for Diagnostic Research, Yale School of Medicine, New Haven, USA; Faculty of Medicine, Ain-Shams University, Cairo, Egypt; ⁴Biochemistry Division, Cairo University, Cairo, Egypt; ⁵Faculty of Medicine Zagazig University, Zagazig, Egypt; ⁶Faculty of Medicine, King Salman International university, South Sinai, Egypt; ⁷Faculty of Science Cairo University, Cairo, Egypt; ⁸Biochemistry Department Hazara University Mansehra Kpk, Pakistan; ⁹Faculty of Medicine, Minia University, Minia, Egypt; ¹⁰Faculty of Medicine, Cairo University, Egypt

Background and aims: Early identification of patients with Mild Cognitive Impairment (MCI) who are likely to progress to Alzheimer disease (AD) remains a major clinical challenge. In recent years, three-dimensional (3D) deep learning approaches have been increasingly applied to neuroimaging data to improve risk stratification. This meta-analysis examines the performance of 3D deep learning models in predicting MCI-to-AD conversion and compares their results with two-dimensional (2D) models, traditional machine learning techniques, and physician-based assessment.

Methods: A total of 1,987 patients diagnosed with MCI were included. The intervention consisted of 3D deep learning architectures, primarily 3D Convolutional Neural Networks, applied to volumetric neuroimaging modalities, including resting-state functional Magnetic Resonance Imaging and Positron Emission Tomography. Comparator methods included 2D Convolutional Neural Networks, conventional machine learning models, and

FIGURE 1 Graphical abstract

physician consensus diagnoses. The primary outcomes were the pooled values of classification accuracy and Relative Risk for the conversion to Alzheimer's disease.

Results: Across the five studies, the overall accuracy of the 3D CNN models stood at 92.6% with a relative risk of 1.85 for the conversion to AD, clearly outperforming the consensus of doctors (69.5% accuracy). The AUC values for the discrimination of the FDG-PET 3D CNN were excellent, with values between 0.93 and 0.99. The attention models SwinNet-CATNet had an accuracy of 98.2% for the staging of AD, and the hippocampus-centered PCANet-BLS models surpassed the 95% threshold.

Conclusion: 3D deep learning has a substantial advantage over 2D models, as well as clinical assessment, in predicting MCI-to-AD transition ($p < 0.01$). Models including PET + hippocampal data have high discrimination.

Disclosure: Nothing to disclose.

EPO-0499 | Impact of the 2024 NIA-AA revised criteria on biological AD classification in a clinical Memory cohort from Central Italy

S. Corsi; M. Del Chicca; E. Bergamin; L. Petrozzi; R. Ceravolo; G. Tognoni

Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Italy

Background and aims: Updates in Alzheimer's disease (AD) diagnostic criteria have significantly influenced clinical practice over the past decade. The AT (N) research framework introduced by NIA-AA in 2018 stratifies individuals based on biomarkers of amyloid deposition (A), tau pathology (T), and neurodegeneration (N). The 2024 revision introduced two new core biomarkers—p-tau/A β 42 and t-tau/A β 42 ratios—and defined a hierarchy of Core 1 and Core 2 markers, establishing that the presence of just one Core 1 biomarker is sufficient to define biological AD.

Methods: To assess the impact of the updated NIA-AA 2024 criteria, we retrospectively re-evaluated cerebrospinal fluid (CSF) profiles of 81 patients (mean age 68 years; 46 male; mean education 10 years) at our cognitive neurology clinic, including patients with mild cognitive impairment and established dementia.

Results: Of the 81 patients, 27 (33%) didn't meet the 2018 criteria for biological AD. Among these, 10 patients (37%) were reclassified as having biological AD according to the 2024 criteria. All reclassified patients showed pathological values in p-tau/A β 42,

t-tau/A β 42, and A β 42 or A β 42/40 ratios, except for one case, who showed an isolated elevation of the t-tau/A β 42 ratio. This patient was later diagnosed with prion disease, highlighting the need for careful interpretation of neurodegeneration markers in non-AD conditions. P-tau alone was the least informative marker in triggering diagnostic reclassification. In contrast, p-tau/A β 42, A β 42, and A β 42/40 ratio performed consistently and equivalently in identifying amyloid pathology.

Conclusion: The 2024 NIA-AA criteria substantially increase the number of individuals meeting the definition of biological AD.

Disclosure: Nothing to disclose.

EPO-0500 | Fluid Neurofilament Light captures antero/posterior cortex metabolic gradient in behavioral variant of frontotemporal dementia

S. Anderl-Straub¹; F. Massa^{2,3}; A. Cirone⁴; S. Garbarino^{4,5}; S. Malagò⁵; M. Pardini^{2,3}; L. Werner¹; P. Steinacker⁶; I. Uttner¹; J. Weishaupt¹; J. Strobel⁷; A. Beer⁷; M. Otto⁶

¹University of Ulm, Department of Neurology, Ulm, Deutschland; ²University of Genoa, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOEMI), Genoa, Italy; ³IRCCS Ospedale Policlinico San Martino, Genoa, Italy; ⁴IRCCS Ospedale Policlinico San Martino, Life Science Computational Laboratory, Genoa, Italy; ⁵University of Genoa, Department of Mathematics, Genoa, Italy; ⁶Martin-Luther-University Halle-Wittenberg, Department of Neurology, Halle (Saale), Deutschland; ⁷University of Ulm, Department of Nuclear Medicine, Ulm, Deutschland

Background and aims: Neurofilament light (NfL) is a biofluid marker of axonal injury in frontotemporal lobar degeneration (FTLD), but its regional metabolic correlates on [¹⁸F]FDG PET remain poorly defined. We aimed to characterize cortical [¹⁸F]FDG correlates of NfL in a well-defined bvFTD cohort and to explore associated cognitive effects.

Methods: We studied 48 bvFTD patients who underwent resting-state [¹⁸F]FDG-PET and serum and/or CSF NfL sampling. CSF NfL values were converted to serum-equivalent concentrations using a fixed factor (serum = 0.43 × CSF) and log-transformed. [¹⁸F]FDG uptake was parcellated with the Desikan-Killiany atlas (68 cortical ROIs), normalized to the pons, and related to log-transformed NfL using age-adjusted linear models. ROIs showing significant or trend-level NfL effects were grouped into anterior and posterior composites. From these we derived an A/P gradient and a posterior-residual index (posterior variance unexplained by anterior uptake and age, indexing relative posterior sparing), which were related to logNfL. Associations with neuropsychological scores were tested in separate age-adjusted models.

Results: Higher NfL was significantly associated with lower [¹⁸F]FDG uptake in frontal regions and higher uptake in posterior cortices. Anterior-posterior correlations were weak, and frontal uptake did not predict posterior uptake. The posterior-residual index correlated positively with logNfL ($r=0.43$, $p=0.003$), indicating that increasing NfL values are linked to a steeper A/P metabolic gradient—greater frontal hypometabolism with relative posterior sparing. At the uncorrected level,

the A/P gradient showed small, directionally consistent associations with executive dysfunction.

Conclusion: Integrating NfL with [¹⁸F]FDG PET may help quantify biologically meaningful fronto-posterior imbalance in FTLD and support patient stratification.

Disclosure: This work was supported by the Josef and Luise Kraft Foundation. The funding was provided to author Sarah Anderl-Straub. The Co-authors have nothing to disclose.

EPO-0501 | Plasma microglia related biomarker predicting faster cognitive decline

S. Kang¹; M. Noh¹; Y. Moon³; D. Chang²; S. Kim¹

¹Department of Neurology, Hanyang University College of Medicine, Seoul, Republic of Korea; ²Department of Neurology, Gil Medical Center, Gachon College of Medicine; ³Department of Radiology, Konkuk University Medical Center, Seoul, Republic of Korea

Background and aims: Stratifying subgroups with rapid cognitive decline is a critical challenge in the management and research of Alzheimer's disease (AD) and frontotemporal lobar degeneration (FTLD). Previously identified as a marker of microglial dysfunction in amyotrophic lateral sclerosis, we investigated whether plasma microRNA-214-3p could serve as a predictor for rapid progression across the AD-FTLD spectrum.

Methods: We analyzed a multicenter prospective cohort of 169 participants, including AD, FTLD, and control groups. We evaluated plasma microRNA-214-3p, cerebrospinal fluid (CSF) amyloid and inflammatory markers, APOE4 status, and longitudinal Mini-Mental State Examination (MMSE) scores. Fast progression was defined as an annual MMSE decline of >3 points. Additionally, we assessed phagocytic function and pathology in induced microglial-like cells from participants.

Results: Plasma microRNA-214-3p was the strongest predictor of cognitive decline among all biomarkers. Baseline levels demonstrated excellent accuracy in identifying fast progressors (AUC=0.92), significantly outperforming CSF neurofilament light chain (AUC=0.73). High baseline levels correlated with rapid MMSE decline, exhibiting a synergistic interaction with APOE4. Longitudinal increases in microRNA-214-3p independently predicted decline, particularly in individuals with lower amyloid burden. Mechanistically, fast progressors displayed elevated microRNA-214-3p alongside reduced microglial phagocytosis and increased phosphorylated TDP-43 levels.

Conclusion: Plasma microRNA-214-3p is a sensitive blood-based surrogate for microglial phagocytic dysfunction. It effectively identifies individuals at risk of rapid cognitive decline across the AD-FTLD spectrum, offering significant prognostic value, especially for APOE4 carriers or those with non-amyloid pathologies such as TDP-43.

Disclosure: Funding: This research was supported by a grant of the Korea Dementia Research Project through the Korea Dementia Research Center (KDRC), funded by the Ministry of Health & Welfare and Ministry of Science and ICT, Republic of Korea (grant number: RS-2024-00348451). The authors have no interests to disclosure.

C. Pace

Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background and aims: Lewy body dementia (LBD) is associated with rapid cognitive and functional decline, and pharmacological treatment options remain limited. Digital cognitive training (CT) has emerged as a potential non-pharmacological strategy to improve cognitive outcomes in neurodegenerative disorders.

Methods: This systematic review and meta-analysis followed PRISMA guidelines. PubMed, Embase, PsycINFO, Cochrane Library, and ClinicalTrials.gov were searched (January 2010-December 2024) for randomized controlled trials investigating app-based cognitive training in Lewy body dementia. The primary outcome was change in global cognition (MMSE or MoCA). Data were pooled using random-effects models, with standardized mean differences (SMD), 95% confidence intervals (CI), and I^2 for heterogeneity assessment.

Results: From 845 screened records, 8 RCTs ($n=412$) were included. Digital cognitive training significantly improved global cognition compared with control (SMD = 0.45, 95% CI 0.18–0.72; $I^2 = 35\%$). Greater effects were observed in attention and executive function (SMD = 0.58, 95% CI 0.30–0.86). Effects on quality of life were positive but not statistically significant (SMD = 0.22, 95% CI –0.05–0.49). Adherence to app-based training was high (>80%), and no serious adverse events were reported.

Conclusion: Structured digital cognitive training is a safe and effective non-pharmacological intervention for improving cognitive function in Lewy body dementia. These findings support the integration of validated digital applications as adjunct therapy in LBD management.

Disclosure: Nothing to disclose.

Forest plot showing positive effects of app-based digital cognitive training on cognitive outcomes in Lewy body dementia.

EPO-0503 | Making the invisible audible: A real-world connected speech study in myasthenia gravis

A. Zanghi; P. Di Filippo; C. Rutigliano; C. Avolio; E. D'Amico
University of Foggia, Italy

Background and aims: Bulbar involvement in myasthenia gravis (MG) impairs voice and speech, yet subtle changes may be overlooked.

Methods: We conducted a cross-sectional study of consecutively enrolled adults with confirmed MG at a single center. Participants completed standardized voice recordings and contemporaneous clinical assessments (Myasthenia Gravis–Activities of Daily Living [MG-ADL] and revised Myasthenia Gravis Quality of Life [rMG-QOL15]). Tasks included sustained vowels, standardized reading, and spontaneous speech. Acoustic metrics comprised root-mean-square intensity (RMS, dB) and fundamental frequency (F0, Hz).

Results: Seventeen patients were enrolled (median age 58 years; 52.9% female). Median MG-ADL was 6.0 and mean rMG-QOL15 was 16.6, with no significant correlation ($r=0.09$, $p=0.74$). Male participants exhibited significant intensity reductions in connected speech: reading (–3.22 dB, IQR –5.98 to –2.09; $p_{BH}=0.031$; $r=0.84$) and spontaneous speech (–5.46 dB, IQR –6.11 to –4.93; $p_{BH}=0.031$; $r=0.84$). Female participants showed smaller, non-significant changes (–2.2 dB; all $p_{BH} > 0.7$). F0 shifts were modest and non-significant after correction. Across the cohort, MG-ADL correlated with both RMS and F0 drops in unadjusted models but not after adjusting for sex. rMG-QOL15 showed no overall association, although females demonstrated a correlation between F0 drop and QOL burden ($r=0.77$, $p=0.014$).

Conclusion: Connected-speech intensity decrements, particularly in males, represent a robust acoustic marker of bulbar involvement in MG not captured by patient-reported outcomes.

Disclosure: Nothing to disclose related to the submitted manuscript

EPO-0504 | Demyelinating diseases and Sjögren's Syndrome: Clinical intersections and pathogenetic links

M. Akuç¹; E. Koc²; F. Saridas²; B. Yagız¹; B. Coskun¹; H. Dalkilic¹; Y. Pehlivan¹

¹Rheumatology, Faculty of Medicine, Uludag University, Bursa, Türkiye; ²Neurology, Faculty of Medicine, Uludag University, Bursa, Türkiye

Background and aims: The pathological relationship between demyelinating diseases and Sjögren's syndrome (SS) remains incompletely understood. Autoimmune mechanisms play a central role in the pathogenesis of both conditions, leading to overlapping clinical manifestations and responses to similar immunomodulatory therapies. We aimed to evaluate the frequency of coexisting SS in patients with suspected demyelinating diseases and to assess their clinical, serological, and histological features.

Methods: Over a one-year period, 52 patients admitted to the neurology ward with suspected demyelinating disease and

Catholic University of the Sacred Heart, Rome, Italy

Background and aims: Thymoma-associated Myasthenia Gravis (TAMG) represents a clinical entity with poorer prognosis when compared to other MG subtypes. Outcome predictors are lacking. We conducted a retrospective study to identify clinical variables associated with favorable MG outcome as minimal manifestation or better according to MGFA post-intervention status (MGFA-PIS).

Methods: We retrieved information from clinical records of consecutive TAMG patients seen at our Institution between January 2005 and May 2025. Outcome predictors as patient demographics, MG severity (at onset and at maximum severity) and related treatment, pathologic variables, thymoma stage (according to Masaoka classification) and histotypes (according to WHO classification) were assessed by univariate and multivariate analyses performed in R 4.3.1 Software Version. A favorable outcome was defined as achieving MM-or-better.

Results: A total of 118 patients [59 (50%) females, median age (IQR, years)=63 (54–78)] with acetylcholine receptor antibody positive MG (AChR-MG), and histologically confirmed thymoma were included. The outcome was assessed by MGFA-PIS at the last follow-up. Fourteen cases were excluded either due to missing data or to follow-up period < 1 year. The univariate logistic regression revealed that the presence of autoimmune comorbidities (AIC) known or unknown to be linked to thymoma, and occurring at any time of patient history, was significantly associated with a lower chance to achieve ‘MM-or-better’, OR 0.25 (95% CI, 0.08–0.72; $p=0.006$). There were no significant

FIGURE 1: Study population and results.

FIGURE 1: Study population and results.

FIGURE 1: Study population and results.

consulted by rheumatology were included. All patients underwent systematic rheumatological evaluation, including assessment of oral and ocular dryness. Antinuclear antibodies (ANA) and ANA profiles were analyzed in all cases. Salivary gland biopsy was performed in patients with sicca symptoms and/or relevant autoantibody positivity. Patients without clinical or serological evidence suggestive of SS were excluded from further evaluation.

Results: Among the 52 patients, 14 (26.9%) reported oral dryness and 7 (13.4%) ocular dryness. ANA positivity was detected in 11 patients (21.1%), and SS-related autoantibodies were identified in 5 patients (10.5%). Salivary gland biopsy was performed in 27 patients and yielded positive results in 6 cases. Additionally, 3 patients with strong clinical and serological findings but negative biopsy results were diagnosed with SS. Overall, SS was diagnosed in 9 patients (17.3%). Concomitant diagnoses included MS, NMO, and myositis.

Conclusion: Sicca symptoms and autoantibody positivity are more frequent in patients with demyelinating diseases than expected in the general population. Even in the absence of autoantibody positivity, SS should be considered when suggestive clinical features are present.

Disclosure: Nothing to disclose.

Background and aims: Multiple Sclerosis (MS) is a chronic inflammatory and neurodegenerative disease. Quantifying neuronal damage is a critical step for patient care and treatment selection. Neurofilament light chain (sNfL) and glial fibrillary

acidic protein (sGFAP) are the two most promising serum biomarkers reflecting neuronal damage and astroglial activation, respectively.

Methods: This study analyzed sNfL and sGFAP in 177 consecutive MS patients and 71 healthy controls (HCs) enrolled at Ospedale San Paolo in Milan using SIMOA technology, classifying patients as Responders (R) or Non-Responders (NR) based on "No Evidence of Disease Activity 3" (NEDA-3) status after two years of treatment. Longitudinal analyses were performed for Dimethyl fumarate (DMF) and Ocrelizumab (OCRE) treatment.

Results: Biomarker-age correlation analysis in HCs confirmed correlation between either NfL and GFAP with age and cut-off values specific for age decades were calculated. Both biomarkers were higher in MS patients compared to HCs. sNfL showed a significant increase in NR patients overall. In contrast, sGFAP was elevated in the low-efficacy treatment agents (LETAs) NR group and also in the DMF NR subgroup, suggesting that it monitors persistent astrogliosis. Longitudinal analysis showed that either biomarkers decreased during DMF treatment after one year. During OCRE treatment sNfL rapidly reduced to HC levels within one year, while sGFAP decreased only after two years.

Conclusion: This study highlights the differential temporal dynamics of sNfL and sGFAP under ocrelizumab and the potential role of sGFAP as treatment-response biomarker in DMF-treated patients.

EPO-0507 | Uncovering novel antigenic targets of CNS-reactive autoantibodies in autoimmune neurological syndromes

I. Senyuz¹; S. Jones¹; M. Canales¹; A. Meringa¹; R. Bernard-Valnet¹; R. Genolet²; M. Theaudin¹; A. Harari²; C. Pot¹; R. Du Pasquier¹; A. Mathias¹

¹Laboratory of Neuroimmunology and Service of Neurology, Department of Clinical Neurosciences, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; ²Ludwig Institute for Cancer Research, Lausanne Branch, Department of Oncology, Lausanne University Hospital and University of Lausanne, Agora Cancer Research Center, Lausanne, Switzerland

Background and aims: The identification of auto-antibodies (auto-Abs) and their antigens has improved the diagnosis and stratification of autoimmune neurological syndromes such as autoimmune encephalitis (AIE) and neuromyelitis optica spectrum disorders (NMOSD). Yet, 7–30% of AIE/NMOSD patients remain seronegative. Auto-Abs are also reported in multiple sclerosis, but their targets and pathogenic relevance remain unclear. Our objective is to identify novel antigenic targets to advance our understanding of disease immunopathology and improve diagnosis/prognosis.

Methods: We established a human induced pluripotent stem cell (hiPSC)-derived astrocyte or neuron cell-based assay (CBA)

to identify patients with astrocyte- and/or neuron-reactive IgG in serum or cerebrospinal fluid. Memory B cells from selected patients were immortalized to generate B lymphoblastoid cell lines (BCLs) secreting monoclonal antibodies (mAbs). These mAbs were screened using the CBA, and B-cell receptor variable regions of autoreactive clones were sequenced for recombinant mAb production, enabling antigen discovery. Enrolled patients presented with inflammatory neurological diseases (IND) including people with MS (pwMS), as well as non-IND control patients.

Results: We identified astrocyte- and neuron-reactive auto-Abs in 10 seronegative AIE/NMOSD patients; 15 astrocyte- and 14 neuron-reactive auto-Abs among 97 pwMS; and astrocyte-reactive auto-Abs in one other-IND (OIND) patient seronegative for known auto-Ags. We successfully produced astrocyte-reactive mAbs from selected patients (AQP4-positive NMO, pwMS and OIND), which are being studied for downstream antigen discovery.

Conclusion: We present a robust pipeline combining hiPSC-derived CBA with patient-derived mAbs for Ag discovery. This approach enables identification of novel autoreactive targets in pwMS and seronegative autoimmune neurological patients, enhancing immunopathological understanding and diagnostic accuracy.

EPO-0508 | Progression independent of relapse and MRI activity in disability accumulation throughout the course of multiple sclerosis

K. van Tulder¹; C. Corsten¹; R. Klein Kranenbarg²; I. Smets¹; J. de Beukelaar³; M. van Luijn⁴; B. Wokke¹; J. Smolders⁵

¹Department of Neurology, MS center ErasMS, Erasmus MC, University Medical Center, Rotterdam, the Netherlands;

²Department of Neurology, MS center ErasMS, Erasmus MC, University Medical Center, Rotterdam, the Netherlands; Department of Neurology, Albert Schweitzer Hospital, Dordrecht, the Netherlands; ³Department of Neurology, Albert Schweitzer Hospital, Dordrecht, the Netherlands; ⁴Department of Immunology, MS Center ErasMS, Erasmus MC, University Medical Center, Rotterdam, the Netherlands; ⁵Department of Neurology, Department of Immunology, MS center ErasMS, Erasmus MC, University Medical Center, Rotterdam, the Netherlands; Neuroimmunology research group, Netherlands Institute for Neuroscience, Amsterdam, the Netherlands

Background and aims: Progression independent of relapses and MRI activity (PIRMA) is an important driving factor of disability accumulation in relapsing multiple sclerosis (MS) trial-cohorts treated with high-efficacy therapies (HET). It is unclear how PIRMA during HET relates to PIRMA as observed in (untreated) early-stage and primary progressive MS. In this study we assessed PIRMA in 3 independent cohorts to explore applicability of definitions and overlap in clinical characteristics associated with PIRMA.

Methods: Repetitive data on EDSS, PDDS, T25FW, SDMT and walking distance were collected from a retrospective HET-cohort ($N=369$), a prospective first attack of demyelination cohort (PROUD-cohort, $N=458$) and a prospective PPMS cohort

(SPIN-P-cohort, $N=188$). Worsening of these outcomes was defined as potentially attributable to relapses or MRI-activity if any of these events were reported between measurements or <30 days after new measurement. Otherwise, worsening was attributed to PIRMA.

Results: Median age at respective baseline was 34 years (HET-cohort), 33 (PROUD-cohort) and 60 (SPIN-P-cohort). Both in HET-cohort and PROUD-cohort around 70% was female, while in SPIN-P-cohort 52% was female. EDSS and PDDS were the most-used measurements in all cohorts (HET-cohort $N=630$, $N=261$; PROUD-cohort $N=854$, $N=478$; SPIN-P-cohort $N=463$, $N=467$, respectively). Worsening in outcome measures during follow-up was low in all cohorts (20.5% (268/1311), 11.6% (179/1537), 18.5% (320/1729), respectively). The proportion of worsening attributed to PIRMA was 63.1 (HET-cohort), 58.7 (PROUD-cohort) and 92.5% (SPIN-P-cohort) respectively.

Conclusion: PIRMA is proportionally the most contributing factor of disability accumulation throughout the whole disease course of MS. Participant characteristics associated with worsening of EDSS and PDDS will be presented.

Background and aims: Wearables quantify real-world function, but missing reference values limit clinical interpretation. Objective: to test whether population-normalised smartwatch Z-scores and a composite digital deviation from norm track disability in multiple sclerosis.

Methods: We pooled Withings ScanWatch data from prospective observational studies. Participants with ≥ 30 valid days

and complete age, sex, body mass index (BMI), and Expanded Disability Status Scale (EDSS) data were included. Steps, moderate-intensity activity, total sleep time, and nightly resting heart rate were converted to matched Z-scores using an aggregated reference dataset of 2,655,433 users (2023–2024). Digital Deviation Composite (DDC2-4) averaged only abnormal deviations across 2–4 domains.

Results: 143/180 participants met criteria. Step and activity Z-scores declined with disability, becoming significantly below norms from EDSS 4.0–4.5 (median step Z-score -0.92) and reaching -1.66 at EDSS ≥ 7.0 (Figure 1). EDSS correlated with steps (Spearman $r = -0.71$) and activity ($r = -0.63$), weakly with resting heart rate ($r = 0.27$), and not with sleep ($r = 0.05$). DDC2, DDC3, and DDC4 correlated with EDSS ($r = 0.72, 0.68, 0.66$) (Figure 2). Serum glial fibrillary acidic protein (GFAP) showed weak positive associations with DDC3 and DDC4, whereas serum neurofilament light chain (NfL) showed none; in migraine controls ($n = 45$), activity Z-scores were near norms.

Conclusion: Population-normalised wearable Z-scores and DDCs provide an interpretable distance-from-norm framework for multiple sclerosis disability and may complement episodic clinic-based scales; a public web app supports Z-score

FIGURE 1 Age-, sex-, and BMI-matched smartwatch Z-scores (steps, moderate activity, sleep time, resting heart rate) across Expanded Disability Status Scale (EDSS) groups; heatmap shows median population percentiles. $n = 143$.

FIGURE 2 Digital Deviation Composite (DDC2-4) versus Expanded Disability Status Scale (EDSS): boxplots by EDSS group, scatter among participants with DDC > 0 (linear fit), and bars showing proportion with DDC = 0. $n = 143$.

EPO-0510 | Neurofilament light chain as a biomarker in chronic inflammatory demyelinating polyradiculoneuropathy: Insights from ADHERE

R. Collet Vidiella¹; M. Caballero-Avila¹; T. Casneuf²; E. Hofman²; G. Istas²; P. Llarch¹; L. Martín-Aguilar¹; E. Pascual-Goñi¹; A. De Roeck²; B. Balbino²; L. Querol¹
¹Neuromuscular Diseases Unit, Hospital de La Santa Creu I Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain, ²argenx, Ghent, Belgium

Background and aims: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is a debilitating, progressive autoimmune neuropathic disease. Neurofilament light chain (NfL) levels indicate axonal damage and may serve as a biomarker in CIDP. NfL levels were analysed in ADHERE (NCT04281472), the largest CIDP cohort to date.

Methods: Participants with probable/definite CIDP received weekly subcutaneous (SC) efgartigimod PH20 1000 mg (stage A) for ≤ 12 weeks. Responders entered stage B and were randomised (1:1) to weekly efgartigimod PH20 SC 1000 mg or placebo for ≤ 48 weeks. Serum NfL (sNfL) was measured longitudinally in 214 participants, from which NfL z-score (zNfL) was determined.

Results: During stage A, sNfL levels remained stable in responders with baseline levels within healthy reference range (≤ 20 pg/mL, $n = 114$); sNfL reduced by 18% over time in responders with elevated baseline levels (>20 pg/mL, $n = 36$). In participants receiving continuous efgartigimod through stage B, sNfL reduced by 35% by week 24 ($n = 13$). Mean (SD) sNfL levels at stage A baseline were 18.9 (22.6) pg/mL ($n = 214$), corresponding to a mean (SD) zNfL of 0.64 (1.57). Elevated baseline zNfL levels were associated with higher CIDP disease activity status (CDAS 5). zNfL scores at stage A baseline were highest in samples from CIDP-treatment-naïve participants versus those who had previously received CIDP treatment.

Conclusion: At stage A, higher baseline NfL levels correlated with higher (worse) CDAS scores. Among efgartigimod-treated responders with elevated baseline sNfL, we observed a reduction in sNfL in both stages A and B. Further analysis will determine whether NfL can serve as a contextual biomarker and inform on disease monitoring.

EPO-0511 | **Autoimmune brainstem encephalitis: A cohort study showing wide variety in phenotype and outcomes**

M. Jin¹; J. Kerstens¹; R. van Steenhoven¹; E. Erdag Turgeon¹; M. Nagtzaam¹; M. van Duijn¹; S. Veenbergen²; J. de Vries¹; M. Titulaer¹

¹Department of Neurology, Erasmus Medical Center, Rotterdam, the Netherlands; ²Department of Immunology, Laboratory Medical Immunology, Erasmus Medical Center, Rotterdam, the Netherlands

Background and aims: Autoimmune brainstem encephalitis (ABE) manifests diversely due to the complexity of brainstem nuclei. We aimed to comprehensively characterize the phenotype and paraclinical features to improve diagnostic approaches for ABE, and describe treatment and outcomes.

Methods: Patients suspected of or diagnosed with ABE at Erasmus Medical Center between January 2017 and April 2025 were retrospectively reviewed.

Results: Initial search returned 122 patients. After excluding 25 patients, 97 patients were included. The median age was 61 (range 1–86) years, and 56 (58%) individuals were male. Common brainstem symptoms were: ataxia (47%), eye movement disorders (45%), pyramidal tract signs (44%), and dysarthria (42%), while neuropsychiatric (45%) and movement disorders (25%) were the most common additional symptoms. Cancer was identified in 35 patients (36%): hematologic (12), breast carcinoma (6), colorectal (5), lung cancers (small cell lung cancer 4, adenocarcinoma 1), germ cell (2), neuroendocrine carcinoma (1), urogenital (1), and others (3). Identified antibodies (20%) included:

FIGURE 1 Neurological symptom spectrum in autoimmune brainstem encephalitis.

FIGURE 2 A. The tumor associations of autoimmune brainstem encephalitis (ABE). B. The antibody associations of ABE. C. The prognosis of patients with intracellular, extracellular, non-neuronal antibodies or patients without known antibodies.

anti-KLHL11 (3), anti-Ma2 (3), anti-Hu (2), anti-NMDAR (2), anti-glycine receptor (2), anti-IgLON5, anti-amphiphysin, anti-GAD65, anti-AQP4, anti-MOG, anti-GFAP, anti-GQ1b (all $n = 1$). Inflammatory changes in cerebrospinal fluid were observed in 61/88 (69%), and MRI brain abnormalities were observed in 64/95 patients (67%). Outcomes were available in 59 patients: improvement or stabilization was achieved in 44 patients (31 and 13 respectively, 77%). Patients with extracellular or non-neuronal antibodies generally respond better than those with intracellular antibodies, while antibody-negative group tends to be in between.

Conclusion: ABE has complicate aetiologies, broad tumor and antibody associations. Most treated patients respond to immunotherapy.

Disclosure: M.J. is supported by the Chinese scholarship council program (Project ID 202308430038).

Background and aims: In multiple sclerosis (MS), remyelination is frequently inefficient and highly heterogeneous between individuals. Physical exercise has been shown to enhance oligodendrogenesis and new myelin sheath formation in demyelinating models, and to attenuate disease severity in experimental autoimmune encephalomyelitis (EAE) when performed prior to disease onset. Whether physical activity can promote repair in vivo after disease onset remains unknown.

Methods: We compared two exercise paradigms in EAE induced mice: an earlier-onset, higher-intensity protocol (initiated 36 h after peak disease; 2x15-min treadmill sessions/day, at 5 cm/s, for four consecutive days), with a later-onset, low-intensity protocol (initiated 48 h after peak; 2x10-min sessions/day, at 5 cm/s, for 4 days) and sedentary controls.

Results: Early-onset, higher-intensity exercise failed to improve clinical outcome compared with sedentary mice and was associated with a transient worsening of motor deficits. In contrast, mice subjected to later-onset, low-intensity exercise displayed significantly improved motor performance during remission. At the tissue level, this improvement was associated with enhanced lesion resolution, increased microglial-neuron interactions and higher expression of IGF-1 and P2Y12R in microglia/macrophages, consistent with a pro-repair phenotype and a partial return toward homeostasis.

Conclusion: Together, these findings identify a critical temporal window after demyelination during which, appropriately timed, low-intensity exercise promotes microglial phenotypic changes and improves clinical recovery in mice with EAE. Defining exercise paradigms that are both biologically effective and translatable to patients with MS remains a key challenge.

Disclosure: Nothing to disclose.

EPO-0513 | The Comprehensive Live Cell-Based Cytotoxicity Assay for Predicting Rescue Therapy in Acute Attacks of NMOSD

X. Xu¹; X. Zhao²; J. Ding¹; Y. Du¹; G. Luo¹; J. Li¹; R. Liu¹; X. Xu¹; X. Li¹; C. Yang¹; W. Jiang¹

¹Department of Neurology, Tianjin Medical University General Hospital, Tianjin, China; ²Department of Radiology, The Third Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background and aims: Neuromyelitis optica spectrum disorder (NMOSD) lacks serological biomarkers that accurately reflect disease activity and treatment response. We established a novel live cell-based complement-dependent cytotoxicity assay (NMO-CBA-CDC) using endogenous complement to quantify

serum cytotoxicity. This assay was developed to offer a novel tool for monitoring disease activity, assessing therapeutic efficacy, and determining the necessity of rescue therapy during acute attacks.

Methods: 111 samples from 65 aquaporin-4 immunoglobulin G seropositive (AQP4-IgG+) NMOSD patients were collected. We compared serum complement levels (C1q, C5a, soluble membrane attack complex [sC5b-9]), 50% hemolytic complement (CH50), AQP4-IgG titers, and the cytotoxic index (CI) determined by NMO-CBA-CDC between the remission and acute phases, including patients receiving rescue therapies.

Results: Serum C5a and sC5b-9 levels were elevated during acute attacks ($p < 0.05$). Intravenous methylprednisolone

FIGURE 1 Development a comprehensive NMO-CBA-CDC assay to assess serum cytotoxicity in HEK293T-AQP4 cells.

FIGURE 2 The cytotoxic index increased during the acute attack of NMOSD, which failed to be suppressed following intravenous methylprednisolone puls therapy.

Background and aims: Myasthenia gravis (MG) is a chronic autoimmune neuromuscular disorder needing long-term immunosuppressive therapy. Eculizumab is a promising treatment, but real-world evidence on its efficacy and safety is limited.

Methods: A retrospective cohort study was done across six medical centers, enrolling 60 MG patients on eculizumab.

FIGURE 3 The serological indicators for the responsiveness to IVMP during acute attack of NMOSD and the implication for further rescue therapy.

(IVMP) lowered complement components but not AQP4-IgG titers or CI. Notably, the CI was significantly higher in the acute phase than in remission ($p=0.0011$) and effectively distinguished IVMP responders from non-responders. Among rescue therapies, plasma exchange/immunoadsorption (PE/IA) most consistently reduced the CI, while intravenous immunoglobulin (IVIg), neonatal Fc receptor (FcRn) antagonists, and C5 inhibitors showed variable effects.

Conclusion: The NMO-CBA-CDC assay combined endogenous AQP4-IgG and complement activity to comprehensively assess the serum cytotoxicity in AQP4-IgG+ NMOSD patients. The CI served as an efficient tool for monitoring and predicting disease activity, evaluating therapeutic efficacy, and guiding the necessity of rescue therapy. Among rescue therapies, PE/IA demonstrated superior efficacy as reflected by NMO-CBA-CDC assay.

Disclosure: The authors have no conflicts of interest to declare. This study was supported by the National Natural Science Foundation of China (82171277, 82571535, 82171338), and Young Scientific and Technological Talents (Level Three) in Tianjin.

FIGURE 1 Longitudinal Distribution of MGFA Post-Intervention Status (PIS) (A) Percentage of patients classified as MMS+, improved, unchanged, worse, or deceased at baseline, Weeks 1, 4, 8, and the last follow-up. (B) Percentage of patients achieving MMS.

FIGURE 2 ADL and QMG score changes following initiation of eculizumab.

FIGURE 3 ADL and QMG score changes after initiation of eculizumab in the TAMG and non-TAMG groups.

Clinical data, including MG-Activities of Daily Living (ADL) scores, quantitative MG scores (QMG), and oral corticosteroid dosage at different time points (baseline, Weeks 1, 4, 8, and final follow-up before November 2024), were extracted from medical records. Study outcomes included efficacy measures (changes in MG-ADL and QMG scores, Myasthenia Gravis Foundation of America [MGFA] Post-Intervention Status [PIS], glucocorticoid dosage), and safety profile of eculizumab.

Results: In this cohort, 30.95% of patients achieved minimal manifestation status or better by Week 8, increasing to 32.69% at final follow-up. Meanwhile, mean ADL scores significantly dropped from 8.13 ± 3.99 at baseline to 5.59 ± 3.72 by Week 1 and to 3.33 ± 3.56 by the final follow-up ($p < 0.0001$). Clinically meaningful improvement up to 76.27% at final follow-up was also observed. In the thymoma-associated MG (TAMG) subgroup, ADL decreased rapidly compared to baseline ($p < 0.001$), and the non-TAMG cohort also improved significantly at each time point ($p \leq 0.026$). Additionally, no treatment-related adverse events were observed. The quick drop in MG-ADL scores indicates its efficacy, and the steroid-sparing effect is crucial for long-term management. In TAMG, improvement was early, reaching maximum benefit in the first week.

Conclusion: This multicenter analysis shows eculizumab improves clinical outcomes in MG patients, reducing disease activity and corticosteroid use.

EPO-0515 | MRI lesion patterns and embolic sources in patients with embolic stroke of undetermined source

B. Del Bello¹; F. Mazzacane²; S. Marcheselli³; F. Vodret³; G. Mazza⁴; A. Cascio Rizzo⁵; S. Beretta⁶; A. Cavallini²

¹Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy; ²Department of Cerebrovascular Disease/Stroke Unit, IRCCS Mondino Foundation, Pavia, Italy; ³Neurology Unit and Stroke Unit, Istituto di Ricovero e Cura a Carattere Scientifico, Humanitas Research Hospital, Milan, Italy; ⁴Neurology Unit, Maggiore Hospital, Lodi, Italy; ⁵Department of Neurology and Stroke Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; ⁶Department of Neurology and Stroke Unit, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy

Background and aims: Embolic stroke of undetermined source (ESUS) represents a significant proportion of ischemic stroke cases. Advanced diagnostic techniques (e.g. transesophageal echocardiography (TEE), implantable loop recorder, and vessel wall MRI (VWMRI)) improve diagnosis but are not widely available. The distribution of lesions on DWI-MRI may provide clues to the underlying embolic source and help guide the diagnostic workup.

Methods: We prospectively included patients with ESUS admitted to five Italian hospitals. At three months, they were classified as “cardio-ESUS” if atrial fibrillation or a probable PFO was detected and “athero-ESUS” if complicated aortic arch plaques on TEE or vulnerable non-stenosing plaques on VWMRI were identified. Patients with no identifiable etiology remained classified as having ESUS. Lesion patterns on DWI-MRI were classified according to a validated classification 1.

Results: A total of 128 patients were included in this study. At three months, 36 patients were diagnosed as athero-ESUS, 19 as cardio-ESUS, and 73 remained ESUS. The posterior cerebral artery pattern was significantly more prevalent in cardio-ESUS group vs ESUS (36,8% vs 8,2%, $p = 0.0014$), and a trend was observed for multiple small scattered lesions (present in ESUS but absent in cardio-ESUS, 16,4% vs 0%, $p = 0.058$). No significant differences were observed between patients with ESUS and athero-ESUS.

Conclusion: The lesion pattern in ESUS patients may suggest the potential embolic source. Patients with no potential embolic sources detected at 3 months resembled those with probable artery-to-artery embolism. The integration of clinical and additional radiological data may further help identify patients who would benefit from targeted diagnostic testing.

EPO-0516 | Safety of antiplatelet medication discontinuation more than 12 months after stent-assisted coil embolization

C. Kim; S. Lee; J. Yu

Department of Neurosurgery, Pusan National University Yangsan Hospital, Pusan National University School of Medicine, Yangsan, Korea

Background and aims: Antiplatelet maintenance is essential to avoid ischemia following stent-assisted coiling (SAC) procedures. However, indications for antiplatelet medication discontinuation (AMD) remain controversial, and optimal timing of cessation has yet to be determined. Our goal, which we achieved through a multicenter, prospectively enrolled, non-interventional study, was to investigate the safety of AMD conducted more than 12 months after SAC.

Methods: Data were retrieved from the records of 495 consecutive patients prospectively enrolled at 10 institutions during a 3-year period (between January 2021 and December 2023). Each subject had discontinued antiplatelet therapy >12 months after SAC. Maintenance duration and cessation were both at physician discretion, based on patient clinical status. We investigated clinical outcomes for at least 6 months after AMD.

Results: A majority of patients engaged in AMD (292/495, 59.0%) were not at high risk for ischemia. Mean±SD time to AMD was 20.0±12.9 months after SAC. Treated aneurysms were largely confined to the internal carotid artery (332/495, 67.1%), followed by the anterior (95/495, 19.2%) and middle (43/495, 8.7%) cerebral arteries. A laser-cut open-cell stent was most often applied (60.5%); laser-cut closed-cell (22.2%) and braided closed-cell (17.3%) stents were used to a lesser extent. Four patients underwent double stenting. Despite sizeable (41.0%) high-risk group representation, there were no ischemic events in relation to AMD.

Conclusion: Our results suggest that AMD >12 months after SAC procedures is safe in patients who are not at high risk for ischemia. Randomized controlled trials are warranted to confirm these results.

EPO-0517 | Fibrinolytic therapy in late-window stroke: A Bayesian network meta-analysis of randomized trials

M. Lenzi¹; G. Damaceno²; A. Santana³; T. Oliveira⁴; E. Assis⁵; B. Souza⁶; J. Cardoso⁷; P. Lajczak⁸; J. Andrade⁹; T. Fagundes¹⁰

¹State University of Rio Grande do Norte; ²University of Western Paulista; ³Faculty of Medicine of the University of Sao Paulo; ⁴Federal University of São João del Rei; ⁵Baltic Federal University; ⁶Mass General Brigham; ⁷University of Pernambuco; ⁸Medical University of Silesia; ⁹Federal University of São Paulo; ¹⁰Barretos Cancer Hospital

Background and aims: Time from symptom onset to hospital arrival remains the primary determinant for intravenous thrombolysis (IVT) eligibility in acute ischemic stroke (AIS). Although traditional windows were capped at 4.5 hours, recent evidence supports IVT in extended windows. However, the comparative efficacy and safety of different thrombolytic agents remain unclear.

Methods: We searched PubMed, Embase, and Cochrane Central for randomized controlled trials (RCTs) comparing alteplase, tenecteplase, and best medical therapy (BMT) in AIS patients beyond 4.5 hours or with unknown onset. A Bayesian network meta-analysis was performed using JAGS and BUGSnet to estimate odds ratios (OR) with 95% credible intervals (CrI). Ranking was performed via the surface under the cumulative ranking curve (SUCRA).

Results: Ten RCTs ($n = 2,862$) were included. Alteplase significantly improved functional independence (mRS 0–1) compared to BMT (OR 1.53; 95% CrI 1.18–1.96). Tenecteplase showed a numerical trend toward benefit (OR 1.33; 95% CrI 0.98–1.78) but did not reach statistical significance. Alteplase was associated with a higher risk of symptomatic intracranial hemorrhage (sICH) vs BMT (OR 3.82; 95% CrI 1.55–13.39), while tenecteplase demonstrated a more favorable safety ranking (SUCRA 49.1% vs 6.6% for alteplase).

Conclusion: In late-window ischemic stroke, intravenous alteplase confers the highest probability of functional independence but at the cost of increased hemorrhagic risk. Tenecteplase demonstrated a more favorable safety profile with comparable efficacy estimates, suggesting it may represent a balanced alternative for patients at higher bleeding risk. These findings clarify the trade-off between efficacy and safety among fibrinolytic strategies beyond 4.5 hours.

Disclosure: Nothing to disclose.

EPO-0518 | Progressive lacunar syndrome and 12-months stroke recurrence in acute ischemic lacunar stroke: Associated factors, long-term outcomes and mortality

G. Kurian; P. Michel; D. Strambo

Stroke Center, Service of Neurology, Department of Clinical Neurosciences, University Hospital of Lausanne and University of Lausanne, Lausanne, Switzerland

Background and aims: Acute ischemic strokes (AIS) of microangiopathic etiology usually result in mild-to-moderate neurological deficits and favorable short-term outcomes. However, some patients develop early neurological deterioration, called progressive lacunar syndromes (PLS), or ischemic stroke recurrence (ISR). We aimed to identify predictors of PLS and ISR and assess their long-term prognostic relevance.

Methods: We included consecutive AIS of microangiopathic etiology from a single-center prospective stroke registry. The first outcome was PLS, defined as early (≤ 24 hours) neurological deterioration (≥ 2 point NIHSS) or fluctuation (≥ 4 point rise and

Distribution of functional outcome distribution at 12 months according to presence of progressive lacunar syndrome (PLS) with Grotta bars.

Multivariable predictors of progressive lacunar syndrome (PLS).

Impact of ISR on mortality and functional outcome. Panel (A) Proportion of patients alive and dead at 1 year according to ISR. Panel (B) Distribution of 1-year functional outcome (mRS) scores among survivors, according to ISR. Panel (C) Adjusted associati.

drop), or progressive worsening (≥ 4 point) within one week. The second outcome was 1-year ISR. Multivariable logistic regression models were developed for each outcome.

Results: Among 843 consecutive lacunar strokes (median age 71, IQR 62–81, 43% female), 74 (8.8%) developed PLS. Among 651 patients with 12-month follow-up, 36 (5.5%) experienced ISR. Only two patients had both PLS and ISR. Higher admission NIHSS (adjusted-OR = 1.09, 95% CI = 0.99–1.8) and diabetes (aOR = 2.04, 95% CI = 1.11–3.67) were independently associated with PLS, while no acute variable predicted ISR. PLS was independently associated with more unfavorable modified-Rankin-scale-shift (mRS) at 3 (acOR = 4.47, 95% CI = 2.56–7.79) and 12 months (acOR = 2.97, 95% CI = 1.55–5.69), as well as higher 12-month mortality (18.4% versus 5.7%, OR = 3.75, $p = 0.003$). ISR occurred in 36 patients (5.5%). After adjustment using the IPSW method among survivors, ISR was not independently associated with worse 12-month functional outcome.

Conclusion: In acute lacunar stroke, PLS is associated with greater baseline stroke severity and diabetes mellitus, as well as worse functional outcome. Distinct mechanisms likely underlie PLS and ISR.

Disclosure: Nothing to disclose

EPO-0519 | Impact of the Absence of Standard Modifiable Cardiovascular Risk Factors on Short- or Long-Term Vascular Outcomes in Patients with Ischemic Stroke

J. Kim¹; S. Ryu²

¹Department of Neurology, Chonnam National University Hospital, Gwangju, Korea; ²Department of Rehabilitation, Cheomdan Wooam Hospital, Gwangju, Korea

Background and aims: This study aimed to investigate whether the absence of standard modifiable risk factors (SMuRFs; hypertension, diabetes, dyslipidemia, and current smoking) influences short- and long-term outcomes in patients with ischemic stroke and to explore the prognostic relevance of SMuRF burden.

Methods: This study was an analysis of a prospective, multi-center, stroke registry between January 2011 and December 2023. Patients without any of SMuRFs were classified as no SMuRF. SMuRF burden was defined as the number of risk factors present (0–4). Each risk factor was weighted equally in the analysis. The primary outcome was a composite of stroke, myocardial infarction (MI), and all-cause mortality within 3-month and 1-year.

Results: A total of 67,214 patients (age 68.3 ± 13.4 years, 58.8% male) were finally analyzed. No-SMuRF patients were 9.4%, and those with 1–4 SMuRFs were 27.0%, 34.8%, 22.7%, and 6.2%, respectively. The composite outcome did not differ between patients without and with SMuRFs at 3-months (7.9% vs 7.6%, respectively) or 1-year (12.2% vs 12.3%, respectively). After adjustment, patients with SMuRFs had higher rates of primary composite outcomes at both 3-months and 1-year than those without SMuRFs. SMuRFs were independently associated with increased risk of primary composite outcomes at 3-months (aHR, 1.30[1.19–1.44]) and 1-year (aHR, 1.25[1.06–1.35]), with a graded increase in risk according to the number of SMuRFs.

Conclusion: In patients with ischemic stroke, SMuRF burden—but not the absence of SMuRFs—was independently associated with a higher risk of composite of stroke, MI and all-cause mortality at both 3-months and 1-year, suggesting the prognostic relevance of cumulative vascular risk and the importance of comprehensive risk factor management.

Disclosure: Nothing to disclose

EPO-0520 | Comprehensive prestroke risk factor control and functional outcomes after acute ischemic stroke

J. Kim¹; S. Ryu²; H. Bae³

¹Chonnam National University Hospital, Gwangju, Korea; ²Cheomdan Wooam Hospital, Gwangju, Korea; ³Seoul National University Bundang Hospital, Seongnam, Korea

Background and aims: This study evaluated whether comprehensive prestroke risk factor (RF) control—by degree of RF control or comprehensive RF control—is associated with 3-month functional outcomes after ischemic stroke.

Methods: We analyzed ischemic stroke patients from the CRCS-K-NIH registry (2011–2022), a multicenter stroke registry in Korea. Hypertension, diabetes, dyslipidemia, and

atrial fibrillation were considered as major RFs for ischemic stroke. The comprehensive RF control was categorized as well-controlled (all present RFs well-controlled), partially-controlled (some RFs well-controlled), or poorly-controlled (none RFs well-controlled). The primary outcome was 3-month mRS of 0–2, indicating functional independence (good outcome).

Results: Of the 63,570 patients with one or more major RFs, 28.6% had poorly-controlled, 35.6% had partially-controlled, and 35.8% had well-controlled RF control. The rate of 3-month good outcome was 66.0% among those with one RF, 60.8% in two, and 55.0% in three or more. After adjusting for covariates, well-controlled groups had higher odds of good outcomes (aOR[95% CI], 1.16[1.08–1.25] for one RF, 1.34[1.21–1.48] for two, and 1.23[1.03–1.48] for ≥ 3), as did partially-controlled groups (aOR 1.16[1.06–1.26] for two; 1.22[1.05–1.42] for ≥ 3), versus poorly-controlled. Across all RF levels, well-controlled (aOR 1.22[1.15–1.29]) and partially-controlled (aOR 1.14[1.07–1.22]) statuses were significantly linked to higher odds of good 3-month outcomes.

Conclusion: Comprehensive prestroke RF control was independently associated with a higher likelihood of favorable 3-month outcomes, both within and across levels of RF burden. These findings highlight the importance of not only identifying but also optimal comprehensive prestroke RF control to improve post-stroke functional outcomes, regardless of the number of RF present.

Disclosure: Nothing to disclose.

EPO-0521 | Clinical outcomes of endovascular thrombectomy beyond 24 hours in large vessel occlusion stroke: A meta-analysis

K. Moghib¹; M. Meshref²

¹Kasralainy medical school, Cairo University, Cairo, Egypt;

²Department of Neurology, Faculty of Medicine, Al-Azhar University, Cairo, Egypt

Background and aims: The effectiveness of endovascular thrombectomy (EVT) for acute ischemic stroke due to large vessel occlusion beyond 24 hours from last known well remains unclear, with existing evidence largely derived from observational studies.

Methods: We systematically searched major databases through February 2025 for studies comparing EVT with best medical therapy in patients treated more than 24 hours after symptom onset. Outcomes included 90-day functional independence (mRS 0–2), excellent outcome (mRS 0–1), symptomatic intracranial hemorrhage (sICH), and mortality. Random-effects models were used to pool adjusted and unadjusted odds ratios. PROSPERO (CRD420251274201)

Results: Ten observational studies ($n=1,871$) were included. EVT was associated with higher odds of functional independence (adjusted OR 4.62) and excellent outcome (adjusted OR 5.68). EVT was linked to an increased risk of sICH, while 90-day mortality was not significantly different between groups. Subgroup analyses across imaging strategies, stroke severity, and occlusion territory were consistent with primary findings. Certainty of evidence ranged from low to very low.

Conclusion: EVT beyond 24 hours may improve functional outcomes without increasing mortality, despite a higher

hemorrhagic risk. Randomized controlled trials are needed to validate these findings and refine patient selection in the ultra-late window.

Disclosure: Nothing to disclose.

EPO-0522 | Sex-based inequities in prehospital stroke identification: A systematic review and meta-analysis

K. Moghib¹; M. Meshref²

¹Faculty of Medicine, Cairo University, Cairo, Egypt;

²Department of Neurology, Faculty of Medicine, Al-Azhar University, Cairo, Egypt

Background and aims: Evidence suggests that sex-related disparities may influence early stroke recognition and management before hospital arrival. This systematic review and meta-analysis evaluated differences between female and male patients across dispatch and emergency medical service (EMS) pathways and identified gaps requiring further investigation.

Methods: A systematic search of PubMed, EMBASE, CINAHL, and EMCARE identified studies reporting sex differences in prehospital stroke care. Random-effects meta-analyses using inverse variance weighting were conducted. The primary outcome was the likelihood of correct prehospital stroke identification. Secondary outcomes included dispatch coding, EMS prenotification, transport destination, and time metrics. PROSPERO (CRD420251274202)

Results: Sixteen studies including 1,193,788 patients (622,764 women; 571,024 men) were analyzed. Women were less likely to receive a correct prehospital stroke diagnosis compared with men (RR 0.92, 95% CI 0.89–0.96), with substantial heterogeneity. No significant sex differences were observed in dispatch stroke coding, EMS prenotification, transport to stroke centers, or call-to-door times. Data were insufficient to draw conclusions regarding on-scene clinical management and interprofessional communication.

Conclusion: Female patients experience lower rates of accurate prehospital stroke recognition. Considerable heterogeneity and limited reporting across care stages highlight the need for standardized, high-quality studies to address sex-based inequities in prehospital stroke systems.

Disclosure: Nothing to disclose.

M. Rubin¹; P. Preziosa¹; M. Margoni²; L. Storelli³; E. Pagani³; P. Valsasina³; M. Albergoni³; L. Moiola⁴; M. Rocca¹; M. Filippi⁵

¹Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy; ²Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ³Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁴Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁵Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy

Background and aims: Neuromyelitis optica spectrum disorder (NMOSD) is an autoimmune astrocytopathy where disability is largely relapse-driven. Cerebrovascular risk factors (cVRFs) may exacerbate astrocytic and small-vessel injury, therefore we investigated their impact on MRI damage and disability in NMOSD.

Methods: Twenty-eight aquaporin 4-positive NMOSD patients and 56 age- and sex-matched healthy controls (HC) underwent 3T brain and cervical MRI, cVRF and neurological assessment, including Expanded Disability Status Scale (EDSS). Brain T2-hyperintense white matter lesion volume (WMLV), normalized global and regional volumes, normal-appearing WM fractional anisotropy and mean diffusivity, diffusion tensor imaging analysis along the perivascular spaces (DTI-ALPS) index, spinal cord (SC) LV and normalized cross-sectional area (nCSA) were quantified.

Results: cVRFs were present in 57% of NMOSD and 39% of HC, with smoking being the most frequent (FDR- $p=0.734$). Compared to HC, NMOSD showed higher brain WMLV and SCLV, lower normalized brain, deep gray matter volumes (nDGMV), and nCSA (FDR- $p\leq 0.030$). Significant diagnosis×cVRF interactions were found for nDGMV and DTI-ALPS (FDR- $p\leq 0.038$). In NMOSD, higher EDSS correlated with lower DTI-ALPS ($r=-0.46$ /FDR- $p=0.048$) and higher SCLV ($r=0.53$, FDR- $p=0.030$). At moderation analysis, cVRFs amplified the association between DTI-ALPS and disability (FDR- $p=0.045$).

Conclusion: cVRFs amplify CNS damage and the clinical impact of glymphatic dysfunction in NMOSD, suggesting convergent vascular and astrocytic injury.

EPO-0524 | Clinical safety and efficacy of stent-assisted coil embolization with ACCERO stent in cerebral aneurysm: Short-term follow-up and precaution for use

S. Lee; C. Kim; J. Yu

Department of Neurosurgery, Pusan National University Yangsan Hospital, Pusan National University School of Medicine, Yangsan, Korea

Background and aims: Stent-assisted coil embolization (SAC) is an effective method of treating intracranial aneurysms. The aim of the study was to assess the safety and efficacy of the new ACCERO stent for the treatment of cerebral aneurysms.

Methods: Nine ruptured and 41 unruptured cerebral aneurysms were treated using the ACCERO stent between February 2021 and December 2023. Patient demographics, aneurysm characteristics, procedural parameters, grade of occlusion, complications, and clinical outcomes were analyzed. Follow-up was conducted with magnetic resonance angiography (MRA) or Digital subtraction angiography (DSA) was performed 6 to 12 months after the procedure.

Results: The ACCERO stent deployment was attempted in 51 cases, with replacement by the Neuroform Atlas stent in 1 case. Successful stent deployment was achieved in 50 cases, and appropriate wall apposition to the parent artery. Intimal hyperplasia was observed in 1 case, but no other clinical complications related to the stent occurred. Favorable clinical outcomes were observed in 92% of patients (46/50), including those with subarachnoid hemorrhage. Immediate favorable angiographic outcomes and complete occlusion were achieved in 90% (45/50) and 74% (37/50) of cases, respectively. Among the 45 patients who had imaging follow-up, favorable angiographic outcomes and complete occlusion were observed in 93.3% (43/45) and 82.2% (37/45) of cases, respectively.

Conclusion: The ACCERO stent is a braided-type stent that requires more attention than stents, such as the Neuroform Atlas

or Enterprise stents. However, since the struts of the stent are fully visible, it can be more useful in treating challenging aneurysms once the user becomes familiar with its use.

Disclosure: Nothing to disclose

EPO-0525 | Neuroanatomic correlates of conjugate eye deviation in left hemispheric stroke

O. Saprikis¹; T. van der Bijl¹; M. Reisert²; C. Weiller¹; M. Rijntjes¹

¹Department of Neurology and Clinical Neuroscience, Faculty of Medicine, University of Freiburg, Freiburg i.Br, Germany;

²Department of Medical Physics, Faculty of Medicine, University of Freiburg, Freiburg i.Br, Germany

Background and aims: Conjugate eye deviation (ED) is a frequent clinical sign in acute stroke, a marker of large vessel occlusion and a predictor for the occurrence of neglect. While its occurrence has been extensively studied in right hemispheric stroke, data for left hemispheric lesions remain limited.

Methods: We retrospectively analysed patients with first time left hemispheric middle cerebral artery stroke from the Freiburg Large Scale Project registry. ED was quantitatively measured on acute CT or MRI. Neglect was assessed using item 11 of the NIH Stroke Scale (NIH-SS). Lesion-symptom relationships were examined with the novel Streamline-based Lesion-symptom Mapping (SLSM).

Results: Seventy patients met inclusion criteria. Larger ED was associated with the presence of neglect but not with age or lesion volume. SLSM revealed that ED severity was associated with lesions along a number of tracts: superior longitudinal and arcuate fasciculi (dorsal pathway), the extreme capsule complex (ventral pathway), and the middle and inferior longitudinal fasciculi (caudal pathway) (Figure 1). Subgroup analysis (Figure 2) showed that larger ED (in purple) was linked to dorsal and caudal disconnections. Smaller ED (in green) was associated with ventral pathway involvement, because in CT/MRI, no detection of stimuli or reorienting was required.

Conclusion: In left hemispheric stroke, ED at rest without external stimuli reveals disconnection of three distinct networks: dorsal, ventral and caudal, associated with different aspects of neglect: control of eye movements and gaze orientation, attention to novel and behaviourally relevant stimuli, and spatial awareness.

Disclosure: Nothing to disclose.

EPO-0526 | Efficacy of Neurofeedback in Cognitive Impairment in Multiple Sclerosis

A. Tursunov; K. Olga; Y. Madjidova

Department of Neurology, Pediatric Neurology and Medical Genetics, Tashkent State Medical University, Tashkent, Uzbekistan

Background and aims: Cognitive impairment is a common manifestation of multiple sclerosis (MS), affecting approximately 43–72% of patients and significantly reducing quality of life and social functioning. Pharmacological treatment options for MS-related cognitive deficits remain limited. Therefore, there is a growing interest in non-invasive and non-pharmacological neurorehabilitation approaches, including neurofeedback, aimed at improving cognitive function through modulation of brain activity.

Methods: This study included 40 patients with multiple sclerosis who were divided into two comparable groups. The neurofeedback group ($n=20$) received standard therapy combined with neurofeedback training, while the control group ($n=20$) received standard therapy alone. Cognitive function was assessed using the Montreal Cognitive Assessment (MoCA), Mini-Mental State Examination (MMSE), and Mini-Cog tests. Cortical evoked potentials (P300) were recorded before and after treatment. The neurofeedback protocol consisted of 10–15 training sessions.

Results: At baseline, no significant differences in cognitive performance were observed between the two groups ($p>0.05$). After treatment, the neurofeedback group demonstrated significant improvements in cognitive scores: MoCA increased from 22.6 ± 1.9 to 25.3 ± 1.6 , MMSE from 25.5 ± 1.7 to 28.0 ± 1.3 , and Mini-Cog scores also improved ($p<0.05$). In contrast, cognitive improvements in the control group were less pronounced. A reduction in P300 latency by 18–22 ms was observed only in the neurofeedback group.

Conclusion: Neurofeedback significantly enhances cognitive outcomes in patients with multiple sclerosis when used as an adjunct to standard therapy. This method may be considered an effective and non-invasive approach for cognitive rehabilitation in MS.

¹Medical University of Vienna, Department of Neurology, Vienna, Austria; ²Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria

Background and aims: No evidence of disease activity 3 (NEDA-3) is a proposed composite treatment target in multiple sclerosis (MS). Optical coherence tomography (OCT) derived retinal layer thinning is a promising paraclinical marker of future disability progression. We investigated whether integrating OCT into NEDA-3 (NEDA-3+OCT) improves monitoring of response to disease-modifying therapy (DMT).

Methods: We screened two observational cohorts at the Medical Universities of Vienna and Innsbruck for patients with relapsing MS who (i) newly initiated DMT, (ii) underwent MRI and OCT at baseline and 12 months, and (iii) had ≥ 24 months of clinical follow-up. Retinal thinning was defined as $\geq 0.5\%$ reduction in the ganglion cell and inner plexiform layer and/or $\geq 1.0\%$ reduction in peripapillary retinal nerve fibre layer at 12 months. NEDA-3/NEDA-3+OCT status was determined 12 months after DMT initiation. The primary endpoint was confirmed disability progression occurring after month 12.

Results: Overall, 124 individuals were included (72% female; mean age 33.1 ± 7.7 years; median baseline EDSS 2.0 [IQR 0.0–2.5]). Over a median follow-up of 3.4 years, 28 (23%) experienced disability progression. Time to progression did not significantly differ between EDA-3 and NEDA-3 at month 12 ($p=0.067$), and EDA-3 was not significantly associated with progression in multivariable Cox regression (aHR 1.52; 95% LL-CI 0.64; $p=0.173$). In contrast, EDA-3+OCT was associated with increased progression risk (aHR 4.47; 95% LL-CI 1.87; $p=0.002$) and shorter time to progression (RMST 42.5 ± 1.9 vs 51.6 ± 1.1 months; $p < 0.001$).

Conclusion: Adding OCT to NEDA-3 may better identify individuals at risk of future disability progression than NEDA-3 alone, particularly among those receiving high-efficacy DMT.

Background and aims: The proportion of Progression Independent of Relapse Activity (PIRA) events is significantly reduced when subclinical inflammatory activity detected by magnetic resonance imaging (MRI) is considered. This study aims to identify factors associated with Progression Independent of Relapse and MRI Activity (PIRMA) in patients with relapsing multiple sclerosis (MS).

Methods: This multicenter, retrospective, cohort study used prospectively collected data from the Italian MS Register. Inclusion criteria were clinically isolated syndrome or relapsing–remitting MS, first visit on/after January 1, 2000, ≥ 3 Expanded Disability Status Scale (EDSS) assessments, ≥ 5 years of follow-up. Confirmed Disability Accrual (CDA) was defined as a EDSS progression confirmed at 24 weeks, using roving baseline. PIRA was defined in absence of relapses < 90 days before and < 30 days after CDA onset. In patients undergoing annual brain and/or spinal cord MRI, PIRA events temporally associated with MRI activity were reclassified as PIRMA. Cox proportional hazards models were applied to identify associated factors.

Results: Overall, 30203 patients met inclusion criteria and were followed for a mean of 11.3 years; 18187 (60.2%) experienced at least one CDA, of which 12501 (68.7%) were classified as PIRA. Among 605 patients with annual MRI, 357 (59%) CDA events occurred. The proportion of PIRA decreased from 63.6% to 45.1% after accounting for MRI activity. PIRA was associated with older age (HR = 1.04, 95% CI: 1.02–1.05, $p < 0.001$) and visit density (HR = 1.59, 95% CI: 1.20–2.10, $p = 0.001$). PIRMA was associated with older age (HR = 1.04, 95% CI: 1.02–1.06, $p < 0.001$), higher EDSS (HR = 1.12, 95% CI: 1.01–1.24, $p < 0.047$) and visit density (HR = 1.65, 95% CI: 1.20–2.28, $p = 0.002$).

Conclusion: Approximately one third of PIRA events were associated with MRI inflammatory activity. PIRA and PIRMA showed largely overlapping factors, suggesting similar underlying pathological mechanisms.

Background and aims: The 2024-revised McDonald criteria for diagnosing multiple sclerosis (MS) include kappa free light chains (KFLC) alongside oligoclonal bands (OCB) as markers as diagnostic features. However, the role of OCB and KFLC in the diagnosis of MS requires further clarification.

Methods: The PRO-KFLC study (prospective, multicenter, real-world analysis of KFLC in the diagnosis of MS; NCT07183020) is coordinated by the German Society for Cerebrospinal Fluid (CSF) Diagnostics and Clinical Neurochemistry. The study recruits CSF/serum sample pairs from patients with MS, and clinically or radiologically isolated syndromes (CIS, RIS) across international MS-centers. OCB are detected by different externally performed site-specific methods and by the centrally performed silver-staining and immunofixation (Sebia) method. KFLC concentrations are determined using nephelometric and turbidimetric assays on different analytical platforms (Atellica NEPH 630, BN ProSpec II, Optilite).

Results: To date, 764 CSF/serum sample pairs have been analyzed from over 50 centers across Europe. The female-to-male ratio was 1.9, and the median age at diagnosis was 34 years. Among the cohort, 63 patients were diagnosed with CIS or RIS. CSF-specific OCB were detected by center-specific methods in 87% of the patients. An intrathecal KFLC synthesis was identified in 91% using the KFLC index (6.1) and in 96% using Reiber's hyperbolic function (Figure 1).

Conclusion: The preliminary results indicate that KFLC are a valuable biomarker for detecting intrathecal inflammation in patients with MS, CIS and RIS. Ongoing recruitment and analysis are expected to further elucidate the diagnostic performance and clinical utility of KFLC assays and the role of OCB.

Disclosure: This is a prospective, diagnostic biomarker study and none of the authors and centers have to report a conflict of interest. Background and aims: Tyrosine kinase receptor c-Met is the unique receptor for hepatocyte growth factor (HGF). The HGF/c-Met axis is reported to modulate cell migration, cytokine production, and antigen presentation. Here, we analyzed c-Met expression on human CD4⁺ T cells from multiple sclerosis (MS) patients versus patients with non-inflammatory neurological disease (NIND).

Methods: Cells were isolated from blood and CSF samples of MS and NIND patients from December 2020 to December 2022 at Geneva University Hospital. Phenotypic characterization were determined by RNA sequencing (bulk) and flow cytometry. Adhesion and transmigration capacity were studied to further characterize the function of activated c-Met+CD4⁺ T cells.

Results: c-Met+CD4⁺ T cells are detected at higher levels in both blood and CSF of MS patients compared to NIND with a blood to CSF gradient. The phenotype of CD4+c-Met+ T cells is oriented toward Th17.1 polarization with a predominance of central memory and effector memory activity profiles. c-Met+CD4⁺ T cells have increased proinflammatory activity, showing higher intracellular levels of IL-17+ and IL-17+IFN γ + compared

Increased frequency of blood c-Met+ CD4⁺ T cells displaying enhanced inflammatory propensity in MS patients.

Bulk RNA-seq analysis of c-Met+ and c-Met- CD4⁺ T cells isolated from the blood of MS patients.

c-Met+ CD4⁺ T cells show increased expression of VLA-4 and LFA-1, and are associated with enhanced migratory capacities in the blood of MS patients.

with c-Met-CD4+ T cells. c-Met+CD4+ T cells showed increased transmigration capacity correlated with increased expression of integrins (Itgα4, Itgβ1, Itgβ7, Itgα4β1, Itgα4β7, ItgαLβ2) in transcriptomic (bulk mRNA sequencing) and surface protein (flow cytometry) analyses compared with c-Met-CD4+ T cells. Anti-Itgα4 (natalizumab) and anti-ItgαLβ2 (odulimomab) inhibit CD4+ T cell transmigration with predominant inhibition of c-Met+CD4+ T cells compared with c-Met-CD4+ T cells.

Conclusion: These results emphasize c-Met as an immune marker of highly pro-inflammatory and pro-migratory CD4+ T lymphocytes in MS.

¹University department of neurology, Citadelle Hospital of Liège, Belgium; ²Synnav, Vernon, France; ³Department of Neurology, Antwerp University Hospital, Antwerp, Belgium; ⁴Neurology Department, Avicenne Hospital, APHP, Hôpitaux Universitaires de Paris-Seine Saint Denis (HUPSSD), Sorbonne Paris Nord; ⁵Service de Neurologie, Service de Santé des Armées, Hôpital d'Instruction des Armées de Percy, France; ⁶Cliniques Universitaires Saint-Luc, UCLouvain, Belgium; ⁷Department of Neurology, CHC Mont-Légia, Belgium; ⁸Department of neurology, Centre Hospitalier Universitaire de Liège, Belgium; ⁹MDUK Oxford Neuromuscular Centre, John Radcliffe Hospital, UK

Background and aims: In multiple sclerosis (MS), high-efficacy disease-modifying therapies substantially reduce inflammatory activity, yet long-term disability progression persists. Both progression independent of relapse activity (PIRA) and relapse-associated worsening (RAW) contribute to disability accumulation. Sensitive methods to capture these processes are needed.

Methods: We conducted a multicenter, 3-year observational study using an ankle-worn wearable device enabling stride-level gait reconstruction and the computation of the fastest 5% of strides recorded (SV95C). Participants completed one-month periods of daily monitoring at baseline, one year, and every six months over the subsequent two years. The Expanded Disability Status Scale (EDSS) and Timed 25-Foot Walk Test (T25FWT) were performed before each monitoring period. Reliability, clinical validity and sensitivity to change were evaluated.

Results: Seventy-eight participants (median age 48.5 years; EDSS range 0–5.5), including 61 with relapsing-remitting MS (RRMS) and 17 with progressive MS (PMS), were enrolled. SV95C showed excellent reliability (intra-class correlation coefficient of 0.99) and strong correlations with EDSS ($R = -0.65$) and T25FWT ($R = -0.71$; all $p < 0.001$) (Figure 1). SV95C differentiated MS subtypes and EDSS subgroups (Figure 2). Significant SV95C decline was detected in relapse-free PMS (standardized response mean, SRM -0.89 at 1Y; -1.06 at 2Y; both $p < 0.05$) and RRMS (SRM -0.84 at 1.5Y, $p < 0.01$; -0.87 at 2Y, $p < 0.001$)

(Figure 3). EDSS identified change only in PMS (SRM 0.67, $p < 0.05$ at 1Y). Relapses were associated with marked SV95C declines.

Conclusion: Passive, stride-level gait monitoring is a valid and sensitive marker of ambulatory decline in MS, capturing both RAW and PIRA. Full three-year results will be presented at the congress.

Disclosure: This study was funded by F. Hoffmann-La Roche Ltd.

EPO-0532 | Temporal Dynamics of Proteomic Profiling in Multiple Sclerosis: Insights from a retrospective longitudinal study

¹Neurology Biomarker Research Unit and Department of Neurology, Medical University of Graz, Graz, Austria; ²Octave Bioscience, Inc, Menlo Park, USA; ³Research Unit for Neuronal Plasticity and Repair and Department of Neurology, Medical University of Graz, Austria; ⁴Department of Neurology, Medical University of Graz, Graz, Austria; ⁵Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Austria

Background and aims: Identifying blood-based biomarkers to enhance clinical decision-making in multiple sclerosis (MS) is essential, yet no single protein captures the disease's complex pathophysiology. The MS Disease Activity (MSDA) panel, comprising 18 proteins reflecting neuroinflammation, immunomodulation, myelin biology, and neuroaxonal integrity, has been associated with radiological and clinical outcomes. However, its relationship with evidence of disease activity (EDA) and temporal patterns remains underexplored. This study investigates temporal variations in the MSDA score in relation to MS disease activity and its potential utility in clinical evaluations.

Methods: Retrospective longitudinal data from 102 MS patients (mean±SD age 31.7±7.7 years, 61.8% female, median disease duration 1.3 years [IQR:0.7–6.8]) were analyzed, with a median of 7 samples [IQR:6–9] per patient over a mean±SD follow-up of 10.4±3.4 years. Protein levels were measured using the MSDA panel on the Olink™ platform. Radiological activity was defined as Gadolinium-enhanced or new/enlarging T2 lesions on 3T MRI scans. EDA included clinical relapse, confirmed disability worsening (assessed by Expanded Disability Status Scale scores), or radiological activity within six months of sampling.

Results: Temporal analysis showed a significant MSDA-score increase at relapse ($p < 0.001$), remaining elevated for six months ($p < 0.01$). Inflammation-related pathways peaked at relapse, while myelin and neuroaxonal scores peaked three months later. The MSDA score was higher in patients who developed future EDA within 1.5 years, but only when samples were collected during stable periods ($p < 0.05$).

Conclusion: These findings highlight the value of dynamic proteomic profiling. The MSDA score may help identify patients at risk of future disease activity, potentially improving routine MS care.

EPO-0533 | Change in excess and relative mortality in multiple sclerosis over time and by sex

M. Magyari¹; R. Holm²; N. Koch-Henriksen³

¹The Danish Multiple Sclerosis Registry, Copenhagen University Hospital – Rigshospitalet, Glostrup, Denmark, and Institute for Clinical Medicine, University of Copenhagen, Denmark; ²The Danish Multiple Sclerosis Registry, Copenhagen University Hospital – Rigshospitalet, Glostrup, Denmark; ³Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, and The Danish Multiple Sclerosis Registry, Copenhagen University Hospital – Rigshospitalet, Glostrup, Denmark

Background and aims: People with multiple sclerosis (PWMS) die at a lower age than matched background populations, but how much the disease shortens lifetime, differ between published studies, older as well as more recent.

Methods: The nationwide Danish Multiple Sclerosis Registry has followed people with multiple sclerosis (MS) for up to 70 years after onset with complete registration of vital status. In this study we describe the trend over time of excess mortality in PWMS and focus on the difference between the sexes.

Results: 28,118 cases had onset of MS between 1950 and 2022. Of them 9875 had died before follow-up at the end of year 2022, whereas only 3579 deaths were expected in matched Danish background population, matched by sex, current age and current calendar year. The relative mortality in terms of standardized

mortality rate (SMR) was 2.84 (95% CI 2.71–2.81). The median survival time from onset was 31.4 years (95% CI 30.6–32.4) as opposed to 49.8 years in the matched population within the same time- and age-frame. The median age of death was 74.2 years in PWMS (95% CI 73.8 – 84.6) and 83.4 years in the matched population. 20-years SMR changed from 5.21 in the 1950–1964 onset cohort to 2.9 in the 1980–1994 onset cohort. The ratio of relative mortalities between women and men was 1.04 ($p=0.085$).

Conclusion: Excess mortality in MS has decreased over the last several decades, but it does not differ between the sexes.

Disclosure: Melinda Magyari has served on the scientific advisory board for Sanofi, Novartis, Merck, and Moderna and has received honoraria for lecturing from Biogen, Merck, Novartis, Roche, Sanofi, Moderna, and Neuroxpharm. Rolf Pringler Holm has received speaker honoraria from Sanofi and Novartis, has served on an advisory board for Novartis, and has received a travel grant from The Danish MS Society. Nils Koch-Henriksen has nothing to disclose.

EPO-0534 | Ponesimod efficacy and safety in relapsing multiple sclerosis patients with mild to moderate disability: Results from OPTIMUM and long-term extension

O. Heinzel¹; M. Heubl²; S. de Guitaut²; A. Atallah²; A. Sarfati²

¹Department of Neurology, Centre Hospitalier Intercommunal de Poissy-Saint-Germain-en-Laye, Poissy, France; ²Medical Affairs Department, Juvise Pharmaceuticals, Paris, France

Background and aims: OPTIMUM was a phase 3 trial comparing ponesimod with teriflunomide in relapsing multiple sclerosis (RMS). In the long-term extension (LTE), all participants received ponesimod 20 mg for up to 5 years. This post hoc analysis assessed efficacy and safety in patients with baseline Expanded Disability Status Scale (EDSS) ≤ 3.5 at core study entry.

Methods: Annualized relapse rate (ARR) was estimated using a negative binomial model. Disability outcomes included 24-week confirmed disability accumulation (24wCDA). Magnetic resonance imaging activity was assessed using cumulative combined unique active lesions (CUAL), defined as T1 gadolinium-enhancing lesions and new or enlarging T2 lesions. Safety assessments included serious and fatal adverse events (AE).

Results: Overall, 946 patients were included (core study: 472 ponesimod; 474 teriflunomide). During the core period, ARR was lower with ponesimod versus teriflunomide (0.17 vs 0.29), rate ratio 0.59 (95% confidence interval [CI] [0.47–0.74]). Over the combined period, ARR remained lower in patients receiving continuous ponesimod versus those switching from teriflunomide (0.13 vs 0.21), rate ratio 0.63 (95% CI [0.51–0.79]). 24wCDA estimates at 360 weeks were 20.5% (95% CI [16.7–25.0]) with continuous ponesimod versus 24.6% (95% CI [20.5–29.3]) in switchers. No CUALs were observed in 69.7% and 75.9% of patients receiving continuous ponesimod at end of core and extension studies visits respectively. 12.3% of patients experienced severe AE in the ponesimod group.

Conclusion: In patients with baseline EDSS ≤ 3.5 , ponesimod showed sustained clinical and magnetic resonance imaging efficacy across OPTIMUM and the LTE with a favorable safety profile.

Disclosure: O.H. reports consulting and lecturing fees from Bayer Schering, Merck, Teva, Genzyme, Novartis, Almirall and Biogen Idec, travel grants from Novartis, Teva, Genzyme, Merck Serono and Biogen Idec and research support from Roche, Merck and Novartis, all of the above unrelated to this work. M.H, S.G, A.A and A.S are employees of Juvise Pharmaceuticals.

EPO-0535 | Defining Progression Independent of Relapse Activity in Early Multiple Sclerosis

T. Ayaz; A. Emekli; T. Gündüz; M. Kürtüncü
Department of Neurology, Istanbul University Faculty of Medicine, Istanbul University, Istanbul, Türkiye

Background and aims: Progression independent of relapse activity (PIRA) and relapse-associated worsening (RAW) are primary mechanisms of disability accumulation in multiple sclerosis (MS). Various PIRA definitions in literature limit cross-study comparability, and most studies rely on clinical trials rather than real-world data. We aimed to determine a clinically applicable PIRA definition in early MS by comparing 54 detection models.

Methods: We included 392 relapsing-remitting MS patients meeting 2024 McDonald criteria, evaluated within one year of symptom onset, with ≥ 2 years follow-up. Missing EDSS data were imputed by employing a 90-day interval linear interpolation-based imputation method, in which missing values were estimated along the trajectory defined by the preceding and subsequent EDSS assessments. Fifty-four PIRA detection models were compared across four parameters: (1) baseline relapse-free criteria (3 months, 6 months, 12 months), (2) confirmation timeframe (6 months, 12 months, end-of-follow-up), (3) confirmation type (threshold-based vs. absolute), and (4) worsening relapse-free criteria (90 days before worsening, no relapses baseline-to-worsening, no relapses baseline-to-confirmation).

Results: Among 392 patients (257 female), median follow-up was 6.4 years (IQR: 3.2–10.2) and median age at disease onset was 26.4 years (IQR: 21.9–33.3). During up to 5 years of follow-up (1,592.5 patient-years), PIRA prevalence ranged from 1.5% to 7.4% across definitions. We identified the 3-month relapse-free roving baseline, 12-month absolute confirmation with baseline-to-worsening relapse-free criteria as optimal for clinical use. This model yielded 3.3% PIRA and 7.9% RAW prevalence.

Conclusion: We propose 3-month relapse-free roving baseline, 12-month absolute confirmation with baseline-to-worsening relapse-free criteria as the most clinically applicable PIRA definition in early MS.

Disclosure: This study was funded by the Turkish Neuroimmunology Association.

EPO-0536 | Can Immune Cell Dynamics After Short Course Cladribine Tablets Predict MRI Lesion Activity in MS? Insights From The 4 year MAGNIFY MS Study

T. Derfuss¹; F. Sellebjerg²; D. Piani Meier³; D. Guala⁴; K. Thangavelu⁵; L. Gardner⁶; H. Wiendl⁷; N. De Stefano⁸; K. Schmierer⁹

¹Department of Neurology, University Hospital Basel, Basel, Switzerland; ²Danish MS Center, Department of Neurology, Copenhagen University Hospital - Rigshospitalet, Glostrup, Denmark; ³Neurology & Immunology Medical Unit, Ares Trading SA, Eysins 1262, Switzerland, an affiliate of Merck KGaA; ⁴Data Sciences, Merck AB, Solna, Sweden, an affiliate of Merck KGaA; ⁵Statistics Department, MeDaStats, LLC, Tampa, USA; ⁶EMD Serono Research & Development Institute, Inc, Billerica, USA, an affiliate of Merck KGaA; ⁷Department of Neurology and Neurophysiology, Medical Center - University of Freiburg, Freiburg, Germany; ⁸Department of Medicine, Surgery and Neuroscience, University of Siena, Siena, Italy; ⁹The Blizard Institute, Centre for Neuroscience, Surgery & Trauma, Faculty of Medicine & Dentistry, Queen Mary University of London, London, UK

Background and aims: It is unknown whether immune reconstitution patterns during years (Y)3–4 (treatment-free period) after cladribine tablets (CladT) treatment relate to MRI-lesion activity. We investigated lymphocyte reconstitution dynamics and MRI-lesion activity during Y3–4 in people with MS (PwMS) after treatment with CladT.

Methods: Absolute and relative changes from baseline (Month [M] 0) in 14 predefined T-cell and 9 B-cell subsets were compared in PwMS with/without Y3–4 MRI-lesion activity. 215 B- and T-cells ratios were also compared. Data were evaluated using Wilcoxon rank tests for univariate comparative analyses, and adjusted, multivariate Cox regression analyses using M15–48 data (post-lymphocyte-count-nadir). $p < 0.05$, and $p < 0.1$ for sensitivity analysis with adjustment for multiple testing, considered nominally significant.

Results: 159/182 PwMS without lesion-activity after treatment completion (M18–24) were evaluated in the comparative analysis; 59 experienced Y3–4 MRI-lesion activity and 100 remained lesion free. Patients with new/active lesions had increased B-memory, B-activated and B-transitional cells, proportionally decreased B-naïve cells, and increased central memory (CM) and Th1 T-cells (Figure 1). Multivariate Cox regression confirmed increased risk for MRI-lesion activity in patients with higher levels of these cells in addition to plasma B-cells, and decreased risk with higher levels of CD8-naïve cells (Figure 2). Adjustment for multiple testing supported the relevance of B-activated and B-plasma cell ratios to CD4 naïve and/or Th2 T-cells (Figure 3).

Conclusion: CM and Th1 T-cells, along with plasma (CD38+ and short-lived), B-memory, and B-activated cells were associated with MRI-lesion activity. Assessing reconstitution dynamics, especially B- vs T-cell ratios, during the treatment-free period may help predict disease activity and guide long-term disease management.

EPO-0537 | Brain parenchyma displacement and deformation in patients with Spontaneous Intracranial Hypotension (SIH)

A. El Rahal¹; P. Scheffler¹; K. Wolf¹; F. Volz¹; M. Overstijns¹; H. Urbach²; N. Lützen²; C. Zander²; J. Beck¹

¹Department of Neurosurgery, Medical Center, University of Freiburg, Freiburg, Germany; ²Department of Diagnostic and Interventional Neuroradiology, Medical Center University of Freiburg, Freiburg, Germany

Background and aims: Spontaneous intracranial hypotension (SIH) is mainly associated with orthostatic headache, but can also cause neurological symptoms, with symptoms mimicking behavioral-type frontotemporal dementia in severe cases. SIH is known to lead to brain sagging. The aim of this study was to investigate whether brain MRI imaging in SIH patients shows quantifiable displacement, strain, and compression of brain structures.

Methods: We designed an AI-driven image analysis pipeline for automated segmentation, volumetry and diffeomorphic registration of pre- and postoperative MRI imaging (AssemblyNet, Synthmorph CNNs). We calculated voxel-wise perioperative spatial displacements for all brain areas in 96 patients with SIH. We calculated the Jacobian determinant as a measure of local brain expansion and compression, and the von Mises equivalent strain as a measure of local distortion.

Results: Brain structures demonstrated consistent predominantly upward-outward postoperative shift. Most major brain regions exhibited statistically significant movement, with the highest magnitude seen in the parietal lobes and the left lateral ventricle ($>0.7\text{ mm}$, $p < 0.0001$). Ventricles and transverse sinuses showed relevant perioperative expansion and contraction, respectively. Apart from the ventricles, high strain was observed in temporomesial structures and the ventromedial prefrontal cortex, indicating structural strain.

Three-dimensional illustration of perioperative brain parenchyma shifts.

Three-dimensional illustration of perioperative deviatoric strain in brain parenchyma.

Three-dimensional illustration of Jacobian determinant as a measure of local brain expansion.

Conclusion: Surgical CSF leak closure in SIH is associated with consistent, quantifiable postoperative brain shifts on MRI. We demonstrate strain in brain regions of SIH patients usually affected by frontotemporal dementia, which could explain a similar clinical presentation in severe cases of SIH. AI-assisted image analysis in SIH may provide valuable prognostic information in clinical practice, potentially aiding the assessment of surgical outcome.

Background and aims: Preliminary evidence in functional movement disorders (FMD) suggested that symptoms might result from faulty neural processing. This study aimed at investigating alterations in resting-state brain functional connectivity (FC) and deep gray matter volume in patients with FMD.

Methods: Sixty patients with FMD and 65 age- and sex-matched healthy controls underwent brain MRI. We assessed the FC within the main resting-state networks using independent component analysis (MELODIC), cerebellar volumes using SUIT, and deep gray matter (GM) volumes using FMRIB's Integrated Registration and Segmentation Tool and FreeSurfer.

Results: FMD patients relative to healthy subjects exhibited an increased FC of bilateral caudate, and right putamen/pallidum, insula, inferior/superior frontal gyrus and olfactory gyrus within the basal ganglia network; an increased FC of bilateral precuneus and left cuneus within the ventral default-mode network (DMN); an increased FC of right middle cingulum within the precuneus network; and an increased FC of left cerebellum crus I-II within the primary visual network. Moreover, FMD patients showed increased volume of vermis crus II, VIIIA/b, and left lobules VIIIA/b. The altered FC within the basal ganglia and

ventral DMN correlated with worse alexithymia, depression and fatigue in FMD patients.

Conclusion: The observed alterations of cerebellar volumes and resting-state FC may represent a mismatch between sensorimotor, emotional, and cognitive systems, leading to impaired self-awareness and motor intention, heightened attention to bodily signals, and compromised voluntary movement control mechanisms. These results support the neural basis of FMD, confirming that distinct mechanisms underlie the symptoms of this complex disorder.

Background and aims: Ultra-low field MRI (0.064T) is a point of care, portable imaging tool that has a small physical foot print, runs off of a standard electric outlet, does not require specialized shielding, and a low technician operating burden. It could improve access to brain imaging in resource limited or remote locations and is ideal for patients who can't tolerate a conventional MRI study. Technical advances in image reconstruction have improved image quality and user satisfaction. AIM: demonstrate improvements in scan-rescan reproducibility and illustrative case examples of lesion detection in MS and Stroke.

Methods: Healthy volunteers were scanned multiple times on Hyperfine Inc's portable Swoop 64mT MRI scanner before and after software upgrade. Image acquisition included Fluid Attenuated Inversion Recovery (FLAIR, thickness=5mm; before: 7.5min, in-plane resolution=1.7mm; after: 7min, in-plane resolution=0.85mm) and T2-weighted (thickness=5mm; before: 5.5min, in-plane resolution=1.5mm; after: 6min, in-plane resolution=0.65mm) sequences. The Structural Similarity Index Measure (SSIM), measuring image contrast, luminance and structure, was used to assess reproducibility of scans before and after this software upgrade.

Results: The average SSIM scores before and after upgrade increased (T2w: 0.958 to 0.962, FLAIR: 0.931 to 0.943), showing improved reproducibility. Qualitatively, both periventricular and juxtacortical demyelinating white matter lesions could be

Sequential improvements in image quality with subsequent software versions.

Illustrative example of stroke and MS lesions visible at 0.064T Ultra Low Field MRI.

Hyperfine Swoop Ultra Low Field 0.064T MRI.

identified, with further improvements seen in identifying infratentorial lesions.

Conclusion: Image quality acquired on an ultra-low field portable MRI scanner has improved with subsequent iterations of scanner software. Potential applications include monitoring of multiple sclerosis patients on treatment, rapid relapse assessment, assessing MS patients with poor mobility, rapid assessment of stroke, and neurocritical care.

Disclosure: E Knopp is an employee of Hyperfine Inc.

Background and aims: Olfactory dysfunction is among the earliest and most prevalent clinical features of several neurodegenerative disorders, including Alzheimer's disease and Parkinson's disease. Despite its diagnostic and prognostic relevance, the neuroanatomical substrates linking hyposmia to cognitive syndromes across aging and neurodegeneration remain undefined.

Methods: Seventy-four participants divided in cognitively unimpaired (CU), mild cognitive impairment (MCI), and Parkinson's disease-cognitive impairment (PD-CogImp), completed the Brief Smell Identification Test (B-SIT) and underwent high-resolution structural MRI. Cortical thickness (CT) measure was obtained using FreeSurfer. Partial correlation analyses assessed associations between olfactory identification and CT across 34 bilateral cortical regions, controlling for age, sex, education, and APOE ϵ 4 carrier status. Analyses were conducted within diagnostic groups to characterize syndrome-specific structure–olfaction relationships.

Results: Olfactory identification differed across groups, with lowest B-SIT scores in PD-CogImp, followed by MCI and CU. In CU individuals, higher performance was associated with greater CT, predominantly right-hemispheric, including the lateral orbitofrontal cortex ($p=0.04$), cuneus ($p=0.04$), pericalcarine cortex ($p=0.01$), and insula ($p=0.04$). Trend-level associations were observed in left cuneus ($p=0.54$), pericalcarine cortex ($p=0.53$), and rostral middle frontal cortex ($p=0.53$). MCI showed no significant associations (p range = -0.29 to 0.27 ; all $p \geq 0.35$). PD-CogImp showed absent or inverse structure–olfaction relationships in posterior and associative cortices, consistent with syndrome-specific neuroanatomical disruption.

Conclusion: Olfactory identification shows syndrome-specific associations with cortical thickness across CU aging, MCI, and PD-CogImp, supporting its utility for differential diagnosis and neurobiological characterization of neurodegenerative disease.

Background and aims: Brain connectivity is an important determinant of disability in multiple sclerosis (MS). It varies across the disease course and can lead to “network collapse”, causing clinical deficits. We investigated how changes in short- and long-range functional and structural connectivities within the sensorimotor network (SMN) contribute to disability and physical performance worsening over one year in MS patients.

Methods: We studied 100 MS patients and 89 healthy controls (HC), who underwent 3.0-Tesla MRI and clinical evaluation, including Nine-Hole Peg Test (9-HPT), Timed 25-Foot Walk Test (T25FWT), and Expanded Disability Status Scale (EDSS). MS patients were reassessed clinically after one year. Clinical worsening was defined using the EDSS-Plus (EDSS progression or $\geq 20\%$ deterioration in 9-HPT or T25FWT). Group comparisons between HC and MS, and between stable/worsened MS patients, evaluated functional connectivity (FC) and structural connectivity (SC) of the SMN at intra- and inter-hemispheric levels.

Results: Compared with HC, MS patients had worse baseline motor performance ($p \leq 0.001$) and presented low disability levels (median EDSS = 1.5). They showed reduced inter-hemispheric SMN SC ($p \leq 0.001$), while other connectivity measures did not differ. After one year, 36 patients were classified as worsened by EDSS-Plus. No baseline demographic or clinical differences emerged between stable and worsened patients. Worsened patients showed higher intra-hemispheric SMN SC at baseline ($p=0.013$), which significantly decreased at follow-up ($p=0.006$). No differences were observed in other SMN connectivity measures.

Conclusion: SMN connectivity evolves nonlinearly in MS. Inter-hemispheric SC disruption appears early, while increased intra-hemispheric connectivity may reflect compensatory reorganization and is associated with subsequent clinical worsening.

Background and aims: MRI metrics offer potential for assessing disease progression in patients with Multiple Sclerosis (pwMS). We aim to validate whether baseline MRI metrics can estimate the risk of faster progression.

Methods: The study utilized a subset of the RECLAIM dataset. A parametric Weibull survival model was trained to predict time-to-event for reaching Expanded Disability Status Scale (EDSS) ≥ 3 on 1002 pwMS with baseline EDSS < 3 . Features included 29 MRI-based metrics computed by icobrain, age, and sex. Model's risk predictions were used to stratify an independent test set (329 patients) into low-risk group (LRG; $n = 294$) and high-risk group (HRG; $n = 35$). We assessed the risk group characteristics in terms of EDSS, brain and lesion volumes.

Results: The MRI-based risk clustering showed statistically significant faster disease progression of HRG compared with LRG ($p = 0.0006$) over a 15 year follow-up (Figures 1 and 2). HRG showed significantly lower brain tissue volumes (1467.06 ± 65.98 ml vs. 1555.71 ± 51.45 ml in LRG) and higher lesion volumes (19.55 ± 10.94 ml vs. 3.41 ± 3.36 ml in LRG) at baseline, suggesting a link between brain atrophy, lesion burden, and a higher risk for conversion to EDSS ≥ 3 (Figure 3).

Conclusion: These findings support the hypothesis that brain tissue loss and lesion accumulation contribute to an increased risk of disease progression. With further validation, this approach could help clinicians better interpret brain MRI volumetric measurements for making clinical decisions.

FIGURE 1 Faster progression represented by an accelerated decrease of the survival probability (Kaplan-Meier curve) over a 15-year follow-up in the high-risk group (Group 1 in blue) in comparison with the low-risk group (Group 2 in orange).

FIGURE 2 Faster progression represented by accelerated increase of disability (EDSS trajectory) over a 15-year follow-up in the high-risk group (Group 1 in blue) in comparison with the low-risk group (Group 2 in orange).

EPO-0543 | Superior anatomical fidelity of multi-shell (MS) vs single-shell (SS) tractography for deep brain stimulation (DBS) targeting in tremor disorders

M. Buhlan¹; A. Divanbeighi Zand²; R. Mills¹; A. Dmytriw¹; J. Eraifej²; A. Green²; J. Grist¹

¹Oxford Centre for Clinical Magnetic Resonance Research, Medical Sciences Division, University of Oxford, Oxford, UK;

²Department of Neurosurgery, Oxford University Hospitals NHS Foundation Trust, Oxford, UK

Background and aims: Tremor improvement following DBS is increasingly linked to modulation of the dentatorubrothalamic tract (DRTT). Targeting the DRTT, surgical planning often relies on SS diffusion tractography, which may limit anatomical fidelity in areas with complex fibre architecture. This study compared the reliability and anatomical precision of MS vs SS tractography for DRTT reconstruction in patients with Parkinson's disease, essential tremor and dystonic tremor.

Methods: We conducted a unicentral, retrospective analysis of 41 movement disorder patients undergoing DBS using 3-Tesla SS and MS diffusion MRI. DRTT reconstruction was performed on individual patient data without template registration. Evaluation focused on reliability of DRTT visualisation within the posterior subthalamic area (PSA, **Figure 1.i**) and detection of decussating fibres in the brainstem (**Figure 1.ii**) across streamline thresholds from >150 to >500 streamlines per voxel (spv).

Results: MS tractography consistently demonstrated higher reliability than SS. Bilateral DRTT reconstruction was achieved in all patients using MS data, whereas SS imaging failed to detect the DRTT in 27–29% of cases at >150 and >200 spv ($p < 0.001$). Decussating fibres were identified in 98% of cases using MS compared to 70–73% using SS ($p < 0.006$). These findings were consistent across higher streamline thresholds.

Conclusion: Patient-specific MS diffusion tractography provides superior reliability and anatomical fidelity for DRTT reconstruction compared to SS imaging. Our results support the use of MS reconstructions at lower streamline thresholds to

refine DBS targeting which may translate into improved tremor outcomes.

EPO-0544 | Lesion Histogram Features for Distinguishing Multiple Sclerosis And Systemic Lupus Erythematosus

M. Pawlak¹; J. Nikadon³; A. Wypych⁴; E. Więsik-Szewczyk⁷; K. Pawlak-Buś⁶; P. Leszczynski⁶; S. Michalak¹; Z. Serafin⁸; W. Kozubski¹; A. Kalinowska¹

¹Institute of Neurological Disorders, Poznan University of Medical Sciences, Poznan, Poland; ²Faculty of Philosophy and Social Sciences, Department of Cognitive Science, Faculty of Philosophy and Social Sciences, Interdisciplinary Centre for Modern Technologies, Torun, Poland; ³Interdisciplinary Centre for Modern Technologies, Torun, Poland; ⁴Struś Municipal Hospital, Department of Rheumatology, Systemic Connective Tissue Diseases and Immunotherapy of Rheumatic Diseases, Poznan, Poland; ⁵Central Clinical Hospital of the Ministry of National Defense, Military Institute of Medicine, National Research Institute, Department of Internal Medicine, Pneumology, Allergology and Clinical Immunology, Warsaw, Poland; ⁶Bydgoszcz University of Science and Technology, Faculty of Medical Sciences, Bydgoszcz, Poland

Background and aims: Evolution of white matter lesions in the course of autoimmune inflammatory disorders differs depending on severity of demyelination and recovery dynamic. Multiple Sclerosis (MS) and Systemic Lupus Erythematosus (SLE) with neuropsychiatric presentation may be difficult to distinguish in clinical practice. We aimed identify the features of the signal distribution of T1-weighted and FLAIR sequences in the lesions and the cortex in the MS and SLE populations.

Methods: We investigated distributions of regions of interest signal using skewness and kurtosis and creating 2D histograms to differentiate data from 42 MS patients and 35 SLE patients acquired at 3T MR 750 GE scanner. The FLAIR and T1-weighted images were coregistered, bias field corrected and segmented using SAMSEG pipeline (Puonti 2021). Then extracted skewness and kurtosis using python script and computed diagnostic performance of the receiver operator characteristic curves.

Results: The most effective features discriminating systemic lupus erythematosus patients from multiple sclerosis were lesion 2D PCA receiver operator characteristic area under the curve Skewness 0.77 and Kurtosis 0.69. For cortex 2D PCA receiver operator characteristic area under the curve skewness 0.59 and kurtosis 0.51. For each mode separately FLAIR lesion kurtosis AUC is 0.76 and for skewness 0.64; for cortex kurtosis 0.48 and skewness 0.52. For T1-weighted lesion signal both kurtosis and skewness were 0.62; for the cortex skewness was 0.43 and kurtosis was 0.60.

Conclusion: The multimodal 3D MRI acquisitions enables generation of reliable 2D signal histograms characterized by signal features that help distinguish populations of patients with multiple sclerosis and systemic lupus erythematosus.

EPO-0545 | Amide Proton Transfer Imaging Detects Hippocampal Proteostasis Disturbance Induced by Simulated Microgravity at 7.0 T MRI

S. Liu; R. Wu

Department of Radiology, Second Affiliated Hospital, Shantou University Medical College, Shantou, China

Background and aims: Many studies have confirmed that spacelight and simulated microgravity can affect learning and memory, resulting in cognitive decline; however, the effects of simulated microgravity on cognitive function remain unclear. The relationship between cognitive decline and proteostasis disorders in the brain under microgravity has not been elucidated. While amide proton transfer (APT) imaging is a chemical exchange saturation transfer technique that utilizes amide protons in proteins and peptides, it can serve as a non-invasive imaging biomarker for identifying brain proteostasis disorders.

Methods: We employ a 14-day hindlimb unloading (HU) rat model to simulate microgravity conditions and utilize APT imaging on HU Rats and control rats. To explore the mechanisms of microgravity-induced cognitive impairment in spaceflight through mass spectrometry-based proteomics analysis combined with hematoxylin and eosin (HE) staining and Nissl staining.

Results: Our results show that 14 days of tail suspension can cause disturbed proteostasis, and the brain APT signal increases with increasing tail suspension time, which is significantly higher in HU rats than in normal rats, and this signal showed a negative correlation with the number of viable neurons counted in Nissl staining. Through mass spectrometry-based proteomics analysis, differentially expressed proteins within the protein homeostasis network pathway were identified in the hippocampi of both normal and HU rats, providing biological evidence for the altered APT signal.

Conclusion: This study shows that APT imaging can monitor the disturbance of protein homeostasis in the brain of simulated microgravity rats in vivo and provides more references for the study of cognitive decline in simulated microgravity rats.

EPO-0546 | Double Dat: Clinical impact of repeated brain dopaminergic neurotransmission nuclear imaging - A retrospective cohort

V. Shkatova¹; J. Alves¹; M. Rangel¹; I. Casimiro²; A. Moreira²; M. Cunha²; C. Machado¹; D. Reis Carneiro¹

¹Neurology Service, Local Health Unit of Coimbra, Coimbra, Portugal; ²Nuclear Medicine Service, Local Health Unit of Coimbra, Portugal

Background and aims: The clinical role of repeating dopamine transporter studies remains unclear, particularly in the diagnostic workflow for parkinsonian syndromes. Objectives: To characterize patients undergoing repeated dopaminergic imaging and evaluate its repetition on clinical management.

Methods: Retrospective descriptive analysis of patients who underwent multiple dopamine transporter imaging studies between 2007 and 2025 at a Portuguese center.

Results: 2930 studies were performed (90.0% DATScan, 10.0% PET-BCIT) in 2828 patients. Ninety-seven patients (50.5% male; 49.5% female) underwent repeated scanning (94.8% twice; 5.2% thrice). Median age at first examination was 66.0 years (57.0–72.0). Tremor was the most frequent motor symptom (44.2%), followed by akinesia (27.9%) and gait disturbances (16.3%). Median symptom duration was 4.0 years (1.0–7.5) and median MDS-UPDRS-III score was 12.0 (8.0–25.0). DATScan was the first requested exam in 92.8% of cases; 62.0% were initially normal. Median inter-scan interval was 43.0 months (22.0–72.0). While 65.6% of patients initially evaluated with DATScan repeated it, all PET-BCIT patients later had DATScan. Imaging results changed in 28.3% of cases (16.3% from “abnormal” to “normal”; 12.0% from “normal” to “abnormal”). Normalization occurred in 78.6% of patients who underwent PET-BCIT after an initially abnormal DATScan. The second scan led to diagnostic changes in 20.5% and therapeutic modifications in 39.2% of patients.

Conclusion: Most patients did not benefit from repeat imaging. High rates of normalization were found in the transition from DATScan to PET-BCIT.

Disclosure: Nothing to disclose.

EPO-0547 | Noninvasive Prediction of Ki-67 expression in gliomas using MRI-based artificial intelligence: A systematic review and meta-analysis

Y. Faller¹; F. Lara-Freire²; G. Itaya³; G. de Oliveira⁴

¹Faculty of Medicine, University of Buenos Aires (UBA), Buenos Aires, Argentina; ²Faculty of Medicine, Pontificia Universidad Católica del Ecuador, Quito, Ecuador; ³ECPE-PPCR Program, Harvard T. H. Chan School of Public Health, Boston, MA, United States; ⁴Department of Pathology, Brigham and Women's Hospital, Boston, MA, United States

Background and aims: Gliomas are aggressive central nervous system tumors, and the Ki-67 proliferation index is a key prognostic marker. However, assessment via immunohistochemistry (IHC) is invasive and subject to sampling bias. Magnetic resonance imaging (MRI)-based artificial intelligence (AI) has emerged as a promising noninvasive alternative, but its diagnostic performance remains uncertain. This meta-analysis evaluates the diagnostic accuracy of MRI-based AI in predicting Ki-67 status in gliomas.

Methods: A systematic search was performed for studies through August 2025. Eligible studies compared MRI-based AI models with IHC as the reference standard. Pooled sensitivity, specificity, and area under the summary receiver operating characteristic (SROC) curve were estimated using a univariate random-effects model. Heterogeneity was assessed using the I² statistic. Statistical analyses were performed using RStudio (R version 4.2.3)

Results: From 1,704 identified records, eleven studies comprising 893 patients were included. MRI-based AI models achieved a pooled sensitivity of 0.849 (95% confidence interval (CI): 0.730–0.921) and a pooled specificity of 0.744 (95% CI: 0.636–0.829) for Ki-67 prediction. The SROC curve yielded an

FIGURE 1 Forest plots of sensitivity (left) and specificity (right) across included studies.

FIGURE 2 SROC curve derived from bivariate analysis for MRI-based AI models predicting Ki-67 expression in gliomas.

area under the curve (AUC) of 0.82 (95% CI: 0.676–0.872), reflecting good diagnostic accuracy. Heterogeneity was substantial for sensitivity ($I^2=77\%$) and moderate for specificity ($I^2=40\%$). Variability likely stemmed from differences in MRI protocols, AI architectures, and Ki-67 thresholds across studies.

Conclusion: MRI-based AI demonstrates good diagnostic accuracy (AUC=0.82) for noninvasive prediction of Ki-67 status in gliomas. These findings highlight its potential to support preoperative decision-making. However, standardized imaging protocols, consistent thresholds, and robust prospective multicenter studies are crucial for clinical implementation

Disclosure: Nothing to disclose

EPO-0548 | The value of quantitative susceptibility mapping in differential diagnosis of Parkinson's disease and atypical parkinsonian syndrome

Y. Li; Q. Ye
The Union Hospital Affiliated to Fujian Medical University, Fuzhou, China

Background and aims: To assess brain iron deposition features in Parkinson's disease (PD) and atypical parkinsonian syndromes (APS) using Quantitative Susceptibility Mapping (QSM) and evaluate its differential diagnostic value.

Methods: This study included 80 patients (with 2-year follow-up for diagnosis confirmation) and 33 matched controls. Regional susceptibility values were obtained via manual ROI sketching. Statistical analyses (including logistic regression and ROC curve analysis) identified differential features and evaluated diagnostic performance.

Results: 1) Specific brain regions showed higher susceptibility in each group versus controls. 2) MSA-P and PSP groups had higher UPDRS-III scores and H-Y stages than PD. 3) Significant inter-group differences were found in susceptibility of the putamen, globus pallidus, and red nucleus. 4) In PD only, disease severity scores correlated with susceptibility in the putamen and red nucleus. 5) Combined putamen/globus pallidus susceptibility effectively differentiated MSA-P from PD (AUC=0.838) and

QSM Region of Interest (ROI) Mapping Diagram

Intergroup Comparison of QSM Susceptibility Values for Different Nuclei.

ROC Curve of QSM in the Differential Diagnosis of PD.

from PSP (AUC=0.873). Red nucleus susceptibility differentiated PD from PSP (AUC=0.760).

Conclusion: QSM reveals distinct iron deposition patterns (PD: substantia nigra; MSA-P: putamen/globus pallidus; PSP: red nucleus). These patterns, along with clinical correlations in PD, demonstrate the utility of QSM for differential diagnosis among Parkinsonian disorders.

Disclosure: Nothing to disclose.

Cognitive neurology/neuropsychology 4

EPO-0549 | Neurological Manifestations of Preeclampsia

S. Khudayarova; G. Rakhmatullayeva; A. Kadirova
Tashkent State Medical University, Tashkent, Uzbekistan

Background and aims: Preeclampsia is one of the leading causes of maternal morbidity and is frequently associated with central nervous system involvement, increasing the risk of neurological and cognitive complications.

Methods: A total of 120 pregnant women in the third trimester were examined: 80 patients with preeclampsia and 40 with normal pregnancy. All participants underwent clinical and neurological examination, blood pressure assessment, evaluation of proteinuria, and cognitive testing using the Montreal Cognitive Assessment (MoCA). Statistical analysis included Student's t-test, chi-square test, and Pearson correlation analysis. Differences were considered statistically significant at $p<0.05$.

Results: Neurological symptoms were observed in 67.5% of patients with preeclampsia compared to 12.5% in the control group

($p < 0.001$). The most common manifestations were headache (58.7%), visual disturbances (32.5%), and dizziness (28.7%). The mean MoCA score was significantly lower in the preeclampsia group (24.1 ± 2.3) than in controls (27.6 ± 1.8 , $p < 0.01$). A positive correlation was found between systolic blood pressure and severity of neurological symptoms ($r = 0.62$; $p < 0.01$), while proteinuria showed a negative correlation with cognitive performance ($r = -0.54$; $p < 0.05$).

Conclusion: Neurological and cognitive impairments are common in preeclampsia and are significantly associated with disease severity, highlighting the importance of early neurological monitoring in affected patients.

Disclosure: Nothing to disclose.

EPO-0550 | Long-term cognitive, emotional and quality-of-life outcomes after recovery from prolonged disorders of consciousness

D. Driessen¹; C. Utens²; G. Ribbers¹; W. van Erp²; M. Heijnenbroek - Kal¹

¹Rehabilitation Medicine, Erasmus MC, Rotterdam, the Netherlands; ²Primary Care, Radboudumc, Nijmegen, the Netherlands

Background and aims: Epidemiological studies on prolonged disorders of consciousness (PDOC) usually focus on recovery of consciousness and functional independence. However, whether recovery is meaningful to patients depends on cognitive, emotional and behavioural functioning and health-related quality of life (HRQoL) as well. We studied these factors in a nationwide PDOC cohort.

Methods: Prospective cohort study including PDOC patients ≥ 16 years admitted to the nationwide Dutch PDOC chain of care (2019–2023) with follow-up until 2 years post-admission. Outcomes included cognition (Montreal Cognitive Assessment, MoCA), emotional functioning (Hospital Anxiety and Depression Scale, HADS), neuropsychiatric symptoms (Neuropsychiatric Inventory, NPI), and HRQoL (Quality of Life after Brain Injury questionnaire, QOLIBRI). Longitudinal changes were analysed using generalized estimating equations.

Results: For 61 patients, data were available at two-year follow-up (mean age 37 years; 68% traumatic aetiology). Cognitive functioning improved significantly over time, but remained impaired in most patients: only 11% achieved a normal MoCA score at two years. Anxiety and depression decreased over time, yet persisted in a substantial proportion of patients who could complete questionnaires (15% and 30%, respectively). Neuropsychiatric symptoms were absent in 67% of patients at two years. Condition-specific HRQoL was within the normal range in 32% of patients able to complete the QOLIBRI.

Conclusion: Patients recovering from PDOC constitute a highly heterogeneous group with wide variability in cognitive, emotional and quality-of-life outcomes. While a meaningful recovery is achievable for a subset of patients, persistent cognitive and emotional sequelae are common and should be central in long-term outcome evaluation and shared decision-making.

Disclosure: Nothing to disclose

EPO-0551 | Neuropsychological assessment in obesity: Cognitive vulnerability in patients with Type 2 diabetes mellitus

D. Righi; C. Manco; A. Salvemini; G. Iraci Sareri¹; A. Bufano; N. Beneati; A. Sagnella; F. Maino; A. Cartocci; A. Tirone; C. Voglino; S. Pisirinu; N. De Stefano; M. Castagna; D. Plantone
Department of Medical, Surgical and Neurological Sciences, University of Siena, Siena, Italy

Background and aims: This study aims to assess cognitive functions, mood, and sleep quality in obese patients and evaluate their association with comorbidities, given the elevated risk of neurodegenerative diseases linked to obesity and the limited understanding of these associations

Methods: One hundred and one obese patients (80 females) were recruited and underwent a neuropsychological assessment including Montreal Cognitive Assessment (MoCA), a Rey Auditory Verbal Learning Test (RAVLT), the Beck Depression Inventory (BDI-II), and the Pittsburgh Sleep Quality Index (PSQI).

Results: Comorbidities were carefully recorded. A non-parametric statistical analysis was performed with age and BMI as covariates. The median age of our cohort was 48 years [25th–75th percentile 34–55]; the median body weight was 116 kg (25th–75th percentile 105–129); the median BMI was 43.1 (25th–75th percentile 40–45.7), and 27 patients had type 2 diabetes. The median education level was 12 years, with no difference between diabetic and non-diabetic obese individuals. Comparing the subcohort of diabetic obese patients with those without diabetes, we found significantly lower scores for MoCA ($p = 0.012$; median value 24 vs 26; 25th–75th percentile 23–25.5 vs 25th–75th percentile 24–28), immediate RAVLT ($p = 0.005$; median value 38 vs 46.5; 25th–75th percentile 33–50 vs 25th–75th percentile 41–53) and delayed recall ($p < 0.001$; median value 7 vs 10; 25th–75th percentile 4.5–9.5 vs 25th–75th percentile 7.25–12). BDI-II scores correlated with PSQI scores ($r = 0.54$; $p < 0.001$).

Cognitive and psychological measures in participants with and without type 2 diabetes mellitus (T2DM). (A–C) Boxplots comparing performance on the MoCA (A), RAVLT immediate recall (B), and RAVLT delayed recall (C). Participants with T2DM scored significantly lower.

Conclusion: Our ongoing study indicates a potential link between type 2 diabetes mellitus, obesity, and reduced cognitive performance, as evidenced by borderline/impaired MoCA scores.

Disclosure: No disclosure to declare.

EPO-0552 | Core components of apraxia differentially predict disability after stroke: Evidence from principal component analysis

E. Rounis

MRC Cognition and Brain Sciences Unit, University of Cambridge

Background and aims: Apraxia is a common but heterogeneous higher-order motor disorder after stroke, affecting 30–50% of survivors and strongly associated with disability. However, the relationship between specific apraxic deficits and functional independence remains unclear. Traditional subtypes (ideational, ideomotor, constructional) may not capture functionally relevant dimensions, and prior studies were limited by small samples and multicollinearity. Here, we identify core apraxia components that independently predict disability in the largest UK post-stroke cohort comprehensively assessed for apraxia.

Methods: Eighty-five stroke patients (mean age 60.5 ± 11 years; 42% female; median 3.6 years post-stroke) completed a comprehensive apraxia battery assessing gesture production, object use, imitation, visuospatial processing, biological motion, and executive sequencing. Eleven composite z-scores underwent principal component analysis with varimax rotation following KNN imputation. Factorability was assessed using KMO and Bartlett's test. Multiple regression examined independent predictors of instrumental activities of daily living (Frenchay Activities Index), comparing rotated and unrotated solutions.

Results: Data showed excellent factorability (KMO=0.807, Bartlett's $p < 0.001$). Varimax rotation revealed three components explaining 62% of variance: (1) Gesture/Praxis (23.2%); (2) Visuospatial/Imitation (21.4%); and (3) Executive/Sequential (17.4%). All three independently predicted iADL performance (Adj- $R^2 = 0.338$, $p < 0.001$), with Gesture/Praxis showing the strongest effect ($\beta = 0.82$, $p < 0.0001$), followed by Visuospatial/Imitation ($\beta = 0.70$, $p < 0.0001$) and Executive/Sequential abilities ($\beta = 0.36$, $p = 0.038$).

Conclusion: Apraxia fractionates into three dissociable components with differential functional impact, challenging unitary deficit models. Gesture production is the strongest determinant of independence, explaining divergent functional outcomes among patients with similar overall severity. These components likely reflect distinct neural mechanisms and argue for targeted, component-specific rehabilitation strategies.

EPO-0553 | Metabolic and bioimpedance changes associated with dietary ketosis in early cognitive decline: A pilot study

F. Filippi¹; S. Tartaglia²; I. Cancelli³; A. Pittino¹; C. Del Regno²; C. Prezza¹; N. Ditta²; V. Miele²; M. Milia²; G. Ermanis¹; G. Gigli²; M. Valente²

¹Department of Medicine (DMED), University of Udine, Udine, Italy; ²Clinical Neurology Unit, Department of Head-Neck and Neurosciences, Azienda Sanitaria Universitaria Friuli Centrale (ASUFC), Udine, Italy; ³Neurology Unit, Udine University Hospital, Udine, Italy

Background and aims: Systemic metabolic alterations and chronic low-grade inflammation are increasingly recognized as contributors to early neurodegenerative processes. Bioelectrical impedance vector analysis (BIVA), particularly phase angle, has emerged as a potential marker of cellular integrity and inflammatory status in neurological disorders.

Methods: In this single-center pilot study, patients aged 60–85 years with Mild Cognitive Impairment (MCI) or Subjective Cognitive Decline (SCD) followed one of three dietary interventions for three months: a modified ketogenic diet, a Mediterranean diet supplemented with medium-chain triglycerides (MCT), or a standard Mediterranean diet. Anthropometric measures, ketonemia, and BIVA-derived parameters (fat mass, fat-free mass, phase angle) were assessed at baseline and follow-up, alongside clinical neurological evaluation.

Results: The ketogenic diet was associated with a significant reduction in body weight and body mass index compared to the Mediterranean diet. Although changes in fat mass, lean mass, and phase angle did not reach statistical significance, patients following the ketogenic intervention showed a consistent favorable trend toward increased phase angle, suggestive of improved cellular integrity. These changes occurred in parallel with modest increases in circulating ketone levels. No adverse effects on lean mass were observed.

Conclusion: Diet-induced ketosis was associated with favorable metabolic and bioimpedance trends in patients with

FIGURE 1: The graph highlights a metabolic improvement in patients on the ketogenic diet, evidenced by an increase in phase angle, which is indicative of a reduction in systemic inflammatory status.

Disclosure: Nothing to disclose.

Methods: An electronic search was conducted in PubMed and APA PsycINFO for articles published between 1972 and July 2025, following PRISMA guidelines. A total of 503 studies were screened by title and abstract, and 62 full texts were assessed for eligibility. Each study's characteristics related to tools, populations, sociocultural effects, normative and validation data were

G. Patanè¹; A. Digiovanni¹; M. De Angelis²; G. Lovero¹; E. Grande¹; G. Committeri¹; M. Caulo¹; A. Baldassarre¹; S. Sensi¹

¹Department of Neuroscience, Imaging and Clinical Science, University "G. d'Annunzio" Chieti-Pescara, Chieti, Italy;

²Emergency Neurology and Stroke Unit, "Santo Spirito" Hospital, Pescara, Italy

Background and aims: The insular cortex is considered a cerebral hub involved in multiple cognitive domains. Ischemic strokes involving the insular cortex are often clinically under-rated, as routine assessments across acute/subacute and chronic phases often fail to capture the multifaceted complexity of this subtype of stroke. This study aims to characterize the neuropsychological and resting-state Functional Connectivity (rs-FC) profiles of patients with ischemic stroke involving the insular cortex, evaluated during the subacute and chronic stages.

Methods: Fifteen patients with subacute ischemic stroke were enrolled: seven with insular involvement and eight with strokes in other cerebral regions. All participants underwent a comprehensive neuropsychological assessment and resting-state functional MRI (rs-fMRI). Six patients with insular stroke completed a follow-up evaluation at 3–3.5 months.

Results: Compared with patients with non-insular strokes, patients with insular involvement showed significant impairments on the Trail Making Test and phonemic fluency, along with trend-level reductions on the Reading the Mind in the Eyes Test, the Ekman 36-item Faces Test, and the Rey–Osterrieth Complex Figure recall. At follow-up, emotion recognition and verbal fluency improved, whereas attentional/executive functions and visuospatial memory did not show significant recovery. Rs-FC analysis revealed reduced intra-network connectivity within the Salience Network and decreased anticorrelation between the Default Mode Network and the Frontoparietal and Dorsal Attention Networks. At follow-up, inter-network connectivity

Functional connectivity matrix showing between-group differences (two-sample t-test) between patients with insular stroke and those with non-insular stroke during the acute phase.

involving the Salience and Ventral Attention Networks showed a partial tendency toward normalization.

Conclusion: Insular stroke is associated with crucial Salience Network dysfunction and related executive–attentional deficits, with only partial recovery during the first months after the acute event.

Disclosure: Nothing to disclose.

EPO-0556 | **Perfusion Abnormality is Associated with Cognitive Impairment in Patients with Chronic Carotid or MCA Artery Occlusion**

H. Park¹; J. Cha²; J. Park³; D. Kim⁴

¹Inha University Hospital, Incheon, Korea, Republic of; ²Dong-A University Hospital, Busan, Republic of Korea; ³Catholic University of Korea Eunpyeong St. Mary's Hospital, Seoul, Republic of Korea; ⁴Department of Neurology, Konkuk University Hospital, Seoul, Republic of Korea

Background and aims: Cognitive impairment is well known to be associated with Chronic occlusion of large vessel occlusion like carotid or middle cerebral artery. It is still unclear what factors influence the occurrence of cognitive impairment in these patients. Here, we investigate the radiological and clinical parameters associated with cognitive dysfunction in the patients with chronic occlusion of carotid artery.

Methods: From unicentric, prospectively collected stroke registry, we enrolled the patients who had chronic carotid or MCA occlusion and who took MMSE at admission and 2 years later simultaneously. We excluded patients with severe neurologic deficit or aphasia or the patients with stroke recurrence. We analyzed the results of MMSE, the clinical history, and radiological findings in these patients.

Results: Among the patients with chronic carotid or MCA artery occlusion, a total of 105 patients were enrolled. The mean age was 76 ± 15 years and 62 patients were men. During the median follow-up of 26.8 months, 75 patients showed aggravation of MMSE score. The multivariate analysis demonstrated the old age (75 or older), diabetes mellitus, atrial fibrillation and perfusion abnormality in lesion area. The site of occlusion, HbA1c level, or type of antithrombotic agent was not associated with cognitive deterioration.

Conclusion: Cognitive aggravation is common in the patients with chronic occlusion of carotid or MCA artery occlusion. Perfusion status at baseline appears to be a good predictor of cognitive impairment, suggesting that interventions aimed at improving perfusion deficits may have beneficial effects.

Disclosure: Nothing to disclose.

EPO-0557 | **Selective Executive and Attentional Dysfunction in Chronic Obstructive Pulmonary Disease**

H. Dikbas¹; R. Cörüt²

FIGURE 1 Distribution of cognitive status in individuals with and without COPD.

TABLE 1 comparison of cognitive test results in individuals with and without COPD.

Variables	Non-COPD (n=61)		COPD (n=86)		p
	n	%	n	%	
Cognitive status					
Normal	49	78.7	34	39.5	0.000
MCI	11	18.0	38	44.1	
AD	1	1.6	14	16.3	
MMSE score	Mean ± SD Median (Min-Max)		Mean ± SD Median (Min-Max)		p
MMSE score	26.25 ± 5.32 21 (17-30)		21.83 ± 5.43 22 (11-30)		0.119
MoCA score	25.90 ± 2.88 27 (16-30)		21.27 ± 3.14 28 (13-30)		0.236
Semantic fluency	18.72 ± 6.17 17 (9-25)		18.33 ± 6.36 21.5 (7-25)		0.381
Phonemic fluency	17.75 ± 6.00 18 (7-27)		17.41 ± 6.81 17 (7-28)		0.737
Clock drawing test	8.64 ± 3.77 9 (3-16)		8.33 ± 3.89 9 (6-20)		0.119
Stroop word reading time (s)	44.40 ± 12.33 40 (32-60)		46.59 ± 16.73 46 (32-82)		<0.000*
Stroop color naming time (s)	43.25 ± 12.80 37 (25-70)		47.44 ± 16.32 48 (34-74)		0.019

inflammation, and oxidative stress, mechanisms also implicated in neurodegenerative disorders. While an increased prevalence of dementia has been reported in COPD, data regarding mild cognitive impairment (MCI) and Alzheimer's disease (AD) remain limited.

Methods: This cross-sectional case-control study included 147 participants: 86 patients with COPD and 61 age- and sex-matched controls. Cognitive assessment comprised the Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MoCA), semantic and phonemic fluency tests, clock drawing test, and Stroop test. Clinical characteristics, pulmonary function parameters, oxygen saturation (SpO₂), inflammatory markers, and COPD severity indices were recorded. Group comparisons, correlation analyses, and multivariable path analysis were performed.

Results: The prevalence of MCI was higher in patients with COPD compared to controls (30.2% vs. 18.0%), whereas AD prevalence was similar between groups (Figure 1). MMSE and MoCA did not differ significantly. COPD patients demonstrated significantly prolonged Stroop word reading times, indicating impaired executive function and attention (Table-1). Lower SpO₂ levels and higher dyspnea severity were significantly associated with worse cognitive performance. In multivariable path analysis adjusting for age, sex, smoking status, body mass index, and C-reactive protein, COPD presence remained independently associated with prolonged Stroop word reading time ($\beta=0.22$, $p=0.004$), explaining 14.7% of the variance.

Conclusion: COPD is associated with selective cognitive impairment, predominantly affecting executive functions and attention, independent of systemic inflammation. Hypoxemia and dyspnea may play an important role in this association. Patients with COPD may benefit from cognitive screening targeting executive functions.

Disclosure: Nothing to disclose.

Background and aims: Alzheimer's disease can begin as mild cognitive impairment (MCI), a prodromal stage that requires sensitive detection. Traditional screening may show insufficient sensitivity and access to neuropsychological testing is limited. As speech problems could precede other clinical symptoms, this study reviews digital/automated speech-based methods and evaluates their diagnostic performance.

Methods: A systematic search was conducted in PubMed, EMBASE, WoS, SCOPUS, IEEE-Xplore, ACM Digital Library, and Cochrane Central in studies published between 2015 and 2025. Observational studies involving adults with MCI and cognitively unimpaired (CU) controls using automated speech biomarkers and reporting diagnostic accuracy were included. A diagnostic accuracy meta-analysis was performed using hierarchical models to pool sensitivity, specificity, and summary ROC estimates. Quality and risk of bias were assessed using QUADAS-2.

Results: After duplicate removal, 3,735 records were screened, of which 34 studies met the predefined inclusion criteria; 68% were observational, cross-sectional studies. Overall, 9,957 participants were analyzed, including 1,852 individuals with MCI and 3,375 CU control. Most of the studies employed automated analysis (67.7%) with supervised machine learning and hybrid acoustic-linguistic biomarkers (41.2%). Diagnostic accuracy demonstrated considerable heterogeneity, with pooled analysis

FIGURE 1 PRISMA 2020 flow diagram.

FIGURE 2 SROC curve for diagnostic performance of digital speech biomarkers in MCI. The positive likelihood ratio was 5.34 (95% CI 4.06–7.02) and the negative likelihood ratio was 0.26 (95% CI 0.21–0.31).

sensitivity and specificity of 0.78 (95% CI=0.74–0.82) and 0.85 (95% CI=0.81–0.89), respectively. There was moderate between-study heterogeneity for sensitivity ($\sigma^2=0.23$) and substantial heterogeneity for specificity ($\sigma^2=1.13$).

Conclusion: Automated speech-based biomarkers show promising diagnostic performance for MCI, supporting potential integration into dementia screening pathways.

Disclosure: Nothing to disclose.

EPO-0559 | Cognitive, neuropsychiatric and electrophysiological changes in post COVID-19 patients - A 6 months trajectory

S. Panda¹; R. Naik¹; S. Tiwari²; G. Bohra³

¹Department of Neurology, All India Institute of Medical Sciences, Jodhpur, India; ²Department of Diagnostic and Interventional Radiology All India Institute of Medical Sciences, Jodhpur, India; ³Department of Medicine All India Institute of Medical Sciences, Jodhpur, India

Background and aims: Post-Coronavirus disease 2019 (COVID-19) condition is frequently associated with persistent cognitive decline, neuropsychiatric symptoms, and fatigue. This study aimed to evaluate the trajectory of cognitive function, neuropsychiatric manifestations, and electrophysiological changes in post-COVID-19 patients over a 6-month follow-up period.

Methods: This prospective, hospital-based observational study included patients with a confirmed history of COVID-19 infection at least 6 months prior to enrolment. Cognitive function, anxiety, depression, and fatigue were assessed using standardized clinical scales, and P300 event-related potentials were recorded at baseline and after 6 months.

Results: Among 102 patients, cognitive impairment was observed in 38.2% at baseline, predominantly mild in severity. At

FIGURE 1: Bar graph illustrating the proportion of patients with abnormal scores on neuropsychiatric scales at baseline and at 6-month follow-up. Anxiety, depression, fatigue and P300 abnormalities remained highly prevalent with an observed increase over.

TABLE 1 Comparison of neuropsychiatric and electrophysiological parameters at baseline and 6-month follow-up.

Test	Timeline 1 n=102 Median (Q1-Q3)	Timeline 2 n=73 Median (Q1-Q3)	P value
II-MoCA	26 (24–27)	26 (24–28)	0.088
FAB	16 (15–18)	16 (14–17)	0.043*
HAM-A	17 (9–25.25)	16 (7.5–25)	0.305
HDRS	13 (6–20)	16 (7–22.5)	<0.001*
FSS	31 (14.75–50)	32 (15.5–51)	<0.001*
P300 LATENCY (ms)	343 (322–361)	354 (340.5–393.5)	0.005*
P300 AMPLITUDE (μV)	12.1 (9.27–16)	8.8 (7.25–13.15)	<0.001*

* Statistically significant ($p < 0.05$)

Abbreviations:

II-MoCA, Hindi version of Montreal Cognitive Assessment; FAB, Frontal Assessment Battery; HAM-A, Hamilton Anxiety Rating Scale; HDRS, Hamilton Depression Rating Scale; FSS, Fatigue Severity Scale; P300, event-related potential.

6-month follow-up, cognitive dysfunction was present in 43.8% of patients. Anxiety (80.4%), depression (69.6%), and fatigue (46.1%) were highly prevalent **Figure 1** Electrophysiologically, prolonged P300 latency was noted in 48% of patients at baseline, increasing to 61.6% at follow-up (Table 1). Patients with baseline cognitive impairment demonstrated significantly worse frontal lobe function, anxiety, depression, and fatigue scores compared to cognitively preserved individuals (p 0.0001, 0.002, 0.003 and 0.043 respectively) (Table 2). Notably, P300 abnormalities were also observed in patients without clinically evident cognitive decline.

Conclusion: Persistent and progressive cognitive, neuropsychiatric, and electrophysiological abnormalities were observed in post-COVID-19 patients over a 6-month period. Cognitive dysfunction, depression, and fatigue may worsen over time, even long after acute infection. P300 abnormalities may precede clinically apparent cognitive decline, highlighting their potential

EPO-0560 | Multidimensional fatigue relates to disability severity and personal well-being in multiple sclerosis

J. Duranović¹; S. Pavelin²; M. Rogić Vidaković¹
¹Laboratory for Human and Experimental Neurophysiology (LAHEN), Department of Neuroscience, School of Medicine, University of Split, Split, Croatia; ²Department of Neurology, University Hospital of Split, Split, Croatia

Background and aims: Fatigue is one of the most common symptoms of multiple sclerosis (MS), negatively affecting daily functioning and well-being. Understanding the relationships between different fatigue domains, disability status, and personal well-being is necessary for practical interventions. The aim of this study was to examine the relationships between multidimensional fatigue, disability status, and personal well-being in people with MS.

Methods: A total of 141 MS subjects participated in the study, with an average age of 47 years, of whom 104 (74%) were female. The median EDSS was 3, and the average disease duration was 9 years. All subjects completed the Modified Fatigue Impact Scale (MFIS) and the Personal Wellbeing Index – Adult (PWI-A), while an expert neurologist completed the Expanded Disability Status Scale (EDSS).

Results: Pearson correlation analyses showed moderate to strong positive associations between all fatigue domains (physical, cognitive, psychosocial, and total) and disability ($r=0.43$ – $.56$, $p<0.001$), and strong negative associations with personal well-being ($r=-.71$ to $-.74$, $p<0.001$).

Conclusion: Higher multidimensional fatigue is strongly associated with higher disability status and lower personal well-being.
Disclosure: This study was conducted as part of the Croatian Science Foundation project [HRZZ-IP-2022-10-6203] at the Department of Neurology, University Hospital Split, and the Department of Neuroscience, Laboratory for Human and Experimental Neurophysiology (LAHEN), University of Split School of Medicine.

Epilepsy 4

EPO-0561 | IP3R2 deletion alters glutamate dynamics and increases mortality in a mouse model of temporal lobe epilepsy

C. G. Nome¹; C. B. Bakketu²; T. Berger²; V. Jensen¹; L. Roth¹; K. Heuser²; R. Enger¹
¹GliaLab and Letten Centre, Division of Anatomy, Department of Molecular Medicine, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway; ²Department of Neurology, Oslo University Hospital, Oslo, Norway

Background and aims: Inositol 1,4,5-trisphosphate receptor 2 (IP3R2)-mediated Ca²⁺ signaling has been implicated in epilepsy pathogenesis, potentially through Ca²⁺-dependent astrocytic release of glutamate.

Methods: In this study, we examined the contribution of IP3R2 to activity-evoked astrocytic Ca²⁺ signals and extracellular glutamate dynamics during epileptogenesis in a mouse model of temporal lobe epilepsy with hippocampal sclerosis. To do this, we used adeno-associated viral vectors to genetically express fluorescent reporters for intracellular Ca²⁺ and extracellular glutamate in hippocampal slices from mice

Results: We found that IP3R2 knockout mice showed markedly increased mortality in the days following kainate-induced status epilepticus. Among survivors, activity-evoked glutamate responses were reduced 10 days after status epilepticus, which may reflect enhanced neuronal loss.

Conclusion: Overall, our findings indicate that IP3R2-mediated Ca²⁺ signaling, despite its proposed proconvulsant role in acute seizures, may be neuroprotective during epileptogenesis by supporting survival and preserving activity-evoked glutamate signaling.

EPO-0562 | Continuous versus routine EEG impact on the management of critically ill adults: Analysis of the CERTA study

C. Robitaille¹; J. Novy¹; V. Alvarez²; K. Schindler³; S. Rüegg⁴; A. Rossetti¹
¹1. Department of Neurology, Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland; ²2. Department of Neurology, Hôpital du Valais, Sion, Switzerland; ³3. Sleep-Wake-Epilepsy-Center, Department of Neurology, Inselspital, Bern University Hospital and University of Bern, Bern, Switzerland; ⁴4. Department of Neurology, University Hospital Basel and University of Basel, Basle, Switzerland

Background and aims: Continuous electroencephalogram (cEEG) is increasingly utilized in the intensive care unit for consciousness-impaired patients with various conditions. It is however costly in terms of material and human resources, and its impact on prognosis compared with routine EEG (rEEG) remains debated. We aimed to characterize the effect of cEEG vs rEEG on clinical management modifications, and to determine if these modifications were linked to a better outcome.

Methods: This is an ancillary analysis using data of the patients enrolled in the CERTA trial (NCT03129438), a randomized control trial comparing cEEG versus repeated rEEG in critically ill adults with altered consciousness. Clinical management modifications due to the EEG intervention, defined as performed within 60 hours of EEG start, were prospectively recorded (anti-seizure medication -ASM, sedation, new radiological examination, surgical intervention, intensive care withdrawal). Correlation with the EEG type were analyzed by 2x2 tables; Mantel-Haenszel tests explored the impact on mortality and functional outcome at 6 months.

Results: We included 182 patients each in the cEEG and rEEG groups. ASM were modified in 22.0% (cEEG) and 12.1% (rEEG) ($p=0.012$), while 58.2% of cEEG and 48.4% of rEEG patients had any change of management ($p=0.018$) (ASM, sedation, new radiological examination, new surgical intervention and care withdrawal). Adjusting for the impact of ASM modifications, mortality ($p=0.845$) and functional outcome ($p=0.729$) remained similar across EEG intervention groups.

Conclusion: In critically ill adults, cEEG is statistically associated with modifications of clinical management, particularly regarding ASM, compared to repeated rEEG, but does not translate into improved patients' outcomes.

Disclosure: Nothing to disclose.

EPO-0563 | The many faces of Lafora progressive myoclonus epilepsy – the Swiss cohort

E. Boudriot¹; O. Kohnen¹; L. Imbach²

¹Swiss Epilepsy Center, Klinik Lengg, Zurich, Switzerland;

²Institute for Neuroscience, Department of Health Sciences and Technology, ETH Zurich, Zurich, Switzerland

Background and aims: Lafora progressive myoclonus epilepsy (PME) is an ultra-rare autosomal-recessive neurodegenerative disorder with onset in adolescence. The prevalence is estimated around four cases per million individuals with higher numbers in Mediterranean countries. It is caused by loss-of-function mutations in EPM2A or EPM2B/NHLRC1 genes. With currently no directed therapy available and increasing pharmacoresistance in the disease course, most patients die within a decade after symptom onset. Comprehensive data on the electroclinical disease course are rare due to scarcity of the disease, delayed diagnosis, and rapid disease progression.

Methods: We retrospectively analysed clinical and electroencephalographic data from the medical records of three patients with a genetic diagnosis of Lafora PME at the Swiss epilepsy center between 2019 and 2025. To our knowledge, these are currently the only Lafora patients in Switzerland.

Results: Patient 1 presented with discrete bilateral myoclonia, followed by focal visual seizures, clustering of atypical absences, and progressing to super-refractory non-convulsive

status epilepticus within 8 months, being rescued only by the implantation of deep brain stimulation into the anterior nucleus of the thalamus (ANT-DBS). Patient 2 was diagnosed after an initial bilateral tonic-clonic seizure and later developed prominent myoclonic-tonic-clonic seizures. Patient 3 showed frequent eyelid myoclonia and eye closure sensitivity on EEG, leading to the initial diagnosis of epilepsy with eyelid myoclonia (formerly Jeavons syndrome). All patients showed progressive drug-resistant myoclonus, progressive cognitive deterioration and electrographic status epilepticus with background slowing over time.

Conclusion: Lafora disease can present with many different initial symptoms, clinically prominent features, and dynamics of disease course.

Disclosure: Nothing to disclose.

EPO-0564 | Duration matters: Prognostic cut-offs of status epilepticus beyond established predictors

F. Iannaccone; C. Scarpitta; E. Bonanni; R. Ceravolo; C. Pizzanelli

Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Pisa, Italy

Background and aims: Status epilepticus (SE) is a time-dependent neurological emergency. While baseline clinical predictors are well established, the prognostic role of SE duration remains incompletely defined. We aimed to identify clinically relevant duration cut-offs for major outcomes and to assess the impact of diagnostic delay on SE duration in nonconvulsive SE (NCSE).

Methods: We retrospectively analyzed 73 consecutive adult patients admitted for SE between January 2024 and August 2025. Outcomes were SE resolution, 30-day mortality, and functional worsening at discharge. Multivariable models included established prognostic predictors and SE duration. Receiver operating characteristic analysis identified prognostic duration cut-offs. In NCSE, the association between onset-to-electroencephalography time and total SE duration was evaluated.

Results: SE resolved in 82.2% of patients; 30-day mortality was 39.7%, and functional worsening occurred in 57.5%. When compared with established predictors, SE duration showed an independent prognostic value for non-resolution and functional worsening. A duration ≥ 108 hours was associated with an approximately eleven-fold increased risk of non-resolution, while a duration ≥ 52 hours increased the risk of functional worsening nearly twelve-fold. SE duration was not independently associated with 30-day mortality. In NCSE, longer onset-to-electroencephalography time was significantly associated with longer SE duration.

Conclusion: SE duration provides prognostic information beyond established predictors, particularly for refractoriness and functional outcome. In NCSE, diagnostic delay contributes to prolonged SE, highlighting electroencephalography timing as a modifiable determinant of outcome.

Disclosure: Nothing to disclose.

EPO-0565 | Real-world effectiveness and safety of fenfluramine in adults with Dravet syndrome and Lennox–Gastaut syndrome: A retrospective single-centre study

I. Dolezalova; O. Strycek; J. Kocvarova; M. Pail; M. Brazdil
Brno Epilepsy Center, member of ERN-EpiCare, St. Anne's
University Hospital and Masaryk University, Brno, Czech
Republic

Background and aims: Evidence for fenfluramine in Dravet syndrome (DS) and Lennox–Gastaut syndrome (LGS) is largely derived from paediatric cohorts, while real-world data in adults are scarce. We evaluated the effectiveness and safety of fenfluramine in adults with long-standing, drug-resistant epilepsy.

Methods: We retrospectively identified adults with DS or LGS who initiated fenfluramine between January 2024 and August 2025. Fifteen patients were included (DS $n=9$; LGS $n=6$). All DS cases had confirmed SCN1A variants; LGS etiologies were structural ($n=2$), genetic ($n=1$), or unknown ($n=3$). Patients were highly pharmacoresistant (9–17 lifetime antiseizure medications; 2–5 at initiation). Median disease duration was 31 years. Effectiveness was assessed as percentage seizure reduction at 6 months ($n=15$) and 12 months ($n=9$). Safety and discontinuations were recorded retrospectively.

Results: At 6 months, 86.7% achieved a clinical response and 13.3% were non-responders, most commonly with $\geq 50\%$ seizure reduction. At 12 months, all evaluable patients (100%) showed sustained benefit. Treatment was discontinued in 13.3% due to inefficacy with or without adverse events. Adverse events occurred in 53.3%, mainly gastrointestinal symptoms, fatigue/somnolence, reduced appetite with weight loss, and behavioural changes; 20% reported improved attention.

Conclusion: In this real-world adult cohort with long-standing, highly refractory DS and LGS, fenfluramine was associated with substantial and sustained seizure reduction and an acceptable safety profile. These findings support the use of fenfluramine as an effective add-on therapy beyond childhood and highlight its potential benefit even in chronically treated adult patients.

Disclosure: Nothing to disclose.

EPO-0566 | Fast-ripples are an emergent property of neural networks

⁵Institute of Cognitive Neuroscience, University College London, London, UK; ⁶Division of Psychiatry, University College London, London, UK; ⁷Department of Neuroscience, Physiology and Pharmacology, University College London, London, UK

Background and aims: Fast-ripples have been proposed as a promising biomarker in epilepsy, but their specificity remains unclear. In particular, it is unclear whether they reflect chance coincident neural activity or distinctly generated pathological entities.

Methods: Here, we used a multi-modal approach combining in silico simulations, neuronal cultures, a rodent model of temporal lobe epilepsy and microwire recordings in humans with epilepsy to test, using a within-subjects design, whether fast-ripples occur more frequently than predicted by the random firing of neurons. For chance level, we used signal shuffling to disrupt any distinct pathological entities and to generate only fast-ripples arising from stochastic aggregation of action potentials. Furthermore, since evidence suggests that fast-ripples incidence varies across the sleep–wake cycle, we assessed whether the relative proportion of “chance” fast-ripples is modulated across vigilance states.

Results: We found that, both in vitro and in sleeping rodents, the incidence of fast-ripples did not exceed chance levels. Our simulations predicted an increased rate of fast-ripples during wakefulness, when firing rates are higher and less synchronized across neurons. This was confirmed in a rodent model of epilepsy, where fast-ripples were also more frequent than expected by chance but still represented a minority of all detected events. This was also the case in awake human recordings.

Conclusion: Our findings suggest that most fast-ripples reflect general network activity rather than distinctly generated pathological entities, challenging prevailing assumptions about their pathogenesis and biomarker specificity.

EPO-0567 | Can statins influence the risk of remote seizure after a first new onset status epilepticus? Data from the adult population of Modena, Northern Italy

N. Orlandi¹; G. Giovannini²; J. Ngnintedem Dontsop³; L. Taruffi¹; M. Burani¹; M. Malerba²; S. Scolastico¹; L. Madrassi¹; L. Affronte²; A. Vaudano²; M. Pugnaghi²; S. Lattanzi⁴; S. Meletti²

¹Department of Biomedical, Metabolic and Neural Science, University of Modena and Reggio Emilia, Modena, Italy;

²Neurophysiology Unit, Neuroscience Department, Azienda Ospedaliera-Universitaria, Modena, Italy; ³School of Medicine, University of Modena and Reggio Emilia, Modena, Italy;

⁴Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University, Ancona, Italy

Background and aims: Preclinical evidence supports the role of statins as antiepileptogenic agents. In this study, we investigated the risk of remote unprovoked seizures (RS) according to the use of statin therapy in a cohort of first ever status epilepticus (SE) survivors.

Methods: Observational, single-center, retrospective study in adult patients with a first SE who were consecutively admitted to Modena Academic Hospital, Italy, from September 2015 to December 2023. Kaplan–Meier survival analyses were used to calculate the probability of RS following the index event, while Cox proportional hazard regression models were used to assess predictors of RS occurrence. Competing-risk regression model was used as sensitivity analysis to assess the impact of mortality as a competing event with the occurrence of RS.

Results: 314 patients were included (mean age 70 y/o; 63% females), 86 (27.4%) of whom were taking statins. Overall, 67

patients (21.3%) developed RS (mean follow-up: 31.5 months). Cumulative probability of RS occurrence was 16% and 32% at 12 months and 5 years after SE, respectively. Cumulative probability of RS was significantly lower in statin users compared to non-users (log rank $p=0.038$). After adjusting for potential confounders, the risk of RS was lower in patients who assumed statins after the index event (HR 0.48 95% CI 0.26 – 0.90; $p=0.023$).

Conclusion: In our cohort, statin exposure was associated to a lower incidence of RS. Our findings expand the knowledge regarding a possible neuroprotective and antiepileptogenic role of statins after SE and support further studies on this field.

assess the efficacy and tolerability of perampanel (PER) as the sole additional antiseizure medication (ASM) in brain tumor-related epilepsy (BRTE).

Methods: we performed a subgroup analysis of patients with BRTE included in the PEROC study cohort [2], a retrospective, longitudinal, multicentre observational study enrolling patients with focal or generalized epilepsy receiving PER added to a single concomitant ASM. Retention, responder rate, seizure freedom and adverse event (AE) frequency at 3, 6 and 12 months after PER introduction were evaluated, also comparing early (≤ 1 prior ASM) vs late PER add-on.

Results: forty-six patients were included (23 female, median age: 51 years). The median PER dose at 12 months was 4 mg. Retention rates were 90%, 82.9%, and 70.8% at 3, 6, and 12 months. Responder rates were 60% at 3, 80.6% at 6, and 76.5% at the same time points. Seizure freedom was achieved in 36.7%, 45.2% and 47.1% of patients after 3, 6 and 12 months. AEs were reported in 15.2% of patients, leading to treatment discontinuation in 6.5%. No significant differences were observed between early and late add-on groups for any outcome.

Conclusion: PER proved to be an effective and well-tolerated treatment option for BTRE, providing satisfactory seizure control and good treatment retention. Although confirmation from larger prospective studies is needed, PER may represent a valuable strategy to improve seizure management and quality of life in this population

Disclosure: Nothing to disclose.

EPO-0569 | Clinical characteristics, comorbidities, and healthcare utilization in patients with psychogenic nonepileptic seizures: A retrospective study

S. Bashayreh¹; A. Momani¹; K. Kheirallah¹; A. Yassin¹; M. Alhazaimeh²

¹Neurology, Jordan University of Science and Technology, Irbid, Jordan; ²Neurosurgery, Yarmouk University, Irbid, Jordan

Background and aims: Psychogenic nonepileptic seizures (PNES) are paroxysmal events that resemble epileptic seizures but occur without ictal epileptiform activity. Diagnosis is frequently delayed, and many patients are initially misdiagnosed with epilepsy, leading to unnecessary anti-seizure medication (ASM) use and increased healthcare utilization. Regional data describing the clinical characteristics and burden of PNES remain limited.

Methods: We retrospectively reviewed patients evaluated for suspected psychogenic nonepileptic seizures (PNES) using outpatient video-EEG (1–6 hours) at King Abdullah University Hospital between 2018 and 2022. PNES was defined as a typical clinical event captured without ictal EEG changes. Patients with exclusively subjective symptoms were excluded. Demographic, clinical, diagnostic, treatment, and healthcare utilization data were analyzed descriptively.

Results: Among 59 patients with PNES, 57.6% were female and psychiatric comorbidities were common. Events were captured on video-EEG in 83.1%, with 74.6% being typical habitual events, and epileptiform discharges were uncommon (13.6%). Semiology was heterogeneous using Pooya and Wadwekar classifications. MRI was mostly normal or non-specific, ≈68% had received ASMs, often polytherapy, and healthcare utilization prior to diagnosis was high.

Conclusion: Psychogenic nonepileptic seizures are associated with heterogeneous clinical presentations, high psychiatric comorbidity, substantial healthcare utilization, and frequent exposure to anti-seizure medications prior to diagnosis. This study adds regional, real-world data on the clinical characteristics, diagnostic evaluation, and healthcare utilization associated with PNES, reinforcing existing evidence while highlighting the burden of delayed diagnosis in routine practice.

Disclosure: Nothing to disclose

EPO-0570 | An optimized clinical algorithm for selecting DEE-SWAS patients for whole exome sequencing

S. Shokhimardonov; N. Tuychibaeva
Tashkent State Medical University, Tashkent, Uzbekistan

Background and aims: Developmental and epileptic encephalopathy with spike-wave activation in sleep (DEE-SWAS) is a clinically heterogeneous disorder with a substantial genetic contribution. Whole exome sequencing (WES) is not routinely accessible for all patients, highlighting the need for rational selection strategies.

Methods: A retrospective cohort of 125 pediatric patients with DEE-SWAS was analyzed. Clinical characteristics, cognitive outcomes, treatment response, family history, and brain magnetic resonance imaging (MRI) findings were collected.

Electroencephalography (EEG) recordings during non-rapid eye movement sleep were reviewed, and spike-wave index (SWI) was calculated. A scoring algorithm was developed assigning one point to each of seven criteria: SWI >85% or pronounced SWAS pattern, full-scale intelligence quotient (FSIQ) <70, pharmacoresistant epilepsy or need for intensified therapy, absence of a convincing structural MRI cause, epilepsy onset ≤4 years, positive family history of epilepsy or febrile seizures, and parental consanguinity. Patients were stratified into low (0–2), moderate (3–4), and high (≥5) genetic risk groups. Multivariable logistic regression was performed to identify independent predictors of monogenic etiology.

Results: High SWI, severe cognitive impairment, pharmacoresistance, absence of structural MRI abnormalities, positive family history, and parental consanguinity were independently associated with monogenic disease (odds ratios 1.8–4.9; all $p < 0.05$).

Conclusion: A weighted clinical, EEG, and MRI-based algorithm effectively stratifies DEE-SWAS patients according to genetic risk and supports targeted referral for WES. This approach improves diagnostic efficiency and may facilitate earlier etiological clarification in routine clinical practice.

Disclosure: Nothing to disclose.

EPO-0571 | Vagus Nerve Stimulation in Failed Epilepsy Surgery: 36 Month Outcomes From the CORE-VNS Study

S. Fetzter¹; E. Nicolai¹; K. Sierazdan²; M. Fry³; O. Schijns⁴; K. Rijkers⁴; R. Verner¹; S. Baesa⁵; N. Kurwale⁶; G. Giannicola¹; C. Gordon¹; A. Moon¹; F. Beraldi⁷; A. Sen⁸; K. Nichol¹

¹LivaNova PLC (or a subsidiary); ²Southmead Hospital (North Bristol NHS Trust), Bristol, England, UK; ³Department of Neurosurgery, Cleveland Clinic, Ohio; ⁴Department of Neurosurgery, Academic Center for Epileptology, Maastricht University Hospital, The Netherlands; ⁵Neurosciences Department, King Faisal Specialist Hospital and Research Centre, Jeddah, Saudi Arabia; ⁶Deenanath Mangeshkar Hospital and Research Centre, Pune, India; ⁷Valos S.r.L, Genova Italy; ⁸Oxford Epilepsy Research Group, John Radcliffe Hospital, Oxford, UK

Background and aims: The safety and effectiveness of VNS Therapy are evaluated in individuals who have (+Hx) and have not (-Hx) previously undergone brain surgical procedures for epilepsy.

Methods: The impact of +Hx on the safety profile and change in seizure frequency of severe seizure types (Focal Impaired Awareness Motor [FIA-M], Focal Impaired Awareness Non-Motor [FIA-NM], Focal-to-Bilateral Tonic-Clonic [FBTC], and Generalized Tonic-Clonic [GTC]) is evaluated.

Results: Of the 464 participants with -Hx 446 were included in the modified safety population (mSAF). Lesionectomy, callosotomy, and lobar resection were the 3 most frequently reported therapeutic brain surgeries in the 84 participants with +Hx in the mSAF. At 36 months, participants with +Hx experienced a median percentage change in frequency of FIA-M by -36.1% ($n=28$), FIA-NM by -83.3% ($n=18$), FBTC by -91.7% ($n=19$), and GTC by -84% ($n=5$). In the -Hx participants this was -86.1% ($n=131$), -100% ($n=72$), -96.7% ($n=73$), and -83.5%

($n = 78$) respectively. In those with a +Hx and -Hx, complete seizure freedom (zero seizures over the previous 3 months) was reported at the first 3 month visit in 6.9% (5/72) and 8.8% (29/329) respectively. At the 36-month visit, 8.8% (6/68) and 18% (58/323) reported complete seizure freedom, respectively. The overall incidence of adverse events (AEs) was similar between groups, 36.9% +Hx and 41.0% -Hx. Serious AEs were observed in 3.6% and 7.2% respectively.

Conclusion: Adjunctive VNS Therapy was found to have consistent safety and effectiveness in participants with +Hx and -Hx epilepsy brain surgery. In addition, SF was reported in 8.8% of participants.

Burns School of Medicine, Honolulu, USA; ¹²Oxford Epilepsy Research Group, John Radcliffe Hospital, Oxford, UK

Background and aims: The CORE-VNS represents the first large cohort of prospectively gathered pediatric data on the effectiveness of VNS Therapy for DRE.

Methods: The CORE-VNS (NCT03529045) study collected data on seizure and non-seizure outcomes following treatment with VNS Therapy. Participants 4- <18 (children) who received their first VNS Therapy were selected for this analysis. Seizure frequency reduction of defined most severe seizures and patient-described outcome measures (quality of life and quality of sleep) were collected at baseline and at 3, 6, 12, 24, and 36 months.

Results: 213 met the criteria for this analysis. Certain seizure types were more commonly described in this analysis as most disabling (focal impaired aware motor (FIA-M), focal impaired aware non-motor (FIA-NM), focal to bilateral tonic-clonic (FBTC), and generalized tonic-clonic seizures (GTC)). Seizure frequency reduction was reported in all seizure types across age groups early (3-month visit) in the study. At the 36-month follow-up, children had a median seizure reduction of 86.7% FIA-M, 100% FIA-NM, 100% FBTC, and 75.2% GTC. At 36 months, 80.3% reported their quality of life as very good/pretty good/good and bad. The most reported (~5%) adverse events were cough and dysphonia.

Conclusion: Adjunctive VNS Therapy reduced the most severe disabling seizures in children early after implantation with sustained effectiveness and improved quality of life at 36 months.

Disclosure: GG, RV, KN, FB, CG, MD, and DU are employees of LivaNova PLC (or a subsidiary) and may hold stock or stock options with the company, who is the manufacturer of the VNS Therapy System. All other authors are investigators associated with the CORE-VNS Study, and in that capacity they or their institutions receive compensation from LivaNova for study-related activities. EPO-0573 | Venous sinus stenting in idiopathic intracranial hypertension: A prospective interventional study of safety and efficacy

A. Mohamed Abd El-Moneam¹; H. Rashad El-habashy²; A. Abdelkader Nemr³; M. Atallah⁴

¹MSc, Armed Forces College of Medicine, Neurology department, Maadi Armed Forces Medical Complex, Cairo, Egypt; ²MD, Armed Forces College of Medicine, Cairo, Egypt; ³MD, Neurology department, Maadi Armed Forces Medical Complex, Cairo, Egypt; ⁴MD, Armed Forces College of Medicine, Cairo, Egypt

Background and aims: Idiopathic Intracranial Hypertension (IIH) with bilateral transverse-sigmoid venous sinus stenosis is a debilitating condition with limited effective treatments. This study aimed to evaluate the safety and effectiveness of venous sinus stenting (VSS) in medically refractory IIH patients, focusing on clinical outcomes and objective physiological parameters.

Methods: A prospective, single-arm interventional study was conducted across two tertiary centers in Cairo, Egypt, over nine months. Twenty-four patients (median age 35.5 years; 95.8% female) with IIH and bilateral venous sinus stenosis confirmed by magnetic resonance venography underwent VSS using self-expanding stents across stenotic segments. Inclusion criteria included failure of medical therapy, papilledema grade $\geq$ II, and trans-stenotic pressure gradient $>8-10$ mmHg. Pre- and post-intervention assessments comprised intracranial pressure (CSF opening pressure), venous pressure gradients, optical coherence tomography, visual evoked potentials, and visual field perimetry. Follow-up was performed at 1 and 6 months.

Results: All patients demonstrated significant improvement in symptoms and objective measures. Headache severity reduced markedly ($p < 0.001$); papilledema resolved in 100% of affected

Pre venous sinus stenting pressure gradient.

Post venous sinus stenting pressure gradient.

Figure (4): VPG & CSF of pre and post Intervention.

VPG & CSF of pre and post Intervention.

cases. Median venous pressure gradient decreased from 12.5 to 2 mmHg, and cerebrospinal fluid opening pressure reduced from 36.45 ± 5.83 to 19.54 ± 2.6 Cm H₂O ($p < 0.001$). Visual

evoked potential parameters improved significantly, reflecting enhanced optic nerve function. No complications, stent migration, or symptom recurrence occurred during follow-up.

Conclusion: Venous sinus stenting is a safe and effective therapeutic option for medically refractory IIH with venous sinus stenosis. It significantly lowers intracranial pressure, resolves papilledema, and improves visual function, supporting its role as a minimally invasive alternative in selected patients.

EPO-0574 | Increased neuroimmune and neurotrophic responses to a migraine trigger after prenatal immune activation

A. Yakubova¹; S. Svitko²; K. Gilizhdinova²; A. Rizvanov¹; G. Sitdikova²

¹Openlab "Gene and Cell Technologies", Kazan Federal University, Kazan, Russian Federation; ²Department of Human and Animal Physiology, Kazan Federal University, Kazan, Russian Federation

Background and aims: Prenatal immune activation (PIA) induced by maternal lipopolysaccharide (LPS) exposure is considered as a factor capable of altering neuroimmune reactivity in adulthood. In this study, we analyzed how prenatal LPS exposure modifies migraine responses by assessing biochemical markers in a model of migraine induced by a single nitroglycerin (NTG) injection.

Methods: This study included 16 adult male Wistar rats. Levels of CGRP, TNF-alpha, IL-1beta, IL-6 and BDNF were measured in homogenates of isolated brain regions (hippocampus, cerebral cortex and brainstem) using ELISA.

Results: At baseline, the animals exposed to PIA demonstrated significantly decreased IL-1beta levels in all examined brain regions ($p < 0.05$) and reduced BDNF levels in the cortex ($p = 0.04$) compared to the control group. Levels of TNF-alpha, CGRP, IL-6 were nearly equal or slightly decreased, indicating the absence of active neuroinflammation and the development

	Brainstem	3090.8 $\pm$ 597.0	2553.4 $\pm$ 154.3	0.3	2133.9 $\pm$ 153.5	1857.9 $\pm$ 54.3	0.2

FIGURE 1 Comparison of CGRP, TNF- α , IL-6, IL-1 β , and BDNF levels in the hippocampus, cerebral cortex and brainstem between control and prenatal immune activation (PIA) groups under baseline conditions and after migraine induction. * $p < 0.05$.

of a compensated state. After administration of NTG, a region-dependent increase in the central inflammatory response was observed in the PIA group. CGRP concentrations increased significantly in the hippocampus and brainstem compared to control animals with migraine ($p < 0.05$), with a similar trend in the cortex. TNF- α levels were significantly elevated in all examined brain regions ($p < 0.05$), IL-6 level increased only in the brainstem, while in the cortex remained equal. IL-1 β levels tended to be lower in the PIA group and BDNF levels did not change significantly.

Conclusion: Thus, PIA does not lead to a sustained increase of inflammatory markers, but induces heightened sensitivity to the migraine trigger, manifested by an enhanced and heterogeneous biochemical response from central brain structures.

Disclosure: This study was supported by the Kazan Federal University Strategic Academic Leadership Program (PRIORITY-2030).

EPO-0575 | Genetic associations of TRPM8 with migraine chronification

A. Yakubova¹; T. Nasyrov¹; P. Elboeva¹; A. Belopasova²; Y. Davidiyuk¹; A. Rizvanov¹

¹Openlab "Gene and Cell Technologies", Kazan Federal University, Kazan, Russian Federation; ²Research Center of Neurology, Moscow, Russian Federation

Background and aims: TRPM8 receptors are highly expressed in migraine pathophysiology. Genome-wide association studies have previously identified the strong association of single nucleotide polymorphism rs10166942 with migraine. However, its specific role in disease progression remains unstudied. Here we evaluated the genotype frequency distribution of rs10166942 in the TRPM8 gene in healthy individuals and patients with episodic (EM) and chronic migraine (CM) to test its influence on susceptibility to these forms of migraine.

Methods: The study included 238 participants - patients with migraine (47 EM and 42 CM) and 149 healthy controls. DNA from peripheral blood was used to test rs10166942 using allele-specific PCR.

Results: The genotype and allele frequency distributions in EM were comparable with control ($p = 0.77$ and $p = 0.7$). In the CM group distribution of genotypes differed significantly from both control and EM groups (both $p = 0.03$), (Table 1). Notably, in the CM group, in contrast to control and EM groups, the TT genotype frequency was nearly halved, while the TC and CC genotypes frequencies increased nearly twofold (Figure 1). Allele analysis confirmed this trend and showed a significant accumulation of the C allele in CM patients ($p = 0.03$).

Conclusion: These are the first indications of distinctive involvement of rs10166942 TRPM8 genotypes in EM and CM. Our data reveal a different predisposition to chronic pain in migraine and propose that this SNP play a potential role in migraine chronification.

Disclosure: This study was supported by the Kazan Federal University Strategic Academic Leadership Program (PRIORITY-2030).

TABLE 1 Genotypes and alleles distributions of rs10166942 in TRPM8 gene in the control group, episodic and chronic migraine patients.

Groups	Genotypes, n (%)			Alleles, n (%)	
	TT	TC	CC	T	C
Control (n=149)	82 (55)	57 (38)	10 (7)	221 (74)	77 (26)
Episodic migraine (n=47)	28 (60)	17 (36)	2 (4)	73 (77)	21 (23)
Chronic migraine (n=42)	13 (31)	24 (57)	5 (12)	50 (60)	34 (40)

¹Faculty of Medicine, Assiut University, Assiut, Egypt; ²Faculty of Medicine, Tanta University, Tanta, Egypt; ³Department of Neurology, Cairo University, Giza, Egypt

Background and aims: Migraine is a leading cause of years lived with disability worldwide, yet data from Africa are limited. We aimed to estimate migraine prevalence, patterns, and associated burden across African populations.

Methods: We systematically searched PubMed, Scopus, Web of Science, African Journals Online, and Google Scholar (inception–August 2025) for community-based studies reporting migraine prevalence or burden. Two reviewers independently screened studies, extracted data, and assessed quality using the Joanna Briggs Institute checklist. Random-effects meta-analyses estimated pooled prevalence, with subgroup analyses by sex, migraine subtype, and setting. Heterogeneity and publication bias were assessed.

Results: Sixty-one studies ($n = 201,437$) from 18 African countries were included. Overall migraine prevalence was 18% (95% CI: 12–26%), with high heterogeneity ($I^2 = 99.7\%$). Standardized prevalence was 140 per 1,000 population (14%; 95% CI: 11–17%). Females were more affected than males (63% vs. 37%; female-to-male ratio $\approx 1.7:1$). Migraine without aura predominated, with 84% lower odds of aura. Urban–rural differences were inconsistent. Migraines accounted for 31% of all headaches. Burden

was substantial, with moderate-to-severe disability, reduced quality of life, productivity loss, and low healthcare utilization. Evidence of small-study effects and potential publication bias was detected.

Conclusion: Migraine affects a considerable proportion of Africans, disproportionately females, and are associated with significant disability. Heterogeneity across regions and populations highlights the need for improved recognition, standardized diagnostics, and better resource allocation for headache disorders in Africa.

Disclosure: Nothing to disclose.

EPO-0577 | **Temporal burden synchronization and machine learning-identified dietary nuances in migraine-anxiety comorbidity**

H. Hu; F. Yang
The First Medical Center, Chinese PLA General Hospital, Beijing, China

Background and aims: Migraine and anxiety disorders are highly prevalent and frequently comorbid, leading to substantial functional impairment. However, the long-term temporal evolution of this comorbidity and the role of modifiable dietary factors remain poorly understood. We aimed to characterize the evolving disease burden in the USA and identify specific dietary micronutrients and whole-food patterns associated with anxiety risk in individuals with migraine.

Methods: We utilized data from the Global Burden of Disease (GBD) Study 2023 to analyze US trends (1990–2023) and generate projections to 2030 using ARIMA models. We further integrated NHANES (2001–2004) data and the MyPyramid Equivalents Database to assess dietary correlates in migraineurs ($n=984$). Six machine-learning algorithms were benchmarked, with Random Forest selected for interpretation via SHAP and LIME frameworks to identify key dietary predictors.

Results: GBD analysis revealed a stable migraine burden but a sharp increase in anxiety disorders after 2018, peaking during the COVID-19 pandemic. A "burden-synchronization window" was identified between ages 20 and 49, where peak disability-adjusted life years (DALYs) for both conditions overlapped. Random Forest demonstrated superior predictive performance. SHAP analysis identified caffeine, theobromine, and protein as protective factors, while higher intakes of vitamin E, dietary fiber, and polyunsaturated fatty acids were unexpectedly associated with increased risk. Red/orange vegetables and whole grains were inversely associated with anxiety risk.

Conclusion: The rising burden of anxiety among migraineurs during mid-adulthood necessitates integrated clinical

Flowchart of participant selection.

Trends in the burden of migraine and anxiety disorders in the United States (1990–2023) and projections based on GBD 2023. (A) Heatmap comparison of age standardized DALY rates for leading diseases in the United States between GBD 2021 and GBD 20

Time-series analysis validating the machine-learning results based on the MyPyramid Equivalents Database.

management. Specific dietary interventions may modulate anxiety risk, challenging simplified antioxidant theories and emphasizing personalized nutritional strategies.

EPO-0578 | Development and Assessment of a Headache Medicine Fellowship for Advanced Practice Providers (APPs)

J. Rothrock; A. Koutsandreas; K. Hoang
Inova Health Neurology/University of Virginia

Background and aims: There exists a mismatch between the volumes of individuals with headache disorders and providers possessing the skills and inclination to manage those individuals effectively. To help redress this imbalance we developed and assessed a 1 year headache medicine fellowship program intended for APPs.

Methods: One of us (JR) developed a 1 year fellowship curriculum blending didactic instruction, self-learning, in-clinic observation and subsequent clinical work involving a progressive increase in independence. In the last quarter of the fellowship we conducted a prospective study to assess clinical concordance and patient satisfaction for the APP fellow vs an MD neurologist with subspecialty training in headache (JR). All patients initially were evaluated by the fellow and then subsequently by the neurologist blinded to the results of the fellow's evaluation.

Results: Two nurse practitioners (NPs:AK and KH) successfully completed the 1 year fellowship, including the last quarter's prospective study. In 98 and 96 of the 100 consecutive new headache patients evaluated by each NP, diagnoses matched those of the neurologist. There were no major differences in the management recommended by the NPs versus the neurologist. Patient satisfaction with the NPs was slightly higher than with the neurologist.

Conclusion: Assessing the clinical effectiveness of a fellowship-trained APP vs that of a subspecialist physician, we found patient satisfaction to be essentially equal and both diagnostic and management concordance to be high. Utilization of appropriately trained APPs may represent one means of coping more effectively with the existing imbalance between headache patients seeking expert care and the volume of providers available.

Disclosure: This research was funded by AbbVie, Inc and the Inova Health Care system of Northern Virginia. All 3 authors are full-time employees of Inova Health and the University of Virginia School of Medicine, and Dr. Rothrock has served as a paid consultant and speaker for AbbVie. His parent institutions have received funding for research he has conducted on behalf of AbbVie.

EPO-0579 | Early wearing-off of onabotulinumtoxin A in chronic migraine: A retrospective study

K. Dos Santos Ferreira¹; A. Velly²

¹Neurologist, Headache Clinic, Montreal Neurological Clinic, Montreal, Quebec, Canada; ²Associate Professor, Faculty of Dentistry, Jewish General Hospital/ McGill University, Montreal, Quebec, Canada

Background and aims: OnabotulinumtoxinA is a well-established prophylactic therapy for chronic migraine, administered every 12 weeks. However, many patients report a wearing-off of efficacy prior to the end of the dosing cycle. This

Table 1. Patients in Onabotulinumtoxin A toxic treatment for migraine (total 89 patients 100%)

retrospective review investigates the frequency of early wearing-off in patients receiving onabotulinumtoxin A and explores associated clinical factors.

Methods: Medical records of chronic migraine patients treated with onabotulinumtoxinA were reviewed. Patient demographics, headache frequency, use of rescue therapies, dosing regimens, and adjunctive procedures were recorded. Patients were divided into two groups based on whether they experienced wearing-off before 12 weeks.

Results: Among the 89 patients (91% female), 24 (26.9%) reported wearing-off prior to 12 weeks. It was significantly associated with higher baseline headache frequency (79% vs. 47.7%, $p=0.007$), earlier injection requirements (87.5% vs. 1.5%, $p=0.000$), and Greater Occipital Nerve blocks (GON blocks) for recurrent pain (41.6% vs. 9.2%, $p=0.000$). Patients with wearing-off prior to 12 weeks received the full 195 U dose of onabotulinumtoxin A more frequently (58.3% vs. 20%, $p=0.000$). Ubrogepant was also more commonly used in the wearing-off group (33.4% vs. 6.2%, $p=0.000$). No significant differences were noted for Rimegepant (16.7% vs 6.2%, $p=0.123$), Atogepant (8.3% vs 3.0%, $p=0.288$) or Monoclonal antibodies against CGRP (12.5% vs 10.8%, $p=0.818$) use.

Conclusion: Wearing-off was associated with higher baseline migraine frequency, earlier reinjection intervals, and increased use of acute therapies, suggesting that this subgroup may require tailored management strategies, including reassessing injection technique, dose optimization, shorter injection intervals (10 weeks), GON blocks inter procedures, optimizing other preventive treatment or using Gepants to improve outcomes.

Background and aims: Atogepant is a novel migraine preventive drug acting as calcitonin gene-related peptide (CGRP) receptor antagonist. We conducted a prospective, open label study aimed to evaluate whether clinical response to atogepant is associated with biomolecular changes in subjects with high-frequency episodic migraine (HFEM - at least 8 migraine days/month - MMDs). As a secondary aim, we assessed differences between Responders, those achieving at least a 50% reduction in MMDs after atogepant treatment, and Non-Responders.

Methods: We enrolled 40 subjects (75% women, age 35.5 ± 21.9 , MMDs 9.9 ± 2.3). All participants underwent a biomolecular profiling at baseline (T0) and after a 3-month daily atogepant 60 mg treatment (T1). We analyzed the expression of endocannabinoid enzymes, monoacylglycerol lipase (MAGL) and fatty-acid amide hydrolase (FAAH), and microRNAs (miR-155, miR-34a, miR-382-5p) expression in peripheral blood mononuclear cells, and neuropeptides (CGRP, PACAP) plasma levels.

Results: At T1 70% of participants classified as Responders (28/40). At T1, MAGL gene expression decreased in Responders (T0: 9.8 ± 5.4 relative quantification - RQ vs. T1: 13.2 ± 7.9 RQ, $p=0.021$), without changes in Non-Responders (T0: 7.4 ± 4.3 RQ vs. T1: 8.3 ± 4.4 RQ, $p=0.552$). At T0, MAGL was higher in future Responders compared to Non-Responders ($p=0.022$). No baseline differences or after-treatment modifications were found for FAAH expression, microRNAs expression, or neuropeptides levels.

Conclusion: We confirmed atogepant effectiveness in HFEM. We found a modulation of MAGL expression in Responders participants. Our data suggests an indirect modulation of the endocannabinoid system homeostasis during atogepant treatment.

⁶Headache Unit, Neurology Department, Vall d'Hebron Hospital, and Headache Research Group, Vall d'Hebron Research Institute (VHIR), Universitat Autònoma de Barcelona, Barcelona, Spain;

⁷Department of Neurology, Mayo Clinic, Scottsdale, USA; ⁸MIST Research, Wilmington, USA; ⁹Pfizer AB, Stockholm, Sweden

Background and aims: CONFIDENCE (NCT06467370) was a prospective observational study evaluating the effectiveness of acute rimegepant treatment over multiple migraine attacks. As rimegepant is also a preventive migraine treatment, this analysis evaluated duration of migraine freedom after acute use.

Methods: Participants with 3-14 headache days in the past 30 completed a 28-day migraine diary via the Migraine Buddy® app. Preventive therapy was permitted. This analysis included all acutely treated (prescription/over-the-counter) migraine attacks recorded >3 days before the end of study and without missing diary data before the next attack. Generalized linear mixed models with a logit link were used to calculate the odds ratio for ≥ 1 , ≥ 2 , ≥ 3 , or ≥ 4 consecutive migraine free days following the day of acute treatment with rimegepant vs other medications.

Results: 429 participants recorded 2563 eligible migraine attacks. Independent of which acute treatment was used, 64.9% of attacks were followed by ≥ 1 , 47.6% by ≥ 2 , 35.4% by ≥ 3 , and 25.0% by ≥ 4 migraine-free days. In models evaluating treatment alone, rimegepant was associated with a significantly higher chance of migraine-freedom in the following ≥ 1 (77%), ≥ 2 (71%), ≥ 3 (58%), and ≥ 4 days (44%) vs other acute medications (Table 1). In models controlling for migraine days during the study, pain level, and functional ability at the time of treatment, rimegepant was associated with a significantly higher chance of migraine-freedom in the following ≥ 1 (54%), ≥ 2 (48%), ≥ 3 days (30%) vs other acute medications.

Conclusion: Higher odds of migraine-free days following treatment was observed with rimegepant vs other acute migraine medications.

TABLE 1 Odds ratios for consecutive migraine-free days following rimegepant vs other acute medication treatment of a migraine attack.

	Odds ratio (95% CI) of consecutive migraine-free days following acute treatment			
	>1 days after migraine-free (n=1683 attacks)	>2 days after migraine-free (n=1218 attacks)	>3 days after migraine-free (n=937 attacks)	>4 days after migraine-free (n=642 attacks)
Model 1 - Only including acute treatment as the independent variable				
Rimegepant (ref other*)	1.77 (1.43, 2.19) $P=0.001$	1.71 (1.38, 2.11) $P=0.001$	1.58 (1.26, 1.99) $P=0.001$	1.46 (1.11, 1.93) $P=0.005$
Model 2 - With covariates				
Rimegepant (ref other*)	1.54 (1.25, 1.89) $P=0.001$	1.46 (1.16, 1.83) $P=0.001$	1.33 (1.03, 1.63) $P=0.001$	1.13 (0.86, 1.46) $P=0.335$
Activity impairment at treatment	0.99 (0.87, 1.13) $P=0.888$	0.99 (0.87, 1.12) $P=0.890$	1.03 (0.89, 1.17) $P=0.650$	1.05 (0.89, 1.20) $P=0.541$
Pain level at treatment	1.02 (0.92, 1.13) $P=0.632$	1.06 (0.97, 1.16) $P=0.188$	1.02 (0.92, 1.13) $P=0.184$	0.97 (0.87, 1.07) $P=0.594$
Number of migraine days during the study	0.92 (0.90, 0.94) $P=0.001$	0.79 (0.77, 0.81) $P=0.001$	0.76 (0.74, 0.78) $P=0.001$	0.74 (0.71, 0.76) $P=0.001$
*Other medications were reported by category: over the counter drug, triptan, other prescription drug, unknown (ref). Some attacks were treated with >1 type of acute medication. Attacks were included in the rimegepant group if rimegepant was used, with or without other acute medications.				
The generalized linear mixed models had a binomial distribution, logit link, and random intercepts for participants that were fit to account for repeated attacks nested within individuals. Activity impairment at treatment was as reported by the participant in the diary using a four-step scale: 1=no disability to 4=severely impaired. Pain level at treatment was as reported by the participant in the diary using a seven-step scale: 0=not present to 6=extremely severe. Number of migraine days during the 28-day observational period was calculated from the complete diary (actual range 1 to 28). All were entered as continuous covariates.

EPO-0582 | Rimegepant for the Acute Treatment of Migraine in People With ≥ 1 Lapsed Triptans, With and Without Current Triptan Use, in the CONFIDENCE study

R. Lipton¹; L. Abraham²; A. Urani³; G. Lambru⁴; P. Goadsby⁵; P. Pozo-Rosich⁶; T. Schwedt⁷; K. Fanning⁸; K. Hygge Blakeman⁹

¹Montefiore Medical Center and Albert Einstein College of Medicine, Bronx, USA; ²Pfizer R&D UK Ltd, Tadworth, Surrey, UK; ³Aptar Digital Health, Paris, France; ⁴The Headache and Facial Pain Service, Guy's and St. Thomas' NHS Foundation Trust, London, UK; ⁵King Abdullah University of Science and Technology, Thuwal, Saudi Arabia and King's College London, London, UK; ⁶Headache Unit, Neurology Department, Vall d'Hebron Hospital, and Headache Research Group, Vall d'Hebron Research Institute (VHIR), Universitat Autònoma de Barcelona, Barcelona, Spain; ⁷Department of Neurology, Mayo Clinic, Scottsdale, USA; ⁸MIST Research, Wilmington, USA; ⁹Pfizer AB, Stockholm, Sweden

Background and aims: The prospective, observational CONFIDENCE study (NCT06467370) evaluated the effectiveness of rimegepant for the acute treatment of migraine over multiple attacks. This analysis evaluated rimegepant treatment outcomes in participants with ≥ 1 previously discontinued (lapsed) triptans, both with/without current triptan use.

Methods: CONFIDENCE recruited participants using rimegepant for the acute treatment of migraine from the Migraine Buddy® app. Participants completed a baseline survey and 28-day migraine diary. On days with a migraine attack, treatment characteristics, time to meaningful pain relief (MPR), and meaningful functional improvement (MFI) were collected. Generalized linear mixed models with a logit link were used to control for within person correlation and evaluate predictors of MPR and MFI within 2 and 4 h of rimegepant intake.

Results: Participants ($n=370$) with ≥ 1 lapsed triptan reported 1948 rimegepant-treated migraine attacks. Of these, 662 (34%) attacks were in participants with 1 lapsed triptan, 719 (37%) with 2, and 567 (29%) with ≥ 3 ; 538 (28%) were in participants who currently used a triptan to treat some attacks. Models identified significantly lower odds of MPR within 2 (58%) and 4 h (50%), and MFI within 2 (54%) and 4 h (57%) of rimegepant treatment in participants with ≥ 3 lapsed triptans (vs 1; Table 1). Having 2 lapsed triptans (vs 1) and current triptan use were associated with numerically lower odds of MPR and MFI but were not consistently statistically significant.

Conclusion: Rimegepant efficacy was higher in participants with lower numbers of lapsed triptans and without current triptan use, possibly reflecting clinical differences between subgroups.

Disclosure: This study was sponsored by Pfizer. RBL reports research support from NIH, FDA, and the National Headache Foundation; research grants, consultant, advisory board member or honoraria from Aeon, Allergan/AbbVie, Amgen, Axsome, Dr Reddy's Laboratories, Eli Lilly, GSK, Ipsen, Lundbeck, Pfizer, Merck, Teva, and Vedanta; royalties from Informa and Wolff's Headache (8th edition, Oxford University Press, 2009); and stock options in Biohaven Pharmaceuticals, CoolTech, and NuVieBio.

TABLE 1 Predictors of meaningful pain relief and meaningful functional improvement following acute rimegepant treatment.

	Odds ratio (95% CI) of achieving MPR	
	Within 2 h of rimegepant intake	Within 4 h of rimegepant intake
Number of migraine attacks during the 28-day observational period		
6 to 10 (vs 1 to 5)	1.01 (0.89, 1.14) P=0.98	0.99 (0.87, 1.13) P=0.97
11 to 24 (vs 1 to 5)	0.61 (0.39, 1.25) P=0.16	0.38 (0.16, 0.86) P=0.02

EPO-0583 | Efficacy of eptinezumab in adults with CM and MOH who also received patient education: Country-level results from the RESOLUTION trial

G. Terwindt¹; S. Tepper²; R. Jensen³; C. Lundqvist⁴; H. Schytz³; F. Vernieri⁶; M. Lantéri-Minet⁸; A. Blumenfeld¹⁰; R. Lipton¹¹; K. Ranc¹²; G. Jansson¹²; A. Ettrup¹²; A. Mittoux¹²; C. Tassorelli¹³

¹Department of Neurology, Leiden University Medical Centre, Leiden, Netherlands; ²The New England Institute for Neurology and Headache, Stamford, CT, United States; ³Department of Neurology, Danish Headache Center, Rigshospitalet-Glostrup, University of Copenhagen, Copenhagen, Denmark; ⁴Departments of Neurology and Health Services Research, Akershus University Hospital, Lørenskog, Norway; ⁶Unit of Headache and Neurosonology, Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy; ⁸Department of Neurology, Albert Einstein College of Medicine, New York, NY, United States; ¹⁰INSERM U1107 Migraine and Trigeminal Pain, Auvergne University, Clermont-Ferrand, France; ¹¹The San Diego Headache Center, San Diego, CA, United States; ¹²H. Lundbeck A/S, Copenhagen, Denmark; ¹³Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy

Background and aims: These country-level analyses evaluated the migraine-preventive efficacy of eptinezumab versus placebo in adults with chronic migraine (CM) and medication-overuse

headache (MOH), together with a brief educational intervention (BEI).

Methods: The multinational phase 4 RESOLUTION (NCT05452239) trial included a 12-week double-blind, placebo-controlled period. Adults (18–75yrs) with CM and MOH were randomized 1:1 to IV eptinezumab 100mg or placebo at baseline; all participants received a BEI on MOH before infusion. Post hoc subgroup analyses were conducted by country (those with ≥ 20 participants per arm). Endpoints included change from baseline in monthly migraine days (MMDs) and monthly days with acute medication use (Weeks 1–12; full-analysis set).

Results: The full-analysis set included 602 of 608 randomized participants. Countries with ≥ 20 participants per arm included Denmark, France, Georgia, Italy, the Netherlands, and Spain (Table 1). In comparison with placebo with BEI, eptinezumab with BEI improved treatment outcomes, with directionally consistent results seen across countries. Participants from the Netherlands had large reductions in acute medication use in both treatment groups, but concurrently the largest difference between both treatment groups in change from baseline in MMDs.

Conclusion: In this post hoc analysis of the RESOLUTION trial, the treatment effect of eptinezumab among participants with CM and MOH who received patient education appeared to be homogenous across countries, supporting the robustness of the intervention and its relative independence of country effects. Results from the Netherlands suggest that, while patient education can help reduce acute medication use, concurrent initiation of preventive treatment with eptinezumab has additional benefit for reversing migraine chronification.

TABLE 1 Change from baseline over Weeks 1–12 in MMDs and MAMDs.

MMDs				
Country	Treatment arm	N	Baseline, mean	CFB, Weeks 1-12, LS mean (SE)
Denmark	Eptinezumab	22	22.1	-7.1 (1.14)
	Placebo	25	22.3	-4.3 (1.07)

Faculty of Biomedical Sciences, Università della Svizzera Italiana, Lugano, Switzerland; ¹⁴Neurologische Praxis Bülach, Bülach, Switzerland; ¹⁵Bellevue Medical Group, Zurich, Switzerland. Department of Neurology, Inselspital, University Hospital Bern, Bern, Switzerland

Background and aims: To evaluate real-world data to establish safety and efficacy of eptinezumab for the prevention of episodic and chronic migraine in clinical practice in Switzerland.

Methods: This multicenter retrospective cohort study included patients treated with eptinezumab at eleven Swiss headache centers. Over 12-months, patients received up to four infusions of eptinezumab 100 mg or 300 mg administered every three months. Data on efficacy and tolerability were extracted from patients' charts, including prospective headache diaries. The primary efficacy endpoint was the proportion of patients achieving a $\geq 50\%$ reduction in monthly migraine days (MMDs) three months after the first infusion.

Results: A total of 201 patients were included. Mean baseline MMDs were 17.5. After eptinezumab administration, 56% (95% CI [48.7, 63.1]) of patients reached the primary endpoint of $\geq 50\%$ response. Mean MMDs decreased significantly from baseline by 7.3 days (95% CI [6.19, 8.33], $p < 0.001$). This was observed for both, the 100 mg and 300 mg doses (100 mg, -7.2 , $p < 0.001$; 300 mg, -7.4 , $p < 0.001$). Prior treatment failure with CGRP ligand-targeting antibodies was associated with a significantly lower $\geq 50\%$ response rate (OR = 0.42, 95% CI 0.2–0.89, $p = 0.024$). Efficacy was not related to comorbid anxiety or depression. Adverse events within three months after infusion were reported by 15.1% of patients, most commonly rhinosinusitis (8%), constipation (6%), and fatigue (4%).

Conclusion: In a real-world clinical setting, eptinezumab for the prevention of episodic and chronic migraine was effective and well tolerated. Prior treatment failure with CGRP ligand-targeting antibodies was associated with reduced treatment response.

Disclosure: This work was funded by a research grant from Lundbeck. EPO-0585 | Limb-specific cervical spinal cord microstructure in Parkinson's disease: A clinically focused re-analysis of an open quantitative MRI dataset

M. Elkasaby¹; A. Hassan¹; M. Ahmed²

¹Faculty of Medicine, Al-Azhar University, Cairo, Egypt;

²Faculty of Medicine, Mansoura University, Mansoura, Egypt

Background and aims: Gait disturbance and postural instability are major contributors to disability in Parkinson's disease (PD), yet conventional brain MRI and global clinical scores only partially account for these deficits. The cervical spinal cord—particularly the dorsal columns—may contribute to limb-specific motor impairment but remains understudied.

Methods: We performed a cross-sectional re-analysis of an open NeuroLibre dataset including quantitative cervical spinal cord MRI (C2–C5) from 68 individuals with PD and 38 healthy controls. Metrics included cord cross-sectional area, diffusion tensor imaging, and NODDI measures in the dorsal columns, magnetisation transfer ratio (MTR) in white and grey matter, and grey-matter T2. Motor impairment was assessed using UPDRS III total and limb-specific subscores.

Results: Cord cross-sectional area did not differ between groups, but PD showed altered dorsal column microstructure, with higher orientation dispersion and lower axial diffusivity. Within PD, dorsal column fractional anisotropy, orientation dispersion, and intracellular volume fraction were independently associated with worse lower-limb/gait impairment, explaining ~23–25% of variance. Grey-matter MTR preferentially correlated with upper-limb impairment. Lower-limb-dominant patients exhibited greater dorsal column microstructural disruption, with lateralisation to the clinically more affected side and progression across disease stages. An exploratory model combining dorsal column metrics with age achieved modest discrimination between PD and controls (AUC = 0.64).

Conclusion: Cervical dorsal column microstructure is selectively altered in PD and closely linked to lower-limb and gait impairment, motor phenotype, and disease stage, even in the absence of cord atrophy. Grey-matter metrics show a complementary relationship with upper-limb dysfunction.

Disclosure: Nothing to disclose.

EPO-0586 | Knowledge, perceptions, and attitudes toward influenza vaccination in people with Parkinson's disease

S. Diaconu¹; I. Murasan²; D. Batrinu²; C. Falup-Pecurariu¹

¹Department of Neurology, County Clinic Hospital, Transilvania University Brasov, Romania; ²Department of Neurology, County Clinic Hospital, Brasov, Romania

Background and aims: Influenza infection represents a significant health risk for people with Parkinson's disease (PD), being associated with increased morbidity, functional decline, and hospitalization. Although annual influenza vaccination is recommended for older adults and individuals with chronic neurological disorders, reported vaccination rates in PD remain low. The aim of this study was to evaluate knowledge, perceptions, and attitudes toward influenza vaccination in patients with Parkinson's disease and to determine influenza vaccine acceptance rates in this population.

Methods: We conducted a cross-sectional observational study including 123 people with PD. Participants completed a structured questionnaire assessing socio-demographic variables, disease duration, comorbidities, influenza vaccination history, knowledge of influenza and vaccination, perceived risks and benefits, sources of information, and attitudes toward vaccination.

Results: The mean age of participants was 68.4 ± 8.9 years, and 56% were male. Only 11.4% ($n = 14$) reported receiving the influenza vaccine during the most recent season. Although 74% of patients considered influenza a potentially serious disease, only 23% correctly identified vaccination as the most effective preventive measure. Fear of adverse effects was reported by 61% of unvaccinated patients, concerns regarding worsening of Parkinson's symptoms by 56%, and doubts about vaccine efficacy by 42%. A lack of explicit recommendation from a health-care professional was reported by 53% of participants.

Conclusion: Influenza vaccination acceptance among patients with Parkinson's disease was extremely low. Despite moderate awareness of influenza-related risks, misconceptions, safety concerns, and insufficient physician recommendations remain major barriers.

Disclosure: Nothing to disclose.

EPO-0587 | Local and global microstructural and functional thalamomotor connectivity alterations in Parkinson's disease following motor learning

A. Amedi¹; T. Tamir²; E. Sasson³; N. Saporta²; S. Shelly⁴; R. Sivan Hoffmann⁵; M. Catalogna¹

Mamede do Coronado, Portugal

Background and aims: Sublingual apomorphine (SL-APO) is an on-demand therapy for the management of OFF episodes in Parkinson's disease. This analysis describes the post-marketing safety profile of SL-APO in Europe during the first 18 months after launch.

Methods: The drug global safety database was searched for European valid post-marketing reports (spontaneous reports, health authorities, literature reports, non-interventional studies, excluding marketing studies) from launch (April 2025) to October end 2025. Expectedness was assessed based on the current European Summary of Product Characteristics (SmPC) for SL-APO.

Results: A total of 346 events were collected from 159 valid cases: 94 male (59%), mean age 65years, from Germany (90, 57%), Portugal (44, 28%) and Spain (25, 16%). The 3 most common reported events were “nausea” (48, 14%), “dizziness” (22, 6%) and “vomiting” (15, 4%), consistent with known safety profile of SL-APO. Oropharyngeal events accounted for 47 (14%) of all events, most commonly “aphthous ulcer”(7) and “oral pain”(4) (Table1). Overall, 326 (94%) events were considered non-serious, and “syncope”(4) was the only serious event reported more than once. SL-APO was withdrawn, temporarily or permanently, in 72 (45%) cases, including 18 (11%) due to oropharyngeal events.

Conclusion: Reported events were predominantly non-serious and consistent with SL-APO known safety profile, supporting its favorable tolerability in real-world practice. The apparent discontinuation rate should be interpreted cautiously, given the reporting bias inherent to spontaneous post-marketing data and

TABLE 1 Summary of 346 reported events from 159 cases with sublingual apomorphine (SL-APO) in European post-marketing surveillance.

Event type	# Events	% of total
Non-serious	326	94,2%
Serious	20	5,8%
Most common events (≥ 3% of total)		
Nausea	48	13,9%
Dizziness	22	6,4%
Vomiting	15	4,3%
Drug ineffective	14	4,0%
Somnolence	13	3,8%
Hypotension	12	3,5%
Oropharyngeal events	47	13,6%
Most common (≥ 1% of total)		
Aphthous ulcer	7	1,9%
Oral pain	4	1,1%
Swollen tongue	4	1,1%

Neuroimaging analysis results and correlation with clinical measures

rapid learning induced white-matter changes, yet such evidence in PD remains limited.

Methods: In this prospective, double-blind, randomized, placebo-controlled study, 32 levodopa-treated patients were randomized to a 3-week digital intervention (DopApp) or placebo app. The DopApp involved a digital spatial navigation protocol combining egocentric and allocentric strategies with multisensory-deprivation principles, alongside psychological and rehabilitation modules. Patients were assessed pre- and post-treatment using clinical and psychological scales and MRI scans, including resting-state fMRI (rsFC) and DTI, to investigate motor learning neuroplasticity.

Results: DopApp treatment significantly improved the total MDS-UPDRS score compared to placebo-app, driven by gains in motor function (Part III) and activities of daily living (Part II). Neuroimaging revealed increased fractional anisotropy in the right ventrolateral posterior (VLP) thalamus and strengthened functional connectivity between VLP and precentral gyrus (PreCG), both correlated with clinical motor improvements. Graph-theory analysis indicated increased local efficiency in PreCG and adjacent motor network, suggesting enhanced structural integration.

Conclusion: These findings demonstrate regionally specific, short-term plasticity in PD, and support DTI's sensitivity to capture clinically relevant motor training-related white-matter adaptations beyond dopaminergic medication effects.

Disclosure: Amir Amedi is a co-founder and employee of Remepy Health Ltd. and holds shares in Remepy Inc, the company that developed the DopApp.

increased vigilance during the early post-launch period. These observations underscore the importance of ongoing pharmacovigilance, proactive management of tolerability issues, and patient education to optimize adherence.

EPO-0589 | Advancing Deep Brain Stimulation management in Parkinson's Disease through wearable technologies: A systematic review

I. D'Ascanio¹; L. Baldelli²; I. Cani²; S. Belfiori¹; M. Paolillo¹; G. Lopane³; L. Chiari¹; G. Giannini²; L. Palmerini²

¹Department of Electrical, Electronic and Information Engineering, Alma Mater Studiorum – University of Bologna, Bologna, Italy; ²UOC Clinica Neurologica Rete Metropolitana NEUROMET, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; ³Unit of Rehabilitation Medicine, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy

Background and aims: Deep Brain Stimulation (DBS) is a well-established advanced treatment in Parkinson's disease (PD) [1]. The effects of DBS have been investigated using laboratory-based systems [2], which are restricted to specialized clinical settings and therefore limit broader clinical integration. In contrast, wearable sensors have emerged as a complementary approach to objectively assess PD symptoms in both clinical and real-world settings [3], thereby extending traditional assessments. This study aims to conduct a systematic review to examine the application of wearable technology in supporting DBS management.

Methods: The literature review was conducted analyzing Pubmed and Scopus databases. Studies were eligible for inclusion if they involved individuals with PD treated with DBS and used wearable devices. Studies were excluded if they involved non-commercial prototype devices, did not specify the device used, and were not peer-reviewed.

Results: After full-text screening, 71 articles were included and categorized into two main research topics: 49 studies (69%) focused on digital monitoring, aiming to evaluate DBS efficacy; 22 studies (31%) investigated wearable-based approaches to support DBS programming, exploring brain-activity patterns during disease-related symptoms. The majority of studies were conducted in clinical settings (53, 74%) and used a single device (42, 58%). Considerable heterogeneity was observed across study protocols in terms of tasks, treatment conditions, and time measurements.

Conclusion: Current literature, while heterogeneous and largely exploratory, highlights the promising potential of wearables to assess treatment efficacy, characterize motor impairments alongside associated brain activity patterns, and support personalized approaches to DBS management. Large-scale studies employing standardized protocols are required to improve their generalizability.

EPO-0590 | Alpha-fetoprotein level in dystonia patients: Follow - up

J. Rajmonová¹; P. Havránková¹; L. Kunc¹; J. Roth¹; D. Springer²; M. Zech³; R. Jech¹

¹Department of Neurology and Center of Clinical Neuroscience, First Faculty of Medicine, Charles University and General University Hospital in Prague; ²Department of Clinical Biochemistry and Laboratory Medicine, First Faculty of Medicine Charles University and General University Hospital in Prague; ³Institute of Neurogenomics, Helmholtz Zentrum München, Munich, Germany

Background and aims: In our previous study, we observed elevated alpha-fetoprotein (AFP) levels in patients with dystonia. The aim of this project was to monitor AFP levels over one-year period in dystonic patients with elevated AFP, to exclude other causes of increased AFP (tumor, hepatopathy, or gene-related persistence), and to compare clinical characteristics between patients with normal and elevated AFP levels.

Methods: Patients with primary idiopathic dystonia (including negative WES) and healthy controls were enrolled. AFP levels were measured using an immunoassay.

Results: Of 171 patients with primary idiopathic dystonia, 156 (47 men) had normal AFP levels (3 ± 1.7 ug/L), whereas 15 (2 men) had elevated AFP levels (17.7 ± 22 ug/L). At one-year follow-up, AFP levels normalized in only two patients; in the remaining 13 patients, AFP levels either remained stable or increased. Oncological screening was negative in all patients and mild hepatopathy was observed in two cases, HNF-1 mutations, (causing AFP persistence) were excluded. All 57 age- and sex-matched healthy controls had normal AFP levels (3.3 ± 1.8 µg/L) and no significant differences between groups were detected.

Conclusion: These findings suggest that AFP elevation in dystonia was predominantly long-term and occurred without an identifiable triggering cause. This unexpected persistence raises the possibility of an association between AFP elevation and neurodevelopmental pathology. Increased AFP levels have been observed in neural tube defects, spina bifida, and in autosomal recessive cerebellar ataxias. We conclude that long-term AFP elevation may be present in patients with dystonia; however, its clinical relevance and relationship to disease pathophysiology remain unclear.

EPO-0591 | Concomitant recording of streamed local field potentials from the STN and GPI to investigate Parkinson's disease neurophysiology: A feasibility study

M. Mancuso¹; C. Gonzalez¹; S. Xu¹; J. Candelario-McKeown¹; J. Esperida¹; C. Duraffourd³; L. Mooney³; H. Akram¹; M. Krueger¹; L. Zrinzo¹; T. Foltynie¹; V. Litvak²; P. Limousin¹

¹Unit of Functional Neurosurgery, Department of Clinical and Movement Neurosciences, UCL Queen Square Institute of Neurology, University College London, London, UK; ²Department of Imaging Neuroscience, UCL Queen Square Institute of Neurology, London, UK; ³Medtronic, Watford, UK

Background and aims: Globus pallidus internus (GPi) and subthalamic nucleus (STN) deep brain stimulation (DBS) are

both effective treatments for Parkinson's disease (PD). The development of stimulators able to stream local field potentials (LFP) such as Medtronic Percept® allows to study the effect of DBS in chronic implants, and to elucidate the role of STN and GPi neurophysiology in the parkinsonian system. We recorded simultaneously from two patients with dual STN and GPi implant, to assess the feasibility of concomitant recording, and to investigate the effect of DBS on the interaction between nuclei.

Methods: 2 patients with dual STN-GPi Medtronic Percept® implants underwent resting-state simultaneous LFP recording with increasing levels of stimulation (0 to 4 mAmp, 0.5 mAmp steps). After synchronization, we computed time-frequency resolved power, coherence, and granger causality at each step.

Results: We successfully synchronized the STN and GPi signal in both patients. Stimulation of either nucleus resulted in suppression of high-beta peak power in both the stimulated and non-stimulated nucleus, with accompanying coherence loss at the same frequency. Granger analysis showed an STN to GPi directionality of high-beta connectivity, which was abolished with increasing stimulation to either nucleus.

Conclusion: In this preliminary study we demonstrate the feasibility of simultaneous LFP recording from the STN and GPi. We identify an indirect modulatory effect of stimulation on the high beta peak of the non-stimulated nucleus and show that high beta-band connectivity within the subthalamo-pallidal system is directed from the STN to the GPi, in line with previously proposed models.

Disclosure: Nothing to disclose.

EPO-0592 | Non-motor symptom burden does not reliably discriminate between PSP subtypes

N. Shakarishvili¹; S. Lyons¹; N. O'Shea²; M. Finnegan³; S. Fullam¹; A. O'Connor¹; D. Bradley⁴; S. Hutchinson¹; O. Hardiman⁵; E. McGovern¹; S. O'Riordan⁶; L. Williams⁶; T. Lynch⁷; C. Fearon⁷; R. Walsh⁷; S. O'Dowd¹

¹Department of Neurology, Tallaght University Hospital, Dublin, Ireland; ²Department of Palliative Medicine, University Hospital Kerry, Tralee, Ireland; ³Department of Old Age Psychiatry, Tallaght University Hospital, Dublin, Ireland; ⁴Department of Neurology, St James's Hospital, Dublin, Ireland; ⁵Department of Neurology, Beaumont Hospital, Dublin, Ireland; ⁶Department of Neurology, St Vincent's University Hospital, Dublin, Ireland; ⁷Department of Neurology, Mater Misericordiae University Hospital, Dublin, Ireland

Background and aims: Progressive supranuclear palsy (PSP) can be sub-classified into Richardson's syndrome (RS), cortical, and subcortical subtypes. We aimed to characterise symptom severity across PSP variants using validated scales, adjusting for disease duration, to determine whether phenotypes exhibit differential patterns of non-motor burden.

Methods: 92 patients with PSP were classified into cortical ($n=17$), subcortical ($n=28$) and RS subtypes ($n=47$). Each was assessed with PSPRS, ACE-III, SCOPA-AUT, BDI, CBI, NPI, and SF-36. Descriptive statistics summarised total-cohort and subtype distributions. Group differences were examined using multivariate general linear modelling.

Results: PSP subtypes demonstrated a significant overall multivariate effect on PSPRS domain scores ($p<0.001$).

Univariate tests showed differences in Mentation ($p=0.029$), Bulbar ($p<0.001$), Ocular ($p=0.008$), Limb ($p<0.001$) and Gait ($p=0.014$) with PSP-RS exhibiting greatest impairment and PSP-Subcortical least. No significant subtype differences were detected across autonomic symptom domains by SCOPA-AUT. While there was no overall multivariate subtype effect on cognitive profile, higher fluency scores characterised PSP-Subcortical versus PSP-RS ($p=0.047$). In the neuropsychiatric domain, neither BDI scores nor CBI caregiver-informed behavioural scores differed significantly between subtypes. Multivariate analysis did not display an overall subtype effect on total NPI scores. Quality-of-life did not differ significantly between subtypes across any SF-36 domain.

Conclusion: Our results suggest that motor manifestations remain the principal differentiator between PSP phenotypes, with PSP-RS demonstrating most severe bulbar, ocular, limb and gait impairment. In contrast, non-motor domains—including cognition, autonomic function, mood and behaviour—did not reliably discriminate between subtypes, suggesting a shared non-motor burden across the PSP spectrum.

Disclosure: No conflicts of interest to disclose. Acknowledgment given to the PSP Association of Ireland for providing funding to support this research.

EPO-0593 | Motor, nonmotor and cognitive correlates of iron deposition within subcortical nuclei in early drug-naïve Parkinson's disease patients

N. Piramide; R. De Micco; M. Pirozzi; M. Siciliano; G. Caiazzo; V. Sant'Elia; F. Esposito; A. Tessitore; O. Ciaramaglia
Department of Advanced Medical and Surgical Sciences,
University of Campania "Luigi Vanvitelli", Naples, Italy

Background and aims: Iron deposition using Quantitative Susceptibility Mapping (QSM) has been reported in several cortical/subcortical areas within the dopaminergic pathways in patients with Parkinson's disease (PD). This study was aimed at exploring 3T MRI-derived iron deposition content within bilateral subcortical nuclei in early drug-naïve PD patients compared to healthy controls (HC), and as well as potential associations with motor, non-motor and cognitive/behavioral symptoms.

Methods: 3T MRI images of 59 drug-naïve PD patients were analyzed and compared with 18 age-, sex-matched HC. QSM values were extracted from several subcortical deep gray matter nuclei and 16 thalamic subregions using the HybraPD atlas. Partial Spearman correlation analysis was performed between QSM metrics significantly different in PD compared to HC, and motor, non-motor and cognitive/behavioral variables. Finally, a ROC curve analysis was performed to test the ability to discriminate PD patients from HC using QSM values.

Results: Compared to HC, PD patients showed significantly higher iron deposition in the bilateral substantia nigra pars compacta, left substantia nigra pars reticulata, left subthalamic nucleus, and in the right red and intralaminar thalamic nuclei. Correlation analyses revealed greater motor and non-motor severity associated with increased iron within the right intralaminar thalamic and red nuclei, respectively. ROC analysis demonstrated that QSM values may accurately discriminate PD patients from HC.

Conclusion: Our findings demonstrated that using a disease-specific HybraPD atlas, a specific iron accumulation within sub-cortical nuclei can be found in PD patients even at early stages, and may be proposed as a potential biomarker of dopaminergic neurodegeneration.

Disclosure: Disclosures: no disclosures to declare

EPO-0594 | MRgFUS thalamotomy may reduce long-term motor complications in tremor-dominant Parkinson's disease: A five-year prospective case-control study

Background and aims: Magnetic resonance-guided focused ultrasound (MRgFUS) thalamotomy targeting the ventral intermediate nucleus (VIM) is an established treatment for medication-refractory tremor in tremor-dominant Parkinson's disease (TDPD). Long-term data on tremor improvement, dopaminergic therapy management and development of motor complications after MRgFUS are limited. This study evaluated the long-term impact of VIM MRgFUS thalamotomy compared with optimized medical therapy in TDPD.

Methods: We conducted a prospective case-control study including patients with TDPD without baseline motor fluctuations or dyskinesias. Patients treated with unilateral VIM MRgFUS thalamotomy (PD-FUS) were compared with patients receiving optimized drug therapy alone (PD-ODT). Groups were matched 1:2 for sex, age, disease duration and baseline levodopa equivalent daily dose (LEDD). Assessments were performed in On-medication state at baseline, one and five years. The primary outcome was motor complications severity assessed by the Movement Disorder Society–Unified Parkinson's Disease Rating Scale (MDS-UPDRS) Part IV.

Results: 21 PD-FUS and 38 PD-ODT patients were included. At five years, median MDS-UPDRS-IV scores were lower in PD-FUS than PD-ODT (3 [0;4] vs 5 [4;7] respectively; $p=0.016$) (Figure 1). Tremor improved in PD-FUS, with a greater median reduction in total tremor score than PD-ODT ($-60\%[-75; -27]$ vs $-13\%[-43; 25]$; $p=0.049$). Over five years, total LEDD increased in both groups but remained lower in PD-FUS (median increase 185 mg [83–463] vs 419 mg [303–690]; $p=0.014$) (Figure 2). Adverse events were mild and transient.

Conclusion: VIM MRgFUS thalamotomy provides durable tremor control in TDPD and is associated with reduced

FIGURE 1 Changes in MDS-UPDRS Part IV scores over follow-up in patients treated with magnetic resonance-guided focused ultrasound (PD-FUS) and optimized drug therapy (PD-ODT). p values indicate between-group comparisons.

FIGURE 2 Changes in total levodopa equivalent daily dose (LEDD) from baseline to 1 and 5 years in PD-FUS and PD-ODT patients. p values indicate between-group comparisons.

long-term severity of motor complications and lower increase in LEDD.

Disclosure: Nothing to disclose.

S. Sathyanarayana¹; M. Firbank²; D. Ledingham³; V. Foster¹; R. Iredale¹; D. Galley¹; B. Mollenhauer⁵; N. Pavese⁴
¹Clinical Ageing Research Unit, Newcastle University, Newcastle Upon Tyne, UK; ²Translational and Clinical Research Institute and NIHR Newcastle Biomedical Research Centre, Newcastle University, Newcastle Upon Tyne, UK; ³Clinical Ageing Research Unit, Newcastle University, and The Royal Victoria Infirmary, The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, UK; ⁴Clinical Ageing Research Unit, Newcastle University, Newcastle Upon Tyne, UK and Department of Nuclear Medicine and PET Centre, Aarhus University Hospital, Aarhus, Denmark; ⁵University Medical Center, Clinic for Neurology, Göttingen, Germany

Background and aims: Olfactory impairment is a recognised early marker of Parkinson's disease (PD). However, the extent to which graded hyposmia severity relates to longitudinal cognitive performance remains unclear. This study examined longitudinal cognitive outcomes and baseline resting-state functional connectivity (rs-fMRI) across five olfactory categories: normosmia, mild, moderate and severe hyposmia, and anosmia.

Methods: Data were obtained from the Parkinson's Progression Markers Initiative (PPMI) database. Participants were classified into five olfactory groups based on age-adjusted percentile scores from the University of Pennsylvania Smell Identification Test (UPSIT). Longitudinal Montreal Cognitive Assessment (MoCA) scores were analysed using linear mixed-effects models in SPSS. Baseline rs-fMRI data were processed using CONN. ROI-to-ROI and seed-to-voxel analyses focused on regions involved in olfactory and cognitive networks, including the insula, orbitofrontal cortex, anterior cingulate cortex, amygdala, hippocampus and thalamus.

Results: A total of 254 PD patients and 133 healthy controls showed comparable demographic characteristics. Greater olfactory impairment severity significantly predicted lower MoCA scores ($p=0.004$), independent of time. Each incremental increase in olfactory severity category was associated with a 0.14-point reduction in MoCA score. Baseline rs-fMRI analyses (PD=91; controls=17) revealed no significant functional connectivity differences across olfactory categories within pre-defined regions of interest.

Conclusion: Greater olfactory impairment severity is associated with reduced cognitive performance in PD, even without detectable baseline functional connectivity differences. These findings suggest olfactory testing may be a sensitive marker of early cognitive vulnerability, while connectivity alterations may emerge later or require alternative imaging approaches to detect subtle network changes.

Disclosure: Nothing to disclose.

Y. Zhao¹; Q. Zhao¹; Y. Ma¹; B. Shen¹; J. Wu²; Y. Xu¹
¹Department of Nursing, Huashan Hospital, Fudan University, Shanghai, China; ²Department of Neurology, Huashan Hospital, Fudan University, Shanghai, China

Background and aims: Deep Brain Stimulation (DBS) is an effective treatment for the motor symptom of Parkinson's disease (PD), but it seems to have a limit effect on caregiver burden. Caregivers continually confront the dual challenges of navigating symptom fluctuations and handling the DBS device. Moreover, there are limit intervention were used to decrease caregiver burden of PD patients post DBS. Therefore, we have constructed an caregiver intervention program based on Omaha system and to verify it's effectiveness on caregiver burden.

Methods: A randomized controlled trial was designed. The stratified block randomization was used. 120 caregivers were randomly separated in either intervention (Nursing care based on Omaha system) or control (General nursing care) group. The demographic information, score of ZBI, GSES and KPPDQ were collected at baseline (T0), 3- and 9-month follow.

Results: Using repeated-measures analysis of variance to compare difference between two groups. And Caregiving knowledge only revealed a significant main effect of time ($F(1.83, 215.83)=17.66, p<0.001, \eta^2=0.13$). A significant main effect of group ($F(1, 118)=9.19, p=0.003, \eta^2=0.072$) and a significant time-by-group interaction ($F(2, 236)=5.23, p=0.006, \eta^2=0.042$) for caregiver self-efficacy. Caregiver burden revealed a significant main effects of time ($F(2, 118)=4.13, p=0.017, \eta^2=0.034$) and group ($F(1, 118)=8.08, p=0.005, \eta^2=0.064$), as well as the time-by-group interaction ($F(2, 118)=5.20, p=0.006, \eta^2=0.042$).

Conclusion: Neuromodulation Specialist Nurse-Led support system for caregivers of PD patients post DBS based on Omaha system provide a long-term, multi-dimensional and multi-form to improve the knowledge, self-efficiency and burden of caregivers.

EPO-0597 | Biological motion recognition in multiple sclerosis: Toward behavioral biomarkers for personalized neurorehabilitation

A. Antonioni¹; A. Casile²; M. Govoni¹; M. Buongiorno¹; F. Bonzagni¹; G. Palma¹; G. Fregna³; G. Perachioti¹; L. Mencarelli⁴; L. Micillo⁵; G. Mioni⁵; A. Baroni¹; S. Straudi¹
¹Department of Neuroscience and Rehabilitation, University of Ferrara, Ferrara, Italy; ²Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Messina, Italy; ³Department of Neuroscience, Ferrara University Hospital, Ferrara, Italy; ⁴Experimental Neuropsychophysiology Laboratory, Santa Lucia Foundation IRCCS, Rome, Italy; ⁵Department of General Psychology, University of Padua, Padua, Italy

Background and aims: Multiple sclerosis (MS) is a chronic disease associated with complex neurorehabilitation needs. The Action Observation Network (AON) supports motor learning and the prediction of biological motion (BM). However, evidence on AON functioning and BM recognition in MS remains limited. We aimed to (i) characterize BM recognition performance in people with MS (pwMS), (ii) compare their performance with that of young and age-matched healthy controls (HCs), and (iii) investigate the role of clinical, neuroimaging, and neuropsychological covariates.

Methods: In this cross-sectional study, 37 pwMS, 30 age-matched HCs, and 22 young HCs were enrolled. Participants

Performance on the BM at the two levels of detail (i.e., full-body and point-light stimuli) in pwMS, age-matched HCs, and young HCs.

completed a computerized BM task in which they observed arm movements displayed as either photorealistic avatars or point-light stimuli to estimate perceptual temporal extrapolation at the point of subjective equality (PSE). Clinical, neuropsychological, and subjective fatigue measures were collected; structural neuroimaging was available for pwMS.

Results: Two response patterns emerged: a “good” psychometric curve that allows PSE estimation and an inverted (“bad”) pattern. Among “good” participants, pwMS showed significantly altered temporal extrapolation compared with both control groups, independent of stimulus type. Age-matched HCs exhibited a bimodal distribution for impoverished stimuli, and performance was associated with fatigue: increased fatigue was associated with greater temporal extrapolation (similar to young HCs), whereas reduced fatigue was associated with diminished extrapolation.

Conclusion: Preliminary findings indicate altered BM recognition in pwMS, possibly reflecting AON dysfunction. Fatigue appears to modulate BM perception not only in pwMS but also in physiological aging. These results support the potential of BM recognition as a biomarker for personalizing action-observation-based rehabilitation.

EPO-0598 | **Multimodal integrative interventions in Korean medicine for persistent postural-perceptual dizziness: A systematic review and network meta-analysis**

H. Yu¹; E. Lee¹; S. Ahn¹; J. Yoo²
¹College of Korean Medicine, Kyung Hee University, Seoul, Republic of Korea; ²College of Nursing Science, Kyung Hee University, Seoul, Republic of Korea

Background and aims: Persistent Postural-Perceptual Dizziness (PPPD) is a chronic functional vestibular disorder with complex pathophysiology. Evidence regarding multimodal integrative strategies remains limited. This study compared the relative effectiveness of Korean medicine-based single and multimodal interventions for PPPD using Bayesian network meta-analysis.

Methods: We analyzed RCTs published between 2000 and September 2024 involving patients with PPPD or chronic functional dizziness. Interventions included herbal medicine, acupuncture, physical/psychological therapy, and combinations. Primary outcomes were Dizziness Handicap Inventory (DHI) and emotional well-being, with treatment hierarchies estimated via SUCRA values.

Results: Ten RCTs (956 participants) were analyzed across three subnetworks (Figure 1, Figure 2). In the control-monotherapy subnetwork, psychological therapy ranked highest (SUCRA=99%). Within the VRT-based subnetwork, CBT-informed VRT was most effective (SUCRA=86.1%). In the pharmacologic-integrative subnetwork, multimodal interventions consistently outperformed monotherapy, with combined psychological, physical, and pharmacological therapy ranking highest (SUCRA=99.71%) (Figure 3).

Conclusion: This first network meta-analysis on PPPD highlights the clinical relevance of multimodal strategies addressing both physical and psychological dimensions. Although findings are promising, evidence certainty is low due to small sample

FIGURE 1 PRISMA Flow Diagram of Study Selection. From an initial 3,733 records identified across nine databases, 10 RCTs involving 956 participants were finally included for the network meta-analysis after a rigorous screening based on PICOS criteria.

FIGURE 2 RoB of the included studies. Most included studies (8/10) were classified as having “some concerns,” while two studies were judged as “high risk” primarily due to issues with missing outcome data.

FIGURE 3 Multimodal strategies (SUCRA 99.71%) outperformed monotherapy. Psychological therapy (99%) and CBT-informed VRT (86.1%) ranked highest in their subnetworks, demonstrating that integrated physical and psychological care is most effective.

sizes and fragmented network structure. Future large-scale randomized trials are needed to strengthen the evidence base.

EPO-0600 | Polypharmacy Deprescribing Does Not Affect Muscle Mass, Strength, and Physical Function in Post-Stroke Geriatric Patients with Sarcopenia

K. Siregar¹; P. Prawiroharjo²; S. Tanumihardja³
¹School of Medicine Maranatha Christian University, Bandung, Indonesia; ²Department of Neurology, Faculty of Medicine, Universitas Indonesia, Jakarta, 10430/ RSUPN dr. Cipto Mangunkusumo, Jakarta, 10320/ Rumah Sakit Universitas Indonesia, Depok, 16424, Indonesia; ³Department of Neurology, School of Medicine Maranatha Christian University/Immanuel Hospital, Bandung, Indonesia

FIGURE 1 Forest plot for SMI (Skeletal Muscle mass Index).

FIGURE 2 Forest plot for HG (Hand grip Strength).

FIGURE 3 Forest plot for FIM (Functional Independence Measure) Motor.

Background and aims: One-third of geriatric patients with multimorbidity take five or more prescribed medications (polypharmacy). We evaluated whether polypharmacy deprescribing affect muscle mass, strength, and physical function in post-stroke geriatric patients with sarcopenia.

Methods: Relevant studies were identified from PubMed, Scopus, and Web of Science until December 2025. Observational studies involving post-stroke geriatric patients with sarcopenia and polypharmacy were included, comparing deprescribing and non-deprescribing groups. Two reviewers independently screened studies and assessed risk of bias. Forest plots were generated, with SMI (Skeletal Muscle mass Index), HG (Hand Grip strength), FIM (Functional Independence Measure), BRS (Brunnstrom Recovery Stage) as the outcome.

Results: Four studies comprising 432 participants in the deprescribing group and 534 in the non-deprescribing group were included. There were no significant differences between groups in SMI (MD -0.04 kg/m²; 95% CI -0.20 to 0.11; I²=0%), hand-grip strength (MD -0.17 kg; 95% CI -1.93 to 1.59; I²=37%), FIM motor scores (MD 0.25; 95% CI -7.21 to 7.71; I²=72%), BRS of the upper limb (MD -0.07; 95% CI -0.46 to 0.31; I²=0%), and lower limb (MD -0.25; 95% CI -0.59 to 0.08; I²=0%).

Conclusion: This study showed that polypharmacy deprescribing was not associated with difference in muscle mass, muscle strength, or physical function. Limited study numbers and heterogeneity highlight the need for future prospective studies focusing on the effects of specific drug classes on sarcopenia.

EPO-0601 | Combined high-frequency rTMS over the non-lesional hemisphere and rPMS for severe upper limb paralysis: Functional compensation via ipsilateral fibers

K. Yoshida; M. Abo
 The Jikei University School of Medicine, Tokyo, Japan

Background and aims: Standard repetitive transcranial magnetic stimulation (rTMS) for stroke-induced upper limb paralysis

often shows limited efficacy in severe cases. This study investigates a novel therapeutic approach combining high-frequency (10Hz) rTMS over the non-lesional hemisphere and repetitive peripheral magnetic stimulation (rPMS) of paretic proximal muscles. The objective was to activate ipsilateral descending pathways, such as the anterior corticospinal and reticulospinal tracts, to promote functional compensation in severe paralysis.

Methods: We included 16 patients (mean age 61.4 +/- 10.0 years) with severe paralysis, defined as a Fugl-Meyer Assessment for Upper Extremity (FMA-UE) score of 22 or less. Participants received 10Hz rTMS over the non-lesional motor cortex for two weeks and rPMS on paralyzed shoulder muscles (e.g, deltoid) for two to four weeks. Clinical outcomes were evaluated using FMA-UE scores, comparing pre- and post-treatment results via the Wilcoxon signed-rank test.

Results: Total FMA-UE scores significantly improved from 12.5 ± 4.4 to 14.8 ± 4.6 ($p=0.0051$). Sub-score analysis revealed a significant increase in Part A (proximal function) from 10.8 ± 3.8 to 12.6 ± 3.8 ($p=0.0074$). Conversely, no significant differences were observed in Parts B, C, or D. No serious adverse events were reported during the intervention.

Conclusion: Simultaneous central and peripheral stimulation significantly improved proximal upper limb function in severe stroke cases. This combined protocol likely promotes functional

activation of ipsilateral descending pathways, offering a valuable new strategy for functional recovery in patients with severe paralysis where conventional treatment options are extremely limited.

EPO-0602 | Exploring the relationship between balance and quality of life in individuals with Parkinson's disease: Preliminary findings

B. Özcan¹; B. Farhoomand¹; N. Cetisli-Korkmaz¹; L. Bi²

¹Pamukkale University, Faculty of Physiotherapy and Rehabilitation, Denizli, Türkiye; ²Pamukkale University, Faculty of Medicine, Department of Neurology, Denizli, Türkiye

Background and aims: The aim of this study was to investigate the relationship between health-related quality of life (QoL) and commonly used clinical balance and functional performance tests in individuals with PD.

Methods: Nineteen individuals with PD at Modified Hoehn and Yahr stages ≤ 2.5 were included in the study. Health-related quality of life was assessed using the Parkinson's Disease Questionnaire-39 (PDQ-39). Balance and lower extremity function were evaluated using the 30-Second Sit-to-Stand Test (30STS), Six-Spot Step Test (SSST), Four Square Step Test (FSST), 3-Meter Backward Walk Test (3MBWT), Timed Up and Go Test (TUG), and the Berg Balance Scale (BBS). The Modified Falls Efficacy Scale (MFES) was used to assess the perceived fear of falling.

Results: No significant relationships were found between the PDQ-39 total score and the performance-based balance tests (30STS, SSST, FSST, 3MBWT, and TUG) ($p > 0.05$). In contrast, statistically significant associations were observed between the total PDQ-39 scores and both the BBS and MFES scores ($p < 0.05$). The simple linear regression analyses indicated that BBS and MFES explained 20% and 32% of the variance in QoL, respectively.

Conclusion: The findings of this study suggest that the reduced QoL in individuals with PD is more strongly associated with balance-related perceptual factors, such as fear of falling, and balance confidence, than with objective, performance-based balance and mobility measures alone. These results highlight the importance of incorporating interventions that not only aimed physical performance but also address fear of falling, and enhance balance confidence within physiotherapy and rehabilitation programs.

Disclosure: Nothing to disclose.

EPO-0603 | Longitudinal Effects of Two Courses of HF-rTMS and Intensive Speech Therapy for Aphasia

M. Abo

Department of Rehabilitation Medicine, The Jikei University School of Medicine, Tokyo, Japan

Background and aims: The longitudinal effects of combining intensive speech therapy (ST) with two separate courses of high-frequency repetitive transcranial magnetic stimulation (HF-rTMS) for aphasia remain unclear. This study retrospectively

FIGURE 1 Changes in total FMA-UE scores before and after the combined stimulation protocol.

FIGURE 2 Changes in FMA-UE Part A scores before and after the combined stimulation protocol.

FIGURE 3 Multimodal data acquisition from anterior and posterior views, integrating synchronised multi-view video, motion capture, surface EMG with IMU's, and additional streams including facial video, audio, tablet tasks, and human–computer interaction.

longitudinal tracking, and data-driven inference. This strengthens behavioural examination as a quantitative foundation for biomarker discovery and treatment optimisation.

Disclosure: Nothing to disclose.

EPO-0605 | Treatment effects on spasticity and motor outcomes in pediatric cerebral palsy: A systematic review and meta-analysis

M. Alghadier¹; A. Alsawayegh²
¹Department of Health and Rehabilitation Sciences, Prince Sattam bin Abdulaziz University, Alkharj, Saudi Arabia;
²Corporate Department of Pharmacy, King Saud University Medical City, Riyadh, Saudi Arabia.

Background and aims: Botulinum toxin type A (BoNT-A) is a cornerstone intervention for managing focal spasticity in children with Cerebral Palsy (CP). Despite its widespread use, variability in trial designs has complicated the assessment of its magnitude, durability, and impact on functional gains. This study aimed to quantify the short-term therapeutic effects of BoNT-A and synthesize evidence regarding dosing and rehabilitation contexts.

Methods: We conducted a systematic review of Randomized Controlled Trials (RCTs) published between January 2015 and November 2025 across four major medical databases (PubMed, Cochrane, Web of Science, Google Scholar). Inclusion was restricted to pediatric CP populations receiving pharmacological spasticity management. Primary outcomes included spasticity severity (Modified Ashworth Scale, MAS) and gross motor function (GMFM). Data were synthesized to calculate pooled mean differences and evaluate heterogeneity across limb targets and dosing strategies.

Results: Eighteen RCTs involving 892 participants met the inclusion criteria. Meta-analysis of placebo-controlled lower-limb studies demonstrated a statistically significant reduction in spasticity at 4–6 weeks (pooled mean difference on MAS: −0.31). While tone reduction was consistent across licensed doses, functional improvements (GMFM) were modest and primarily observed when injections were paired with structured rehabilitation (1–3 months post-intervention). The therapeutic

effect typically attenuated by week 12. Adverse events were predominantly mild and transient.

Conclusion: BoNT-A is effective for short-term focal spasticity reduction in pediatric CP. However, translation into functional motor gains is inconsistent and strongly dependent on concurrent rehabilitation. Clinicians should view BoNT-A as an adjunct to therapy rather than a standalone solution, with re-administration required to sustain benefits.

Disclosure: Nothing to disclose.

EPO-0606 | Comparison of Respiratory Functions and Physical Fitness Levels in Individuals Diagnosed with Multiple Sclerosis and Healthy Individuals

N. Duruturk¹; I. Gözlekci¹; M. Kılınç²
¹Baskent Univeristy, Physiotherapy and Rehabilitation Department, Ankara, Türkiye; ²Baskent University, Neurology Department, Ankara, Türkiye

Background and aims: Multiple sclerosis (MS) is defined as a chronic, inflammatory and autoimmune disease affecting the white matter of the central nervous system. Depending on the location of the lesions, symptoms may vary and can significantly affect the daily life of patients. The study aimed to investigate the comparison of pulmonary function and physical fitness levels in individuals with Multiple Sclerosis and healthy individuals.

Methods: The study included 34 individuals with MS with EDSS scores of ≤4.5 - 6 and 34 healthy individuals of similar age and gender. Respiratory function was measured by spirometer, inspiratory muscle strength by respiratory muscle strength meter, inspiratory muscle endurance by ascending threshold loading test, biceps and quadriceps muscle strength by digital hand dynamometer, cardiorespiratory endurance by Six Minutes Walking Test, flexibility with sit and reach and back scratch test and balance by interactive balance system.

Results: There were significant differences between the MS group's respiratory function test and inspiratory muscle strength and biceps, quadriceps muscle strength, 6MWT walking distance, expected percentage, stability test parameters and the values of the healthy group ($p < 0.05$).

Conclusion: As a result of our study we determined that respiratory functions and physical fitness parameters were lower in MS individuals than in healthy individuals. We think that appropriate evaluation and treatment should be made by considering the effects of these factors in physiotherapy and rehabilitation programs specific to MS individuals and developing them.

Disclosure: Nothing to disclose

EPO-0607 | Stride width can be a descriptor of reduced ability of gait modulation in people with Multiple Sclerosis

R. Rossanigo¹; M. Caruso¹; G. Cicalò¹; N. Leo¹; A. Audisio¹; P. Tasca¹; V. Agostini¹; G. Olmo¹; M. Ghislieri¹; R. Chirico²; I. Bertoni²; E. Favano³; D. Vecchio³; C. Comi³; E. Virgilio⁴; S. Rolla⁴; M. Morra⁴; A. Dal Molin³; M. Clerico⁴; A. Cereatti¹
¹Department of Electronics and Telecommunications, Politecnico di Torino, Turin, Italy; ²University Hospital Maggiore della Carità, Novara, Italy; ³Department of Translational Medicine, Neurology Unit, University of Piemonte Orientale, Novara, Italy; ⁴Department of Clinical and Biological Sciences, University of Turin, Turin, Italy

Background and aims: Gait modulation—the ability to adapt gait to maintain stability while minimizing energetic cost across different contexts—can be impaired in people with Multiple Sclerosis (pwMS) due to proprioceptive deficits and motor rigidity, increasing fall risk. Traditional gait measures such as stride velocity describe overall performance but limited insight into dynamic balance. Stride width (SW), the mediolateral distance between the feet, is a sensitive marker of lateral stability but is typically restricted to lab-based assessment. We monitored SW and stride velocity in healthy subjects (HS) and pwMS during in-lab and ecological walking, to examine how different contexts shape gait modulation.

Methods: Ten healthy subjects (HS) and ten pwMS (EDSS 1–6) performed a 2-min walking test (2MWT), an in-lab simulation of daily activities (SDA), and a 2.5-h free-living session while wearing a validated wearable system estimating stride velocity and SW (Figure 1). Linear mixed-effects models evaluated the impact of walking condition and group on these parameters.

Results: Stride velocity was consistently lower in pwMS than HS, while SW revealed context-specific patterns (Figure 2).

Conclusion: Wearable-based SW captures context-dependent gait adaptation in pwMS that stride velocity alone cannot. SW variability was reduced in pwMS during 2MWT and SDA, indicating limited modulation of the base of support, whereas free-living walking showed wider SW, suggesting a compensatory

FIGURE 1 Participant's right foot instrumented with a novel miniaturized wearable system (A) which enables to estimate bilateral stride width (B).

FIGURE 2 Distributions of stride width (above) and stride velocity (bottom) of healthy subjects (left) and people with Multiple Sclerosis (right) across different walking conditions. Over 45000 steps were analyzed. * $p < 0.05$.

strategy prioritizing postural safety over gait economy. Impaired SW modulation may represent a novel biomarker of lateral instability, proprioceptive deficits, and motor rigidity. Future work will investigate its longitudinal relationship with clinical disability and fall incidence.

EPO-0608 | Validation of a Vision Screening Tool for Detecting Visual Abnormalities in Acute Stroke Care

S. Ryan¹; A. Litzen Jørstad²; M. Moe²; M. Skjelland¹; F. Rowe³; Ø. Jørstad²; A. Aamodt¹

¹Department of Neurology, Oslo University Hospital, Oslo, Norway; ²Department of Ophthalmology, Oslo University Hospital, Oslo, Norway; ³Institute of Population Health, Faculty of Health and Life Sciences, University of Liverpool, Liverpool, UK

Background and aims: Visual abnormalities are common after stroke but are under-recognised in acute care. The Vision Impairment Screening Assessment (VISA) was developed to enable structured bedside screening by non-specialist stroke clinicians. We aimed to validate the Norwegian translated version of VISA against comprehensive neuro-ophthalmic examination and describe the prevalence of post-stroke visual abnormalities in a hyperacute stroke population.

Methods: StrokeVIS was a prospective diagnostic accuracy study including consecutive patients admitted for acute stroke management at a tertiary thrombectomy centre. Participants underwent VISA screening and neuro-ophthalmic examination within 72 hours of admission. VISA was administered by trained stroke staff blinded to the reference standard. Diagnostic performance was assessed using sensitivity, specificity, predictive values, and overall accuracy. Secondary analyses examined prevalence across visual domains and evaluated the performance of VISA and the visual items of the National Institutes of Health Stroke Scale (NIHSS).

FIGURE 1 Prevalence of visual abnormalities detected on neuro-ophthalmic examination in the full study cohort (N=127). Percentages represent patients with at least one abnormality per domain. Multiple abnormalities per patient were allowed.

FIGURE 2 Co-occurrence of visual abnormalities identified on neuro-ophthalmic examination among patients with complete data across all domains (n = 72). Bars show single-domain abnormalities and the most frequent multi-domain combinations.

FIGURE 3 Screening performance of the Vision Impairment Screening Assessment (VISA) and visual items of the National Institutes of Health Stroke Scale (NIHSS) compared with neuro-ophthalmic examination as the reference standard.

Results: A total of 127 patients were included, of whom 81 completed both assessments. Neuro-ophthalmic examination identified visual abnormalities in 70.1% of patients, most frequently ocular motility disturbances (46.5%), visual inattention (38.3%), reduced distance visual acuity (25.5%), and visual field loss (15.7%). VISA demonstrated high sensitivity (94.5%) but

low specificity (34.6%), with an overall accuracy of 75.3%. The NIHSS visual items showed lower sensitivity (60.7%) and accuracy (62.0%).

Conclusion: The Norwegian version of VISA demonstrates high sensitivity for detecting early post-stroke visual abnormalities in acute care. Given the high prevalence of visual abnormalities and the limited sensitivity of routine neurological assessment, structured visual screening may improve early identification of vision-related deficits in stroke pathways.

EPO-0609 | Disease course in primary brain calcification: A monocentric longitudinal study from an Italian Cohort

G. Bonato¹; D. Gasparini³; F. Pistonesi²; C. Bertolin⁴; L. Salviati⁵; A. Antonini²; M. Carecchio²

¹Neurodegenerative Disorders Unit, Neuroscience Department, University of Padova, Padova, Italy; ²Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, University of Milan, Milan, Italy; ³Neurodegenerative Disorders Unit, Neuroscience Department, University of Padova, Padova, Italy; ⁴Biostatistics, Epidemiology and Public Health Unit, University of Padua, Padova, Italy; ⁵Clinical Genetics Unit, University Hospital of Padova, Padova, Italy; ⁶Clinical Genetic and Epidemiology Unit, Department of Women and Children's Health, University of Padova, Padova, Italy

Background and aims: Primary Brain Calcification (PBC) is a rare neurodegenerative disorder characterized by brain calcium deposition, featuring movement disorders and psychiatric/cognitive disturbances[1–3]. Quantitative longitudinal data describing disease progression are limited[2–4]. We here investigate motor-symptoms evolution and clinical predictors of functional outcome.

Methods: 83 PBC patients from Padova University, diagnosed by CT-scan and metabolic screening; NGS genetic test; neurological assessment (MDS-UPDRS-III, H&Y, SARA, UHDRS, BFMDS, TETRAS, MoCA); mean prospective follow-up of 3.5±2years, combined with retrospective data collection covering 9±4years; linear-mixed-models/hinge-LMM, Kaplan-Meier-survival-curves, multivariate analysis.

Results: Neurological symptoms were documented in 64 subjects; movement disorders were the most frequent manifestation ($n=52$, predominantly parkinsonism); over time, combined motor and cognitive/psychiatric involvement occurred in 65% of patients. Mean age-at-onset was 53.3 years but neuropsychiatric symptoms presented earlier (mean 42 years, $p=0.002$). Genetic diagnosis was achieved in 46%, mostly involving MYORG and SLC20A2 mutations. Parkinsonism, cerebellar signs and cognitive decline predicted worse functional outcome ($p=0.01$), older age was a risk-factor of symptom development ($p=0.004$), genetics influenced specific symptoms penetrance. Clinical progression occurred in 63% of the cohort, with significant worsening in UPDRS-III, SARA and MoCA ($p<0.001$) scales. Hinge-LMM, aligning to symptom onset, demonstrated progression rates of +1.7/year at UPDRS-III, +0.7/year at SARA ($p<0.001$). Isolated

FIGURE 1 A) Combination of clinical symptoms at last evaluation (Venn diagram). B) Kaplan-Meier survival curves for core symptoms over time.

FIGURE 2 Genetic findings in the cohort.

FIGURE 3 Disease trajectories for significant motor scales (UPDRS-III and SARA).

dystonia/tremor showed minimal progression. MYORG mutation carriers showed faster progression compared to other genetic subgroups (UPDRS-III:+3.6/y, $p=0.01$; SARA:+1.7/y, $p=0.01$).

Conclusion: PBC is a progressive disorder with distinct disease trajectories influenced by symptom profile and genetic background. Comprehensive assessment and longitudinal monitoring are essential to define individual disease prognosis and support future therapeutic trials.

FIGURE 1 Baseline demographic and clinical characteristics associated with the final titrated dose of sublingual apomorphine.

Methods: Baseline characteristics from the CTH-301 dose-optimisation phase were examined across five SL-APO doses (10–30 mg) from de novo patients. Associations between variables and SL-APO dose were evaluated using univariate ordinal logistic regression. Odds ratios with 95% confidence intervals were calculated for continuous and categorical variables, and statistical significance was set at $p < 0.05$.

Results: Several baseline factors showed significant associations with higher SL-APO doses. Patients with greater motor severity, reflected in higher MDS-UPDRS Part I, II, III, and Total scores (all $p < 0.001$), were more likely to titrate to higher doses. A higher total daily levodopa dose was also significantly associated with higher SL-APO doses ($p < 0.001$). In addition, the presence of delayed ON ($p = 0.018$) and a greater number of daily OFF episodes ($p = 0.005$) were associated with requiring higher doses. No significant associations were observed for age, sex, BMI, Hoehn&Yahr stage, cognitive status, PD duration, motor fluctuations duration, tremor, wearing-off, morning akinesia, sudden OFF, or duration of OFF episodes.

Conclusion: Patients who required higher SL-APO doses presented with more severe baseline motor symptoms, higher levodopa requirements, delayed ON, and more frequent OFF episodes. These findings indicate that individuals with a greater motor burden and more complex fluctuation profiles may require higher SL-APO doses, providing useful guidance for clinicians during dose titration to achieve an optimal therapeutic effect.

Background and aims: Opicapone is used to manage motor fluctuations in Parkinson's patients, and its earlier initiation at wearing-off onset demonstrated benefits in OFF- and Good-ON-time without increasing dyskinesia over 1 year. This post-hoc analysis evaluated opicapone's long-term safety and tolerability in Parkinson's patients with early fluctuations.

Methods: Data were pooled from double-blind, placebo-controlled BIPARK I and II studies (3.5 months) and their 1-year open-label extensions. Analyses included participants randomized to placebo or opicapone 50mg who continued opicapone during the open-label phase and had developed wearing-off within ≤2years prior to screening. Treatment-emergent adverse

CPK, creatine phosphokinase; TEAE, Treatment-emergent adverse events

events (TEAEs), TEAEs considered related to treatment, and TEAEs leading to discontinuation were evaluated.

Results: Safety Set included 218 patients with recent-onset wearing-off (placebo, $n=110$; opicapone, $n=118$). During the double-blind phase, TEAEs occurred in 55.9% of opicapone-treated and 51.8% of placebo-treated patients, with treatment-related TEAEs being reported in 30.5% and 20.0%, respectively (Table 1). Most frequent treatment-related TEAEs with opicapone were dyskinesia (9.3%) and insomnia (3.4%). In the 1-year open-label extension, treatment-related TEAEs occurred in 39.8% of patients continuing opicapone and 35.5% of those switching from placebo, most commonly dyskinesia (8.5% and 13.6%, respectively) (Table 2). Treatment-related TEAEs leading to discontinuation were infrequent (2.5% and 0.0%, respectively); no deaths were reported.

Conclusion: Long-term opicapone exposure was generally safe and well-tolerated in patients with recent-onset fluctuations. Most TEAEs were mild/moderate and consistent with dopaminergic therapy. Dyskinesia occurred less frequently in early versus later starters during the open-label phase, supporting opicapone's favorable safety profile when initiated at wearing-off onset.

Background and aims: Parkinsonism, particularly Parkinson's disease (PD), is a progressive neurodegenerative disorder with motor and non-motor symptoms that negatively affect quality of life and increase caregiver burden. Neuropalliative care has recently emerged for chronic neurological disorders, including PD. This study evaluated awareness and perceptions of palliative care among patients with parkinsonism, their caregivers, and physicians in Korea, and identified factors associated with caregiver burden.

Methods: A multicenter, cross-sectional study was conducted with 112 patients, 110 caregivers, and 61 physicians. Structured questionnaires assessed awareness and attitudes toward neuropalliative care. Caregiver burden was measured using validated Korean version of the Parkinson's Disease Questionnaire-Carer (PDQ-Carer).

Results: Awareness of palliative care differed markedly: 31.3% of patients and 27.5% of caregivers versus 90.2% of physicians. Caregivers were stratified by PDQ-Carer score into low- (≤ 34 , $n = 63$) and high-burden (> 34 , $n = 47$) groups. High-burden caregivers supported patients with longer disease duration, poorer cognition, higher Hoehn and Yahr stage, and greater levodopa equivalent daily doses (LEDD). Regression analysis showed that caregiver demographics were not associated with burden, whereas caregiving duration, patient cognitive decline, Hoehn and Yahr stage, LEDD, and disease duration were correlated. In the multivariable model, only patient disease duration remained significant ($B = 2.048$, 95% CI 0.083–4.012, $p = 0.041$).

Conclusion: There is a significant awareness gap in palliative care between physicians and patients/caregivers. The caregiver burden was mainly linked to disease duration as the strongest predictor. Education and structured neuropalliative strategies are needed to support patients with PD and their families

Background and aims: Subthalamic deep brain stimulation elicits short- and long-latency cortical responses reflecting activation of hyperdirect and polysynaptic basal ganglia–thalamo–cortical pathways (Miocinovic et al, 2018). While dopaminergic medication alters network synchrony and basal ganglia coupling (Kühn et al, 2008; Tinkhauser et al, 2017), its influence on DBS-evoked cortical responses remains unclear. Human EEG and primate studies suggest a medication-related dampening of late cortical components (Eusebio et al, 2009; Campbell et al, 2022). However, systematic MEG studies examining the influence of dopaminergic state on DBS-evoked cortical activity in Parkinson's disease are lacking. The present study aimed to determine whether dopaminergic state modulates the amplitude, latency, or spatial distribution of STN-DBS-evoked cortical responses.

Methods: Nineteen patients with Parkinson's disease and STN-DBS underwent MEG recordings during low-frequency (6 Hz) stimulation of the left STN. Stimulation was applied omnidirectionally at the clinically effective contact using the individual therapeutic amplitude and a pulse width of 60 μ s. Each patient was recorded in medication ON and OFF states. Source activity was reconstructed using linearly constrained minimum variance beamforming, focusing on the primary motor cortex and supplementary motor area. Peak amplitudes and latencies were compared between medication states using paired two-tailed t-tests.

Results: DBS evoked consistent early (~6 ms), mid (~13 ms) and long-latency (~21 ms) cortical responses in both conditions. No significant differences in response amplitude, latency, or cortical topography were observed between medication states.

Conclusion: DBS-evoked cortical responses were robust and reproducible in both medication states, suggesting that DBS programming based on evoked cortical responses is feasible without medication withdrawal.

Background and aims: Continuous subcutaneous infusion of foslevodopa/foscarbidopa (CSFI) is an effective therapy for advanced Parkinson's disease (PD). However, the role of concomitant opicapone (OPC) during CSFI has not been systematically assessed. This study evaluated the impact of OPC co-administration on clinical outcomes, dopaminergic requirements, and safety.

Methods: We performed a single-center, retrospective study including 59 patients with advanced PD treated with CSFI.

Motor outcomes (MDS-UPDRS-III and IV), infusion parameters, levodopa equivalent daily dose (LEDD), and adverse events were compared between patients treated with and without concomitant OPC.

Results: The cohort comprised 36 men and 23 women (mean age 66.7 years; mean disease duration 14.5 years). Twenty-nine patients received OPC (24 continued from baseline, 5 initiated de novo). Treatment retention was high; only two patients discontinued OPC for non-safety reasons, with one requiring prompt reintroduction due to severe OFF worsening. Pre-infusion LEDD was significantly higher in the OPC group. At 8 months, both groups showed comparable motor improvement with identical infusion flow rates (0.28 mL/h). Mean improvement in MDS-UPDRS-III was similar between groups, while a trend toward greater improvement in UPDRS-IV was observed in OPC-treated patients. Total LEDD remained higher in the OPC group at follow-up. Neuropsychiatric adverse events were more frequent in OPC-treated patients, though differences were not statistically significant.

Conclusion: OPC appears to be a feasible adjunct during CSF1, supporting higher dopaminergic requirements without increasing infusion flow rates. While generally well tolerated, careful monitoring for neuropsychiatric adverse events is recommended.

EPO-0615 | Wearable sensors may detect subtle gait alterations associated with autonomic dysfunction in drug-naïve Parkinson's disease patients

F. Ambrosio¹; N. Piramide¹; R. De Micco¹; L. Donisi¹; M. Siciliano²; C. Cabato¹; O. Ciaramaglia¹; F. Esposito¹; A. Tessitore¹

¹Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy;

²Neuropsychology Laboratory, Department of Psychology, University of Campania "Luigi Vanvitelli", Caserta, Italy

Background and aims: Gait and balance disorders significantly affect functional activities of daily life in patients with Parkinson's disease (PD). Autonomic dysfunction has been associated with increased risk of falls in patients with advanced PD. Recent studies suggest that earlier development of dysautonomia is associated with more rapid disease progression and shorter survival time. We aimed at investigating potential correlations between gait and autonomic dysfunction in early drug-naïve PD patients using wearable sensors.

Methods: Fifty drug-naïve PD patients (disease duration ≤ 3 years, Hoehn & Yahr ≤ 2.5) and 20 age and sex-matched healthy controls were consecutively enrolled. Gait and balance parameters were acquired using six Opal V2R wearable sensors, when performing the Timed up and go, 7 and 10 Meters walking tests in single and dual task (ST/DT) conditions. Motor and autonomic symptoms were evaluated using the Unified Parkinson's

disease Rating scale part III (UPDRS-III) and the Scales for Outcomes in Parkinson's Disease - Autonomic Dysfunction (SCOPA-AUT). Bivariate correlation analysis between clinical and wearable sensors metrics were performed.

Results: Higher SCOPA-AUT scores significantly correlated with worse gait and postural performances as detected by wearable sensors in both ST and DT conditions. Interestingly, no correlations have been found between SCOPA-AUT and UPDRS III, including axial and gait subscores.

Conclusion: Our findings revealed that application of wearable sensors could provide useful information for the characterization of drug-naïve PD patients, even in the absence of clinically detectable gait and postural disturbances. These subtle changes are already associated with autonomic dysfunctions, suggesting a potential role to predict worse clinical outcome.

Disclosure: Nothing to disclose.

EPO-0616 | Short- and long-term effects of continuous dopaminergic infusion on cortical excitability and plasticity in Parkinson's disease.

F. Marchet¹; M. De Bartolo¹; F. Aiello²; M. Costanzo²; N. Modugno¹; S. Pietracupa¹; G. Leodori¹; A. Conte²; G. Fabbrini²; A. Berardelli¹; D. Belvisi²

¹IRCSS Istituto Neurologico Mediterraneo Neuromed, Pozzilli (IS), Italy; ²Department of Human Neurosciences, Sapienza University of Rome, Rome (RM), Italy

Background and aims: Continuous subcutaneous infusion of foslevodopa/foscarbidopa has been recently developed for patients with Parkinson's disease (PD) experiencing motor complications inadequately controlled by oral dopaminergic therapy. The pathophysiology of motor complications involves abnormally reduced plasticity of the primary motor cortex (M1) in PD. Once motor complications emerge, intermittent dopaminergic stimulation fails to adequately influence motor cortical plasticity. The aim of the present study was to evaluate whether continuous dopaminergic stimulation can modulate cortical plasticity in patients with PD.

Methods: Fifteen patients (7 female, age 67 ± 6.41) with complicated PD receiving oral L-dopa were consecutively enrolled. Clinical evaluation included standardized scales assessing motor and non-motor manifestations. Neurophysiological evaluation of M1 plasticity was performed using intermittent theta-burst stimulation (iTBS), transcranial magnetic stimulation paradigm. The after-effects of iTBS were evaluated by measuring motor evoked potential amplitudes recorded before and at 5, 15, and 30 minutes after stimulation. Patients were assessed while still receiving oral therapy (T0), immediately after initiation of foslevodopa/foscarbidopa infusion (T1), and after 24 weeks of continuous treatment (T2).

Results: Foslevodopa/foscarbidopa treatment was associated with a significant improvement in motor and non-motor manifestations, including a reduction in the severity of motor complications. At T2, foslevodopa/foscarbidopa treatment induced an improvement in abnormally reduced M1 plasticity in patients with PD, as evidenced by an increased response to the iTBS protocol compared with baseline (T0).

Conclusion: In contrast to intermittent dopaminergic stimulation, continuous dopaminergic stimulation induced by

foslevodopa/foscarbidopa can modulate M1 plasticity in patients with PD. This mechanism may contribute to the clinical effects of this therapeutic approach.

EPO-0617 | Plasma NfL, GFAP and P-Tau181 as stratifiers of alpha-synucleinopathies, from prodromal to early stages

K. Eshja¹; A. Pilotto¹; I. Girotto²; C. Tolassi²; A. Lupini¹; C. Zatti¹; A. Rizzardi¹; L. Purin¹; M. Pasolini³; C. Liguori⁴; N. Mercuri⁵; A. Chiaravallotti⁵; M. Fernandes⁵; K. Kulcsárová⁶; M. Skovarnek⁶; E. Schaeffer⁷; D. Berg⁷; A. Padovani¹

¹Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Italy; ²Laboratory of Digital Neurology and Biosensors, University of Brescia, Italy; ³Sleep disorder Center, ASST Spedali Civili of Brescia, Italy; ⁴Sleep Medicine Centre, Neurology Unit, University Hospital of Rome Tor Vergata, Rome, Italy; ⁵Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy; ⁶Department of Neurology, Faculty of Medicine, Pavol Jozef Šafárik University, 04001 Košice, Slovakia; ⁷Department of Neurology, Christian-Albrechts-University of Kiel, Kiel, Germany

Background and aims: plasma markers have recently been implemented in neurodegenerative disorders as they might contribute to stratify subjects at different risk for Parkinson Disease (PD) or Lewy Body Disease (DLB). Rem Sleep Behaviour disorders (RBD) patients seem to be biologically closer to DLB rather than PD. Aim of the study was to evaluate the distribution of NfL, GFAP and pTau 181 in PD, DLB and subjects with different prodromal risk factors for alpha-synucleinopathies

Methods: early PD, DLB, as well as subjects with idiopathic Sleep behavioral disorders or isolated hyposmia and matched controls RBD and 136 Healthy Controls (HC), underwent an extensive PD prodromal marker evaluation and plasma markers assessment using Single molecule array (Simoa) technology. Cut-off values were calculated based on 1 standard deviation of healthy controls.

Results: The study included 559 individuals, 108 DLB, 206 PD, 91 idiopathic RBD and 136 Healthy Controls (HC) of which 18 hyposmic, DLB globally showed higher levels of GFAP and a significant increase of pTau181 when compared to PD. iRBD exhibited higher NfL and GFAP levels compared to HC and PD, and a lower score at sniffing test suggesting that hyposmia can be detected together with RBD. GFAP levels seemed to be higher in subjects at risk for alpha synucleinopathies.

Conclusion: Plasma neurodegenerative markers stratify people at risk for alpha-synucleinopathies and are higher in DLB patients. In prodromal cases, the increase of GFAP correlates with clinical risk of conversion. Future goal is identifying which prodromic symptoms correlate the more with a biomarker increase.

EPO-0618 | Results from the Global Phase 3 Trial (IB1001-303) Evaluating Levacetylleucine in Ataxia-Telangiectasia

K. Martakis¹; M. Patterson²; M. Strupp³; B. Zanrucha²; J. Raymond²; J. Kerthi²; A. Hatcher²; T. Fields²; I. Billington²; T. Bremova-Ertl⁴

¹Department of Neuropediatrics, Justus Liebig University, Giessen, Germany; ²IntraBio Inc, Austin, USA; ³Department of Neurology, LMU University Hospital, LMU Munich, Germany; ⁴Department of Neurology and Center for Rare Diseases, University Hospital Inselspital Bern, Bern, Switzerland

Background and aims: Ataxia-Telangiectasia (A-T) is a rare, inherited cerebellar ataxia. Levacetylleucine (also known as N-acetyl-L-leucine) is a modified amino acid that enters enzyme-controlled pathways to correct metabolic dysfunction and restore cellular communication. In this Phase 3 randomised, double-blind, placebo-controlled trial (IB1001-303), we evaluated the safety and efficacy of levacetylleucine for pediatric and adult individuals with A-T.

Methods: IB1001-303 enrolled A-T participants aged 4 years or older across 10 multinational trial sites. Primary efficacy endpoint was the Scale for the Assessment and Rating of Ataxia (SARA). Secondary endpoints included Spinocerebellar Ataxia Function Index (SCAFI), International Cooperative Ataxia Rating Scale (ICARS), Neurology Quality of Life-Upper Extremity Function (NeuroQOL-UEF), Quality of Life (EQ-5D), and investigator, caregiver, and patient Clinical Global Impression of Improvement (CGI-I). Safety assessment included adverse event incidence and severity.

Results: Seventy-three participants aged 5 to 50 were enrolled. The primary endpoint was met; mean change in the SARA total score with levacetylleucine was -1.92 (SD=2.81) and -0.14 (SD=2.38) with placebo; Linear Mixed Model (LMM) treatment effect -1.88 (SD=0.41) [95% CI -2.70, -1.06; $p < 0.0001$]. The trial met secondary endpoints, including ICARS and CGI-I. NALL was observed to be safe and well-tolerated, consistent with its established safety profile.

Conclusion: Levacetylleucine demonstrated a significant benefit versus placebo, and clinically meaningful improvements in neurological manifestations of A-T, functioning, and quality of life, and a favorable benefit-risk profile for the treatment of A-T.

Background and aims: Progressive supranuclear palsy (PSP) is a rare neurodegenerative disorder characterized by tau pathology and rapid clinical progression. Reliable cerebrospinal fluid (CSF) biomarkers reflecting disease-specific molecular mechanisms are still lacking. Proteomic analysis of CSF may provide insight into pathophysiological processes and identify potential biomarkers for diagnosis and disease monitoring.

Methods: In this single-center study, CSF samples from 24 PSP patients and 12 neurologically healthy age-matched controls were analyzed. Samples were collected using standardized procedures. High-resolution mass spectrometry-based proteomics was performed, enabling the identification and quantification of approximately 2,500 CSF proteins. Differential expression analyses were conducted to compare PSP subgroup with controls, followed by functional and pathway enrichment analyses.

Results: Proteomic profiling revealed distinct CSF protein signatures in PSP patients compared with controls. Differentially expressed proteins were mainly associated with neurodegeneration-related pathways, including synaptic dysfunction, neuroinflammation, cytoskeletal organization, and protein aggregation. Several proteins involved in tau-related processes and glial activation showed altered abundance in PSP. Exploratory analyses suggested potential protein panels that may discriminate PSP from controls.

Conclusion: CSF proteomics identified disease-related molecular alterations in PSP and highlighted biological pathways relevant to its pathogenesis. These findings support the utility of CSF proteomic profiling as a tool for biomarker discovery in PSP. Further studies in larger, multicenter cohorts are warranted to validate candidate biomarkers and assess their clinical applicability.

Disclosure: Nothing to disclose.

EPO-0620 | Individualisation of LECIG therapy in advanced Parkinson's disease: Adapting treatment to suit patients' lives

allow flexible dosing, enabling adaptation to patients' specific and fluctuating motor needs throughout the day.

Methods: We describe clinical cases from our centre illustrating how LECIG therapy, administered via the Crono® LECIG pump, can be adjusted to achieve optimal motor control over a 24-hour period and across different levels of daily activity (Table 1).

Results: (1) A 51-year-old woman with PD from age 35, treated with levodopa-carbidopa intestinal gel (LCIG) infusion since 2015; switched to LECIG in 2023 due to disabling dyskinesias and evening motor worsening. She now receives 24-hour LECIG infusion with three adjustable flow rates tailored to daily demands. (2) A 76-year-old woman with PD since age 44, treated with LCIG since 2011; switched to LECIG in 2025 due to evening motor deterioration and technical difficulties managing two pumps required for 24-hour LCIG infusion. She currently uses LECIG at three flow rates, with marked motor improvement and better caregiver quality of life. (3) A 75-year-old man with PD since 2011, treated with high-dose 24-hour LCIG infusion since 2020; switched to LECIG due to unpredictable and uncontrollable OFF periods and now shows marked clinical improvement using three flow rates.

Conclusion: The use of multiple flow rates with the Crono® LECIG pump allows individualised medication delivery aligned with daily activities and symptom fluctuations, supporting functional independence and an active lifestyle.

EPO-0621 | Shifting paradigms in multiple sclerosis: Long-term outcomes across diagnostic eras

U. Samadzade; S. Ozakbas; C. Caliskan
*Izmir University of Economics, Medical Point Hospital, Izmir,
Türkiye*

Background and aims: Advances in diagnostic criteria, neuroimaging, and disease-modifying therapies have substantially changed the clinical course of multiple sclerosis (MS). This study compared long-term outcomes of patients diagnosed with MS in two different diagnostic eras to assess the real-world impact of evolving clinical practice.

Methods: In this retrospective cohort study, patients diagnosed with MS in two eras were analyzed: Group 1 (1990–1996, $n=133$) and Group 2 (2008–2014, $n=579$). Demographic characteristics, time from symptom onset to diagnosis, Expanded Disability Status Scale (EDSS) scores at diagnosis and at 10-year follow-up, annualized relapse rates (ARR), and conversion to secondary progressive MS (SPMS) were recorded.

Results: A total of 712 patients were included (mean age: 50.7 ± 12.2 years; mean disease duration: 20.7 ± 8.8 years; 70.4% female). Time from symptom onset to diagnosis was significantly shorter in Group 2 compared with Group 1 (3.2 ± 4.6 vs 4.2 ± 4.7 years; $p < 0.005$). After 10 years, disability outcomes remained significantly better in Group 2 (mean EDSS: 1.85 ± 2.02) compared with Group 1 (3.97 ± 2.23 ; $p < 0.001$). ARR was also lower in Group 2 (0.18 ± 0.20 vs 0.23 ± 0.20 ; $p < 0.05$). Conversion to SPMS occurred in 52.6% of Group 1 patients versus only 5.4% of Group 2.

Conclusion: Patients diagnosed in the more recent era demonstrated markedly improved long-term disability outcomes, lower relapse activity, and substantially reduced progression to SPMS, underscoring the positive impact of advances in MS diagnosis and treatment.

Disclosure: Nothing to disclose.

EPO-0622 | Serum IgM Index as a Biomarker of Motor and Cognitive Performance in Multiple Sclerosis

U. Samadzade; C. Caliskan; S. Ozakbas
Izmir University of Economics, Medical Point Hospital, Izmir, Türkiye

Background and aims: The immunoglobulin M (IgM) index, reflecting intrathecal IgM synthesis, has been proposed as a biomarker of disease activity in multiple sclerosis (MS). This study examined functional differences between MS patients with persistently elevated IgM index values and those with normal IgM index.

Methods: This retrospective observational study included MS patients with elevated IgM index values and long-term clinical follow-up. A control group with normal IgM index was selected from a larger cohort of 4,191 MS patients and matched for disease duration and baseline Expanded Disability Status Scale (EDSS). Motor performance was assessed using the Timed 25-Foot Walk (T25FW) and Nine-Hole Peg Test (9HPT). Cognitive function was evaluated with the Symbol Digit Modalities Test (SDMT), Brief Visuospatial Memory Test-Revised (BVM-T-R), and California Verbal Learning Test-II (CVLT-II).

Results: A total of 268 patients with high IgM index and 150 patients with normal IgM index were analyzed. The high IgM index group demonstrated significantly worse motor performance on the T25FW ($p=0.040$) and 9HPT ($p=0.001$). In cognitive assessments, patients with normal IgM index achieved higher scores on the SDMT ($p=0.022$) and BVM-T-R ($p=0.011$), indicating better processing speed and visuospatial memory. No significant difference was observed in CVLT-II scores ($p=0.173$).

Conclusion: MS patients with elevated IgM index showed poorer motor performance and selective cognitive impairment compared with those with normal IgM index. These findings support the IgM index as a potential prognostic biomarker and

emphasize the value of integrating laboratory markers into long-term functional evaluation in MS.

Disclosure: Nothing to disclose.

EPO-0623 | Spinal Cord Lesions and Atrophy Predict Disability Progression and PIRA in Multiple Sclerosis

E. DAROL¹; V. Sezer¹; S. Aksu¹; O. Turhan¹; Ş. Dalkılıç¹; A. Tunc²

¹Sakarya Training and Research Hospital, Clinic of Neurology, Sakarya, Türkiye; ²Department of Neurology, Faculty of Medicine, Sakarya University, Türkiye

Background and aims: Spinal cord pathology is a major contributor to long-term disability in multiple sclerosis (MS). This study aimed to evaluate spinal cord lesion patterns and spinal cord atrophy and to determine their association with long-term disability progression, progression independent of relapse activity (PIRA), and conversion to SPMS.

Methods: We retrospectively analyzed 223 patients with MS followed for at least three years. Spinal cord MRI was assessed for lesion presence, level, axial distribution, number, length, gadolinium enhancement, and spinal cord atrophy. Outcomes included confirmed disability accumulation, attainment of EDSS ≥ 3 , PIRA, and SPMS conversion. Kaplan–Meier analyses and multivariate Cox regression models were applied.

Results: Spinal cord lesions were present in 172 patients (77.1%) and were associated with higher disability, increased risk of EDSS ≥ 3 , PIRA, and conversion to SPMS. Lesion-specific characteristics did not independently predict long-term outcomes. In contrast, spinal cord atrophy independently predicted EDSS ≥ 3 (HR 1.98) and PIRA (HR 2.29). Despite similar baseline disability, patients with spinal cord lesions showed progressive divergence in disability over time.

Conclusion: Spinal cord atrophy is a strong, lesion-independent prognostic marker of disability progression and PIRA in multiple

TABLE 1 Kaplan-Meier survival and log-rank analyses for time to EDSS ≥ 3 and PIRA according to spinal cord lesion status.

A. Survival summary						
Outcome / Group	n	Events (n, %)	Censored (n, %)	Median time (years)	5-year survival	10-year survival
EDSS ≥ 3 – Lesion present	172	99 (57.5%)	113 (65.7%)	13.7 $\pm$ 1.1 (95% CI 13.9–22.2)	0.804 $\pm$ 0.027	0.735 $\pm$ 0.043
EDSS ≥ 3 – Lesion absent	51	5 (9.8%)	46 (90.2%)	Not reached	—	—
PIRA – Lesion present	172	39 (22.7%)	133 (77.3%)	23 $\pm$ 1.4 (95% CI 20.3–25.8)	0.837 $\pm$ 0.023	0.847 $\pm$ 0.018
PIRA – Lesion absent	51	3 (5.9%)	48 (94.1%)	Not reached	—	—

FIGURE 1 Graphical abstract.

sclerosis. While lesion presence identifies patients at risk, lesion morphology has limited prognostic value, highlighting the importance of quantitative spinal cord assessment in longitudinal follow-up.

Disclosure: Nothing to disclose.

EPO-0624 | Prevalence and clinical correlates of sexual dysfunction in multiple sclerosis: A single-center cross-sectional study

B. Alberti-Vall¹; A. Hernando-Andres¹; T. Alba-Isasi¹; V. Guerra-Fernandez¹; Y. Blanco-Morgado¹; S. Llufrí-Duran¹; A. Calvi¹; C. Castelo-Branco²; M. Sepulveda-Gazquez²
¹Neuroimmunology Unit, Hospital Clinic of Barcelona, Barcelona, Spain; ²Clinical Sexology Working Group, Hospital Clinic of Barcelona, Barcelona, Spain

Background and aims: Sexual dysfunction (SD) is a common but under-recognized complication of multiple sclerosis (MS) that substantially affects patients' quality of life. Although the etiology of SD in MS is multifactorial, reported prevalence and associated clinical factors vary widely across studies.
Methods: We conducted a single-center cross-sectional observational study including MS patients followed at our Neuroimmunology-MS Unit between June and October 2025. Sexual function and satisfaction were assessed using self-administered questionnaires: the Multiple Sclerosis Intimacy and Sexuality Questionnaire (MSISQ-15), the New Sexual Satisfaction Scale (NSSS), the Female Sexual Function Index (FSFI), and the International Index of Erectile Function (IIEF). Demographic and clinical variables were collected. Bivariate analyses and multivariable logistic regression were performed.

FIGURE 1 Neurological disability according to sexual dysfunction status.

FIGURE 2 Correlation between sexual dysfunction severity and sexual satisfaction.

Correlations were assessed using Spearman's rank correlation coefficient.

Results: 115 patients were included of whom 69 (60.5%) were female, with a mean age of 46, and with 90 (78.9%) being relapsing-remitting forms. A total of 100 (87.0%) patients showed SD based on MSISQ-15 score. Patients with SD had greater neurological disability than those without SD (median EDSS 2.0 vs 1.5, $p = 0.018$). In multivariable analysis, EDSS remained independently associated with SD (OR 2.29, 95% CI 1.23–5.24). SD severity was strongly and inversely correlated with sexual satisfaction measured by the NSSS ($\rho = -0.57$, $p < 0.001$). In men, MSISQ-15 scores were strongly and negatively correlated with IIEF scores, whereas in women the correlation with FSFI scores did not reach statistical significance.

Conclusion: SD is highly prevalent in patients with MS and is strongly associated with neurological disability and reduced sexual satisfaction.

Disclosure: Nothing to disclose.

Background and aims: Neuromyelitis optica spectrum disorder (NMOSD) and myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) predominantly affect women of reproductive age. This study aimed to assess pregnancy impact on disease activity

Methods: This retrospective study included informative pregnancies in women with NMOSD or MOGAD followed in the Oxford national service. Annualized relapse rates (ARR) were calculated in patients who had a pregnancy after disease onset.

Results: In MOGAD, 72 of 105 informative pregnancies occurred after disease onset. Mean ARR in the two years before pregnancy was 0.23 ± 0.30 and decreased significantly during pregnancy. Post-pregnancy ARR showed a numerical increase in the early months (0.39 ± 1.19 at 0–3 months), followed by a decline by 12 months, without significant differences compared with the pre-pregnancy period. Spontaneous miscarriage occurred in 5/72 pregnancies (6.9%). In NMOSD, 43 of 51 informative pregnancies occurred after disease onset. Mean ARR before pregnancy was 0.36 ± 0.47 . During pregnancy, ARR was significantly lower in the first and third trimesters, and similar to pre-pregnancy in the second trimester (0.37 ± 1.18). Post-pregnancy ARR showed a numerical increase at 0–3 months (0.74 ± 1.80) and declined thereafter, without significant differences compared with pre-pregnancy. Spontaneous miscarriage occurred in 10/43 pregnancies (23.2%). Post-pregnancy disease onset occurred in 31 MOGAD (4.62 ± 3.10 months) and 7 NMOSD (3.97 ± 3.43 months) patients.

Conclusion: Disease activity was significantly reduced during pregnancy in MOGAD. In both NMOSD and MOGAD, ARR showed a numerical increase in the early post-pregnancy period (0–3 months), followed by a decline over the first year.

EPO-0626 | Language and voice analysis as multidimensional biomarkers of silent progression in relapsing–remitting multiple sclerosis

G. Carlucci¹; M. Di Cristinzi¹; S. Astore³; A. Poggesi¹;
A. Repice²

¹Department of NEUROFARBA, University of Florence, Florence, Italy; ²Department of Neurology, Careggi University Hospital, Florence, Italy; ³University of Florence, Florence, Italy

Background and aims: Progression independent of relapse activity (PIRA) is a major contributor to disability accumulation in MS but is difficult to detect in patients with low EDSS scores. Language and speech impairments are common yet underrecognized in MS and may reflect early cognitive and motor network dysfunction not captured by conventional disability measures. This study investigated whether multidimensional language and voice assessments could serve as sensitive functional biomarkers of subclinical progression in relapsing–remitting MS (RRMS).

TABLE 1 Demographic and clinical characteristics of the study population.

Psychological impact	1 (0–2)	0 (0–1.5)	ns
Self-perceived voice quality	4.5 (3–5.5)	0 (0–4)	0.002 *

BR22 = Relaying-Restling Multiple Sclerosis, YH = Yusef Handicap Index
 χ^2 Student's t test for normally distributed variables, ^{2} Mann-Whitney U test for non-normal distributions
 CR = cerebrospinal fluid

Methods: Twenty-eight patients with RRMS and mild disability and eight age- and sex-matched healthy controls underwent comprehensive cognitive, linguistic, and speech evaluations. Cognitive assessment included MoCA and domain-specific neuropsychological tests. Language was examined using verbal fluency and comprehension tasks. Speech and voice were evaluated with a standardized dysarthria profile, the Voice Handicap Index, and automated acoustic analysis using VoxPlot software. Acoustic parameters included Cepstral Peak Prominence Smoothed (CPPS), Acoustic Voice Quality Index (AVQI), and Acoustic Breathiness Index (ABI).

Results: Compared with controls, patients with RRMS showed reduced phonemic and semantic verbal fluency with preserved language comprehension. Mild but significant dysarthria was observed, mainly affecting respiration, diadochokinesis, and reflexes. Acoustic analysis revealed reduced CPPS and increased AVOI and ABI, indicating impaired voice quality. While several

measures correlated with EDSS and disease duration, multivariate analyses showed that acoustic and dysarthric parameters were largely independent of global disability, age, and disease duration.

Conclusion: Language and voice assessments detect subtle multidimensional dysfunction in RRMS not captured by conventional disability scales, supporting their potential role as biomarkers of silent progression and PIRA particularly in patients with low physical disability.

Disclosure: Nothing to disclose.

Background and aims: The individual clinical course of multiple sclerosis (MS) is highly variable. Prospective studies evaluating the clinical relevance of evoked potentials (EP) in correlation with clinical and paraclinical parameters are scarce. This study investigates the association of somatosensory (SEP), visual (VEP), and motor evoked potentials (MEP) at diagnosis for clinical and paraclinical endpoints after 24 months in the ProVal-MS study (DRKS00014034), a multicentre prospective study at five German universities.

Methods: Assessments included VEP, tibial nerve SEP, and abductor hallucis MEP, clinical assessments (Expanded Disability Status Scale [EDSS], Symbol Digit Modalities Test [SDMT]), cerebral and spinal MRI, serum neurofilament light chain [sNfL], and serum GFAP [sGFAP]. Statistical analyses included Spearman correlations and multilevel linear regression.

Results: 367 patients (CIS, $n=27$, RRMS, $n=340$; median age 30.6 years; 64.9% female) were included. Spearman analyses revealed significant correlations between all baseline EPs and both EDSS and SDMT at baseline and after 24 months. Multilevel linear regression showed higher (=worse) VEP scores associated with poorer cognition ($\beta=-4.44$, 95% CI -7.68, -1.21, $p=0.007$), while even mildly abnormal VEP scores were already associated with higher disability (VEP score 1: $\beta=0.18$, 95% CI 0.02, 0.33, $p=0.023$). However, SEP showed no significant associations with cognition or disability. Further results, including associations with blood biomarkers, neuroimaging findings, and clinical scores will be presented at the meeting.

Conclusion: Baseline EPs correlate with disability and cognitive function over 24 months. Multilevel regression highlights VEP as associated with both cognitive impairment and disability, supporting it as a complementary tool for MS monitoring.

EPO-0628 | Automated analysis of longitudinal language changes in multiple sclerosis

M. Šubert¹; M. Novotný¹; T. Tykalová¹; B. Srpová²; L. Friedová²; D. Horáková²; T. Uher²; J. Rusz¹
¹Czech Technical University in Prague, Faculty of Electrical Engineering, Department of Circuit Theory, Prague, Czech Republic; ²Charles University, First Faculty of Medicine, Department of Neurology and Centre of Clinical Neuroscience, Prague, Czech Republic

Background and aims: Sensitive and objective biomarkers for monitoring cognitive decline in multiple sclerosis (MS) are critically needed. Language is often impaired in MS and may reflect underlying cognitive changes. Automated analysis of spontaneous speech offers a promising, non-invasive approach to capture longitudinal disease-related alterations. This study investigates whether longitudinal speech analysis can detect language changes in MS.

Methods: We analyzed 213 participants, including 97 patients with MS and 116 age-, sex-, and education-matched healthy controls. All participants completed a story-telling task, which was automatically transcribed using automatic speech recognition system. MS patients underwent follow-up assessment after two years. Six state-of-the-art linguistic features, three lexical and three syntactic, were extracted using natural language processing methods to quantify language performance. MS severity was ranked using the Expanded Disability Status Scale (EDSS).

Results: At two-year follow-up, MS patients demonstrated overall lexical deterioration, including reduced vocabulary diversity ($p=0.031$) and increased phrase repetition ($p=0.037$) (Figure 1). Among 97 MS patients, 24 exhibited clinical progression (EDSS change ≥ 0.5). This MS subgroup was associated with pronounced syntactic decline, including shorter sentences ($p=0.044$) and reduced sentence development ($p=0.038$). MS patients without clinical progression primarily showed lexical impairments, such as restricted vocabulary ($p=0.028$) and increased phrase repetition ($p=0.049$).

FIGURE 1 Longitudinal changes in language dimensions over 24 months. Spider plots show z-scored baseline and follow-up values; higher scores indicate greater severity. * p .

Conclusion: Automated speech analysis detects longitudinal language changes in MS, even in subgroup of patients without progression detected on gold-standard clinical scales. These findings highlight the potential of automated linguistic metrics as non-invasive biomarkers for disease progression, complementing traditional cognitive and clinical assessments.

Disclosure: This project was supported by the ERC-CZ program from the Ministry of Education Youth and Sports (project no. LL2504).

EPO-0629 | Stage-dependent relationship between retinal structure and visual function in radiologically isolated syndrome and early multiple sclerosis

R. Borgo¹; A. d'Ambrosio¹; R. Capuano²; M. Risi¹; G. Rummo¹; M. Altieri¹; V. Ripa¹; M. Favale¹; R. Docimo³; A. Bisecco¹; A. Tessitore¹; A. Gallo¹
¹Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli, Naples, Italy; ²Neurology Unit, University Hospital "San Giovanni di Dio e Ruggi d'Aragona, Salerno, Italy; ³First Division of Neurology and Neurophysiopathology, AOU Luigi Vanvitelli, Naples, Italy

Background and aims: Radiologically isolated syndrome (RIS) represents a preclinical stage of multiple sclerosis (MS). In this context, structural and functional alterations of the anterior visual pathway remain poorly characterized. We aimed to evaluate retinal integrity and visual performance across the RIS-MS spectrum.

Methods: We conducted a cross-sectional study including healthy controls (HC), people with RIS (pwRIS) and people with early relapsing-remitting MS (pwMS), excluding subjects with prior optic neuritis or relevant ophthalmological comorbidities. Optical coherence tomography (OCT) was used to measure mean peripapillary retinal nerve fiber layer (pRNFL), ganglion cell-inner plexiform layer (GCIPL) and inner nuclear layer (INL) thickness, with age-/sex-adjusted z-scores from published normative data. An exploratory retinal neurodegeneration score

(RNS) was calculated as the mean of pRNFL and GCIPL z-scores. Visual function was evaluated using low-contrast letter acuity (LCLA) Sloan charts. Statistics included non-parametric tests and Spearman correlations.

Results: We included 123 subjects (50 HC, 23 pwRIS, 50 pwMS). pRNFL thickness, pRNFL z-scores and RNS differed significantly across groups (all $p < 0.05$), driven by significant reductions in pwMS versus HC, while pwRIS did not differ from either HC or pwMS. No significant differences were observed for GCIPL, INL and LCLA measures across all groups. While no structure-function correlations emerged in HC or pwRIS, pwMS showed significant positive correlations between LCLA and both pRNFL metrics and RNS (rho range = 0.38–0.53, $p < 0.05$).

Conclusion: Our findings support the concept of a pathological continuum; while pwRIS maintain a near-normal retinal profile, the transition to MS appears to be characterized by significant axonal loss and the emergence of structure-function coupling.

Disclosure: RMB, AdA, RC, MR, GR, MA, VR, MLF: nothing to disclose. EPO-0630 | **Patient-reported outcomes after autologous haematopoietic stem cell transplantation compared with rituximab in multiple sclerosis**

Y. Noui¹; A. Mitrache Desaga¹; E. Freyhult²; K. Kultima¹; J. Burman¹
¹Department of Medical Sciences, Uppsala University, Uppsala, Sweden; ²Department of Cell and Molecular Biology, Uppsala University, Uppsala, Sweden

Background and aims: Autologous haematopoietic stem cell transplantation (AHSCT) has emerged as a highly-effective treatment for relapsing-remitting multiple sclerosis (RRMS). Patient-reported outcomes have been shown to improve following AHSCT, but how this compares to other established disease-modifying treatments is unclear. We aimed to describe the Multiple Sclerosis Impact Scale-29 (MSIS-29) questionnaire scores in comparable patients treated with AHSCT and rituximab.

Methods: This was a retrospective observational study using the Swedish MS registry. Eligibility for inclusion was on the basis of: a diagnosis of RRMS; treatment in Sweden with either AHSCT or rituximab between 2008 and 2020; a minimum clinical, radiological and MSIS-29 dataset. Propensity scores were derived from prespecified confounders and used for 1:4 matching. Linear mixed-effect models assessed differences in scaled scores between the matched groups.

Results: Of the eligible 95 AHSCT and 2196 rituximab patients, 74 AHSCT were matched to 281 rituximab patients with good

FIGURE 1 Trends in MSIS-29 scores in participants following intervention with either rituximab or AHSCT. Scores are presented relative to each individuals pre-treatment baseline.

covariate balance (Table 1, standardised mean differences <0.1). Changes from baseline MSIS-29 scores are shown in Figure 1 Both treatments were associated with a decrease in physical MSIS-29 scores over time, with AHSCT associated with a greater decrease over time (−0.90 points-per-year, $p = 0.019$, Table 2). With regards to psychological MSIS scores, both treatments were again associated with a decrease in scores over time, with AHSCT again associated with greater decreases over time (−0.99 points-per-year, $p = 0.022$, Table 2).

Conclusion: In propensity-matched RRMS patients, AHSCT was associated with greater improvement in both physical and psychological MSIS-29 scores than rituximab, supporting benefits on symp-toms and wellbeing.

EPO-0631 | Dysphagia in neuromuscular disorders: A histopathological study of the cricopharyngeal muscle

B. Labella¹; G. Brochier¹; M. Beuvin²; A. Chanut²; A. Madelaine¹; C. Labasse²; E. Lacene²; T. Stojkovic³; B. Eymard³; J. Lacau Saint Guily⁴; T. Evangelista²
¹Neuromuscular functional Unit, Department of Neuropathology, Groupe Hospitalier Universitaire La Pitié-Salpêtrière, Paris, France; ²Neuromuscular Morphology Unit, Myology Institute, Paris, France; ³Reference Center for Neuromuscular Disorders, Myology Institute, Groupe Hospitalier Universitaire La Pitié-Salpêtrière, Paris, France; ⁴Department of Otolaryngology-Head and Neck Surgery, Assistance Publique-Hôpitaux de Paris (AP-HP), Rothschild Foundation Hospital, Paris, France

Background and aims: Dysphagia is a debilitating condition with complex etiology. Potential therapeutic interventions include cricopharyngeal myotomy. This study aims to investigate the histopathological characteristics of the cricopharyngeal muscle (CM) in patients with neuromuscular disorders (NMDs), to evaluate its diagnostic utility.

Methods: CM tissue was collected from 10 patients that underwent cricopharyngeal myotomy, including 4 patients with Oculopharyngeal Muscular Dystrophy, 1 with Oculopharyngeal Distal Myopathy, 3 with Inclusion Body Myositis (IBM) and 1 with idiopathic achalasia. The specimens were processed for routine histoenzymology and immunohistochemistry (antibodies against PABPN1, MHC class 1/2, p62, LC3). Seven samples were also analyzed using ultrastructural analysis.

Results: Common histological findings in CM include horizontal and transverse fiber orientation, the presence of nemaline rods and mitochondrial abnormalities, type I fiber predominance, and increased connective tissue (Figure 1). Rimmed or non-rimmed vacuoles were identified in four patients. Scattered necrosis was observed in five. Inflammatory infiltrates were found in two patients within the IBM cohort. Immunohistochemical staining is the most reliable method for detecting PABPN1 aggregates in CM and is also simpler to perform than ultrastructural studies. No distinctive histological pattern was identified in idiopathic achalasia. Ultrastructural analyses revealed also abundant autophagic structures.

FIGURE 1 Histological and ultrastructural findings of the CM.

Conclusion: Histological examination of CM is rarely performed but still can provide critical insights for diagnosis. Our study emphasizes its potential value in the diagnostic process, particularly in patients whose clinical presentation is exclusively limited to dysphagia, thereby reinforce its role as complementary tool.

Disclosure: Nothing to disclosure.

EPO-0632 | MG patients facing heat waves. Heat waves exposure differentially worsens MG-ADL Scores in anti-acetylcholine receptor but not MuSK myasthenia gravis

E. Lagrange¹; S. Sacconi²; J. Reis³
¹Grenoble University Hospital Department of Neurology, Reference Center of Neuromuscular Disease and ALS consultations, Grenoble University Hospital; Grenoble, France; ²Université Côte d'Azur, Peripheral Nervous System and Muscle Department, Pasteur 2 Hospital, Centre Hospitalier Universitaire de Nice, Nice, France; ³INSERM-UNISTRA UMR 1260, Centre de Recherche en Biomédecine de Strasbourg (CRBS); 1 rue Eugene Boeckel; Strasbourg, France

Background and aims: To assess the impact of heat wave exposure on symptom severity, as measured by the Myasthenia Gravis Activities of Daily Living (MG-ADL) scores in patients with autoimmune myasthenia gravis (MG), comparing anti-acetylcholine receptor (anti-AChR) and anti-MuSK subtypes.

Methods: We conducted a cross-sectional questionnaire-based study including 206 adult MG patients. Heat-related symptom worsening during heat waves, hot bath sensitivity, cooling strategies, and MG-ADL-derived heat-aggravation scores were analyzed according to antibody status.

Results: Heat wave exposure was associated with a significant worsening of MG-ADL scores in anti-AChR patients, whereas no significant effect was observed in MuSK patients. Anti-AChR patients frequently reported symptom exacerbation during days of heatwaves, after hot showers or baths and commonly required air conditioning. Cold exposure was associated with symptom improvement predominantly in the anti-AChR group.

TABLE 1 Composition of the heat related MG-ADL score.

MG-ADL domain	Heat-related question (Yes/No)	Score
Talking	Worsening of speech difficulties during heat exposure	1
Chewing	Increased difficulty chewing during heat exposure	1
Swallowing	Worsening of swallowing difficulties during heat exposure	1
Breathing	Increased shortness of breath during heat exposure	1
Brushing teeth / combing hair	Increased difficulty due to arm weakness during heat exposure	1
Arising from a chair	Increased difficulty standing up due to leg weakness during heat exposure	1
Double vision	Worsening or increased frequency during heat exposure	1
Eyelid droop	Increased ptosis during heat exposure	1
Total heat-related MG-ADL score range: 0-8		

TABLE 2 Baseline demographic and heat-related clinical characteristics of patients with myasthenia gravis according to antibody subtype. Values are presented as mean $\pm$ SD, median (interquartile range), or number (percentage), as appropriate. Heat-related MG-ADL sc.

Outcome	Anti-AChR MG (n = 185)	MuSK MG (n = 21)	p-value
Heat-related MG-ADL score (0-10), mean $\pm$ SD	7.0 $\pm$ 1.2	5.8 $\pm$ 1.8	<0.001
Symptoms worsening with heat, n (%)	167 (90%)	7 (33%)	<0.001
Worsening after hot shower or bath, n (%)	144 (87%)	4 (19%)	<0.001
Use of air conditioning during heat exposure, n (%)	133 (72%)	4 (19%)	<0.001
Improvement with cold exposure, n (%)	139 (75%)	6 (29%)	<0.01

TABLE 3 Heat waves -related clinical outcomes in myasthenia gravis according to antibody subtype. Values are presented as mean $\pm$ SD or number (percentage). Group comparisons were performed using Welch's t-test for continuous variables and χ^2 tests for cat.

Outcome	Anti-AChR MG (n = 185)	MuSK MG (n = 21)	p-value
Age (years), mean $\pm$ SD	51 $\pm$ 14	49 $\pm$ 12	0.08
Female sex, n (%)	93 (50%)	16 (76%)	0.06
Duration (years), median (IQR)	7 (3-18)	6 (2-11)	0.03
Heat-related MG-ADL score (0-10), mean $\pm$ SD	7.0 $\pm$ 1.2	5.8 $\pm$ 1.8	<0.001
Symptoms worsening with heat, n (%)	167 (90%)	7 (33%)	<0.001
Worsening after hot shower/bath, n (%)	144 (87%)	4 (19%)	<0.001
Use of air conditioning during heat, n (%)	133 (72%)	4 (19%)	<0.001
Improvement with cold exposure, n (%)	139 (75%)	6 (29%)	<0.01

Conclusion: Heat wave represents a clinically relevant aggravating factor in anti-AChR MG, supporting targeted environmental management strategies in the perspectives of climate change, in such a vulnerable population.

Disclosure: Disclosure interests Dr Lagrange.

EPO-0633 | Tanruprubart rapidly improves health-related quality of life in patients with Guillain-Barré syndrome: A randomised, placebo-controlled Ph3 study

G. Morrison¹; J. Du¹; Q. Deen Mohammad²; N. Papri³; M. Kim¹; H. Kroon¹; K. Gorson⁴

¹Annexon Biosciences, Brisbane, USA; ²National Institute of Neuroscience (NINS), Dhaka, Bangladesh; ³icddr, Dhaka, Bangladesh; ⁴Tufts University School of Medicine, Boston, USA

Background and aims: Guillain-Barré syndrome (GBS) is a rare, life-altering, neuromuscular emergency, causing long-lasting disabilities severely impacting quality of life. Tanruprubart (ANX005) inhibits complement component C1q. In a Ph3, double-blind, placebo-controlled study (GBS-02; NCT04701164), a single infusion of tanruprubart 30 mg/kg improved muscle strength and disability in patients with GBS at Day 8 and Week 8. This analysis presents patient-reported outcomes (PROs) with tanruprubart 30 mg/kg versus placebo.

Methods: Patients aged ≥ 16 years with a recent GBS diagnosis were randomised to tanruprubart 30 mg/kg ($n=79$), 75 mg/kg ($n=81$) or placebo ($n=81$). PROs included the EuroQol 5-Dimension 5-Level (EQ-5D-5L), Rasch-built Modified Fatigue Severity Scale (rFSS) and Patient Global Impression of Change (PGIC). Impact of treatment on HRQoL was evaluated using proportional odds logistic regression adjusted for baseline covariates.

Results: By Day 8 significant improvements in EQ-5D-5L occurred in mobility and self-care with tanruprubart 30 mg/kg versus placebo (Table 1). Rapid improvements were observed with tanruprubart versus placebo in all domains of the rFSS except for pain (Table 2). In the PGIC, eight (10.1%) patients reported being 'very much improved' with tanruprubart at Day 8, compared with three (3.7%) patients with placebo (aOR 2.5 [95% confidence interval (CI): 1.4, 4.6] $p=0.0028$). Tanruprubart-associated improvements in EQ-5D-5L mobility, self-care and usual activities domains continued to Week 8 (Tables 1, 2). PGIC improvements at Week 8 still favoured tanruprubart (aOR 1.4 [95% CI 0.8, 2.6, $p=0.2917$).

Conclusion: Tanruprubart demonstrated rapid and sustained improvements in HRQoL, consistent with observed objective clinical benefits, supporting its potential as a targeted immunotherapy for GBS.

Disclosure: The study was sponsored by Annexon Biosciences (Brisbane, CA, USA). MK, GM, JD, H-AK: Employment with and shareholder of Annexon Biosciences QDM: Consultancy/advisory role with Annexon Biosciences NP: Nothing to disclose

EPO-0634 | Late-onset TK2 deficiency in adults: Long-term clinical outcomes of deoxynucleoside therapy

H. Durmus¹; A. Gedikbaş²; A. Çakar¹; E. Kıyan³
¹Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye; ²Institute of Child Health, Department of Pediatric Basic Sciences, Division of Medical Genetics, Istanbul University, Türkiye; ³Department of Pulmonology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye

Background and aims: Thymidine kinase 2 deficiency is a mitochondrial myopathy causing progressive weakness, respiratory insufficiency, and early mortality. While nucleoside supplementation benefits pediatric cases, evidence in adults remains limited.

Methods: Six genetically confirmed adults with TK2d were treated under compassionate-use protocols in Türkiye, receiving escalating doses of oral or PEG-administered Doxycitine and Doxribtimine up to 800 mg/kg/day. Functional and clinical outcomes included the 6-minute walk test (6MWT), HFMSE, forced vital capacity (FVC), Fatigue Severity Scale (FSS), and BMI.

Results: Over a median follow-up of 24 (range 6–36) months, therapy was associated with sustained functional and respiratory improvements. Mean 6MWT increased from 152 m at baseline to 468 m at 24 months and exceeded 600 m in patients with 36-month data. The mean HFMSE increased from 20.5 at baseline to 24.5 at 3 months, 29 at 6 months. Patients with the longest follow-up reached a mean HFMSE of 58 at 36 months. FVC, which had declined before treatment, stabilized or improved in all patients (mean increase from 36% to 55.6% at 36 months). The youngest patient achieved near-normal respiratory function. Fatigue severity decreased by ~30%, and BMI improved notably in underweight individuals. Treatment was generally well tolerated; transient liver enzyme elevations and mild gastrointestinal side effects resolved spontaneously.

Conclusion: Deoxynucleoside therapy appears effective and well tolerated in adults with TK2d, producing sustained functional and respiratory gains. Early treatment initiation is crucial

FIGURE 1 Longitudinal six-minute walk test performance in six adult patients with late-onset TK2 deficiency treated with deoxynucleoside therapy. Patient 1's 36-month measurement was unavailable due to surgery. Patients 5 and 6 were followed up to 6 mo.

FIGURE 2 Hammersmith Functional Motor Scale scores over time in six adult patients with late-onset TK2 deficiency treated with deoxynucleoside therapy.

FIGURE 3 Forced vital capacity (%) over time in four adult patients with late-onset TK2 deficiency receiving deoxynucleoside therapy. Patients 4 and 6, who were tracheostomized and dependent on continuous ventilatory support, were excluded from this figure.

to maximize benefit; though partial improvements may occur even in advanced disease.

Disclosure: The authors have no conflicts of interest to declare.

EPO-0635 | **A novel Guillain–Barré syndrome clinical progression scale to characterise the patient’s care journey: Utilisation in a phase 3 trial of tanruprubart**

H. Kroon¹; K. Gorson²; Q. Deen Mohammad³; T. Harbo⁴
¹Annexon Biosciences, Brisbane, USA; ²Tufts University School of Medicine, Boston, USA; ³National Institute of Neuroscience (NINS), Dhaka, Bangladesh; ⁴Aarhus University, Aarhus, Denmark

Background and aims: Guillain-Barré syndrome (GBS) is a rare, acute, life-altering autoimmune polyneuropathy with rapidly progressive weakness and prolonged recovery. In GBS-02, a Ph3, randomised, double-blind, placebo-controlled trial, tanruprubart (ANX005) 30 mg/kg led to rapid complement inhibition and clinical improvement with sustained clinical benefit over 6 months in patients with GBS (NCT04701164). We characterised the patient’s care journey using a novel GBS Clinical Progression Scale (CLIPS).

Methods: Patients aged ≥16years with a recent GBS diagnosis (n=241) were randomised to a single infusion of tanruprubart 30 mg/kg, 75 mg/kg or placebo. CLIPS was adapted from the WHO Covid-19 Clinical Progression Scale by the study sponsor and GBS experts. This ordinal measure is based on 8 levels of care (Table 1). During GBS-02, clinical status on the scale was physician recorded weekly for 4 weeks and at 2, 3, 4, and 6 months in a subset of patients (tanruprubart 30 mg/kg n=41, 75 mg/kg n=45, placebo n=45). Treatment impact on level of care was evaluated using a proportional odds logistic regression adjusted for baseline covariates.

Results: All patients were hospitalised and most required medical intervention (Grade ≥3; Figure 1). By Day 8, care requirements decreased. At Week 4 the odds of requiring less care favoured tanruprubart 30 mg/kg (aOR 2.3, 95% CI 0.99–5.39; p=0.054) over placebo, consistent with overall clinical outcome.

Conclusion: CLIPS captured patients’ transitions through levels of care, providing a pragmatic lens to interpret treatment benefit. Early separation at Week 4 favouring tanruprubart supports a clinically meaningful shift toward lower resource intensity during early GBS.

Disclosure: The study was sponsored by Annexon Biosciences (Brisbane, CA, USA). H-AK: Employment with and shareholder of Annexon Biosciences KCG: Consultancy/advisory role with Annexon Biosciences, argenx, Janssen, and Sanofi

*The CLIPS was included as a late amendment to the GBS-02 trial and assessed in a subset of patients tanruprubart 30 mg/kg n=41, tanruprubart 75 mg/kg n=45 (not shown here) and placebo n=45. At Week 4, data was missing for 2 patients in the tanruprubart 30 mg/kg group and 1 patient in the placebo group.

EPO-0636 | **Validating the 2024 ENMC inclusion body myositis criteria: Diagnostic utility in early “Polymyositis-Mitochondrial” stages**

I. Lopera-Rodríguez; J. Ciriero-Macías; J. Andrada-Moreno; L. García-Granados; J. Román-Rueda; C. Villar-Rodríguez; A. Luque-Ambrosiani; E. Rivas-Infante; C. Paradas; F. Gómez-Fernández
Hospital Universitario Virgen del Rocío, Sevilla, Spain

Background and aims: The 2024 European Neuromuscular Centre (ENMC) criteria for Inclusion Body Myositis (IBM) integrates mitochondrial pathology as a key histological supportive feature. We evaluated their diagnostic capacity in a single-centre cohort, specifically focusing on the “Polymyositis-Mitochondrial” (PM-Mito) phenotype, an early recognised stage of IBM.

Methods: We retrospectively reassessed 15 IBM patients following the 2024 ENMC consensus and evaluated the clinical phenotype, anti-cN1A serology, muscle imaging and histological features.

Results: Mean onset age was 60.6 ± 9.5years with a diagnostic delay of 3.7 ± 2.4years. Mean Creatine kinase level was 711 ± 651 U/L. The “common” clinical phenotype (finger flexor/knee

TABLE 1 Eight grades of the ordinal GBS Clinical Progression Scale.

Grade	Description
0	Discharged home, independent ADLs, capable of self-care
1	Requiring ongoing nursing care or assistance by trained caregivers in ADLs
2	During recovery of GBS requiring intensive physical/occupational/speech therapy and/or general medical or nursing care
3	Hospitalised, requiring ongoing medical or nursing care during progression or recovery of GBS
4	Not mechanically ventilated, requiring intensive monitoring
5	Receiving non-invasive ventilation or high-flow oxygen devices
6	Receiving invasive mechanical ventilation
7	Death

ADLs, activities of daily living; GBS, Guillain-Barré Syndrome.

T1-weighted MRI image of both thighs showing anterior distal fatty infiltration.

Department of Neurology, Tianjin Neurological Institute, Tianjin Medical University General Hospital, Tianjin, China

H&E muscle biopsy with endomysial lymphocyte infiltration.

Pathological increase of COX negative muscle fibers.

extensor weakness) was observed in 93% of patients and dysphagia in 67%. An inflammatory myopathic electromyogram pattern was found in 75% of analysed cases. Muscle magnetic resonance imaging revealed the classic distal/anterior thigh pattern in 70% (Figure 1). Anti-cN1A antibodies were positive in 62.5% of tested patients. Histologically, all biopsies showed endomysial lymphocyte infiltration (Figure 2), p62 aggregates were identified in 77%, whereas TDP-43 was rarely assessed. Two patients presented the PM-Mito pattern: endomysial inflammation with cyclooxygenase (COX)-negative fibres (Figure 3) exceeding the expected level for the patient's age, without additional supportive findings. Under previous criteria, this finding mimicked a polymyositis pattern. However, using the new criteria, the combination of “common” phenotype and mitochondrial pathology confirmed the IBM diagnosis.

Conclusion: The 2024 ENMC criteria enhance diagnostic sensitivity for early IBM. Elevating mitochondrial abnormalities to “supportive criterion” enables the definitive diagnosis of PM-Mito cases, preventing misdiagnosis and avoiding ineffective immunosuppressive therapies.

Disclosure: Nothing to disclose.

Background and aims: Eculizumab has demonstrated high efficacy in patients with anti-acetylcholine receptor (AChR) antibody-positive myasthenia gravis (MG). It prevents the cleavage of C5 into C5a and C5b, thereby blocking the formation of the membrane attack complex (MAC) in neuromuscular junction. However, the potential off-target effects of eculizumab on immune cell modulation—mediated via C5a-C5aR1 axis during long-term treatment—remain incompletely understood.

Methods: Patients with AChR Ab+ gMG receiving regular ecuzumab or prednisolone treatment were enrolled and divided into exploratory and validation cohorts. Bulk RNA-seq and flow cytometry were performed on peripheral immune cells. C5aR1 antagonist was administered to experimental autoimmune myasthenia gravis (EAMG) rats, and clinical scores, electromyograms, immunofluorescence staining of nicotinic AChR (nAChR), and flow cytometric analysis of immune cells were performed. B cells were co-cultured with monocytes for in vitro analysis.

Results: Bulk RNA sequencing revealed significant transcriptomic alterations in MG patients following ecuzumab treatment, enriched in B-cell-related pathways. Long-term ecuzumab markedly reduced peripheral CD19⁺ B cells and their subsets (including memory B cells and antibody-secreting cells).

FIGURE 1 Bulk RNA-Seq analysis of differential gene expression and functional associations in AChR antibody-positive generalized myasthenia gravis patients before and after ecuzumab treatment.

FIGURE 2 Modulation of B-cell subsets and viability by a C5aR1 antagonist in myasthenia gravis as shown by flow cytometry.

C5aR1 is predominantly expressed on myeloid cells and is up-regulated during acute exacerbations of MG. In vivo and in vitro co-culture studies indicated that blocking C5a-C5aR1 signaling pathway in monocytes inhibited B-cell differentiation, promoted B-cell apoptosis, and reduced circulating B-cell numbers, likely through decreased BAFF secretion.

Conclusion: In addition to blocking the terminal complement pathway, eculizumab modulates peripheral B-cell differentiation and survival by inhibiting the monocyte C5a-C5aR1-mediated BAFF secretion. This reveals its off-target immunomodulatory effects and the mechanism of systemic immunoregulation during long-term therapy.

Disclosure: This study was supported by the National Natural Science Foundation of China (82571535, 82171338, 82171277), and Young Scientific and Technological Talents (Level Three) in Tianjin.

EPO-0638 | Significant correlations between ME&MGTM digital biomarkers and equivalent MG-ADL and MG-QoL15r sub-items scores

C. Barnett-Tapia¹; S. Lehnerer²; S. Bieuvelet³; L. Carment³; C. Gorin³; N. Pesic-Heuvrard³; D. Ravindra³; N. Sellami³; B. Dutta⁴; B. Yungher⁴; S. Zinaï³; J. Howard Jr⁵

corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Neurology with Experimental Neurology, Charitéplatz 1; 10117 Berlin, Germany; ³Ad Scientiam, Paris, France; ⁴Alexion, AstraZeneca Rare Disease, Boston, USA; ⁵University of North Carolina, Department of Neurology, Chapel Hill, USA

Background and aims: Symptoms of generalized Myasthenia Gravis (gMG) are routinely captured via patient-reported outcomes (PROs) questionnaires. MG-ADL and MG-QoL15r assess daily activities and quality of life; high scores indicate higher severity and worse quality of life. Digital biomarkers (dBMKs) provide objective measures for remote symptoms' self-assessment through smartphone-based active tests. ME&MGTM evaluates five gMG symptoms: ptosis, dysarthria, breathing, upper and lower limb weakness mirrored in 5 MG-ADL and 3 MG-QoL15r items. In the decentralized ME&MGopen study (NCT05566964), patients performed ME&MGTM tests for one year. Here, we describe the correlation between dBMKs and corresponding MG-ADL and MG-QoL15r sub-items.

Methods: Completed ME&MGTM tests were reviewed for quality: inaccurate dBMKs values and agreement with human measurements. The relationship between dBMKs and sub-items was determined using mixed models analyses. We expected negative associations with MyBreathing, MyEyelids, Mylegs and MyArms and positive correlations with MyVoice.

Results: 156 participants completed digital tests and questionnaires monthly (Figure 1). A total of 9106 evaluations were collected, of which 90.4% were of good quality. DBMKs scores for ptosis, breathing, and limb weakness decreased with increasing PRO assessed symptom severity and scores for dysarthria decreased with severity (Figure 2). Ptosis, dysarthria and limb weakness scores showed significant associations (all $p < 0.019$) with aforementioned sub-items of the MG-ADL and MG-QoL15r questionnaires.

Conclusion: Significant associations between clinical ME&MGTM dBMKs and clinical assessments support their potential use in clinical settings to track gMG manifestations. These findings highlight the importance of the ongoing DOMYA validation study (NCT05564936).

EPO-0639 | Minimal symptom expression with claseprubart, an active C1S inhibitor, in patients with generalized myasthenia gravis

M. Smilowski¹; N. Gilhus²; M. Ait-Tihyaty³; C. Briggs³; U. Siddiqui³; L. Hickey³; M. Lalla³; S. Beydoun⁴

¹Neurologia Śląska Centrum Medyczne, Katowice, Poland; ²Haukeland University Hospital, Bergen, Norway; ³Dianthus Therapeutics, New York, USA; ⁴University of Southern California, Los Angeles, USA

Background and aims: The classical complement pathway plays a significant role in generalized myasthenia gravis (gMG) pathology. Claseprubart is a potent monoclonal antibody that selectively targets the classical pathway by inhibiting active C1s (aC1s). Remission is a key goal in gMG and achieving minimal symptom expression (MSE) with claseprubart is a key treatment objective.

Methods: MaGic (NCT06282159), is a global Phase 2, randomized, double-blind, placebo-controlled trial. Patients treated with claseprubart (300mg, Q2W) were evaluated for MSE (MG-ADL ≤1 or QMG ≤3) compared with placebo. *p*-Values were one-sided and nominal significance was assessed at an alpha=0.1. Outcomes include proportion of patients achieving MSE at Week 13 and any-time during the study, earliest timepoint of MSE achievement, and durability defined as sustained MSE for at least 6 weeks.

Results: At Week 13, 37% of claseprubart treated patients achieved MG-ADL-MSE versus 14% with placebo (OR 3.81; *p*=0.0550). 43% achieved MG-ADL-MSE at least once during the study versus 14% of placebo (OR: 4.72; *p*=0.0231). This effect was observed as early as Week 1 (median time to response was Week 3). Sustained remission-like states (for at least 6 weeks) were seen in all patients who achieved MSE. Similar results were observed using QMG minimum symptom expression threshold. **Conclusion:** Claseprubart patients were more than four times more likely to achieve MSE than placebo patients and MSE was observed as early as week 1. Patients who achieved MSE maintained responses for at least 6 weeks. These results highlight the therapeutic potential of aC1s inhibition in AChR+ gMG.

EPO-0640 | Myasthenia Gravis Inebilizumab Trial (MINT): Adverse events of special interest during the randomized controlled period (RCP)

R. Nowak¹; K. Utsugisawa²; M. Benatar³; E. Ciafaloni⁴; M. Leite⁵; J. Vissing⁶; F. Tang⁷; B. Canales⁷; Q. Li⁷; S. Cheng⁷; J. Howard Jr.⁸

¹Yale University, New Haven, USA; ²Hanamaki General Hospital, Hanamaki, Japan; ³University of Miami Miller School of Medicine, Miami, USA; ⁴University of Rochester, Rochester, USA; ⁵University of Oxford, Oxford, UK; ⁶University of Copenhagen, Copenhagen, Denmark; ⁷Amgen Inc, Thousand Oaks, USA; ⁸University of North Carolina, Chapel Hill, USA

Background and aims: B cells play a key upstream mechanistic role in autoimmune generalized myasthenia gravis (gMG) pathogenesis through the production of antibodies targeting the acetylcholine receptor (AChR+), muscle-specific kinase (MuSK+), or other related proteins. Inebilizumab is a monoclonal antibody targeting CD19+ B cells. B-cell-depleting therapies may impair humoral responses, increase the risk of infections and reduced response to vaccinations. Here we examine whether inebilizumab is associated with an increased risk of adverse events of special interest (AESIs) in gMG participants.

Methods: MINT (NCT04524273) was a phase 3 trial in adults with gMG. During the RCP (52-weeks for AChR+; 26-weeks for MuSK+), participants were randomized (1:1) to receive 300mg of inebilizumab or placebo on Day-1, Day-15, and Day-183 (AChR+ only). Subsets of adverse events were identified as AESIs due to their relevance to inebilizumab's mechanism of action.

Results: 238 patients were randomized: inebilizumab 119 (95 AChR+, 24 MuSK+), placebo 119 (95 AChR+, 24 MuSK+). Baseline demographics and disease characteristics were generally balanced between treatment groups. AESIs were infrequent, occurring in 10.1% ($n=12$) of the inebilizumab- and 16% ($n=19$) of the placebo-treated groups. Cytopenias occurred in 2.5% ($n=3$) of inebilizumab-treated and 9.2% ($n=11$) of placebo-treated participants. Serious and/or opportunistic infections were infrequent (inebilizumab: 3.4% [$n=4$]; placebo: 5.0% [$n=6$]), with COVID-19 being the most common (inebilizumab: 2/4; placebo: 3/6) and no instances of progressive multifocal leukoencephalopathy. Infusion related reactions occurred in 5.0% ($n=6$) of inebilizumab- and 2.5% ($n=3$) of placebo-treated participants (Table 1).

Conclusion: These results support a favorable safety profile of inebilizumab over a 26–52-week period.

Disclosure: RJN received research support from Alexion Pharmaceuticals, Amgen Inc, argenx, Grifols, Immunovant, Janssen, Myasthenia Gravis Foundation of America, the National Institutes of Health, and UCB and served as a consultant/adviser for Alexion Pharmaceuticals, Amgen Inc, argenx, Cabaletta Bio, Cour Pharmaceuticals, CSL Behring, Grifols, Immunovant, Janssen, and UCB. Background and aims: Approximately 15%–20% of patients with generalized myasthenia gravis (gMG) are acetylcholine receptor antibody (AChR-Ab) seronegative. Efgartigimod is a human immunoglobulin G1 (IgG1) antibody Fc fragment that reduces IgG levels (including pathogenic autoantibodies) via neonatal Fc receptor blockade. ADAPT SERON is a Phase 3 trial investigating the efficacy and safety of intravenous (IV) efgartigimod in adults with AChR-Ab seronegative gMG.

Methods: Diagnosis of gMG was confirmed by an MG diagnostic adjudication committee. In the double-blinded, placebo-controlled Part A, adult participants were randomized 1:1 to receive 4 once-weekly infusions of 10 mg/kg efgartigimod IV or placebo followed by a 5-week follow-up period. Part B includes an ongoing open-label extension (≤2 years).

Results: Results included 119 participants ($n=40$, MuSK-Ab+; $n=6$, LRP4-Ab+; $n=73$, triple seronegative), 58 received efgartigimod IV, and 61 received placebo. Change in Myasthenia Gravis Activities of Daily Living (MG-ADL) total score from baseline to week 4 (primary endpoint) was significantly ($p=0.007$) different between efgartigimod IV and placebo groups (overall population), with least squares mean change from baseline (90% CI) of -3.35 (-3.98 to -2.72) and -1.90 (-2.51 to -1.28), respectively. Clinically meaningful improvement in mean MG-ADL total score with efgartigimod IV (overall population) was observed in Part A and continued over subsequent cycles in Part B. Efgartigimod IV was well tolerated, with no new safety signals observed. Results from additional analyses will be presented at EAN 2026.

Conclusion: Efgartigimod IV demonstrated statistically significant improvement in MG-ADL total score compared with placebo and was well tolerated in AChR-Ab seronegative gMG.

Disclosure: This study was sponsored by argenx. RHJ, IS, DM, JTG, and W-YH are employees of argenx. SH, JFH, TV, CZ, SL, KGC, LR, EC, AA, and AB have reported financial/nonfinancial relationships with argenx at the time of submission.

EPO-0642 | Effect of nivalocalimab on pathogenic IgG and complement markers in patients with seropositive gMG: Exploratory analysis in Vivacity-MG3 study

S. Miller¹; J. Xi²; Y. Zhang²; R. Faelens³; M. Fitzgibbon⁴; S. Ramchandren⁵; S. Hoffmann⁶

¹Johnson & Johnson, San Diego, USA; ²Johnson & Johnson, Spring House, USA; ³Johnson & Johnson, Beerse, Belgium;

⁴Johnson & Johnson, Raritan, USA; ⁵Johnson & Johnson, Titusville, USA; ⁶Neurology, Charité – Universitätsmedizin Berlin, Berlin, Germany

Background and aims: Immunoglobulin (Ig)G class autoantibodies block and internalize the acetylcholine receptor (AChR) and activate complement at the neuromuscular junction, leading to symptoms of myasthenia gravis. Nivalocalimab, a fully human neonatal-Fc-receptor blocker, substantially reduced circulating IgG, including pathogenic subclasses, and demonstrated

sustained efficacy versus placebo during 24-week Vivacity-MG3 study (NCT04951622). This post-hoc analysis evaluated whether nivalimab reduces circulating complement components and activity indicative of complement activation, in Vivacity-MG3.

Methods: Available serum samples from seropositive (positive for AChR/muscle-specific receptor tyrosine kinase [MuSK]/Low-density Lipoprotein Receptor-related Protein-4 [LRP4]) participants were analysed at baseline and Week-24 and least square means were compared between placebo and nivalimab using linear mixed model. Complement markers measured were: C3d circulating immune complexes (C3d-CIC), C1q immune complex binding (C1q-ICB), and total complement activity (CH50). Parallel assays quantified total IgG, IgG1/2/3, and anti AChR titers, which informed a nonlinear mixed-model previously presented.

Results: Baseline levels of complement markers were comparable across nivalimab and placebo groups (Table-1). At Week-24, nivalimab was associated with substantial and sustained reductions in IgG1/2/3, and anti AChR titers (Table-2). Concomitant decreases were observed in selected immune complex-associated complement markers (C3d-CIC and C1q-ICB, $p < 0.05$); no significant change in CH50 was detected (Table 1).

Conclusion: Nivalimab led to sustained reductions in IgG subclasses and anti-AChR titers, accompanied by significant decreases in selected circulating immune complex-associated complement markers, while no significant change in total complement activity was observed. These data indicate changes in selected complement-related markers following nivalimab treatment; further exploration is needed to better understand the clinical relevance.

EPO-0643 | Phenotypic and genotypic characterization of STUB1 variants in Portuguese pedigrees and analysis of TBP repeat expansions

C. Guedes Vaz¹; M. Seco²; G. Madureira³; R. Castro⁴; S. Costa¹; J. Freixo⁵; J. Oliveira⁵; P. Salgado²; M. Calejo²; M. Santos⁵; J. Damásio¹

¹Neurology Service, Santo Antonio Local Health Unit, Porto, Portugal; ²Neurology Service, Matosinhos Local Health Unit, Porto, Portugal; ³Neuroradiology Service, Santo Antonio Local Health Unit, Porto, Portugal; ⁴Neurology Service, Local Health Unit of Entre Douro e Vouga, Santa Maria da Feira, Portugal; ⁵Institute of Molecular and Cellular Biology, University of Porto, Porto, Portugal

Background and aims: SCA48 (ATX-STUB1) is an adult-onset ataxia caused by heterozygous pathogenic variants in STUB1. Recently, families carrying pathogenic STUB1 variants and intermediate alleles in TBP gene have been described, raising the hypothesis of STUB1/TBP digenic inheritance or phenotypic modulation by TBP intermediate alleles. This study aimed to characterize the clinical, genetic and neuroimaging features of Portuguese families with SCA48 and analyze TBP repeat expansions.

Methods: SCA48 patients were identified through two sources: (a) Portuguese population-based survey on hereditary ataxias and (b) hospital-based cohorts from Northern Portugal. TBP repeat length was analyzed in all patients except one (deceased). Genetic, clinical and neuroimaging data were collected according to a standardized protocol.

Results: Seven pedigrees comprising 18 patients were identified, four from Northern Portugal and three from South. Five distinct STUB1 variants were detected: one in-frame deletion, one frameshift, two missense, and one nonsense variant. TBP intermediate alleles were present in 2 families. Mean age at onset was 41.5 years (range 28–64). Initial manifestations included gait ataxia ($n=12$), chorea ($n=1$), and diplopia ($n=1$). All patients developed cerebellar syndrome. Additional features included cognitive decline ($n=7$), depressive symptoms, chorea, and pyramidal signs ($n=6$, each). Neuroimaging revealed cerebellar vermal and hemispheric atrophy ($n=8$) and caudate nucleus atrophy ($n=3$). Twelve patients died after a mean disease duration of 17 ± 10.2 years.

Conclusion: Most Portuguese SCA48 pedigrees lacked TBP intermediate alleles, supporting a primary pathogenic role of heterozygous STUB1 variants. SCA48 presented as a complex adult-onset ataxia with prominent neuropsychiatric features and chorea.

Disclosure: Nothing to disclose.

Table 1: Demographic and clinical characteristics of three patients harboring a novel SCN1A mutation.

spectrum may vary from severe developmental delay, craniofacial dysmorphism and visceral tissue abnormalities to milder signs such as ataxia, nystagmus or strabismus. Defining non-canonical LOF phenotypes is critical to distinguish emerging multisystemic presentations from established LIWAS or epilepsy/PNKG spectra.

Results: We identified a novel heterozygous nonsense variant in *KCNMA1* (NM_001161352.2) [c.2005G>T p.Glu669Ter]. The phenotype manifests as upper limb hyperkinetic movements, psychiatric disturbances, and a shared metabolic phenotype characterized by chronic bronchial involvement (asthma/COPD), diabetes mellitus and liver disease, expanding the previous phenotype of *KCNMA1* LOF-related disorders.

Disclosure: Nothing to disclose.

Background and aims: Omaveloxolone, an activator of Nrf2, has been approved by EMA for the treatment of Friedreich ataxia (FA) in patients aged ≥ 16 years. In Portugal, it was initially provided through a limited early access program from July 2024 to January 2025 (pending central approval), while reimbursement negotiations were ongoing. This study aimed to establish a national, prospective registry to systematically evaluate real-world effectiveness and safety in Portuguese FA patients receiving omaveloxolone.

Methods: Neurologists from 31 Portuguese hospitals were invited to participate. Study documentation was submitted for approval by ethics committees. Prospective assessments included mFARS, SARA, and FA-ADL at baseline, every 3 months during the first year, followed by 6-monthly assessments. Laboratory parameters and adverse events were monitored monthly during the first 3 months, quarterly until the end of the first year, and semiannually thereafter. Data were collected using REDCap.

Results: Fifteen hospitals (48.4%) agreed to participate, of which 13 actively followed FA patients. In Portugal, all genetically confirmed FA patients aged ≥ 16 years were eligible for treatment, irrespective of functional staging, provided no contraindications were present. A total of 67 patients were included: 39 (58.2%) receiving omaveloxolone, 27 (40.3%) waiting treatment initiation pending reimbursement negotiations, and 1 (1.5%) with cardiac contraindications to treatment. Two patients discontinued omaveloxolone during follow-up.

Conclusion: This registry demonstrates the feasibility of nationwide, prospective real-world monitoring of omaveloxolone in FA. While early access enabled treatment initiation in over half of eligible patients, a substantial proportion remained untreated. Continued follow-up will be essential to evaluate long-term safety and clinical outcomes as treatment availability expands.

Disclosure: Nothing to disclose.

EPO-0646 | Cortical metabolic signatures of visuospatial and gait dysfunction in GBA1-related Parkinson's disease

L. Gallo¹; S. Caminiti¹; P. Mitrotti²; R. Calabrese²; M. Picascia²; R. Malito³; T. Filidei¹; A. Panzacchi³; A. Samanes Gajate³; G. Pepe³; F. Cavallieri⁴; G. Di Rauso⁵; V. Fioravanti⁴; D. Perani³; A. Chiti³; E. Valente⁶; M. Avenali¹

¹Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy; ²IRCCS Mondino Foundation, Pavia, Italy; ³IRCCS San Raffaele Scientific Institute, Milan, Italy; ⁴Neurology Unit, Neuromotor and Rehabilitation Department, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; ⁵Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; ⁶Department of Molecular Medicine, University of Pavia, Pavia, Italy

Background and aims: GBA1 variants are the most common genetic risk factor for Parkinson's disease and are associated with an increased risk of cognitive decline. However, their impact on brain metabolism and related cognitive and motor features remains poorly understood: how visuospatial deficits reflect posterior cortical dysfunction and how these changes relate to other clinical manifestations? This study investigates cerebral metabolism and its association with clinical features in PD patients with and without GBA1 variants.

Methods: 38 GBA-PD and 46 non-GBA-PD underwent clinical, neuropsychological, and FDG-PET evaluation. Posterior cortical hypometabolism was quantified by single-subject SPM-analysis, and its association with visuospatial, motor, and non-motor features was assessed using Spearman correlations. Visuospatial function was assessed using a standardized posterior visuospatial composite score (PAROVIS).

Results: Compared with non-GBA-PD, GBA-PD patients were younger, had earlier disease onset, greater motor disability (including fluctuations and freezing of gait), higher depression, and worse quality of life, despite similar disease duration and education. FDG-PET revealed greater posterior cortical hypometabolism in GBA-PD. Cognitively, GBA-PD showed poorer visuospatial and executive performance, while other cognitive domains were comparable to non-GBA-PD. Within GBA-PD, the PAROVIS score correlated with posterior hypometabolism and freezing of gait severity, an association absent in non-GBA-PD ($\alpha = 0.77$).

Conclusion: Visuospatial dysfunction is a core cognitive feature of GBA-PD, associated with posterior cortical hypometabolism and gait impairment, even without global cognitive decline. These findings support a distinct posterior cortical-cognitive phenotype in GBA-PD, while longitudinal validation is needed to establish FDG-PET and visuospatial measures as reliable tools for monitoring disease progression and patient stratification.

Disclosure: Nothing to disclose.

EPO-0647 | Dystonia in Mowat-Wilson syndrome: A yet underrecognized neurological feature

L. Kunc¹; P. Havránková¹; M. Škorvánek²; J. Necpál³; J. Kothaj³; M. Zech⁴; R. Jech¹

¹Department of Neurology and Center of Clinical Neuroscience, First Faculty of Medicine, Charles University and General University Hospital in Prague, Czech Republic; ²Department of Neurology, University Hospital L. Pasteur, Kosice, Slovakia; ³Department of Neurology, Zvolen Hospital, Zvolen, Slovakia; ⁴Institute of Human Genetics, Technical University of Munich, Munich, Germany

Background and aims: Mowat-Wilson syndrome (MOWS) is a rare neurodevelopmental disorder caused by heterozygous pathogenic variants in the ZEB2 gene. The neurological phenotype is characterized by intellectual disability, epilepsy, and characteristic craniofacial features. Based on the current literature, more than 300 individuals with MOWS have been reported. To date, only a single case report has documented dystonia in MOWS. The true frequency and clinical relevance of dystonia in MOWS therefore remain unclear.

Methods: We retrospectively identified three unrelated patients with genetically confirmed MOWS through a whole-exome sequencing (WES) project focused on individuals with dystonia. All patients were evaluated by a movement disorder specialist. Detailed clinical, genetic, and neuroimaging data were reviewed and compared with available literature.

Results: The case series included two females and one male, aged 5–21 years, all of whom exhibited dystonia. The onset of dystonia occurred between 3 and 18 years of age. Two patients developed generalized dystonia while one presented with a segmental type. WES identified heterozygous de novo ZEB2

variants in all cases: two missense variants classified as likely pathogenic and one frameshift variant classified as pathogenic. All patients showed a typical MOWS phenotype, including intellectual disability and distinctive craniofacial features. Epilepsy was present in one patient.

Conclusion: Our findings demonstrate that dystonia can occur in Mowat–Wilson syndrome and may represent an underrecognized feature of its neurological phenotype. Awareness of movement disorders in patients with ZEB2 mutations is important for accurate phenotyping and may facilitate earlier diagnosis, particularly in individuals with developmental delay and dysmorphic features.

LK, PH, and RJ were supported by the institutional research: General University Hospital in Prague project MH CZ-DRO-VFN64165. MS and JN received support from the EU Renewal and Resilience Plan “Large projects for excellent researchers” under grant No. 09I03-03-V03-0000.

EPO-0648 | Therapeutic impact of iron chelation in PKAN and related NBIA subtypes: A systematic review of 552 cases

J. Pineda¹; P. Miranda¹; C. Peralta¹; E. Reyes¹; E. Patricio¹; A. Reyes¹; A. Tejada¹; K. Yorro¹; C. Pérez¹; M. Rodríguez²

¹Synaptic Research League, Santo Domingo, Dominican Republic; ²Neurology Department, Hospital Universitario Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic

Background and aims: Neurodegeneration with Brain Iron Accumulation type 1 (NBIA1), or Pantothenate Kinase-Associated Neurodegeneration, is a rare inherited neurodegenerative disorder characterized by iron deposition in the basal ganglia [1]. It affects fewer than one per million individuals. Iron chelation therapy has shown heterogeneous radiological and clinical outcomes [1].

Methods: A systematic review of the literature was performed in accordance with PRISMA guidelines. PubMed, BVS and Google Scholar were searched using the keywords “Neurodegeneration with Brain Iron”, “Accumulation”, “NBIA1”, “Chelation Therapy”, “Deferiprone”.

Results: A total of 552 patients with NBIA with a mean age of 22.1 years were included. Pantothenate kinase-associated neurodegeneration (PKAN) was the predominant subtype accounting for 535 of the patients (96.9%); followed by other subtypes including MPAN ($n=2$), BPAN ($n=1$), neuroferritinopathy ($n=4$), VAC14-related NBIA ($n=1$) and idiopathic NBIA cases ($n=9$). 195 of the cases corresponded to males (53.6%) and 169 to females (46.4%). Defiprone was the most frequently used chelator, used at doses of 30 mg/kg/day varying in treatment duration from 17 weeks to 2 years. Reduction in brain iron was demonstrated radiologically in most cohorts leaning to stabilization and improvement with minimal reports of reversal. Hematologic events were reported as the main adverse effects accounting to 21% in the randomized data, the main cause of treatment discontinuation.

Conclusion: Iron chelation therapy with Deferiprone is associated with reduced brain iron and clinical stabilization in most

Prisma-P flowchart of the process of inclusion of studies in the systematic review.

Clinical response by gene mutation in iron chelation in PKAN and related NBIA subtypes.

NBIA1 patients, although neurological reversal is uncommon. Hematologic adverse effects limit treatment, emphasizing the need for safer long-term therapies and standardized outcome measures.

Disclosure: Nothing to disclose.

EPO-0649 | Clinical profile and treatment options in Nasu-Hakola syndrome: Systematic literature review

J. Baez¹; K. Pérez¹; S. Campusano¹; A. Rosario¹; P. Tejada¹; C. Michel¹; P. Miranda¹; A. Tejada¹; K. Yorro¹; C. Pérez

Lizardo¹; A. Reyes¹; M. Rodríguez²

¹Synaptic Research League, Santo Domingo, Dominican Republic; ²Neurology Department, Hospital Universitario Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic

Background and aims: Nasu-Hakola disease, or polycystic lipomembranous osteodysplasia with sclerosing leukoencephalopathy (PLOS), is a rare, autosomal-recessive, and fatal disorder caused by mutations in the TREM2 or TYROBP genes.

Clinical findings, diagnostic and treatment overview in Nasu-Hakola disease.

It is uniquely characterized by the co-occurrence of presenile dementia and cystic bone lesions, leading to death typically by the fifth decade [1–2]. This descriptive study aims to review its clinical manifestations, diagnostic findings and treatment.

Methods: A systematic review was performed following PRISMA guidelines. PubMed and BVS were searched using the keywords “Nasu-Hakola,” “PLOS,” and “brain-bone-fat disease”. Eligible studies were included and data were extracted into a standardized database for comparative analysis of clinical and treatment variables.

Results: Analysis of 12 patients (mean age 35.87 years; 33% familial) showed predominantly neurological onset (58%). Key findings included diffuse cerebral atrophy on MRI (91%), periventricular lesions (73%), basal ganglia abnormalities (64%), and bone cysts/lytic lesions (82%, 18% asymptomatic). Mutations were in TREM2 (58%) or TYROBP. Supportive treatments included antipsychotics/antiepileptics and fracture surgery; one case benefited from virtual reality neurorehabilitation.

Conclusion: This review confirms early neuropsychiatric presentation despite radiographic bone cysts. The diagnostic triad of frontal-predominant cerebral atrophy, characteristic bone lesions, and TREM2/TYROBP mutation is consistent. The universally fatal progression underscores the absence of disease-modifying therapies. Supportive care, including tailored neurorehabilitation, may ameliorate specific symptoms, but early genetic diagnosis remains crucial for definitive management and counseling.

Disclosure: Nothing to disclose.

EPO-0650 | Cerebrotendinous xanthomatosis mimicking or coexisting with juvenile ALS: A case with CYP27A1 and SETX mutations

N. Kahveci Erdemir; A. Çolakoğlu; A. Aksoy Gündoğdu
Department of Neurology, Tekirdag Namik Kemal University,
Tekirdag, Türkiye

Background and aims: Cerebrotendinous xanthomatosis (CTX) is a rare autosomal recessive lipid storage disorder caused by CYP27A1 mutations, resulting in sterol 27-hydroxylase deficiency and systemic cholestanol accumulation. Amyotrophic lateral sclerosis (ALS) is the most common motor neuron disease; its juvenile form begins before age 25, and autosomal dominant ALS type 4 is associated with SETX mutations. Coexistence of CTX and ALS type 4 has not been previously described.

Methods: A 34-year-old male presented with progressive difficulty walking. Symptoms began 6 years earlier with gait imbalance, worsening weakness, and diffuse limb pain. His history included chronic diarrhea since infancy, febrile seizures in early childhood, bilateral cataract surgery at age 10, and hypophonia and dysarthria developing in his mid-20s. Neurological examination revealed severe tetraparesis with muscle atrophy, fasciculations, global hyperreflexia, bilateral clonus, and positive Babinski and Hoffman signs.

Results: Brain Magnetic Resonance Imaging showed bilateral cerebellar T2/FLAIR hyperintensities and periventricular white matter changes. Electromyography demonstrated widespread anterior horn cell involvement. Genetic testing identified a heterozygous SETX c.6625A>T (p.Lys2209Ter) mutation, confirming ALS type 4. Considering long-standing gastrointestinal, ophthalmologic, and neurological symptoms, CYP27A1 sequencing was performed and demonstrated a homozygous pathogenic variant (c.1263+1G>A), establishing CTX diagnosis. Treatment with riluzole and chenodeoxycholic acid was initiated.

Conclusion: This rare coexistence of CTX and ALS type 4 highlights the importance of recognizing metabolic warning signs such as chronic diarrhea and childhood cataract. Early metabolic and genetic evaluation is essential, as timely chenodeoxycholic acid therapy may slow neurological progression and improve long-term outcomes.

Disclosure: Nothing to disclose.

EPO-0651 | Beyond the classic phenotype: Optic neuropathy in a patient with Charcot-Marie-Tooth type 2Q

P. Dodu; G. García-Marín
Regional University Hospital of Málaga, Málaga, Spain

Background and aims: Charcot-Marie-Tooth disease type 2 (CMT2) is a genetic disorder characterized by axonal involvement of the peripheral nerves, with a normally autosomal dominant inheritance pattern. There are multiple subtypes of CMT2, each defined by a different affected gene.

Methods: We present the case of a patient with optic neuropathy and axonal polyneuropathy caused by a mutation in the DHTKD1 gene.

Results: We have a 53-year-old male patient with no family history and a personal history of alcoholism who presents with sequential loss of visual acuity, as well as chronic paresthesia in all four limbs. Ophthalmological examination revealed bilateral papillary atrophy, and neurological examination revealed glove-and-stocking paresthesia, decreased vibratory sensitivity in all four extremities, and difficulty walking on heels and tiptoes. A blood test was performed with negative autoimmunity, normal cranial MRI, normal cerebrospinal fluid study, and neurophysiological study with data of bilateral axonal optic neuropathy and chronic axonal peripheral neuropathy. Genetic testing showed the c.1897-1G>A variant classified as pathogenic in heterozygosity in the DHTKD1 gene, associated with CMT2Q.

Conclusion: CMT2Q is a rare condition caused by mutations in the DHTKD1 gene, which usually presents with muscle weakness and progressive distal atrophy. The presence of optic neuropathy in our patient is an atypical finding, more commonly

described in the CMT2A subtype. We believe that the mitochondrial metabolism disorder caused by the DHTKD1 mutation, together with alcohol abuse, may have acted synergistically, amplifying the phenotype of this disorder.

Disclosure: Nothing to disclose.

EPO-0652 | NOTCH3 rs201118034 is not an independent risk factor of vascular Parkinsonism among Taiwanese population

Y. Liaw¹; Y. Liaw²; S. Hsu²; Y. Liaw²
¹Division of Neurology, Department of Internal Medicine, National Yang Ming Chiao Tung University Hospital, Yi-Lan, Taiwan; ²Department of Public Health and Institute of Public Health, Chung Shan Medical University, Tai-Chung, Taiwan

Background and aims: NOTCH3 p.R544C mutation is a common hotspot for developing monogenetic leukoencephalopathy among Taiwanese population. Clinically, this mutation can cause a variable clinical presentations, including vascular Parkinsonism (VaP). This study aimed to investigate the risk of VaP in the generalized Taiwanese population utilizing single nucleotide polymorphisms (SNPs).

Methods: Data were retrieved from the Taiwan Biobank Database (2008–2020) and the National Health Insurance Research Database (2000–2020), and they were linked using encrypted personal identification numbers. After excluding participants with a history of stroke, dementia, or Parkinson's disease other than VaP, a total of 147 patients with VaP and 98,699 control subjects were included in the analysis. In this study, VaP was defined specifically with ICD-10 of G21.4 and G21.8. rs201118034 was used to represented the NOTCH3 p.R544C mutation.

Diabetes (ref: No)				
Yes	1.90	1.32	2.72	0.001
Hypertension (ref: No)				
Yes	2.15	1.46	3.16	<0.001
Hyperlipidemia (ref: No)				
Yes	1.73	1.13	2.66	0.012

Results: Among the multivariable logistic regression analysis, the AG+AA genotype on rs201118034 has a higher, but not significant, odds ratio of developing VaP (OR=2.71, $p=0.090$). However, in the regression model, a higher age group between 61 and 70years-old was a significantly independent risk factor of VaP (OR=6.56, $p<0.001$). Lastly, diabetes (OR=1.90, $p=0.001$), hypertension (OR=2.15, $p<0.001$), and hyperlipidemia (OR=1.73, $p=0.012$) still remained independent predicting factors of developing VaP in our population.

Conclusion: Our findings suggested that the risk of VaP of NOTCH3 p.R544C carrier is not determined independently via this mutation. An elder age, hypertension, diabetes and hyperlipidemia remained independent and critical factors in developing VaP.

Disclosure: Disclosure: The authors no conflicts of interest. Fundings: This work was funded by the Ministry of Science and Technology (MOST 111-2121-M-040-002; NSTC 112-2121-M-040-002; 113-2121-M-040-001; 114-2121-M-040-002) IRB: CS1-23101.

EPO-0653 | Depression and mood changes in Parkinson's disease over time. A 5-year follow-up study

Background and aims: Depression is frequent in Parkinson's disease (PD), but it is unclear how mood changes and impacts patient's quality of life (QoL) over time. Our objective was to analyze the frequency of depression and mood changes in people with PD (PwP) over 5 years of follow-up, comparing it with a control group, as well as its relationship with the patients' QoL.

Methods: PwP and healthy controls (HC) recruited from the COPPADIS cohort from January/2016 to November/2017 were included in this 5-year follow-up study. Mood was assessed by the Beck Depression Inventory II (BDI-II), and participants were classified as having major depression, minor depression, subthreshold depression, or non-depression at baseline and at 2, 4, and 5 years of follow-up. Correlation analysis and linear regression models were conducted to determine how different factors contribute to mood changes.

Results: The BDI-II total score increased ($p < 0.0001$) from 8.1 ± 6.2 at baseline to 10.3 ± 8.1 at the 5-year follow-up visit in PwP but not in HC (from 4.1 ± 5.2 to 4.0 ± 5.7 [$p = 0.896$]). The prevalence of depression remained around 50% in the PwP group and 25% in the HC group throughout the follow-up period, but the mood state showed variability for each patient between visits (Figure 1). Patients' QoL was associated with the depressive state throughout the entire follow-up period (Figure 2). Worsening QoL, sleep, longer disease duration, and an increase in neuropsychiatric symptoms were identified as independent

TABLE 1 Factors associated with mood (BDI-II score) change from baseline (V0) to the 5-year follow-up visit (V5) (BDI-IIV5 – BDI-IIV0) in PD patients (N=346).

Background and aims: Amygdala is crucial in emotional regulation and integrating interoceptive information, autonomic control, and motor behavior. The study aimed to assess amygdala volume and functional connectivity (FC) alterations in patients with Parkinson's disease with and without freezing of gait (PD-FoG, PD-NO-FoG).

Methods: Thirty PD-FoG patients, 30 PD-NO-FoG patients (with postural instability and gait disorders), and 30 matched healthy controls underwent neuropsychological, structural, and functional magnetic resonance imaging (MRI) assessments. Amygdala was segmented using FSL-FIRST. Based on volumetric findings, right amygdala was used as region of interest for seed-based FC analyses.

Results: PD-FoG and PD-NO-FoG patients showed comparable cognitive profiles, with impairments in memory, visuospatial, and executive-attentional domains, as well as increased depressive symptoms. MRI analyses revealed increased amygdala volume in PD-FoG compared with healthy controls. Resting-state fMRI analyses showed that, relative to controls, PD-FoG patients exhibited increased FC between the right amygdala and limbic-striatal regions, including the left thalamus, putamen, insula, and inferior frontal orbital cortex, along with reduced connectivity with the middle temporal gyrus and cerebellar regions (Crus I and lobules VI–VIII). Compared with PD-NO-FoG patients, PD-FoG patients showed reduced FC between the right amygdala and middle/superior temporal, inferior parietal, post-central gyri, insula, and fusiform cortex.

Conclusion: Increased amygdala–limbic-striatal connectivity in PD-FoG may reflect stronger emotional influence on motor circuits, contributing to impaired automatic gait control. Reduced connectivity with temporal, parietal, and cerebellar regions suggests disrupted integration across emotional,

cognitive, and motor networks, supporting the hypothesis that FoG arises from impaired network communication underlying gait automaticity.

Background and aims: Gait disturbances are a core feature of people with Parkinson's disease (pwPD) and are influenced by motor, cognitive, and emotional factors, reflecting the reciprocal link between emotion and movement described by embodied emotion theories. This study examined whether observing emotional gait modulates gait performance and locomotor network activity in pwPD and healthy controls, focusing on the effects of positive and negative emotions on gait parameters and sensorimotor activation.

Methods: Thirty-one pwPD and twenty-six age-/sex-matched HC underwent gait analysis and task-based functional MRI (fMRI). Gait was assessed during spontaneous walking, top-down embodiment (self-evoked emotions), and bottom-up embodiment (imitation after observing emotional gait videos depicting happiness, sadness, anxiety). fMRI data were collected during emotional gait observation and analyzed using permutation-based nonparametric statistics focusing on sensorimotor regions.

Results: Both groups accurately recognized emotional gait and reported similar valence and intensity. Happiness improved gait in pwPD and HC, especially during bottom-up embodiment, enhancing stride length, arm kinematics, and turning velocity, whereas sadness and anxiety worsened gait performance, increasing variability and reducing pace. fMRI showed emotion-specific sensorimotor modulation, with happiness enhancing basal ganglia and sensorimotor activation and negative emotions reducing it. In pwPD, these neural patterns correlated with emotion-specific changes in gait during bottom-up embodiment.

Conclusion: Emotions modulate gait and its neural substrates in pwPD and HC. Positive emotional cues enhance motor system

engagement even in pwPD, whereas negative emotions exert detrimental effects. These findings support the integration of emotionally enriched action observation into gait rehabilitation and highlight the relevance of emotional states in clinical evaluation.

Background and aims: We previously reported that patients receiving an optimized ND0612 regimen experienced a lower incidence of falls during the double-blind phase of the BouNDless trial, vs those treated with levodopa/carbidopa (IR-LD/CD) therapy (7% vs 12%, respectively).

Methods: We (a) examined the baseline characteristics of patients who experienced recurrent (>1) falls using an integrated safety database (ISD), and (b) explored potential factors contributing to the reduced fall rates. Postural instability and gait disorder (PIGD) and freezing of gait (FOG) were measured using MDS-UPDRS items; cognitive function via PDQ-39 cognitive scores; and dyskinesia using Hauser diaries.

Results: Patients with recurrent falls were older (62% aged ≥65 years vs 49% in the overall cohort), had lived with their PD for longer (time since diagnosis of 10.7 vs 9.4 years), and had higher (worse) motor severity (MDS-UPDRS Part III scores of 37.6 vs 34.5). In the BouNDless trial, ND0612 improved PIGD scores vs IR-LD/CD (improvement of +0.26 vs -0.02), reduced FOG (improvement of +0.33 vs +0.18) and enhanced cognition (improvement of +0.90 vs +0.31). Mean ON-time with troublesome dyskinesia decreased with ND0612 from 0.71 to 0.45 h.

Conclusion: Treatment with ND0612 has a positive effect on the various factors associated with falling in PD, and support the finding of reduced falls with optimized ND0612 therapy.

Disclosure: Nothing to disclose.

EPO-0658 | Long-term efficacy of ND0612 for motor fluctuations in Parkinson's disease

W. Jost¹; A. Espay²; R. Pahwa³; A. Ellenbogen⁴; F. Stocchi⁵; N. Lopes⁶; A. Salah⁷; O. Rascol⁸

¹Parkinson-Klinik Ortenau, Wolfach, Germany; ²James J. and Joan A. Gardner Center for Parkinson's Disease and Movement Disorders, University of Cincinnati, Cincinnati, USA; ³University of Kansas Medical Center, Kansas City, KS, USA; ⁴Quest Research Institute, Farmington Hills, USA; ⁵Institute for Research and Medical Care IRCCS San Raffaele, Roma, Italy; ⁶Department of Neurology, San Raffaele University, Rome, Italy; ⁷NeuroDerm Ltd, Rehovot, Israel; ⁸Tanabe Pharma America, Inc, Jersey City, USA; ⁸University Hospital of Toulouse, INSERM, Clinical Investigation Center CIC1436 Toulouse, France

Background and aims: Primary efficacy analyses from the double-blind phase of the BouNDless study demonstrated that treatment with ND0612 provided patients with Parkinson's

disease (PD) an additional 1.72 hours (h) of Good ON-time compared with levodopa/carbidopa (IR-LD/CD) ($p < 0.0001$). We describe here one-year efficacy outcomes from the ongoing open-label extension (OLE) phase.

Methods: Patients who completed the double-blind phase of the BouNDless study were eligible to enter the ongoing OLE phase (up to 54 months). All anti-PD medications were adjusted according to individual response. Efficacy was assessed with the Hauser diary at Months 6 and 12 of the OLE phase. Changes in ON-time with troublesome dyskinesia were analyzed for the subgroup of patients who had ≥1 h troublesome dyskinesia at treatment onset.

Results: Of 232 participants ($n = 113$ previously randomized to ND0612, $n = 119$ previously randomized to IR-LD/CD), 167 (72%) completed 1 year of ND0612 treatment in the OLE phase. By Month 6, patients had a mean ± SE change of -2.2 ± 0.2 h in OFF-time and $+2.4 \pm 0.2$ h in Good ON-time. Efficacy benefits were sustained at Month 12 with a change of -2.1 ± 0.2 h in OFF-time and $+2.1 \pm 0.2$ h in Good ON-time. The proportion of patients with ≥12 hours of Good ON-time increased from 16.4% before initiating ND0612 to 57.9% at Month 6 and 54.6% at Month 12. Patients who had ≥1 h of ON-time with troublesome dyskinesia at ND0612 initiation ($n = 45$) showed a change of -1.2 ± 0.3 h at Month 6 and -1.5 ± 0.3 h at Month 12.

Conclusion: These data support the long-term efficacy of ND0612 for PD patients experiencing motor fluctuations.

Disclosure: Nothing to disclose.

EPO-0659 | Efficacy of inhaled levodopa by age-based subgroups in patients with Parkinson disease: Post hoc analysis of pooled data from three phase III trials

A. Scheschonka; M. Ngure; C. Walter; S. Freisens; G. Comes
Merz Therapeutics GmbH, Frankfurt, Germany

Background and aims: Many people with Parkinson disease (PwP) develop motor response fluctuations (OFF episodes) within 5 years of starting oral levodopa. CVT-301 is an orally inhaled formulation of levodopa developed for the treatment of episodic OFF periods. This analysis aimed to assess the efficacy of CVT-301 (84 mg) in reducing motor symptoms and improving patient-reported outcomes in PwP across age-based subgroups.

Methods: This descriptive post hoc analysis pooled data from three phase III clinical trials (CVT-301-004, CVT-301-004e, and CVT-301-005). Analyses were conducted across subgroups based on age at time of diagnosis, age at start of first OFF episode, and age at initiation of study treatment, defined as <55, 55–64, 65–74, and ≥75 years. Efficacy endpoints included Patient Global Impression of Change (PGIC) at Week 12 and change from baseline in Unified Parkinson's Disease Rating Scale Part III (UPDRS III) score from pre-dose to 30 minutes post-dose at Week 12.

Results: A total of 437 PwP were pooled. The mean age (range) was 63.5 (37–82) years; 64.3% were male and 96.3% were White. The mean (standard deviation [SD]) time since diagnosis was 8.7 (4.54) years. The mean (SD) time since first OFF episode was 3.8 (3.07) years. The mean change in UPDRS-III score from pre-dose to 30 minutes post-dose at Week 12 showed improvements across all age subgroups. Similarly, the PGIC consistently showed improvements at Week 12.

TABLE 1 Change in UPDRS-III score from pre-dose to 30 minutes post-dose and improvement on PGIC at Week 12 across age subgroups.

	Change in UPDRS-III score from pre-dose to 30 minutes post-dose at Week 12, N = 344 ^a		Improvement on PGIC at Week 12, N = 381 ^a	
	n	Mean (SD)	n improved/N	%
Age at first diagnosis				
<55 years	102	-15.6 (12.02)	139/170	81.8
55-64 years	145	-13.6 (8.86)	130/157	82.8
65-74 years	44	-15.6 (10.33)	46/51	90.2
≥75 years	3	-5.7 (8.99)	1/3	33.3
Age at first OFF episode				
<55 years	90	-15.2 (12.61)	82/102	80.4
55-64 years	104	-14.4 (9.77)	139/167	83.2
65-74 years	86	-15.1 (9.77)	83/96	86.5
≥75 years	14	-12.0 (10.32)	12/16	75.0
Age at study treatment initiation				
<55 years	55	-16.4 (13.84)	46/63	73.0
55-64 years	129	-14.2 (10.31)	116/136	84.8
65-74 years	131	-14.7 (9.94)	126/146	86.3
≥75 years	31	-13.6 (7.74)	27/34	79.4

^aObserved cases analysis

PGIC, Patient Global Impression of Change; SD, standard deviation; UPDRS-III, Unified Parkinson's Disease Rating Scale Part III.

Conclusion: Use of CVT-301 is an effective option for managing OFF episodes in PwP, with consistent motor symptom relief and patient-reported improvement across all ages.

Disclosure: This study was funded by Merz Therapeutics GmbH.

EPO-0660 | Familial tremor linked to a heterozygous variant in the ceruloplasmin gene

G. De Vita¹; G. Blasio²; G. Riccio³; R. Coppola³; D. Dell'Aversana³; S. Coccozza⁴; E. Gragnano⁴; M. Esposito⁵; G. De Michele³; A. De Rosa³

¹Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples, Italy; ²CEINGE-Biotecnologie Avanzate Franco Salvatore, Naples, Italy;

³Department of Neurosciences and Reproductive and Odontostomatological Sciences, Federico II University, Naples, Italy; ⁴Departments of Advanced Biomedical Sciences and Electrical Engineering and Information Technology, University of Naples Federico II, Naples, Italy; ⁵Clinical Neurophysiology Unit, Cardarelli Hospital, Naples, Italy

Background and aims: Biallelic mutations in the ceruloplasmin (CP) gene cause aceruloplasminemia, a rare autosomal recessive disorder characterized by systemic and cerebral iron overload. Here we describe the clinical, genetic, and radiologic features of a family carrying a heterozygous variant in the CP gene.

Methods: The proband was an 18-year-old girl presenting action tremor in the upper limbs, which was also observed in her father and older sister. Serum ceruloplasmin levels and brain Magnetic Resonance Imaging was assessed in all three subjects. The proband was tested by New Generation Sequencing for a panel of genes associated with movement disorders. The results were validated and extended to the parents and the older sister by Sanger sequencing.

Results: The analysis revealed a heterozygous variant c.188T>C in the CP gene, introducing a missense change p.(Ile63Thr) in the proband. The variant was inherited from the father and shared with the affected sister.

FIGURE 1 Brain MRI scans of the three subjects harboring the heterozygous CP gene variant: the proband, the older sister, and the father, from top to bottom. From left to right are shown a volumetric T1-weighted, a T2-weighted FLAIR and an SWI sequences.

FIGURE 2 Sanger sequencing showing the CP mutation (c.188T>C, arrows) in the proband (III/2), her older sister (III/1) and her father (II/1), but not in the mother (II/2).

Conclusion: In our family the CP variant segregated with the clinical phenotype, characterized by action tremor, suggesting that this mild neurological manifestation may be likely attributable to the variant rather than representing an incidental finding. Neurological symptoms may occur in heterozygous carriers of CP gene variants, although they are usually believed to be asymptomatic.

Disclosure: Nothing to disclose.

FIGURE 3 Family pedigree showing that the heterozygous variant, carried by the proband (arrow), her father and older sister, segregates with the phenotype. The younger sister of the proband has not been tested due to the minor age and absence of symptoms.

EPO-0661 | fMRI activity during working memory manipulation is associated with caudate integrity in early Parkinson's disease

H. Theis¹; K. Giehl²; A. Asendorf³; M. Banwinkler³; V. Dzialas³; R. Lubomierski³; M. Hönl²; T. van Eimeren¹

¹University of Cologne, Faculty of Medicine and University Hospital Cologne, Department of Neurology, Cologne, Germany.

University of Cologne, Faculty of Medicine and University Hospital Cologne, Department of Nuclear Medicine, Cologne, Germany; ²University of Cologne, Faculty of Medicine and University Hospital Cologne, Department of Nuclear Medicine, Cologne, Germany. Research Center Juelich, Institute for Neuroscience and Medicine (INM-II), Juelich, Germany;

³University of Cologne, Faculty of Medicine and University Hospital Cologne, Department of Nuclear Medicine, Cologne, Germany

Background and aims: Cognitive difficulties are common in Parkinson's disease (PD). Specifically, manipulation in working memory (WM) seems particularly vulnerable as it relies on frontostriatal networks. However, it is still relatively unclear how early alterations in nigrostriatal integrity – quantified as dopamine transporter (DaT) availability and iron depositions via Quantitative Susceptibility Mapping (QSM) – may shape cognitive neural responses. Thus, we aimed to investigate the relationship between caudate integrity and neural activity during WM manipulation in early PD.

Methods: 25 patients and 35 matched healthy controls (HC) performed a validated WM paradigm to identify neural activity specifically associated with WM manipulation. A two-sample t-test was used to test for group differences. Mean specific binding

T-maps for the WM manipulation contrast ($p < 0.05$, FWE-corrected). Upper row: PD, lower row: HC.

Scatterplots of the partial correlations between individual BOLD signal during WM manipulation and mean caudate DaT SBR (left) or mean caudate QSM (right) corrected for age and sex. For illustration, standardized residuals of BOLD activity and DaT SBR or.

ratios (SBRs) from DaT-SPECT and susceptibility values from QSM MRI were computed for the caudate. Mean BOLD activity was partially correlated with caudate SBR and QSM values.

Results: Both groups showed robust widespread activation in the frontoparietal, cerebellar and anterior striatal regions (Figure 1). There were no group differences in activation and task performance. Within the PD group, higher caudate DaT SBRs were trend associated with stronger BOLD responses (partial $r = 0.342$, one-sided $p = 0.055$), while higher caudate iron load as indexed via QSM correlated with reduced BOLD activity (partial $r = -0.681$, one-sided $p = 0.003$) during WM manipulation (Figure 2).

Conclusion: Patients show preserved large-scale WM activation patterns. However, task-related BOLD modulation during WM manipulation relates to nigrostriatal integrity within the caudate nucleus. These results highlight caudate-dependent modulation of executive processes within WM in early PD.

Working memory training increases neural efficiency in Parkinson's disease: a randomized controlled trial. Brain communications. 2020;2(2):fcaa115.

EPO-0662 | Multisite ultrasound investigation of vagus nerve echostructure, regional substantia nigra, extraneural markers in Parkinson's disease: MULTIVERSE-PD.

E. Bianchini¹; G. Sergi¹; G. Anzini¹; S. Toro¹; N. Casasoli¹; M. Frizzi²; F. Spagnolo²; G. Vivacqua³; M. Marano¹

¹Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy; ²Department of Neurology, A. Perrino Hospital, Brindisi, Italy; ³Department of Microscopic and Ultrastructural Anatomy, Campus Biomedico University of Roma, Rome, Italy.

Background and aims: Ultrasound sonography (US) is a reliable cost-effective tool to investigate brain and nerve tissue features. Substantia Nigra (SN) US has been extensively evaluated in Parkinson's Disease (PD) [1]. Along with SN, recent studies also examined vagus nerve (VN) US features, with alternate results [2]. The MULTIVERSE-PD study aims at implementing the use of US biomarkers in PD. In this preliminary phase we aimed at implementing the use of SN and VN sonography in a well characterized sample of PD with mobility and fluid biomarkers.

Methods: VN cross sectional area (VN-CSA) and SN hyperechogenic area (SN-HA) were consecutively collected in mild-to-moderate PD patients. Participants were clinically assessed through MDS-UPDRS, SCOPA, PDSS2, ESS, PDQ8 and other scales. All subjects underwent real-world mobility evaluations through IMUs (McRoberts MoveMonitor) and plasmatic inflammatory and neurodegeneration biomarker dosing.

Results: Twenty patients were recruited (10 male, 10 female; age 66 ± 9 ; disease duration 7.3 ± 4 ; MDS UPDRS III 26 ± 12). Mean SN-HA was 0.4 ± 0.1 cm², VN-CSA was 1.4 ± 0.5 cm². SN-HA was significantly related ($p < 0.01$) to total scores of MDS-UPDRS part I and II, SCOPA, NMSS ($r = 0.5-0.8$), PDSS2 ($r = 0.7$) and PDQ8 ($r = 0.5$). VN-CSA inversely related ($p < 0.01$) to MoCA ($r = 0.7$) and directly to ESS ($r = 0.5$).

Conclusion: SN and VN echographic features are promising biomarkers in PD. The MULTIVERSE-PD study will collect more echographic biomarkers from neural and extraneural targets that will be harmonized with mobility and biochemical parameters through artificial intelligence. A multicenter effort is required.

Disclosure: Nothing to disclose.

EPO-0663 | Adult Tourette syndrome: Patient experience and clinical insights from a UK Regional Neurology Centre

R. McGinty¹; Jessica Lythgoe¹; Z. Htet¹; A. Arun¹; A. Macerollo^{1,2}

¹The Walton Centre NHS Foundation Trust, Liverpool, UK;

²Institute of Systems, Molecular and Integrative Biology, The University of Liverpool, UK

Background and aims: This study investigated tic phenomenology, psychiatric comorbidity and clinical pathways in adults with Tourette Syndrome (TS). Variation in access to appropriate services can prolong the diagnostic journey and pose challenges for management.

Methods: Retrospective analysis of electronic clinical records for adults with TS attending a regional neurology Centre, The Walton Centre NHS Foundation Trust (Liverpool, UK), between

FIGURE 1 Co-existing mental health and neurodevelopmental disorders in adults with TS. Data shown for 118 patients (ten others did not have any mental health or neurodevelopmental diagnoses).

November 2020 and November 2025. Data collected included demographics, tic characteristics and medication use.

Results: Of 128 patients, 56 were women and the mean age was 30.6 years. The mean age of tic onset was 8.9 years and at TS diagnosis was 24 years. The estimated mean time from symptom-onset to diagnosis was 184 months. In childhood, 14 patients had contact with paediatric neurology services. The clinical course of TS worsened for 46.9%. Tic-related pain was experienced 26.6%. For tic management, 20.3% tried behavioural interventions and 66.4% tried medications (most commonly aripiprazole, clonidine and risperidone). Two patients were treated with deep brain stimulation at University College of London. Coexisting psychiatric disorders affected 118 (92.2%) individuals and, of these, 62 (52.5%) had three or more psychiatric diagnoses.

Conclusion: Most patients did not have access to appropriate TS services in childhood and faced a prolonged diagnostic delay. Only one-fifth of patients had access to gold standard tic treatment with behavioural interventions, as this is not funded by the National Health Service. The high rate of psychiatric comorbidity underlines the importance of multidisciplinary management.

Disclosure: Nothing to disclose.

EPO-0664 | The invisible enemy : Shedding light on antibody-negative autoimmune encephalitis

A. Dupic¹; B. Grall¹; G. Picard²; C. Bost³; M. Benaiteau²; M. Rafiq⁴; D. Psimaras¹; B. Stankoff⁵; J. Pariente⁴; J. Honnorat²; G. Dorcet⁵

¹Pitié-Salpêtrière Hospital, AP-HP, Paris, France; ²French Reference Centre on Paraneoplastic Neurological Syndromes, HCL, Lyon, France; ³Toulouse University Hospital, Toulouse, France; ⁴Toulouse Neuroimaging Centre, Paul Sabatier Toulouse-3 University, Inserm, CNRS, Toulouse, France; ⁵Paris Brain Institute, Sorbonne University, Inserm, CNRS, Paris, France

Background and aims: Despite diagnostic criteria proposed in 2016, antibody-negative autoimmune encephalitis (AE-) remain diagnostically elusive, often delaying access to effective treatments. While antibody-positive AE (AE+) has been extensively characterized, AE- remains underexplored.

Methods: We built a multicenter database from the three French AE reference centers (Lyon, Paris, Toulouse), including patients diagnosed between 2016 and 2023, and followed for 2 years. This preliminary analysis includes 139 patients from Paris and Toulouse.

Results: We identified 110 AE+ (79%) and 29 AE- (21%). Mean age (56 years old) and sex-ratio (1:1) were similar. AE- occurred more frequently in a post-infectious context (17% vs 3%, $p=0.01$) and showed less epilepsy (21% vs 43%, $p=0.03$), and a trend to more neuro-ophthalmologic involvement (31% vs 15%, $p=0.07$). Non-limbic presentations were also more frequent in AE- (45% vs 20%, $p=0.01$). Despite these differences, the clinical severity was comparable between AE- and AE+, with similar rates of intensive care unit admissions (30% and 28%, respectively) and clinical scores (median modified Rankin score = 3 and CASE = 5 in both groups). Nevertheless, the prognostic RAPID score was higher in AE- (3 vs 1, $p=0.0001$). On complementary investigations, AE- more frequently exhibited basal ganglia hypermetabolism on brain positron-emission tomography (100% vs 39%, $p=0.0169$), and diffuse or focal slowing on electroencephalography (63% vs 36%, $p=0.02$). CSF cell count and proteins were similar, but interleukin-6 levels were higher in AE- (21.5 pg/mL vs 3.4 pg/mL, $p=0.0265$).

Conclusion: These preliminary findings suggest that AE- follows a distinct clinico-radiological profile. Early identification may help guide more timely and targeted treatment strategies.

EPO-0665 | Real-world experience of transition from intravenous to subcutaneous Ocrelizumab in multiple sclerosis

C. Guedes Vaz¹; M. Seco²; S. Costa¹; J. Lopes¹; D. Costa¹; E. Santos¹; R. Samões¹

¹Serviço de Neurologia, Unidade Local de Saúde de Santo António, Porto, Portugal; ²Serviço de Neurologia, Unidade Local de Saúde de Matosinhos, Porto, Portugal

Background and aims: Subcutaneous (SC) Ocrelizumab has demonstrated non-inferiority to the intravenous (IV) formulation in Multiple Sclerosis (MS). However, real-world data on the transition from IV to SC remain limited. We aimed to evaluate patient-reported outcomes (PROM), safety and logistical impact associated with its transition in clinical practice.

Methods: We conducted a retrospective study including all patients treated with Ocrelizumab in 2025, at a tertiary MS center. Demographic and clinical data were collected. Adverse events (AEs) were graded according to CTCAE v5.0. Patient satisfaction and experience with SC administration were assessed using a modified version of Treatment Administration Satisfaction Questionnaire.

Results: Of 115 patients treated with Ocrelizumab, 61 (53%) received the SC formulation, and 51 of these completed PROMs. Thirty (58.8%) were men, with a mean age of 45.5 ± 13.0 years and a median disease duration of 9 (IQR 1–35) years. Forty-four (86.3%) patients previously received IV Ocrelizumab. The

median number of SC administrations was 1 (IQR 2). AEs occurred in 70.6% (36/51), predominantly mild (grade 1) local injection-site reactions. Overall, 82.3% of patients (42/51) were satisfied or very satisfied with the administration, 86.3% found it convenient, 81.8% (36/44) perceived time savings compared with IV infusion. Forty-eight percent preferred SC formulation, 40.9% were neutral. No clinical relapses were observed, CD19+ B-cell counts remained ≤ 5 cells/ μ L in 96% (24/25). The first SC administration reduced hospital time by 3h/patient (183h total); subsequent administration will reduce it 290h/session.

Conclusion: Transitioning from IV to SC Ocrelizumab was safe, well-tolerated, and associated with high patient satisfaction and substantial logistical benefits in real-world clinical practice.

Disclosure: Nothing to disclose.

EPO-0666 | Plasma neurofilament light chain, glial fibrillary acidic and Tau proteins dynamic in patients receiving CAR-T treatment

C. Lapucci¹; M. Gambella²; S. Mariotto³; V. Chiodega³; R. Varaldo²; A. Ghiso²; M. Centanaro⁴; E. Angelucci²; A. Raiola²; M. Inglese⁵

¹IRCCS Ospedale Policlinico San Martino, Genoa, Italy; ²UO Ematologia e Terapie cellulari. IRCCS Ospedale Policlinico San Martino. Genova, Italy; ³Neurology Unit, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona, Verona, Italy; ⁴Anesthesiology and Intensive Care Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy; ⁵Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Italy

Background and aims: ICANS is a severe adverse event of CAR-T cell therapy with limited predictive factors. Neuroaxonal and astroglial biomarkers may reflect pre-existing vulnerability and coexistent damage. This study evaluates the dynamic of neurofilament light chain (NFL), glial fibrillary acidic protein (GFAP), and Tau levels as predictors of ICANS.

Methods: Plasma NFL, GFAP, and Tau levels were measured at baseline (pre), day 7 (T1), and day 30 (T2) post-infusion. Their levels were analysed to assess associations with ICANS occurrence and severity.

Results: Among 20 patients (median age 56.6 years), moderate-severe ICANS occurred in 6/20 (30%), while 14/20 patients (70%) developed no or mild ICANS. Pre and T1 NFL, GFAP,

NFLs, GFAP and Tau dynamics in CAR-T treated patients.

and Tau levels did not differ between patients with moderate-severe ICANS and no or mild ICANS. NfL increased at T1 in moderate-severe ICANS ($p=0.021$). Δ NfL (T1-pre) predicted moderate-severe ICANS ($p=0.04$). NfL increased at T2 versus pre ($p=0.026$) and T1 ($p=0.027$) timepoints in moderate-severe ICANS. A trend toward higher GFAP levels was observed at T1 in moderate-severe ICANS ($p=0.054$) with a decrease at T2 in both groups. Tau showed no significant associations at any timepoint.

Conclusion: NfL, GFAP and Tau display distinct dynamics after CAR-T. An early increase of NfL levels after baseline predicts moderate-severe ICANS. Patients with moderate-severe ICANS also exhibit a higher late rise of NfL compared with baseline and early measurements. GFAP increase may play a role in the early phase but does not appear to be involved in established ICANS.

Disclosure: Nothing to disclose.

EPO-0667 | Persistent synapse-engulfing phagocytes shape the aftermath of encephalitis

G. Di Liberto; A. Mariotte; I. Vincenti; N. Page; G. Shammass; M. Piccinno; K. Egervari; M. Kreutzfeldt; I. Wagner; S. Lemeille; D. Merkler

Department of Pathology and Immunology, University of Geneva, Geneva, Switzerland

Background and aims: T cell-mediated encephalitides often cause neurological deficits that persist after resolution of overt inflammation, suggesting that long-lived innate immune responses may sustain pathology beyond T cell contraction. While IFN- γ -producing T cells initiate disease, how IFN- γ enables phagocytes to acquire persistent pathogenic phenotypes remains unclear. As IFN- γ induces durable epigenetic remodeling of synaptic genes in neurons, we hypothesized that IFN- γ is required for acquisition of a persistent disease-associated phagocyte state driving ongoing synaptic pathology independent of continued T cell activity.

Methods: We used a murine viral déjà vu model of T cell-mediated encephalitis, combining CSF1R-mediated phagocyte depletion with genetic ablation of IFNGR2 or TREM2/APOE signaling. Lineage tracing tracked microglia and macrophages across disease stages. Sorted phagocytes were analyzed by single-cell RNA sequencing, bulk ATAC-seq, and SCENIC. Motor function and synaptic integrity were assessed behaviorally and histologically.

Results: CSF1R-mediated phagocyte depletion ameliorated neurological deficits. Microglia and macrophages persisted in the CNS during late disease stages, when T cell responses declined. Bulk ATAC-seq revealed sustained chromatin remodeling at phagocytosis-, antigen presentation-, and interferon-responsive loci shared by both cell types. During acute disease, phagocytes acquired a synapse-engulfing phenotype that persisted at lower levels later. Single-cell RNA sequencing showed early convergence toward a disease-associated state regulated by interferon-responsive transcription factors. Disruption of TREM2/APOE signaling was not protective, whereas IFNGR2 ablation significantly improved motor performance and synaptic pathology. Similar phagocyte signatures were observed in Rasmussen encephalitis.

Synapse-engulfing phagocytes persist after encephalitis. Acute CD8⁺ T-cell responses coincide with synaptic loss and phagocyte activation. Microglia and macrophages adopt durable DAM-like states with sustained chromatin remodeling and ongoing synaptic pat.

Conclusion: Persistent IFN- γ -dependent phagocyte reprogramming sustains synaptic pathology after encephalitis, identifying CNS phagocytes as key drivers of long-term neurological dysfunction.

Disclosure: Nothing to disclose.

EPO-0668 | The role of the C5a-C5aR1 axis in mediating peripheral immune activation and central nervous system demyelination in MOGAD

H. Xue; C. Yang; W. Jiang

Department of Neurology, Tianjin Medical University General Hospital, Tianjin, China

Background and aims: Complement activation is involved in the pathogenesis of myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD), but whether it acts mainly through complement-dependent cytotoxic effects or through bystander effects on the immune system—and to what extent it contributes—remains unclear.

Methods: Twenty-two patients with MOGAD (10 acute, 12 remission) were enrolled. Peripheral blood was collected for serum complement profiling, immune-cell analysis by flow cytometry, and peripheral blood mononuclear cell (PBMC) bulk RNA sequencing. The C5aR1 antagonist PMX205 was administered in a MOG-IgG-augmented MOG35–55 experimental autoimmune encephalomyelitis (EAE) model. Histopathological and immunophenotypic analyses were performed on the brain and spinal cord; additional co-culture experiments used naïve CD4⁺ T cells and myeloid cells.

FIGURE 1 Acute-phase MOGAD exhibits a “low C5a-high C5aR1” imbalance.

FIGURE 3 C5aR1 shapes macrophage–T cell crosstalk to bias Th1 polarization and Treg induction. (A) Schematic representation of the in vitro co-culture system involving naive CD4⁺ T cells and bone marrow-derived macrophages (BMDMs). (B) Representative flow cytometry plots showing gating of CD4⁺IFN- γ ⁺ cells (upper panels) and CD4⁺CD25⁺FOXP3⁺ regulatory T cells (lower panels). Percentages indicate the frequency within the CD4⁺ T cell gate. (C) Quantification of CD4⁺IFN- γ ⁺ cells and CD4⁺CD25⁺FOXP3⁺ Tregs. Bars represent mean $\pm$ SEM, and dots represent biological replicates. Statistical significance was assessed by one-way ANOVA with multiple-comparisons correction. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$, **** $P < 0.0001$.

FIGURE 3 C5aR1 shapes macrophage–T cell crosstalk to bias Th1 polarization and Treg induction.

Results: Acute MOGAD showed enrichment of inflammatory and chemotactic pathways, along with immune-cell redistribution. The complement axis was upregulated; C5aR1 correlated most strongly with the inflammatory module and was also associated with chemotaxis and antigen-presentation modules. Flow cytometry and enzyme-linked immunosorbent assay (ELISA) indicated increased circulating C5a with increased cellular C5aR1 expression. In augmented EAE, PMX205 improved neurological outcomes, reduced central nervous system (CNS) myeloid infiltration, shifted T-cell polarization ($\downarrow$ Th1, $\uparrow$ Treg), and mitigated demyelination; co-culture supported myeloid-driven T-cell differentiation.

Conclusion: The C5a–C5aR1 axis may contribute to peripheral immune activation in active MOGAD and, via myeloid recruitment and myeloid–T cell crosstalk, relate to CNS inflammation and demyelination.

Disclosure: This study was supported by the National Natural Science Foundation of China (82171277, 82571535, 82171338), and Young Scientific and Technological Talents (Level Three) in Tianjin.

Figure 2. C5aR1 upregulation in the CNS and therapeutic impact of C5aR1 antagonism in a MOG-IgG-augmented MOG 35–55 EAE model. (A) Quantitative RT-PCR analysis of C5aR1 mRNA expression in spinal cord tissue comparing the Control and 8-18CS MOG-IgG groups. Expression was normalized to a housekeeping gene and presented as relative expression; each dot represents one mouse. (B) Schematic of the MOG-IgG-augmented MOG 35–55 EAE induction and treatment schedule. (C) Longitudinal clinical EAE scores assessed using a 10-point neurological disability scale for the indicated groups. Data are presented as mean $\pm$ SEM with individual animals shown. (D) Disease incidence/incubation analysis across the disease course shown as an “incidence-free” (Kaplan–Meier-style) curve comparing the indicated groups. (E) Representative spinal cord histopathology and quantification at day 15. H&E staining was used to evaluate inflammatory infiltration, Luxol fast blue (LFB) staining to assess demyelination, and MBP immunostaining to assess myelin integrity. Corresponding quantitative analysis is shown alongside representative images. Scale bars are indicated in the panels. Statistical tests are indicated in the figure; significance is denoted by asterisks (* $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$, **** $P < 0.0001$).

Background and aims: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), an immune-mediated neuropathy, causes progressive muscle weakness and sensory disturbance. Efgartigimod, a human IgG1 antibody Fc fragment, reduces IgG recycling by blocking FcRn, reducing impact on CIDP pathophysiology. The efficacy and safety of subcutaneous efgartigimod PH20 in patients with CIDP was demonstrated in the registrational ADHERE trial. ADHERE REAL will assess the real-world effectiveness of subcutaneous efgartigimod PH20 in patients with CIDP and describe their treatment journey and healthcare resource utilisation.

Methods: This real-world, prospective, multicentre study will assess adults with CIDP across the US and Germany. Patients will be efgartigimod PH20 naïve at screening and initiate treatment in routine clinical practice. Clinician-assessed and patient-reported outcomes will be recorded regularly, and treatment/dosage changes or relapses will be recorded.

Results: Change over time in scores, including adjusted Inflammatory Neuropathy Cause and Treatment and Inflammatory Rasch-built Overall Disability Score, will assess real-world effectiveness of efgartigimod PH20 and will be monitored via patient questionnaires, nurse assessments and medical record review. Proportions of participants with CIDP relapse and with evidence of clinical improvement will be assessed. Assessment of patient-treatment journeys will include disease course, comorbidities, CIDP treatment, modifications, and timing/rationale for these changes. Healthcare resource utilisation will be assessed by frequency, duration, and reasons for healthcare provider follow-ups, emergency room visits and hospitalisations. As of December 2025, 12 participants have been enrolled in Germany; enrolment has begun in the US.

Conclusion: This study will expand on the ADHERE trial and provide insights into the real-world usage of efgartigimod in patients with CIDP.

Background and aims: Generalized myasthenia gravis (gMG) is a B-cell and antibody-mediated neuromuscular autoimmune disease that can result in substantial disability. Novel therapies are needed to improve disease symptoms. Miv-cel (mivocabtagene autoleucel; KYV-101) is a fully-human, autologous CD19 CAR T-cell therapy with CD28 costimulation, designed for potency and tolerability. Updated data for miv-cel in gMG from KYSA-6 phase 2 (NCT06193889) are presented.

Methods: Adults (18–75y) with gMG (class IIb–IV), history of autoantibodies (AChR, MuSK, LRP4), MG activities of daily living (MG-ADL) score ≥ 6 , and ≥ 2 immunosuppressant/

immunomodulator failures, received lymphodepletion followed by 1×10⁸ CAR T cells.

Results: As of October 3, 2025, 6 patients were dosed (Table). Follow-up was 28 days-9 months (≥24 weeks, n=3). Miv-cel rapidly expanded with CAR T-cell activation evidenced by deep B-cell depletion and transient immunomodulatory cytokine elevation. Of 3 patients with ≥24-weeks follow-up, mean reductions from baseline were 8.0 and 7.7 points for MG-ADL and QMG, respectively, at 24 weeks and 67% achieved minimal symptom expression (Figures 1 and 2). All 6 patients remained immunosuppressant therapy-free up to 24 weeks. No ICANS or high-grade CRS occurred. After miv-cel, alterations in T-cell subsets were observed in the 3 patients with ≥24-weeks follow-up and reconstituted B cells in 2 patients 3–4 months post-infusion were predominantly naïve, supporting immune reset.

Conclusion: With a single dose, miv-cel induced deep B-cell depletion with evidence of immune reset. Patients experienced rapid, robust, and sustained improvements in disease severity with acceptable safety. Miv-cel demonstrates the potential to deliver durable, drug-free, disease-free remission in patients with gMG. Phase 3 is ongoing.

Baseline characteristics		N=6
Age, mean years (range)		45.5 (21–62)

Background and aims: NMOSD is a severe inflammatory demyelinating disease of the central nervous system, primarily affecting the optic nerves and spinal cord. Although NMOSD is classically considered to spare the brain, emerging evidence suggests functional cortical involvement. Altered cortical excitability may provide insights into the pathophysiology of NMOSD and its clinical manifestations.

Methods: A cross-sectional study was conducted on 30 NMOSD patients and 30 age- and sex-matched healthy controls. Transcranial magnetic stimulation (TMS) was used to assess key cortical excitability parameters, including resting motor threshold (RMT), short-interval intracortical inhibition (SICI), intracortical facilitation (ICF), and cortical silent period (CSP). Correlations between TMS measures and clinical parameters, including disease duration, EDSS scores, relapse history, and presence of brain lesions on MRI, were analyzed.

Results: NMOSD patients exhibited significant cortical excitability alterations compared to controls, including increased RMT ($p < 0.05$), reduced SICI ($p < 0.01$), prolonged CSP ($p < 0.05$), and enhanced ICF ($p < 0.05$). Reduced SICI correlated with higher EDSS scores ($r = -0.45$, $p < 0.01$) and greater relapse frequency ($r = -0.42$, $p < 0.05$), suggesting impaired GABAergic inhibition in patients with more severe disease. Patients with supratentorial MRI lesions showed greater cortical excitability changes than those without.

Conclusion: Our findings suggest that NMOSD is associated with significant alterations in cortical excitability. These changes correlate with clinical severity and may reflect underlying neurophysiological dysfunction beyond the spinal cord. TMS could serve as a useful biomarker for cortical involvement in NMOSD and a potential tool for monitoring disease progression and therapeutic response.

Disclosure: Nothing to disclose.

EPO-0672 | Phenotype-driven identification of autoimmune central vitamin B12 deficiency in idiopathic neuroinflammatory myelopathy

A. García Sarreón¹; A. Gifreu-Fraixinó¹; J. Gutierrez Naranjo¹; A. Boix Lago¹; J. Pluvinae²; G. Álvarez-Bravo¹

¹Multiple Sclerosis and Neuroimmunology Unit, Neurology Department, Dr. Josep Trueta University Hospital and Santa Caterina Hospital, Girona, Spain; ²Department of Neurology, University of California, San Francisco (UCSF), San Francisco, USA

Background and aims: The recent description of autoimmune vitamin B12 central deficiency mediated by antibodies against the transcobalamin receptor (CD320) provides a novel

pathophysiological framework for selected idiopathic neuroinflammatory phenotypes. We applied this mechanistic concept to idiopathic neuroimmunological disease with myelopathy resembling subacute combined degeneration.

Methods: Patients were identified from an institutional registry of idiopathic neuroimmunological disorders and screened for predominant spinal cord involvement. Based on the proposed pathophysiological model of autoimmune central vitamin B12 deficiency, patients with clinical and magnetic resonance imaging features suggestive of subacute combined degeneration were selected for targeted anti-CD320 testing in serum and cerebrospinal fluid at reference laboratories.

Results: Eighty-four patients were included in the registry, of whom 23 showed predominant spinal cord involvement (double-seronegative neuromyelitis optica spectrum disorder, $n = 8$; systemic autoimmune disease-associated neurological disease, $n = 5$; other idiopathic inflammatory phenotypes, $n = 10$). Six patients with posterior column-predominant myelopathy and compatible imaging features were prioritised; samples were available in all six (Table 1). Anti-CD320 antibodies were detected in four cases, including one with double-seronegative neuromyelitis optica spectrum disorder and three with other idiopathic inflammatory phenotypes. Seropositive patients presented with progressive myelopathy, posterior column dysfunction and non-inflammatory cerebrospinal fluid profiles. Following antibody identification, two patients initiated rituximab and high-dose intramuscular vitamin B12; follow-up is ongoing.

Conclusion: Anti-CD320 antibodies were identified in a subset of patients with idiopathic neuroinflammatory myelopathy characterised by posterior column-predominant, subacute combined degeneration-like phenotypes, supporting a phenotype-driven approach to targeted autoantibody screening with potential diagnostic and therapeutic relevance.

Background and aims: Progression independent of relapse activity (PIRA) is increasingly recognised as a major driver of disability in multiple sclerosis (MS). Serum neurofilament light chain (NfL) is established for monitoring inflammatory activity, whilst glial fibrillary acidic protein (GFAP) has emerged as a potential marker of astrocytic damage and smouldering neurodegeneration. However, their comparative prognostic value for disability progression remains unclear. We aimed to compare serum GFAP and NfL as predictors of disability progression across MS subtypes.

Methods: We searched PubMed, Embase, Scopus, and Cochrane Library through December 2025. We included cohort studies and post-hoc trial analyses reporting hazard ratios (HRs) for PIRA or confirmed disability worsening (CDW). Random-effects meta-analyses with Hartung-Knapp adjustment were performed. Risk of bias was assessed using Newcastle-Ottawa Scale.

Results: Eighteen studies ($n=15,944$) were included. For PIRA, pooled HRs were 1.85 (95% CI 1.50–2.29; I-squared=0%) for GFAP and 1.51 (95% CI 1.23–1.85; I-squared=0%) for NfL. Overall pooled effects were HR 1.53 (1.28–1.82) for GFAP and HR 1.54 (1.41–1.67) for NfL. The formal GFAP/NfL ratio was 0.91 (0.80–1.04; $p=0.17$), indicating no significant difference between biomarkers. In mutual adjustment analyses, GFAP remained significant after NfL adjustment (HR 1.80; $p=0.008$), whilst NfL became non-significant after GFAP adjustment (HR 1.45; $p=0.09$).

FIGURE 1

FIGURE 2

FIGURE 3

Conclusion: Both serum GFAP and NfL predict disability progression with similar overall effect sizes. GFAP shows stronger association with PIRA and provides independent prognostic information beyond NfL, supporting its complementary role in MS monitoring.

Disclosure: Nothing to disclose.

EPO-0674 | Early escalation of acute immunotherapy with plasma exchange and IVIG is associated with reduced relapse risk in pediatric MOGAD

S. Bartolomeo¹; R. Nistri¹; N. Kim¹; O. Ciccarelli²;
C. Hemingway¹; Y. Hacohen¹

¹Department of Neurology, Great Ormond Street Hospital for Children, University College London, UK; ²Queen Square MS Center, Department of Neuroinflammation, UCL Queen Square Institute of Neurology, Faculty of Brain Sciences, University College London, UK

Background and aims: Acute treatment of myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) includes high-dose intravenous corticosteroids (IVCS),

intravenous immunoglobulin (IVIG), and plasma exchange (PLEX), but the impact of different treatment strategies on long-term outcome remains unclear. We evaluated whether early escalation of acute immunotherapy at the first pediatric MOGAD attack reduces relapse risk.

Methods: We conducted a retrospective single-center cohort study of pediatric-onset MOGAD (<18 years) evaluated between 2015 and 2016 and followed from first attack to last visit (median 3.1 years). Of 114 screened patients, 98 were included. Patients received IV methylprednisolone (IVMP) alone or IVMP followed by escalation with IVIG, PLEX, or both based on disease severity or steroid response. Outcomes were early (≤ 1 year) and overall relapse. Cox regression assessed relapse risk.

Results: Among 98 patients (57.1% female; median age 6.3 years), onset phenotypes included optic neuritis (42.9%), acute disseminated encephalomyelitis (42.9%), cortical encephalitis (9.2%), and myelopathy (5.1%). Seventy received steroids alone and 28 received escalation therapy. Early relapse occurred in 27.1% of

Study flow-chart and relapse outcomes. Summarises the study flow-chart and reports relapse outcomes in paediatric MOGAD patients grouped according to acute treatment strategy.

Kaplan–Meier survival curves illustrating time to first relapse (months) by treatment group. Patients treated with intravenous steroids alone experienced earlier relapses, with a median time to relapse of less than one year, whereas those who underwent t.

Variable	Total cohort (n=98)	Steroid only (n=70)	Steroid Plus (n=28) (+ IVIG or PLEX)	p-value
Age at onset, [IQI], y	6.33 [4.37–11.12]	6.04 [4.02–9.43]	7.08 [4.88–12.02]	0.224
Male/female	42/56	31/39	11/17	0.822
Onset phenotype, n (%)				
Optic neuritis	42 (42.9%)	35 (50.0%)	7 (25.0%)	0.042
ADDEM	42 (42.9%)	29 (41.4%)	13 (46.4%)	0.658
Cortical encephalitis	9 (9.2%)	4 (5.7%)	5 (17.9%)	0.114
Myelopathy	5 (5.1%)	2 (2.9%)	3 (10.7%)	0.138
EDSS at nadir, [IQI]	1.0 [1.0–2.0]	1.0 [1.0–2.0]	2.0 [1.0–3.0]	0.095
Time to steroid, [IQI], days	7.0 [3.0–15.0]	8.0 [4.0–16.0]	7.0 [3.0–10.0]	0.248
Time to escalation, [IQI], days	10.8 [9–14]		10.0 [9–14]	
Follow-up duration, [IQI], y	3.13 [1.49–6.99]	3.58 [1.59–6.54]	2.58 [1.37–4.45]	0.110
EDSS at last follow-up, [IQI]	0.00 [0.00–1.00]	0.00 [0.00–1.00]	0.00 [0.00–1.00]	0.120
Relapse within 1 year, n (%)	20 (20.4%)	19 (27.1%)	1 (3.6%)	0.011
Relapse at final follow-up, n (%)	32 (32.7%)	25 (41.4%)	7 (25.0%)	0.004
Time to first relapse, median [IQI], (days)	184 (90–614)	183 (83–581)	1095 (561–1278)	0.317

Demographic and clinical characteristics of the cohort (N=98).

steroid-only patients versus 3.6% with escalation ($p=0.011$); overall relapse rates were 41.4% versus 10.7% ($p=0.004$). Escalation was associated with reduced relapse risk (adjusted HR0.24, 95% CI 0.07–0.82).

Conclusion: In pediatric MOGAD, early escalation with IVIG and/or PLEX following corticosteroids was associated with a substantially lower relapse risk compared with corticosteroids alone. These findings support the first clinical attack as a critical therapeutic window. Early aggressive therapy may reduce immune-mediated relapses and improve long-term disease trajectory. Prospective studies are needed to determine whether routine treatment escalation should be recommended to minimize relapse risk.

Disclosure: Bartolomeo S. received travel fundings from Biogen, Novartis, Sanofi, Bristol-Myers Squibb. O. Ciccarelli is an NIHR Research Professor (RP-2017-08-ST2-004); acts as a consultant for Biogen, Merck, Novartis, Roche, and Teva; and has received research grant support from the MS Society of Great Britain and Northern Ireland, the NIHR UCLH Biomedical Research Centre, the Rosetree Trust, the National MS Society, and the NIHR-HTA. EPO-0675 | Neuromyelitis optica spectrum disorder in Finland: A population-based study

T. Aronen¹; S. Laakso²; M. Viitala³

¹Translational Immunology Research Program, University of Helsinki, Helsinki, Finland; ²Translational Immunology Research Program, University of Helsinki, and Neurocenter, Helsinki University Hospital, Helsinki, Finland; ³Aastat Ltd, Turku, Finland

Background and aims: Neuromyelitis optica spectrum disorder (NMOSD) is a demyelinating autoimmune disease of the central nervous system. Epidemiology of NMOSD in Finland has not been previously investigated on a national level. We set out to determine the incidence, prevalence and mortality for patients with NMOSD (pwNMOSD) in Finland during the last decades.

Methods: National care registries were searched for all diagnosed pwNMOSD (ICD-10 code 36.0, ICD-9 341.0) during 1994–2023. To evaluate confounders, the Helsinki University Hospital cohort was collected in detail using patient medical records during 2005–2023 and using the 2015 International Panel for NMO Diagnosis (IPND) criteria. Standardized mortality ratio (SMR) and causes of death were assessed using national care registries for 2015–2023.

Results: We identified 128 pwNMOSD in Finland, of which 78% were female. During 2015–2023 standardized national incidence of NMOSD was 0.13/100,000 person-years (95% CI 0.10–0.17). National prevalence increased from 1.10/100,000 in 2014 to 2.05/100,000 in 2023, with no clear regional differences. Peak in incidence was seen for the ages 30–49. SMR was 2.36 (95% CI 1.23–4.53) for pwNMOSD and NMOSD was the underlying or contributing cause of death for 46.7% of all the deaths recorded ($n = 15$).

Conclusion: NMOSD incidence in Finland is somewhat higher compared to other Nordic countries, and unlike reported for multiple sclerosis incidence in Finland, shows no clear East-West gradient. NMOSD has a clear impact on mortality in this population.

EPO-0676 | Insight from Helsinki aneurysm database: Functional recovery in severely disabled survivors of aneurysmal subarachnoid hemorrhage

M. Dabbagh Ohadi; R. Tulamo; M. Niemelä; B. Rezai Jahromi
Department of Neurosurgery, Helsinki University Hospital, Helsinki, Finland

Background and aims: Aneurysmal subarachnoid hemorrhage (aSAH) frequently results in severe neurological disability. With advances in neurocritical and neurosurgical care, prognostication and assessment of functional recovery in patients discharged with severe disability have become increasingly important.

Methods: We retrospectively reviewed our aneurysm database from 1995 to 2015. Patients admitted within 72 hours of aSAH onset who survived hospitalization and were discharged with a mRS score of 4 or 5 were included. The primary outcome was good functional recovery at 3 months (mRS 0–3), with additional assessment at 1 year.

Results: A total of 1253 patients were included; 315 were discharged with mRS 4. Mean age was 57.4 ± 12.7 years, and 65%

FIGURE 1

were women. Good functional recovery occurred in 730 patients (58.3%) at 3 months and in 266 (63.2%) at 1 year. In patients discharged with mRS 4, lower likelihood of recovery was associated with older age (OR 0.92), diabetes (OR 0.03), larger ICH volume (OR 0.96), and postoperative meningitis (OR 0.34). In patients discharged with mRS 5, reduced recovery was associated with older age (OR 0.95), Hunt and Hess grade 5 (OR 0.46), larger ICH volume (OR 0.98), cerebrospinal fluid diversion for hydrocephalus (OR 0.51), postoperative symptomatic brain infarction (OR 0.50), postoperative meningitis (OR 0.36), and pneumonia (OR 0.64).

Conclusion: More than half of patients discharged with severe disability after aSAH achieved good functional recovery within 3 months. Increasing age, severe hemorrhage, and postoperative complications were consistently associated with reduced recovery.

Disclosure: Behnam Rezai Jahromi and Mika Niemelä have patents pending on aneurysm imaging.

EPO-0677 | Endovascular treatment versus best medical treatment in ischemic stroke due to distal to middle vessel occlusions: A meta-analysis

B. Dell'Acqua¹; C. Costa¹; V. Caso²; S. Vidale¹
¹Department of Neurology & Stroke Unit ASST Sette Laghi, Varese, Italy; ²Department of Neurology, ASST Valle Olona Saronno, Italy

Background and aims: While mechanical thrombectomy (MT) is indicated in the treatment of large vessel occlusions, the consensus is still lacking regarding its superiority over the best medical treatment (BMT) in distal to middle vessel occlusions (DMVO). Aim of this pooled analysis was the investigation of the efficacy and safety of MT in DMVO compared to the BMT, including endovenous thrombolysis.

Methods: The study followed PRISMA guidelines. PubMed, EMBASE, and Cochrane Central were searched for studies comparing MT and BMT in adults with acute DMVO. The primary endpoint was good functional outcome at 180 days (mRS <3); secondary endpoints included excellent outcome at 3 months

FIGURE 1 Forest plot of the primary endpoint with distribution by study type (EVT vs BMT).

Fig 3: Forest plots of the secondary endpoints of the pooled analysis EVT vs BMT.

Fig 3A: Forest plot of excellent functional outcome.

FIGURE 2A Forest plot of excellent functional outcome.

Fig 3B: Forest plot of death rate.

FIGURE 2B Forest plot of death rate.

(mRS <2), sICH, and 180-day mortality. Outcomes were pooled using meta-analysis.

Results: A total of 43 studies including 13,049 patients were analyzed. Good functional outcome at 180days was similar between MT and BMT (OR 1.00; 95% CI 0.84–1.19). The two treatment strategies had no differences in excellent outcome at 3 months (OR 1.09; 95% CI: 0.95–1.26; pheterogeneity <0.0001), as well as mortality (OR 1.09; 95% CI: 0.95–1.26; pheterogeneity <0.0001), while sICH rates were significantly higher in the MT group (OR=1.57; 95% CI: 1.20–2.05; pheterogeneity=0.06).

Conclusion: This meta-analysis shows similar functional outcomes between endovascular treatment and BMT in DMVO, with a higher rate of sICH in the MT group. These findings highlight the importance of patient selection based on occlusion site, collateral status, and clinical presentation, and support the need for further studies using stricter selection criteria.

Disclosure: Nothing to disclose.

EPO-0678 | Multiple fusiform cerebral aneurysms and inflammatory vasculopathy associated with cardiac myxoma

C. Ragucci¹; E. Matteo²; F. Naldi³; L. Piccolo³; M. Gentile³; F. Palombo⁴; L. Simonetti⁵; A. Zini³

¹Dipartimento di Scienze Biomediche e Neuromotorie, Università di Bologna, Bologna, Italy; ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Ospedale Maggiore, Neurologia Rete Stroke Metropolitana, Bologna, Italy; ³Dipartimento di Scienze Biomediche e Neuromotorie, Università di Bologna, Bologna, Italy; ⁴IRCCS Istituto delle Scienze Neurologiche di Bologna, Ospedale Maggiore, Neurologia Rete Stroke Metropolitana, Bologna, Italy; ⁵IRCCS Istituto delle Scienze Neurologiche di Bologna, Programma di Neurogenetica, Ospedale Bellaria, Bologna, Italy

Background and aims: Fusiform cerebral aneurysms are a rare complication of cardiac myxomas, possibly due to myxomatous cell embolization to the vasa vasorum. This phenomenon may lead to diagnostic uncertainty in acute cerebrovascular presentations.

Methods: We report a comprehensive diagnostic workup in a patient with recurrent ischemic events, including multimodal computed tomography (CT), digital subtraction angiography (DSA), brain MRI with vessel wall (VW) imaging, cerebrospinal fluid (CSF) analysis, autoimmune and infectious screening, and whole exome sequencing (WES).

Results: A 41-year-old woman with a previous left atrial myxoma resection and multiple cerebral aneurysms presented with acute headache and visual disturbances. Brain CT revealed a right occipital hypodensity of uncertain nature. DSA showed in situ thrombosis of a fusiform aneurysm of the right posterior cerebral artery. Acetylsalicylic acid was started. VW MRI demonstrated concentric wall thickening and enhancement of multiple aneurysms, with leptomeningeal enhancement in cerebellar and temporo-occipital regions. CSF analysis showed pleocytosis, elevated proteins, blood–brain barrier dysfunction, and oligoclonal band mirror pattern. Autoimmune, infectious, and genetic investigations were unremarkable. Whole-body CT angiography revealed an additional small splenic artery aneurysm. During follow-up, she experienced a recurrent ischemic event due to thrombosis of a fusiform aneurysm in the right middle cerebral artery territory. Six-month VW MRI showed persistent enhancement without size change.

Conclusion: This case highlights a dynamic inflammatory cerebral vasculopathy related to cardiac myxoma. Detailed

IMAGE 2 Axial T1-weighted VW MRI after contrast injection showing concentric thickening of one of the aneurysms located in the M2 segment of the right middle cerebral artery, with strong contrast enhancement.

IMAGE 1 Axial FLAIR MRI showing hyperintense signal in the right occipital lobe.

IMAGE 3 Axial T1-weighted MRI showing leptomeningeal contrast enhancement of the cerebellar folia.

vascular characterization is crucial to guide management and avoid misdiagnosis in the acute stroke setting.
Disclosure: Nothing to disclose.

EPO-0679 | **Determinants of acute symptomatic seizures and post-stroke epilepsy after reperfusion therapy: an 18-month Dual Center Cohort Study**

E. Ranxha; O. Çibuku
Neuro Vascular Service, University Hospital “Mother Teresa”,
Tirane, Albania

Background and aims: Seizures are a frequent complication of stroke and are associated with worse functional outcomes. With the widespread use of reperfusion therapies (RTs), including intravenous thrombolysis and mechanical thrombectomy, their potential impact on acute symptomatic seizures (ASS) and post-stroke epilepsy (PSE) requires clarification.

Methods: We conducted a retrospective cohort study over 18 months at the Neuro vascular Department of the University Hospital Centre “Mother Teresa” and Stroke Center American Hospital, Tirana. Consecutive patients with acute ischemic stroke were grouped as intravenous thrombolysis (IV tPA, $n=88$), endovascular thrombectomy with or without thrombolysis (EVT, $n=55$), and non-revascularized controls ($n=66$). ASS was defined as seizures within 7 days and PSE as unprovoked seizures beyond 7 days. Hemorrhagic transformation (HT) was assessed on follow-up imaging.

Results: ASS occurred in 8/88 (9.1%) IV tPA patients, 6/55 (10.9%) EVT patients, and 4/66 (6.1%) controls ($p>0.05$). PSE developed in 6/88 (6.8%), 2/55 (3.6%), and 3/66 (4.5%) patients, respectively ($p>0.05$). When reperfusion-treated patients were pooled, ASS occurred in 14/143 (9.8%) versus 4/66 (6.1%) in controls. HT was present in 4/18 (22.2%) patients with ASS and in 7/11 (63.6%) patients with PSE, indicating a strong association between HT and late epilepsy. Cortical involvement was frequent among seizure patients across all groups. Median NIHSS scores among patients with ASS were similar between groups.

Conclusion: Reperfusion therapies were not associated with an increased risk of ASS or PSE. Hemorrhagic transformation and cortical involvement appear to be the principal determinants of post-stroke epileptogenesis, particularly for late epilepsy.

Disclosure: Nothing to disclose.

Seizure outcomes by treatment group with 95% confidence intervals.

Proportion of hemorrhagic transformation (HT) in patients with ASS and PSE.

Pooled reperfusion versus controls with 95% confidence intervals.

EPO-0680 | **Elevated cerebral venous pulsatility as an independent predictor of hemodynamic compromise and functional outcomes in atherosclerotic ischemic stroke**

F. Mallaev; G. Rakhimbaeva; S. Shokirov
Tashkent State Medical University, Tashkent, Uzbekistan

Background and aims: Venous pulsatility measurements provide insights into distal vascular resistance and intracranial hemodynamic burden, yet remain underinvestigated in cerebrovascular disease. We examined cerebral venous pulsatility as a potential biomarker for stroke severity and three-month functional recovery in patients with major artery atherosclerosis.

Methods: This observational cohort investigation enrolled 120 consecutive patients presenting with acute ischemic stroke attributable to $\geq 50\%$ stenosis of major cerebral vessels. Venous pulsatility index measurements were obtained from deep cerebral veins and principal venous sinuses using transcranial Doppler ultrasonography within 48 hours of symptom onset. Initial neurological impairment was quantified using the National Institutes of Health Stroke Scale, while 90-day functional status was determined through modified Rankin Scale assessment.

Results: Elevated venous pulsatility demonstrated strong associations with greater baseline neurological compromise (NIHSS ≥ 10 : venous pulsatility index 1.46 ± 0.18 versus 1.29 ± 0.16 , $p < 0.001$). Unfavorable three-month outcomes (mRS 3–6) occurred in 52 patients (43.3%) and showed significant

correlation with increased baseline venous pulsatility ($p < 0.001$). Multivariable logistic regression analysis, adjusting for patient age, lesion volume, stenosis severity, and collateral status, confirmed elevated venous pulsatility as an independent predictor of poor functional recovery (OR 2.7, 95% CI 1.5–5.0).

Conclusion: Cerebral venous pulsatility effectively identifies hemodynamic stress and independently forecasts functional outcomes following atherosclerotic ischemic stroke. Assessment of venous pulsatility may offer a valuable non-invasive prognostic instrument for stroke management.

Disclosure: Nothing to disclose.

EPO-0681 | Analysis of the racial differences in the prevalence of risk factors at stroke onset in Italy: a prospective, multicentric study on 2402 patients

Benzi 10, Genoa, Italy; ⁷IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurology Unit, Sant'Orsola-Malpighi University Hospital, Bologna, Italy; ⁸Department of Emergency Neurology and Stroke Unit, IRCCS C. Mondino, Pavia, Italy; ⁹Fondazione IRCCS Policlinico San Matteo, Pavia; ¹⁰Ospedale F. Spaziani, Frosinone; ¹¹AORN Antonio Cardarelli, Napoli; ¹²IRCCS Humanitas Research Hospital, Milan; ¹³Ospedale Maggiore di Crema, Crema; ¹⁴Policlinico Tor Vergata, Roma; ¹⁵Istituto Neurologico Mediterraneo Neuromed IRCCS, Pozzilli; ¹⁶Spedali Civili di Brescia, Brescia; ¹⁷Ospedale SS Filippo e Nicola, Avezzano

Background and aims: Risk factors for Ischemic Stroke (IS) and adherence to primary prevention strategies may differ substantially across racial and ethnic groups. However, available evidence derives from the USA, where the racial/ethnic composition differs markedly from that of Europe. The primary aim of our study was to investigate racial/ethnic differences in the prevalence of stroke risk factors and primary prevention therapies in Italy.

Methods: Consecutive adult patients with IS presenting to 14 Italian stroke centers between October 2024 and November 2025 were prospectively enrolled. Based on self-reported race/ethnicity, patients were classified as White or non-White. Outcomes were the prevalence of stroke risk factors and preventive therapies in use at time of stroke onset. The Mann-Whitney U -test and χ^2 -test were used for statistical comparisons. To identify independent associations between race/ethnicity and stroke risk factors, multivariable logistic regression models adjusted for sex and age were performed.

Results: A total of 2402 patients were enrolled in the study, of whom 2257 were Whites (94.0%). Compared with White

patients, non-White patients were younger (62.9 ± 16.7 vs 74.1 ± 13.9 years; $p < 0.001$) and less frequently women (33.8% vs 47.2%, $p = 0.002$). Cardiopathy ($p = 0.037$), dyslipidaemia ($p = 0.016$), and atrial fibrillation ($p = 0.001$) were more prevalent among White patients, whereas non-White patients more frequently reported no ongoing therapy at admission ($p < 0.001$). However, after adjustment for age and sex, White race was not independently associated with any of these factors.

Conclusion: Non-White patients experience ischemic stroke at a younger age than White patients, potentially reflecting earlier exposure to cardiovascular risk factors and lower awareness of them and their management.

Disclosure: Nothing to disclose.

EPO-0682 | Longer onset-to-door times in non-white patients in Italy: A prospective, multicentric study on 2402 patients

I. Scala¹; P. Rizzo²; M. Monforte³; A. Zini⁴; A. Falcou⁵; M. Del Sette⁶; M. Guarino⁷; A. Cavallini⁸; L. Chiapparini⁹; M. Bagnato¹⁰; V. Andreone¹¹; C. Rapillo¹²; L. Caputi¹³; M. Diomedì¹⁴; D. Centonze¹⁵; A. Morotti¹⁶; S. Sacco¹⁷; A. Bersano¹; P. Calabresi³; G. Frisullo³

¹Cerebrovascular Unit, IRCCS Fondazione Istituto Neurologico C. Besta, Milan, Italy; ²Catholic University of the Sacred Heart, Rome, Italy; ³Department of Neuroscience, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; ⁴IRCCS Istituto delle Scienze Neurologiche di Bologna, Department of Neurology and Stroke Center, Maggiore Hospital, Bologna, Italy; ⁵Emergency Department, Stroke Unit, Policlinico Umberto I, Rome, Italy; ⁶Neurology Unit, IRCCS San Martino Hospital, Genoa, Italy; ⁷IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurology Unit, Sant'Orsola-Malpighi University Hospital, Bologna, Italy; ⁸Department of Emergency Neurology and Stroke Unit, IRCCS C. Mondino, Pavia, Italy; ⁹Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; ¹⁰Ospedale F. Spaziani, Frosinone, Italy; ¹¹AORN Antonio Cardarelli, Napoli, Italy; ¹²IRCCS Humanitas Research Hospital, Milan, Italy; ¹³Ospedale Maggiore di Crema, Crema, Italy; ¹⁴Policlinico Tor Vergata, Rome, Italy; ¹⁵Istituto Neurologico Mediterraneo Neuromed IRCCS, Pozzilli, Italy; ¹⁶Spedali Civili di Brescia, Brescia, Italy; ¹⁷Ospedale SS Filippo e Nicola, Avezzano, Italy

Background and aims: Studies from the USA have reported lower access to reperfusion treatments (RTs) for Ischemic Stroke (IS) among racial/ethnic minorities; however, evidence from Italy is lacking. We aimed to assess the impact of race/ethnicity on RTS administration and onset-to-door time (ODT).

Methods: Consecutive adult patients with IS presenting to 14 Italian stroke centers between October 2024 and November 2025 were prospectively enrolled. Based on self-reported race/ethnicity, patients were classified as White or non-White. Outcomes were Intravenous Thrombolysis (IVT), Endovascular Treatment (EVT), and ODT. Associations between ODT and race/ethnicity were assessed using linear regression adjusted for demographics, comorbidities, baseline NIHSS, premorbid mRS, education level, mode of arrival, occupational status, language barriers, and cohabitation status. Logistic regressions adjusted for the same variables, plus large vessel occlusion, anticoagulant use, and ASPECT score were used to identify predictors of IVT and EVT.

Results: In total 2402 patients were enrolled in the study, of whom 2257 were Whites (94.0%). Overall, 830 patients (35.7%) received IVT and 648 (27.9%) EVT. Compared with White patients, non-White patients were younger (62.9 ± 16.7 vs 74.1 ± 13.9 years; $p < 0.001$) and less frequently women (33.8% vs 47.2%, $p = 0.002$). White category was not associated with IVT and EVT administration (aOR 0.70 95% CI (0.34–1.67), $p = 0.497$ and aOR 2.50 95% CI (0.84–7.40), $p = 0.098$, respectively) but was independently associated with shorter ODT ($\alpha\beta -631.69$ 95% CI (–1100.34 to –163.03); $p = 0.008$).

Conclusion: Our study suggests that racial/ethnic disparities in timely access to stroke care exist even in countries with universal healthcare systems, highlighting the need for public health interventions.

Disclosure: Nothing to disclose.

EPO-0683 | Abstract withdrawn

EPO-0684 | Beyond objective measures: Perceived environment associates with post-stroke quality of life

L. Braadt¹; M. Naumann¹; C. Meisinger²; J. Linseisen²; M. Ertl³; E. Hertig⁴

¹Department of Neurology and Clinical Neurophysiology, University Hospital Augsburg, Augsburg, Germany;

²Epidemiology, Faculty of Medicine, University of Augsburg, Augsburg, Germany; ³Department of Neurology and Neurological Rehabilitation, BKH Günzburg, Günzburg, Germany, Department of Neurology and Clinical Neurophysiology, University Hospital Augsburg, Augsburg, Germany; ⁴Regional Climate Change and Health, Faculty of Medicine, University of Augsburg, Augsburg, Germany

Background and aims: Stroke causes substantial disability and reduced health-related quality of life (HRQoL). Environmental and atmospheric factors are increasingly recognized as health predictors, yet current research predominantly relies on heterogeneous objective measurements (e.g. satellite-based green space indices, air quality monitors), while subjective environmental perception remains underexplored. We investigated associations between perceived environment quality and HRQoL after stroke.

Methods: In a prospective cohort study, stroke patients were surveyed during hospitalization and at 3- and 12-month follow-ups. HRQoL was measured using the Stroke Impact Scale (SIS). Subjective environmental ratings (air quality/noise, green spaces, thermal comfort) were assessed using the Perceived Residential Environment Quality questionnaire (PREQ) and Building Environmental Quality Questionnaire (BEQQ). Multivariable regression models adjusted for age, sex, baseline mRS, baseline NIHSS, and educational background were employed to analyse associations between subjective environmental perception and long-term HRQoL.

Results: Of 531 baseline participants (mean age 68.8 years, 39.4% female), 456 (85.9%) completed 12-month follow-up. First analyses revealed that thermal comfort at 3 months is significantly associated with multiple SIS domains at 12 months. Green spaces and air quality showed no significant associations after correction for multiple testing.

Conclusion: While prior research emphasizes objective environmental measures, our findings highlight subjective perception, particularly thermal comfort, as a potentially relevant factor for post-stroke HRQoL. Thus, a rather easily adaptable factor might already improve long-term outcomes of stroke survivors, if considered in rehabilitation and post-stroke care.

Disclosure: Nothing to disclose.

EPO-0685 | Association between cortical microinfarcts and cortical superficial siderosis in cerebral amyloid angiopathy: Evidence for a double-hit mechanism?

M. Losa¹; M. Zanon Zotin²; T. van Harten¹; H. van den Brink¹; R. Carr¹; L. Roccatagliata³; M. Pardini⁴; S. Greenberg¹; A. Viswanathan¹; S. van Veluw⁵; M. Kozberg¹

¹J Philip Kistler Research Center, Department of Neurology, Massachusetts General Hospital and Harvard Medical School, Boston, USA; ²Center for Imaging Sciences and Medical Physics, Department of Medical Imaging, Hematology and Clinical Oncology, Ribeirão Preto Medical School University of São Paulo Ribeirão Preto SP Brazil; ³Neuroradiology, Department of Health Sciences, University of Genoa, Genoa, Italy; ⁴Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOEMI), University of Genoa, Genoa, Italy; ⁵BHF-UK DRI Centre for Vascular Dementia Research, University of Edinburgh, Scotland, UK

Background and aims: Cerebral amyloid angiopathy (CAA) is characterized by hemorrhagic and non-hemorrhagic injuries. Cortical cerebral microinfarcts (CMI) have been associated with cortical superficial siderosis (cSS), although data are inconclusive. This study aims to determine the spatiotemporal relationship between CMI and cSS in CAA, with the hypothesis that cSS can promote local ischemic injury.

Methods: Probable CAA (Boston Criteria v2.0) were recruited from a prospective Massachusetts General Hospital cohort. CAA-related radiological manifestations—including CMI and cSS—were quantified at baseline and at 24 months. Multivariate logistic regression and generalized linear models were applied to assess associations between baseline radiological features and their predictive value on radiological progression. We compared the local density of CMIs—defined as CMI Density Index, CDI—in regions with and without cSS.

Results: Among 74 probable CAA (age: 73.0 [67.9–78.2] years), 26 (35%) had CMIs ($n = 135$, 39% underlying cSS). At baseline, CMI count demonstrated an exponential relationship with cSS volume ($\text{Exp}(B) = 1.12$ [95% CI 1.07–1.18]; $p < 0.001$) and with lobar lacunes count ($\text{Exp}(B) = 1.65$ [95% CI 1.52–1.80]; $p < 0.001$). The CDI was markedly higher in cSS-covered vs. non-cSS regions (median: 20.84 [0.00–56.95] vs. 0.49 [0.11–0.89]; $p = 0.010$). Follow-up scans ($n = 36$) revealed 23 incident CMIs (43% underlying cSS). Baseline cSS volume predicted CMI occurrence (OR: 1.41 [95% CI 1.02–1.95]; $p = 0.036$), whereas baseline CMI burden did not predict cSS progression.

Conclusion: Our findings demonstrate a CMI/cSS interplay, with cSS predicting incident CMI but not vice versa. Higher CDI in cSS-covered regions suggests local ischemia synergistically worsened by global ischemic burden. Further studies should identify the driving pathophysiology, a possible therapeutic target for preventing cSS-induced injury.

Disclosure: Nothing to disclose.

EPO-0686 | Stress hyperglycemia ratio and risk of cerebral edema in acute ischemic stroke: A systematic review and meta-analysis

M. Serageldin; A. Hegazi; H. O. Hussien; A. Hafez; M. Elfadali; M. Abd EL-Hamied; S. Abouelenein
Faculty of Medicine, Mansoura University, Egypt

Background and aims: Stress hyperglycemia is common following acute ischemic stroke (AIS) and correlates with adverse outcomes. While absolute hyperglycemia is a known risk factor, the Stress Hyperglycemia Ratio (SHR) offers a more physiological metric of relative hyperglycemic stress. However, its specific relationship with life-threatening complications like cerebral edema remains incompletely defined. We aimed to evaluate the association between high SHR and the development of cerebral edema in patients with AIS.

Methods: A systematic review and meta-analysis were conducted in accordance with PRISMA guidelines. We searched major electronic databases including PubMed, Scopus, Web of Science and Cochrane Library up to December 2025 for observational studies that evaluate the predictive impact of SHR on cerebral edema formation in adult AIS patients. The primary objective was to quantify the risk magnitude associated with elevated SHR levels. Pooled odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using a random-effects model.

Results: Five studies comprising a total of 2634 patients were included in the meta-analysis. The pooled analysis demonstrated that high SHR was significantly associated with an increased risk of cerebral edema following ischemic stroke (OR 2.56, 95% CI 1.32–4.96, $p=0.006$). This indicates more than a twofold higher odds of cerebral edema among patients with elevated SHR.

Conclusion: Stress hyperglycemia ratio is a significant predictor of cerebral edema after ischemic stroke. Early calculation of SHR may facilitate the rapid identification of high-risk patients, informing closer neurological monitoring and targeted therapeutic strategies to mitigate edema progression.

EPO-0687 | A decade of audio-vestibular presentations to TIA service: A high-risk cerebrovascular presentation

S. Mariathan¹; R. Alijam¹; C. Tierney¹; T. Serafimova¹; A. Hammam²; N. Koohi³; A. Chandratheva¹; D. Kaski⁴; M. Mahmud⁴; R. Periyasami¹

¹Department of Stroke Medicine, National Hospital for Neurology and Neurosurgery, London, United Kingdom;

²Department of Neuroradiology, National Hospital for Neurology and Neurosurgery, London, UK; ³Department of Clinical and Movement Neurosciences, University College London, London, UK; ⁴Department of Neurology, National Hospital for Neurology and Neurosurgery, London, UK

Background and aims: Vestibular symptoms are common in emergency settings but are perceived as low risk for cerebrovascular disease. Sudden-onset hearing loss and pulsatile tinnitus, whilst recognised as necessitating urgent input, are commonly seen through ENT pathways. We aimed to quantify the burden of respectively vestibular and auditory presentations to a large tertiary transient ischaemic attack (TIA) service and determine associated stroke and TIA diagnoses.

Methods: Prospectively collated consecutive referrals to a central London TIA service between June 2015 and November 2025 were analysed. Referral reasons were categorised into neurological symptom clusters. Vestibular presentations were defined using Bárány Society-informed descriptors, including vertigo, dizziness, imbalance, unsteadiness, and giddiness. Auditory symptoms were defined as hearing loss and tinnitus. We calculated the proportion of referrals for these symptom clusters and subsequent stroke/TIA diagnoses, comparing outcomes using logistic regression.

Results: Vestibular symptoms accounted for 14% ($n=1783$) of 12,760 new referrals. Patients referred with isolated vestibular symptoms had a definite or probable stroke/ TIA diagnosis rate of 24% ($n=241/994$), which significantly increased to 39% ($n=306/789$) for vestibular presentations referred with additional neurological symptoms (OR 1.98, 95% CI 1.62–2.43; $p<0.001$). By contrast, just 46 patients (<0.5%) presented with auditory symptoms, but 5/46 were diagnosed with definite or probable stroke/TIA and 2/46 with cervical artery dissection. One dissection presented with isolated sudden-onset pulsatile tinnitus and headache without other neurological features.

Conclusion: Auditory and vestibular presentations to a specialist TIA clinic have high cerebrovascular diagnostic rates. Findings support low thresholds for specialist assessment to reduce missed neurovascular events.

Disclosure: Nothing to disclose.

EPO-0688 | Comparative evaluation of large language models in differentiating grades of papilledema using optical coherence tomography

A. Mishra; R. Shukla; A. Shukla

All India Institute of Medical Sciences, Raebareli, Uttar Pradesh, India

Background and aims: Accurate grading of papilledema is essential for monitoring disease progression and guiding management in patients with intracranial hypertension. Large language models (LLMs) have emerged as potential clinical decision-support tools; however, their performance in differentiating papilledema grades using Optical Coherence Tomography (OCT) -derived features remains unclear.

Methods: This observational comparative study included 15 de-identified OCT datasets from patients with idiopathic intracranial hypertension, stratified by papilledema severity: mild (Frisén grades I–II, $n=5$), moderate (grade III, $n=5$), and severe (Frisén grades IV–V, $n=5$). Structured OCT descriptions, including peripapillary retinal nerve fiber layer (RNFL) thickness, optic nerve head contour, and macular changes, were

independently analyzed by ChatGPT, Google Gemini, and Microsoft Bing. Model-assigned severity grades were compared with clinician-determined Frisén grades.

Results: Overall accuracy for correct papilledema severity classification was highest for ChatGPT (77%), followed by Google Gemini (69%) and Microsoft Bing (55%). For mild papilledema (grades I–II), ChatGPT correctly classified 80% of cases, Google Gemini 72%, and Microsoft Bing 60%. In moderate papilledema (grade III), accuracy declined across all models, with correct classification rates of 68% for ChatGPT, 70% for Google Gemini, and 48% for Microsoft Bing. For severe papilledema (grades IV–V), ChatGPT demonstrated the highest accuracy (88%), followed by Google Gemini (75%) and Microsoft Bing (58%). Misclassification most frequently occurred between adjacent grades, particularly between mild and moderate papilledema, and moderate and severe papilledema.

Conclusion: Large language models demonstrate moderate accuracy in differentiating papilledema severity using OCT-derived features, with more reliable performance at the extremes of disease severity and reduced accuracy for intermediate grades.

Disclosure: Nothing to disclose.

EPO-0689 | Vestibular agnosia in elderly subjects with small vessel disease and imbalance – preliminary results from an ongoing prospective study

F. Honegger¹; E. Capodaglio²; M. Dapprich²; C. Nickel³; H. Gensicke⁴; S. Engelter⁴; B. Seemungal⁵; C. Stieger⁶; H. Rust²

¹Division of Neurootology, Department of ORL, University of Basel Hospital, Basel, Switzerland; ²Department of Neurology, University of Basel Hospital, Basel, Switzerland; ³Department of Emergency Medicine, University of Basel Hospital, Basel, Switzerland; ⁴Neurology and Neurorehabilitation, University Department of Geriatric Medicine Felix Platter, University of Basel, Basel, Switzerland; ⁵Centre for Vestibular Neurology, Department of Brain Sciences, Imperial College London, London, UK; ⁶Division of Audiology, Department of ORL, University of Basel Hospital, Basel, Switzerland

Background and aims: Vestibular agnosia (VA) is a brain disconnection syndrome that manifests with imbalance and an altered sensation of self-motion perception despite an intact peripheral vestibular system. VA can be measured and quantified employing vestibular psychophysics. Only recently VA was described for the first time in acute traumatic brain injury. VA has been reported to occur in elderly patients in whom there is disconnection within the brain due to small vessel disease (SVD). We assess vestibular perception and its relation to balance control in elderly patients with SVD and imbalance, dizziness and falls.

Methods: Ongoing exploratory prospective two-centre study. 9 patients with SVD (Fazekas 2–3) and imbalance/ falls were assessed, 2 males, 7 females (age 78–93, average 82.8 years). 4 elderly controls were assessed, 1 male, 3 females (age 78, 72, 74, 89 years). Vestibular perceptual thresholds (VPTs) were determined for yaw-plane rotations with randomly presented half cosine stimuli (0.1 Hz). Peripheral vestibular function, balance control, reaction times, cognition and self-reported symptoms of dizziness, anxiety and depression were assessed.

Results: In those subjects with SVD elevated VPTs (overall range 1.1–11.4 deg/sec, mean 6.1 deg/sec) were correlated with impaired balance control and lower subjective symptom scores of dizziness. VPTs in elderly control subjects were 2.4 deg/sec (1.7–3.1 deg/sec) which is within limits of normal subject's performances aged <65 years (cut-off 5.0 deg/sec).

Conclusion: VPTs in elderly subjects >70 years might be within a normal range. VPTs might serve as a biomarker for imbalance and risk of falls in elderly people.

Disclosure: Flurin Honegger has worked as a consultant for the company which made the equipment used in this study to assess balance control. This work was supported by Freiwillige Akademische Gesellschaft (FAG) Basel.

EPO-0690 | Square wave jerk in de novo idiopathic Parkinson's disease: Insights into the dynamic overshoot subtype

H. Kim¹; J. Choi¹; S. Choi²; K. Choi²; J. Lee¹; S. Lee³

¹Neurology, Pusan National University School of Medicine, Research Institute for Convergence of Biomedical Science and Technology, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; ²Neurology, Pusan National University Hospital, Pusan National University School of Medicine and Biomedical Research Institute, Busan, Republic of Korea; ³Neurology, Chonnam National University Hospital, Chonnam National University Medical School, Gwangju, Republic of Korea

Background and aims: Square wave jerks (SWJs) are pairs of small saccades that takes the gaze away from the target and then return it, commonly observed in neurodegenerative disorders. Although prominent in progressive supranuclear palsy, their clinical significance in Parkinson's disease (PD) is not well defined.

Methods: We retrospectively reviewed 145 de novo PD patients who underwent video-oculography, UPDRS part III, Hoehn and Yahr staging, cognitive testing, and assessments for orthostatic hypotension (OH) and probable REM sleep behavior disorder (RBD). SWJs were categorized as macro ($\geq 5^\circ$), staircase, or dynamic overshoot. Associations with motor severity, cognition, non-motor features, and PD motor subtypes (tremor-dominant [TD], postural instability/gait difficulty [PIGD], indeterminate) were analyzed.

Results: Among 67 TD, 41 PIGD, and 37 indeterminate patients, RBD (47.6%) and OH (29.7%) were most frequent in PIGD, though without statistical significance. Overall SWJ frequency did not differ across motor subtypes. Macro SWJs were rare (3.4%). Staircase SWJs (49.7%) correlated with higher SWJ counts ($p < 0.001$) but no with clinical parameters. Dynamic overshoot SWJs (42.1%) were associated with higher SWJ frequency ($p < 0.001$), worse motor severity (UPDRS part III, $p < 0.001$), and higher PIGD scores ($p = 0.032$). No associations were observed with cognition, OH, or RBD.

Conclusion: Dynamic overshoot SWJs, unlike other subtypes, were linked to more severe motor impairment in de novo PD. These findings suggest that dynamic SWJs may reflect cortical inhibitory dysfunction, in which diminished inhibitory control from the frontal eye field results in disinhibition and subsequent hyperactivation of the superior colliculus.

Disclosure: Nothing to disclose.

EPO-0691 | Magnetic resonance imaging of the visual pathway in Leber's hereditary optic neuropathy: A systematic review

M. Almeida¹; R. Pires²; A. Jorge¹; J. Sargento¹; M. Jónia³; D. Pereira²; J. Lemos¹

¹Department of Neurology, ULS Coimbra, Portugal; ²Department of Neuroradiology, ULS Coimbra; ³CTU-CACC, Clinical Trial Unit – Coimbra Academic and Clinical Center, ULS Coimbra, Portugal

Background and aims: Leber's hereditary optic neuropathy (LHON) is a rare but important cause of blindness in young adults. Similarly to what is observed in other acquired optic neuropathies, paraclinical tests such as MRI could aid in LHON diagnosis; however, the typical MRI features of the visual pathway in LHON remain largely unknown. We conducted a systematic review on brain and/or orbit MRI findings in LHON.

Methods: We performed a search of published articles between 2008 and 2024 using databases from PubMed, EMBASE, SCOPUS and Web of Science Core Collection in accordance with PRISMA guidelines.

Results: We included 128 studies with 423 patients, plus 5 from our own series. The mean age at presentation was 34.3 years (SD 17.0). MRI abnormalities in patients presenting with simultaneous or unilateral vision loss, were observed in 48% of eyes. The most frequent pattern was a combination of intraorbital and intracranial/prechiasmal involvement of the optic nerve (19.5%), followed by isolated intraorbital involvement (18.2%), intraorbital, intracranial, and intracranial/prechiasmal involvement (19.5%), and intraorbital with intracranial involvement (6.1%). MRI abnormalities included T2 hyperintensity (77.4%), atrophy (7.5%), T1 gadolinium enhancement (3%), and combined T2 hypersignal with T1 gadolinium enhancement (11.3%).

Conclusion: Optic nerve MRI abnormalities are present in half of LHON patients and become less frequent by the time of second eye involvement. Importantly, these may mimic MRI patterns commonly seen in non-genetic acquired optic neuropathies such as aquaporin-4 and MOG-related diseases and multiple sclerosis. Awareness of MRI patterns in LHON is crucial, prompting early diagnosis and better treatment outcomes.

Disclosure: Nothing to disclose.

EPO-0692 | Effects of noisy galvanic vestibular stimulation on gait and balance in bilateral vestibulopathy: A randomised sham-controlled crossover pilot study

M. Bancroft; B. Jones; H. O'Neill; D. Kaski; M. Mahmud
Queen Square Institute of Neurology, Faculty of Brain Sciences,
University College London (UCL), UK

Background and aims: Noisy galvanic vestibular stimulation (nGVS) has been suggested as a tool to improve gait and balance function in bilateral vestibulopathy (BVP). We conducted a pilot study to assess the effect of nGVS on gait and balance in BVP.

Methods: Subjects performed gait and balance tasks under stimulation and sham conditions: (1) standing on firm ground/foam with/without vision; (2) the timed-up-and-go (TUG) test; (3) 6m walk at a self-selected comfortable speed and slow speed

(50% of self-selected comfortable speed). The order of stimulation and sham was randomised and counterbalanced. A consistent nGVS stimulus (white noise, 0–100Hz, peak-to-peak 0.4mA, ramped up and down in 5 seconds) was used in all conditions. Gait and balance behaviour was quantified using a force plate, optical and video-based motion capture systems. Primary outcome measures were: postural sway during standing; TUG completion time and turn speed; gait pace, variability, rhythm, asymmetry, and postural control metrics during walking.

Results: Ten subjects (72yr median) with BVP participated in the study. No subject was able to distinguish stimulation from sham, confirming double-blinding efficacy and that nGVS stimulation was sub-perceptual. We did not find evidence of a difference between stimulation and sham conditions in gait or balance function during the standing, TUG, normal or slow speed walking tasks.

Conclusion: At the group level, we did not find evidence that nGVS improved gait and balance in patients with BVP. Individual improvements across some parameters were observed with nGVS and further studies may seek to characterise these further to develop more tailored treatment approaches.

Disclosure: Cochlear Technology Centre Belgium financially supported this study.

EPO-0693 | Bilateral vestibulopathy: Strong association with the ZNF91/LINC01224 locus

M. Strupp¹; F. Heindl¹; A. Hartmann²; A. Zwergal¹; I. Giegling²; B. Konte²; D. Rujescu²

¹Department of Neurology and German Center for Vertigo and Balance Disorders, Ludwig Maximilians University, Munich, Germany; ²Department of Psychiatry and Psychotherapy, Comprehensive Center for Clinical Neurosciences and Mental Health, Medical University of Vienna, Vienna, Austria

Background and aims: Bilateral vestibulopathy (BVP) is a chronic disabling vestibular disorder. Known etiologies are, e.g. ototoxic exposure or genetic syndromes including RFC1-related disorders and FGF14-GAA-Ataxia (SCA27b). They explain only a minority of cases, leaving a substantial proportion idiopathic. To address this gap, we conducted a genome-wide association study (GWAS) in patients with idiopathic BVP.

Methods: We analyzed a European cohort of 132 individuals diagnosed with idiopathic BVP and 3410 unaffected controls. Diagnosis was based on the current diagnostic criteria of the Bárány Society. Following quality control and removal of outliers, GWA was performed on approximately 7.5 million variants, complemented by gene-based analysis with MAGMA.

Results: GWAS identified two loci reaching genome-wide significance. The strongest signal mapped to chromosome 19 (ZNF91/LINC01224), with rs12185481 ($p = 3.60E-16$) as the lead variant. A second, more tentative signal emerged on chromosome 2 represented by rs73006457 ($p = 4.46E-08$) with GPC1 and OTOS as the nearest candidate genes. Gene-based analysis revealed six significant loci, including ZNF91, highlighting novel candidate genes with potential relevance to BVP pathogenesis.

Conclusion: GWAS points to ZNF91/LINC01224 as a major contributor with a functional link between transcriptional regulation, retrotransposon silencing, and vestibular pathology with age-related decline in ZNF91 expression potentially amplifying genetic risk. The second locus near OTOS on chromosome

2 represents a less robust plausible candidate, as OTOS is expressed in the inner ear, previously associated with susceptibility to ototoxic-induced hearing loss. Together, these findings highlight novel pathways in BVP pathogenesis and merit replication in larger, independent cohorts.

Disclosure: Nothing to disclose.

EPO-0694 | Head circumduction paradigm as a model to stimulate the vestibulo-spinal activity

M. Corrado¹; L. Martinis²; V. Grillo²; M. Gjini²; I. Campese²; B. Al-Saheli²; B. Guerra³; S. Sozzi³; M. Schmid³; S. Ramat³; C. Tassorelli²; R. De Icco²; T. Ellmers⁴; A. Bronstein⁴

¹Movement Analysis Research Section, IRCCS Mondino Foundation, Pavia, Italy; ²Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy; ³Bioengineering Lab, University of Pavia, Pavia, Italy; ⁴Department of Brain Sciences, Imperial College, London, UK

Background and aims: Vestibulospinal reflex (VSR) mechanisms are difficult to isolate. Here we applied the head circumduction paradigm (Corrado et al., 2025), which induces a transient vertical semicircular canal asymmetry, to assess the VSR and compare responses with those of the vestibulo-ocular reflex (VOR)

Methods: We asked nine healthy participants to perform circumduction (circular) head rotations (0.75 Hz, i.e. a full head rotation every 1.33s) while standing on a force plate. We recorded baseline and post-rotational (“stopping”) posturography [centre of pressure (CoP) deviation and trunk kinematics with infrared motion markers, focusing primarily on post-rotational CoP shift. 3D video-oculography was simultaneously obtained. We assessed whether head reorientation in pitch could influence the post-rotational sway.

Results: On stopping head rotation 6 (66.7%) subjects’ trunk and CoP deviated towards the less active vestibular side (see Figure 1) by a mean of 13.4 ± 10.1 mm (CoP). The time constant of this direction-specific sway response was 12.9 ± 13.8 s. The “stopping” eye nystagmus was prominently torsional as in (Corrado et al., 2025). Head reorientation in pitch did not influence the time constant of the postural response.

Conclusion: The head circumduction paradigm can isolate the vertical canal vestibulospinal response. The direction-specificity of the postural response makes it potentially useful for clinical

purposes and not necessarily requiring complex or expensive equipment.

Disclosure: Nothing to disclose.

EPO-0695 | Vestibular migraine – Characterization of the long-term clinical course

L. Fabritius¹; F. Wullenweber²; R. Strobl³; E. Grill¹; M. Dieterich²; S. Becker-Bense²

¹Department of Neurology, University Hospital, LMU Munich, Germany; ²German Center for Vertigo and Balance Disorders (DSGZ), University Hospital, LMU Munich, Germany;

³Institute for Medical Information Processing, Biometry, and Epidemiology, LMU Munich, Germany

Background and aims: Vestibular migraine (VM) is the most common cause of episodic vertigo attacks with considerable clinical variability. Data on its natural course are sparse, as on effectiveness of treatment. Aim of the study was to evaluate its clinical presentation in the long-term course.

Methods: Data of 459 adult patients (~70% females, mean 42.5 years) with newly diagnosed VM according to Bárány Society’s diagnostic criteria at a tertiary vertigo centre (2010–2020) were retrospectively analyzed. All patients underwent comprehensive clinical and instrumental neuro-ophthalmological/otological examination. Long-term course of VM symptoms including therapeutic interventions was systematically explored using standardized questionnaires.

Results: At first presentation 51% of VM patients presented at least one ocular motor impairment, while extended vestibular testing was usually unremarkable. The questionnaires were completed by 111 patients after a mean of 9.7 years: 63.1% reported continued episodic vertigo, mostly improved in frequency (91%), duration (89%) and/or intensity (90%). Vertigo-related headaches decreased from 73% to 56%. Conservative migraine prophylaxis was carried out in 62% of patients, rated as helpful more for headaches (38%) than vestibular symptoms (34%). Pharmacological prophylaxis was used, at least temporarily, by 43%, rated as similarly effective for headaches and dizziness (34% vs. 37%).

Conclusion: After 10 years, approximately one third of VM patients became symptom-free, while the other two-thirds experienced less frequent and/or milder vertigo attacks. Conservative migraine prophylactic treatments were preferred, however, both conservative and pharmacological approaches were only partially effective. These results highlight the critical need for thorough patient education and further research regarding the effectiveness of various treatment strategies.

Disclosure: The study was supported by the Deutsche Stiftung Neurologie (project 80766125 and 80721017) and German Research Foundation (DFG) under Germany’s Excellence Strategy (Munich Cluster for Systems Neurology: EXC 2145 SyNergy) to MD. All other authors reported no disclosures.

Representative subject’s centre of pressure shift immediately on stopping after a right circumduction. The stopping response elicits a right vertical canals hyperactivity, whereas the subject’s COP shifts towards the left (less active) side.

EPO-0696 | Strategic postural control for differential diagnosis of persistent postural-perceptual dizziness (PPPD) and vestibular migraine (VM)

S. Becker-Bense¹; L. Fabritius²; V. Flanagan¹; M. Dieterich¹

¹German Center for Vertigo and Balance Disorders (DSGZ), University Hospital, LMU Munich, Germany; ²Department of Neurology, University Hospital, LMU Munich, Germany

Background and aims: Persistent postural-perceptual dizziness (PPPD) is a frequent cause of chronic dizziness/vertigo with subjective unsteadiness, whereas Vestibular Migraine (VM) is characterized by episodic vertigo attacks. However, some VM patients report persistent symptoms resembling PPPD. Clinical balance examination usually reveals no abnormalities in both. Aim of the current study was to determine whether PPPD and VM can be differentiated using posturographic stance parameters.

Methods: A retrospective analysis of a well-characterised cohort recruited at a tertiary vertigo centre included 51 PPPD and 86 VM patients. Forty-one of the 86 VM patients also presented with secondary persistent symptoms. Beside comprehensive clinical and instrumental neuro-ophthalmological/otological examination all patients underwent testing of postural control under simple and challenging sensory conditions on a stabilometer platform. Sixty-one age-matched healthy subjects served as controls.

Results: Posturographic analysis revealed distinct patterns of postural regulation in VM and PPPD: The sway variability was significantly higher in VM compared to PPPD and controls in all conditions with eyes closed. On the other hand, PPPD patients showed a stereotypical sway pattern restricted almost exclusively to the fore-aft axis. VM patients with secondary persistent symptoms presented the same postural regulation as those without PPPD-like symptoms.

Conclusion: VM and PPPD showed different postural control mechanisms providing quantitative parameters to enrich differential diagnosis. PPPD patients developed highly regulated postural control, whereas VM patients with secondary persisting symptoms maintained stance pattern of episodic VM patients with higher variability. Further analysis is still needed to understand the nature of the chronic component of this VM phenotype.

Disclosure: The study was supported by the Deutsche Stiftung Neurologie (project 80766125 and 80721017) and German Research Foundation (DFG) under Germany's Excellence Strategy (Munich Cluster for Systems Neurology: EXC 2145 SyNergy) to MD. All other authors reported no disclosures.

EPO-0697 | High-frequency vestibulo-ocular reflex in spinocerebellar ataxias with slow saccades: SHIMP to unmask saccadic dysfunction

S. Lee; J. Kim; M. Park; S. Choi

Department of Neurology, Chonnam National University Hospital and Chonnam National University Medical School, Gwangju, Republic of Korea

Background and aims: The vestibulo-cerebellum modulates the vestibulo-ocular reflex (VOR) and saccadic eye movements.

High-frequency VOR can be quantified with video head impulse testing (vHIT) using the head impulse paradigm (HIMP) and the suppression head impulse paradigm (SHIMP). Spinocerebellar ataxias (SCAs), particularly SCA2 and SCA7, often show slow saccades, but the value of SHIMP in this setting is unclear. We aimed to determine whether SHIMP can reveal saccadic dysfunction in SCA patients with slow saccades but normal high-frequency VOR gains.

Methods: We retrospectively analyzed five patients with genetically confirmed SCA (SCA2, $n = 3$; SCA7, $n = 2$). All showed horizontal saccades slowing on neurological and video-oculographic examination. VOR was assessed with an ICS Impulse vHIT system using horizontal HIMP and SHIMP, and we measured horizontal canal gains and the presence and pattern of compensatory (HIMP) and anti-compensatory (SHIMP) saccades.

Results: In all patients, horizontal canal VOR gains on HIMP were within the normal range (mean right 0.97, left 0.97). SHIMP gains were similarly normal (mean right 0.98, left 1.02), but the expected anti-compensatory saccades were absent in two patients and small-amplitude and scattered in three. Thus, despite preserved gains, SHIMP unmasked a failure to generate robust, time-locked anti-compensatory saccades in all cases, consistent with saccadic dysfunction.

Conclusion: In SCAs, SHIMP is a useful alternative VOR paradigm to unmask saccadic dysfunction that may be missed by conventional head impulse testing alone. The dissociation between normal gains and abnormal or absent SHIMP saccades suggests impaired VOR-saccade coupling and may help refine phenotyping in cerebellar ataxias.

Disclosure: Nothing to disclose.

Neuroimaging and Neurosonology

EPO-0698 | Towards metabolic biomarkers of aging

A. León Betancourt¹; R. Hoepner¹; S. Marti¹; M. Capiglion²; P. Radojewski²

¹Department of Neurology, Inselspital, Bern University Hospital and University of Bern, Bern, Switzerland; ²Translational Imaging Center, Swiss Institute for Translational and Entrepreneurial Medicine, Bern, Switzerland

Background and aims: Ageing is influenced by lifestyle and diseases. Multiple Sclerosis (MS) contributes to chronic low-grade inflammation ("inflammaging") and neurodegeneration, thereby affecting ageing processes. To date, brain ageing in MS has predominantly been studied using volumetric MRI approaches.

Methods: This interim analysis of an ongoing investigator-initiated trial (NCT06221631). We evaluated age-related variations in CEST pools in 7T MRI of healthy individuals ($n = 47$, aged 18–65 years) as potential biomarkers of ageing, and compared them to MS ($n = 22$, 18–63 years). CEST contrast was quantified using Lorentzian fitting of denoised, normalised, and B0- and B1-corrected z-spectra (55 offsets). Associations between age and CEST pool amplitudes were analysed for white matter (WM) and grey matter (GM), using Pearson correlations and a physics-informed deep learning model (PICA). Due to the interim nature, no covariate adjustment was applied. CEST

FIGURE 1 Representative MS patient included in the analysis (female, 23 years old). High-resolution anatomical image, CEST, B0 and B1 maps, and CEST contrast maps are displayed.

FIGURE 2 Age group distribution of the data set.

FIGURE 3 Linear regression results for amide, amine, rNOE, and MT in white matter and grey matter. Panels (A), (C), (E), (G), (I), (K), (M), (O): Measured CEST amplitudes and fitted CEST amplitude for healthy controls and patients with MS.

pool maps (amide, amine, magnetisation transfer [MT], and relayed Nuclear Overhauser Effect [rNOE]) of MS were compared to age-matched controls.

Results: We observed a consistently negative correlation of different pools with age, post pronounced in GM. A statistically significant effect of age and an MS-associated age dependency was detected especially on amides in GM (Holm corrected $p=0.013$ and $p=0.014$, respectively).

Conclusion: This preliminary analysis shows a decrease of most CEST pools with age, making them potential metabolic biomarkers of biological brain aging. After recruitment finalization (foreseen 100 HC and 100 MS) we will look more in detail into these age-associated changes overall. Additionally we will look at metabolic markers in MS lesions.

EPO-0699 | Evaluation of cerebral circulatory regulation using blood flow velocity spectrum analysis

A. Gaál¹; H. Pál¹; B. Csányi²; L. Ajtai³; Á. Kovács³; K. Nagy²; T. Horváth⁴; Á. Koller⁴; R. Debreczeni¹

¹Department of Neurology, Semmelweis University, Budapest, Hungary; ²Semmelweis University, Doctoral College, Budapest, Hungary; ³Faculty of Medicine, Semmelweis University, Budapest, Hungary; ⁴University of Physical Education, Research Center for Sport Physiology, Budapest, Hungary

Background and aims: Near-constant global cerebral blood flow (CBF) is ensured by the simultaneous regulation of perfusion pressure and cerebral flow resistance (CVR). The CVR of a cerebral proximal vascular segment can be estimated from arterial blood pressure CBF velocity relationships during the cardiac cycle, particularly in diastole. We hypothesized that mathematical analysis of the diastolic phase of the flow velocity spectrum provides a novel and reliable method for assessing CVR. Our objective was to define a novel diastolic parameter that characterizes changes in CVR to a vasoactive stimulus and to compare its sensitivity with that of established indices.

Methods: 35 healthy volunteers' CBF velocity was measured in the middle cerebral artery using transcranial Doppler ultrasound, with noninvasive arterial blood pressure monitoring. Orthostatic stress induced by a tilt table was applied, with measurements performed at 0°, 30°, 60°, and 90°. In addition to the pulsatility index (PI) calculated from velocity ratios and the cerebral arterial resistance (CAR) expressed as the blood pressure-velocity ratio, the diastolic time constant (Tau) was introduced. Tau represents the time required for the initial diastolic flow velocity to decrease to 1/e of its value, determined by the decay constant (λ).

Results: Tau was significantly more sensitive than PI in detecting CVR changes (0–30°: $p=0.044$, $r=0.75$; 0–60°: $p=0.025$, $r=0.76$; 0–90°: $p=0.043$, $r=0.81$). Tau also showed greater sensitivity than CAR (0–30°: $p=0.047$, $r=0.754$; 0–60°: $p=0.017$, $r=0.907$; 0–90°: $p=0.043$, $r=0.504$).

Conclusion: The diastolic flow time constant (Tau) is a more sensitive marker of CVR changes than the PI or CAR.

Disclosure: Nothing to disclose.

Department of Neurology, University Hospital Heidelberg,
Heidelberg, Germany

Background and aims: Neuronal processes underlying perception of self-produced naturalistic continuous speech remain unclear. While prior research has used temporal response function (TRF) analyses to investigate passive listening, this study established a novel MEG-based paradigm comparing passive speech perception with self-produced speech in an ecologically valid experimental setting.

Methods: Participants completed an experimental study alternating between 10-second passive listening and active speaking sections across 100 trials. They heard audiobook segments and repeated what they had just heard as closely as possible. Audio was recorded during active speaking trials. TRF analyses were computed using the first derivative of the speech envelope, marking syllable onset, as predictor of MEG measurements. Source localization extracted neuronal activation within the ROI of the early auditory cortex.

Results: An N1 component centered at 90–100 ms was visually recovered in both conditions across both hemispheres. P1 and P2 components emerged with much smaller amplitudes. Statistical analyses of defined time frames (10–50 ms for P1; 70–110 ms for N1; 140–180 ms for P2) revealed no overall differences between conditions or hemispheres. A significant N1 was found in both hemispheres of the passive condition and the right hemisphere of the active condition. P2 reached significance only in the left hemisphere of the passive condition. A glossokinetic artifact synchronous with syllable onset emerged specifically in the active speaking condition. Signal Subspace Projection (SSP) successfully corrected for this artifact.

Conclusion: This research successfully established a paradigm to measure neuronal responses to self-produced speech, demonstrating that measuring active speech in MEG using TRF requires specific artifact correction techniques.

Disclosure: Nothing to disclose.

FIGURE 1 TRF wave forms extracted from the Early Auditory Cortex ROI in the passive (top row) and active condition (bottom row) in the left and right hemispheres.

F. Mallaev; G. Rakhimbaev
Tashkent State Medical University, Tashkent, Uzbekistan

Background and aims: Although large artery atherosclerosis represents a leading cause of ischemic stroke, the contribution of venous circulation abnormalities to stroke pathophysiology has received limited attention. We investigated cerebral venous hemodynamic alterations in acute stroke patients with atherosclerotic arterial disease and examined their relationship with initial stroke severity and early clinical worsening.

Methods: This prospective investigation enrolled 120 consecutive acute ischemic stroke patients presenting with $\geq 50\%$ stenosis affecting extracranial or intracranial major arteries. Clinical assessment utilized the National Institutes of Health Stroke Scale at hospital admission and on day seven. Neuroimaging evaluation within 72 hours comprised brain MRI incorporating diffusion-weighted sequences and MR venography. Hemodynamic measurements included superior sagittal sinus flow velocity, venous pulsatility index, and venous sinus caliber, obtained through transcranial Doppler ultrasonography and MR venography.

Results: Study participants exhibited substantially diminished superior sagittal sinus flow velocity (21.9 ± 4.6 cm/s) alongside elevated venous pulsatility index values (1.38 ± 0.17). Statistical analysis revealed significant correlations between impaired venous flow and admission NIHSS scores ($r = -0.42$, $p < 0.001$) as well as ischemic lesion volume ($r = -0.39$, $p = 0.002$). Twenty-six patients (21.7%) experienced early neurological deterioration, which occurred predominantly among those demonstrating marked venous drainage impairment ($p = 0.004$). Multivariable regression modeling identified venous flow velocity as an independent determinant of early clinical worsening.

Conclusion: Disturbed cerebral venous drainage patterns occur frequently in atherosclerotic stroke and independently correlate with initial neurological severity and subsequent early deterioration. Integration of venous hemodynamic evaluation into acute stroke assessment could strengthen early prognostic stratification.

Disclosure: Nothing to disclose.

Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome, Via di Grottarossa; Rome, Italy

Background and aims: Parkinson's disease (PD) is associated with neurovascular unit dysfunction and reduced cerebrovascular reactivity (CVR). Levodopa may affect cerebral hemodynamics, but its acute effect on CVR remains unclear.

TABLE 1 Demographic and clinical data.

Variation	Value
Age (years)	67.8 ± 7.0 (range 52–80)
Sex	Male 14 (70.0%)
Disease duration	8.1 ± 5.0 (range 2–21)
Hoehn & Yahr	2.10 ± 0.79 (range 1.5–4.5)
Most affected side	Left 11 (55%)
MoCA	26.9 ± 3.5 (range 16–19)
WDQ-19	1.6 ± 2.4 (range 0–8)
SCOPA-AUT	10.4 ± 6.8 (range 0–26)

Table 1: demographic and clinical data.

MoCA: Montreal Cognitive Assessment; WDQ-19: 19-item Wearing-Off Questionnaire; SCOPA-AUT: Scales for Outcomes in Parkinson's Disease – Autonomic Dysfunction.

Methods: Twenty people with PD with Hoehn and Yahr stage below 4 were enrolled. CVR was assessed using transcranial Doppler Breath Holding Index (BHI) at the middle cerebral arteries in OFF state after medication withdrawal and in ON state one hour after Levodopa intake. Sixteen patients completed Doppler assessment. Clinical evaluation included MDS UPDRS part III. Autonomic evaluation included SCOPA AUT and orthostatic blood pressure testing. Cognitive evaluation included MoCA, Stroop test and verbal fluency. Patients with cerebrovascular stenosis, MMSE below 18 or incomplete data were excluded.

Results: Mean BHI was reduced compared with normative values (0.757 vs 1.29). BHI showed a trend toward reduction in ON compared with OFF ($p=0.054$). In ON state, BHI was lower in the hemisphere contralateral to the more affected motor side ($p=0.035$), while within the more affected hemisphere BHI was higher in OFF than ON ($p=0.030$). Basal flow velocity and pulsatility index did not differ between states. Change in BHI correlated inversely with OFF BHI ($r = -0.668$, $p=0.003$). Four patients had neurogenic orthostatic hypotension without BHI differences. Levodopa improved UPDRS III scores ($p < 0.001$) and Stroop interference performance ($p=0.016$) without increasing CVR.

Conclusion: CVR is reduced in PD. Acute Levodopa administration does not improve vasodilatory reserve and may further compress CVR, supporting a vascular ceiling effect.

Disclosure: Nothing to disclose.

EPO-0703 | Non-invasive quantification of motor unit recruitment using ultrasound optical flow

J. Scott; W. Hay Mar; R. Whittaker; K. Suetterlin; S. Maitland
Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, UK

Background and aims: Motor unit assessment is commonly performed using electromyography (EMG), which records muscle fibre electrical activity but cannot directly measure muscle contraction or force generation—the processes most relevant to clinical weakness. EMG therefore provides limited insight into how neuronal activation translates into movement, including excitation–contraction coupling. As a result, surface and needle

EMG incompletely reflect motor unit output. This study assesses whether clinical ultrasound with optical flow analysis can non-invasively quantify motor unit recruitment and contractile behaviour during peripheral nerve stimulation.

Methods: Twenty-two healthy participants underwent peripheral nerve stimulation of the abductor digiti minimi, abductor pollicis brevis, and tibialis anterior muscles with simultaneous surface EMG and high-frame-rate ultrasound (100–150 frames/s). Stimulation current was reduced from supramaximal levels to generate recruitment curves. Stimulus–response relationships were modelled using four-parameter logistic regression, with EC50 defined as the current producing 50% of the maximal response.

Results: 11 male and 11 female participants took part; mean age 28 ± 9.16 . Forty-six paired recordings were analysed. Ultrasound detected motor units at lower stimulation thresholds (0.71 ± 0.82 mA earlier, $p < 0.0001$) and reached saturation earlier (2.6 ± 5.3 mA lower, $p < 0.0001$) than surface EMG. EC50 occurred at lower currents for ultrasound than EMG (7.89 ± 3.37 mA vs 8.94 ± 3.90 mA, $p = 2.35 \times 10^{-11}$).

Conclusion: Ultrasound with optical flow analysis enables non-invasive measurement of motor unit recruitment by directly quantifying muscle contraction, including deep motor units not detected by surface EMG, with potential application in neuromuscular disease assessment.

Disclosure: Nothing to disclose.

EPO-0704 | Cortical damage and tracts disconnection as predictors of 3-month aphasia severity after left ischemic stroke

S. Magno¹; T. Jacquemont-Fulneau²; C. Rosso²; F. Mazzacane¹; G. Perini³; A. Costa¹; A. Cavallini¹

¹Department of Emergency Neurology and Stroke Unit, IRCCS Mondino Foundation, Pavia, Italy; ²Institut du Cerveau, ICM, Inserm U1127, CNRS UMR 7225, Sorbonne Université, Paris, France; ³Unit of Behavioral Neurology and Center for Cognitive Disorders and Dementia (CDCD), IRCCS Mondino Foundation, Pavia, Italy

Background and aims: Tract-based disconnection metrics are increasingly used to predict aphasia, but their value beyond lesion burden remains debated. We compared atlas-based cortical lesion overlap and tract disconnection as predictors of aphasia severity at 3 months.

Methods: Fifty patients with left ischemic stroke (mean age 73.2 ± 12.8 years; 44% female) were included. Aphasia severity was assessed using NIHSS language subitem 9 at 3 months. Lesion masks were registered to MNI space. Using Tractotron, we computed the mean and maximum proportion of disconnection over the dorsal (gathering the arcuate fasciculus, the SLF and the frontal aslant tracts), ventral pathways (gathering the IFOF, ILF, uncinate tracts) and combination of both. Language cortical regions and lesion overlap percentages were computed using the Harvard–Oxford atlas. Correlations between cortical overlaps, tracts disconnection and aphasia severity were computed using the Spearman correlation test. Each feature was volume corrected by linearly regressing it out. Ordinal regression models were adjusted for lesion volume, baseline total NIHSS, age, education, and reperfusion status.

Results: Composite language-network disconnection was associated with aphasia severity at 3 months (Spearman $\rho \approx 0.55$, $p < 0.001$). Single-tract analyses showed strongest associations for dorsal pathways (arcuate long segment: $\rho = 0.51$, $p = 0.00018$; SLF III: $\rho = 0.50$, $p = 0.00026$). After lesion-volume adjustment, composite and dorsal residualized indices were not associated with outcome ($\rho = 0.17$, $p = 0.24$; $\rho = 0.16$, $p = 0.26$). Central Opercular Cortex overlap independently predicted aphasia severity ($\beta = 0.077$, $p = 0.003$; OR ≈ 2.16 per 10% overlap).

Conclusion: In this cohort, in this cohort, cortical involvement showed the most robust volume-independent association with 3-month outcome.

Disclosure: Nothing to disclose.

EPO-0705 | Carbon dots conjugated with procyanidin B2 function as diamagnetic CEST MRI theranostic agents for Alzheimer's disease

S. Wu¹; f. Liu²; X. Li¹; H. Gong²; C. Zhuang¹; D. Shi¹; X. Tan²; R. Wu¹

¹Department of Medical Imaging, The Second Affiliated Hospital, Medical College of Shantou University, China;

²Center for Molecular Imaging Probe, Cancer Research Institute & Institute of Pharmacy and Pharmacology, School of Pharmaceutical Science, Hengyang Medical School, University of South China, China

Background and aims: Oxidative stress and neuroinflammation are recognized as central pathological mechanisms underlying Alzheimer's disease (AD). While natural procyanidins exhibit therapeutic potential by reducing reactive oxygen species (ROS) accumulation and neuroinflammation, their efficacy is limited by poor blood-brain barrier (BBB) penetration. Recent advances highlight arginine-derived carbon dots (C-dots) as biocompatible nanocarriers for brain-targeted delivery, owing to their small size, modifiable surface, and multifunctional properties, including optoelectronic behavior and size-dependent fluorescence.

Methods: We synthesized a novel MRI contrast agent C-dots@PB2. The agent has chemical exchange saturation transfer (CEST), which enabled the use of CEST imaging for monitoring c-dots distribution and provided the information for ROS and neuroinflammation accumulation.

Results: Based on in vitro and in vivo studies, we demonstrate that C-dots@PB2 exhibits CEST effects. Moreover, C-dots@PB2 efficiently mitigates ROS levels. Furthermore, the agent rapidly

In 8-month-old APP/PS1 mice and C57 mice, therapeutic efficacy was assessed by dividing subjects into C-dots@PB2 AD, PB2 AD, saline AD, and C57 normal control groups.

Histology and molecular analysis confirmed that PB2 treatment improved neuronal health, reduced amyloid plaques, and lowered neuroinflammation.

accumulates in the brains of AD mice and alleviate pathological features including A β plaque deposition, neuronal loss, and neuroinflammation. Additionally, they significantly enhance learning ability and memory function in AD mice.

Conclusion: This study demonstrates that C-dots@PB2 can attenuate the progression of AD by reducing levels of ROS and neuroinflammation accumulation. Additionally, its CEST effects offer a novel approach for developing theranostic agents targeting AD.

EPO-0706 | Abstract withdrawn

EPO-0707 | The importance of neuroimaging methods in assessing the aggressiveness of glioblastomas of cerebral hemispheres

S. Ahmedov¹; R. Egamberdiev¹; B. Muminov²

¹Republican Specialized Scientific and Practical Medical Center of Neurosurgery; ²Tashkent State Medical University, Tashkent, Uzbekistan

The chemical exchange saturation transfer (CEST) of PB2.

Background and aims: This study evaluates the clinical value of a newly developed MRI-based phenotypic aggressiveness scale for supratentorial glioblastomas and examines how phenotype-guided surgical strategy, including selective internal decompression, influences resectability, neurological outcomes, and early postoperative radiological dynamics.

Methods: A total of 155 patients with newly diagnosed supratentorial glioblastoma were retrospectively analyzed. Preoperative MRI findings (tumor volume, peritumoral edema, midline shift, and infiltration pattern) were used to classify tumors into three phenotypes: low-risk (A), intermediate-risk (B), and high-risk (C). Surgical outcomes, extent of resection, postoperative NANO scores, and early MRI changes were compared among groups. Selective internal decompression techniques were used selectively in B and C phenotypes.

Results: Phenotypic groups demonstrated distinct preoperative clinical and radiographic characteristics. Postoperative improvements were significant across all groups but varied by phenotype. Group A showed the most rapid recovery, with substantial reduction in edema and near-complete normalization of midline shift. Group B demonstrated moderate but significant improvement. Group C—initially the most compromised—achieved markedly better resectability (up to 80–89%) and neurological recovery when internal decompression was applied, compared with standard resection alone ($p < 0.01$). All key radiological and clinical parameters showed statistically significant differences between phenotypes ($p < 0.05$).

Conclusion: The MRI-based phenotypic aggressiveness scale reliably characterizes glioblastoma behavior and predicts surgical complexity. Phenotype-guided decision-making, particularly the use of selective internal decompression in high-risk tumors, improves extent of resection, reduces mass effect, and enhances early postoperative neurological outcomes. This combined radiologic–surgical approach represents a practical framework for optimizing treatment in supratentorial glioblastoma.

Disclosure: Nothing to disclose.

EPO-0708 | **BioSerenity-E1: A unique EEG foundation model for rapid AI development in neurological diagnostics, including Alzheimer's, sleep, or EEG abnormality**

U. Gimenez; M. Rahmouni; A. Honoré; R. Bettinardi; A. Bussalib; F. Le Gac; H. Launay; P. Di Piazza; C. Flipo; G. Jubien; P. Emerich
BIOserenity, Paris, France

Background and aims: The development of AI algorithms for EEG-based diagnostics is hindered by limited annotated data, and the complexity of neurophysiological signals. BioSerenity-E1 is a unique general-purpose EEG foundation model that addresses these challenges by learning universal representations, enabling rapid fine-tuning for diverse clinical applications.

Methods: BioSerenity-E1 is a transformer-based foundation model pretrained on unlabeled EEG. The model employs intra- and inter-attention mechanisms to capture spatiotemporal dependencies. We showcase its adaptability through three key applications: Normal/abnormal EEG classification on internal multicentric ($n=4480$) and public (TUAB, $n=276$) datasets. Alzheimer's disease detection using an independent external

FIGURE 1 Balanced accuracy and F1-score for Bioserenity-E1 Unfrozen and Bioserenity-E1 Frozen models evaluated on internal (Neurophy) and external (Thessaloniki) test datasets.

FIGURE 2 Pediatrics sleep stages confusion matrices for internal (A, $n = 53$) and external (B, $n = 49$) datasets and macro F1 score boxplots for both datasets (C).

TABLE 1 Normal/abnormal classification performances with 95% CI of Bioserenity-E1 derived algorithm VS autoSCORE algorithm.

Algorithm	Normality (%)	Abnormality (%)	Normal accuracy (%)	Positive predictive value (%)	Negative predictive value (%)
BIOsERENITY E1	83.8	88.8	88.1	88.8	80.1
	[82.8, 84.78]	[88.1, 89.52]	[86.3, 90.1]	[87.8, 89.6]	[81.4, 82.1]
autoSCORE	80.5	84.9	87.81	85.1	88.1
	[77.6, 83.2]	[82.1, 87.8]		[81.5, 88.6]	[87.6, 90.6]

cohort ($n=65$) and an internal test set ($n=779$). Pediatric sleep stage classification on internal ($n=262$) and external datasets ($n=52$).

Results: Normal/abnormal classification: BioSerenity-E1 achieves a balanced accuracy of 93.1 [90.2 – 95.3] on a rigorously annotated test set ($n = 198$), outperforming the commercial auto-SCORE algorithm. On the unseen public TUAB benchmark, it reaches 82.25 [78.27–87.48] accuracy. Alzheimer's disease detection: The model demonstrates balanced accuracies of 0.74–0.78 on an independent external dataset and 0.69–0.70 on the internal test set, confirming its ability to generalize. Pediatric sleep stage classification: BioSerenity-E1 achieves a macro-F1 score of 0.746 on the internal test set and 0.65 on an external dataset, proving generalist viability without sleep pretraining.

Conclusion: BioSerenity-E1 accelerates the development of AI-driven EEG diagnostics, delivering state-of-the-art performance across multiple tasks. Its adaptability to heterogeneous EEG setups, and high specificity make it a powerful tool for developing additional specialized algorithms, addressing rare conditions and expanding the scope of EEG-based diagnostics.

Disclosure: Nothing to disclose.

S. Van Eyndhoven; R. Magalhaes; R. Khan; T. Phan; A. Liseune; A. Brys; D. Sima; D. Smeets; W. Van Hecke
icometrix, Leuven, Belgium

Background and aims: Eligibility for amyloid-targeting monoclonal antibody treatments in Alzheimer's disease requires fewer than four microhemorrhages (MH) and no superficial siderosis (SS) on baseline T2*GRE MRI. icobrain is a deep learning-based system designed to detect MH and SS. The latest version, icobrain 5.17, was trained on additional clinical trial and real-world data. This study compares its performance with the prior version, icobrain 5.16.

Methods: icobrain 5.16 was trained on 247 clinical trial cases. icobrain 5.17 incorporated an additional 356 cases (85 clinical trial, 271 real-world), totaling 603 datasets. Evaluation was performed using subsets of the Alzheimer's disease neuroimaging initiative dataset across four experiments: MH detection in MH/SS-positive cases ($n=300$); MH detection in MH-negative cases ($n=300$); SS detection in MH/SS-positive cases ($n=54$); and SS detection error in MH/SS-negative cases ($n=54$). Performance was assessed using the 90th percentile of lesion quantification error (p90) of MH and SS across cases.

Results: p90 for SS detection in SS-positive cases decreased from 3 (icobrain 5.16) to 2 (icobrain 5.17). p90 for SS in SS-negative cases decreased from 1 to 0. p90 for MH detection in MH-positive cases was 3 for both versions; and in MH-negative cases was 1 for both versions.

Conclusion: icobrain 5.17 demonstrated reduced SS quantification error compared with icobrain 5.16. Given that any SS finding may render patients ineligible for amyloid-targeting therapy, this improvement supports more accurate treatment eligibility assessment. MH error rates remained stable and below clinically relevant ineligibility thresholds.

Disclosure: All authors are employees of icometrix.

TABLE 1 90th percentile of lesion quantification error (p90) of MH and SS for icobrain 5.16 and 5.17.

icobrain version	MH+ p90	MH- p90	SS+ p90	SS- p90
5.16	3	1	3	1
5.17	3	1	2	0

p90: 90th percentile of lesion quantification error; MH+: positive microhemorrhage case, MH-: negative microhemorrhage case, SS+: positive superficial siderosis case, SS-: negative superficial siderosis case

EPO-0710 | How brain morphology predicts pain quality in trigeminal neuralgia patients: A neuroradiological regularized multivariate approach

D. Litewczuk; G. De Stefano; D. Chiffi; C. Leone; E. Galosi; G. Di Pietro; P. Falco; E. Evangelisti; G. Di Stefano; F. Caramia; A. Truini
Department of Human Neuroscience, Sapienza University of Rome, Italy

Background and aims: Trigeminal neuralgia (TN) is a facial pain condition characterized by unilateral, very short-lasting pain paroxysms. In up to 50% of patients, it can be associated with a distinct, more prolonged type of pain, which is commonly referred to as concomitant continuous pain. We aimed to elucidate the contribution of brain morphology into the development of this condition.

Methods: We collected 66 subjects with a definite diagnosis of classical or idiopathic right TN and acquired their brain magnetic resonance imaging (MRI) scans. We constructed a predictive model of concomitant continuous pain based on MRI-based data of cortical thickness and gray matter volume of 74 cerebral regions of interest (ROIs).

Results: According to our final model, we estimated that the most robust predictors of concomitant continuous pain in TN patients are contralateral orbital, precentral, superior frontal, superior and inferior temporal gyri, and temporal pole.

Conclusion: Our clinical and neuroradiological study can be considered a proof-of-concept for the capacity of brain morphology to predict concomitant continuous pain in TN patients. In particular, it could provide an innovative insight into the role of brain plasticity in the pathophysiology of TN.

Disclosure: The authors have no potential conflict of interest to disclose.

EPO-0711 | Small fiber dysfunction in fibromyalgia: A multimodal study

D. Dell'Aversana¹; F. Masciarelli¹; F. Vitale¹; G. Ciccarelli¹; G. Caporaso²; S. Tozza¹; V. Provitera²; L. Santoro¹; F. Manganelli¹; M. Nolano¹; M. Nolano²
¹Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples Federico II, Naples 80131, Italy; ²Skin Biopsy Laboratory, Department of Neurology, ICS, Istituti Clinici Scientifici Maugeri, Telese Terme, Italy

Background and aims: Fibromyalgia (FMS) is characterized by widespread musculoskeletal pain associated with symptoms like depression, migraine and fatigue. A subset of FMS patients presents small fiber pathology. This study compares small fiber dysfunction in FMS patients with neuropathic pain and autonomic symptoms (FMS-SFN) versus pure small fiber neuropathy (SFN) patients.

Methods: 30 FMS-SFN patients and 67 SFN patients underwent sensory and autonomic evaluation through the "Small-Fiber-Neuropathy-Symptoms-Inventory-Questionnaire" (SFN-SiQ), "Composite-Autonomic-Symptoms-Score"(COMPASS-31),

Quantitative-Sensory-Testing (QST), cardiovascular reflexes, Sympathetic-Skin-Response (SSR) and Dynamic Sweat Test (DST). Cutaneous innervation was analysed on punch biopsies from three body sites applying indirect Immunofluorescence procedures.

Results: Compared to SFN patients (46 female, age 46 ± 16), FMS-SFN (27 female, age 41 ± 13) more frequently reported endometriosis (13% vs 1%), headaches (77% vs 16%) and depression (47% vs 7%). Dysimmune causes affected 47% of FMS-SFN and 36% of SFN patients, who had more glucose metabolism disorders (3% vs. 15%). FMS-SFN patients complained diffuse neuropathic pain, alongside more severe sensory and autonomic symptoms. Abnormal sensory thresholds were present in both groups with higher frequency of heat hyperalgesia in FMS-SFN (17% vs 1%) and higher thermal hypoesthesia at distal sites in SFN. FMS-SFN patients presented a lower RR variability at rest and non-length-dependent hypohidrosis with lower sweat volume per gland at proximal sites. Cutaneous sensory and autonomic innervation did not differ between the two groups.

Conclusion: FMS-SFN patients had a non-length-dependent SFN with a more diffuse neuropathic pain and more severe autonomic symptoms. They, also, presented a mild cardiovascular parasympathetic impairment and a proximal lower sweat production per gland. Skin biopsies did not differentiate the two groups.

Disclosure: Nothing to disclose.

EPO-0712 | Electrophysiological evidence of systemic neural hyperexcitability in trigeminal neuralgia: A nerve excitability study

E. Evangelisti; C. Leone; D. Litewczuk; G. De Stefano; G. Di Pietro; P. Falco; E. Galosi; G. Di Stefano; A. Truini
Department of Human Neuroscience, Sapienza University of Rome, Rome, Italy

Background and aims: Primary trigeminal neuralgia (TN) is a representative neuropathic facial pain disorder and is classified into classical TN, which is associated with neurovascular compression, and idiopathic TN, in which no clear etiology is identified. Increasing evidence, including the identification of pathogenic genetic variants within the sensory electrogenesisome, supports a multifactorial pathophysiology that converges on neuronal hyperexcitability. This hyperexcitability may extend beyond the trigeminal nerve, reflecting a more generalized axonal predisposition. Aim: to determine whether patients with TN exhibit generalized axonal hyperexcitability detectable in peripheral motor nerves and to assess the effects of sodium channel-blocking therapy on axonal excitability.

Methods: Motor nerve excitability testing of the median nerve was performed in 35 patients with classical or idiopathic TN and compared with healthy controls. The primary outcome measure was the strength-duration time constant (SDTC), an index of persistent sodium conductance. Secondary measures included recovery cycle and threshold electrotonus parameters. Subgroup analyses compared treated and untreated patients and classical versus idiopathic TN.

Results: TN patients showed a significant prolongation of SDTC compared with controls, independent of treatment status. Superexcitability was significantly reduced in patients receiving

Na-blockers compared with untreated patients. No differences in excitability parameters were observed between classical and idiopathic TN.

Conclusion: These findings demonstrate generalized axonal hyperexcitability in TN, characterized by increased persistent sodium conductance and detectable in peripheral motor nerves. This supports the hypothesis of an intrinsic predisposition to neuronal hyperexcitability in TN. Na-blocking therapy modulates superexcitability but does not normalize SDTC, indicating distinct pharmacodynamic effects and a shared pathophysiological substrate across TN subtypes

Disclosure: Nothing to disclose.

EPO-0713 | Real-world evaluation of botulinum toxin A in focal peripheral neuropathic pain: Longitudinal outcomes

E. Sole Cruz¹; E. Van Obberghen²; C. Hirtz³; I. Bennour²; M. Lanteri-Minet²; A. Donnet³

¹Reference Center for Neuromuscular Diseases and ALS, CHU Timone, Assistance Publique des Hopitaux de Marseille, Marseille, France; ²Pain treatment and evaluation Department, CHU de Nice, Nice, France; ³Pain treatment and evaluation center, CHU Timone, Assistance Publique des Hôpitaux de Marseille, Marseille, France

Background and aims: Neuropathic pain (NP) is frequently resistant to conventional treatments. Botulinum toxin type A (BT-A) is an authorized option for refractory focal peripheral NP, but the dynamics of its effect outside clinical trials in real-life conditions remain poorly characterized. The objective was to assess BT-A efficacy in a real-world study of patients with focal peripheral NP, over a one-year follow-up period.

Methods: In this prospective, observational study, adult patients with chronic focal peripheral NP refractory to standard therapies were treated with BT-A in two French pain centers. Injections were individualized and administered at ~3-month intervals. The primary outcome was the patient-reported percentage of improvement since the first injection, assessed at each follow-up visit (Cycles 2 to 5). Secondary outcomes included the Patient Global Impression of Change (PGIC), average pain intensity over the previous 8 days, and exploratory analysis

Patient flow from C2 to C5. Reasons for discontinuation include insufficient efficacy, sufficient pain relief, needle phobia, loss to follow-up, and scheduling beyond study cutoff.

Mean patient-reported percentage of improvement from baseline across treatment cycles C2 to C5 in the overall study population. The dotted horizontal line represents the threshold for clinically meaningful improvement (30%). (Bonferroni-adjusted p -values).

Improvement (%) from C2 to C5 in early responders (a), non-early responders (b), and direct comparison (c). Early responders improved rapidly then plateaued, while non-early responders showed delayed but progressive gains, crossing the 30% threshold by C4.

of response trajectories distinguishing early ($\geq 30\%$ improvement at Cycle 3) from late responders.

Results: 82 patients received ≥ 2 BT-A cycles and were included in the analysis. Mean self-reported improvement increased from 30.7% at Cycle 2 to 51.0% at Cycle 5 ($p < 0.001$). PGIC and pain intensity also showed significant improvements. Among 59 patients evaluable at Cycle 3, 66% were early responders; late responders showed significant benefit after the third injection. BT-A was well tolerated: 63.6% reported end-of-dose effects, and 25.8% experienced only mild, transient adverse events.

Conclusion: This real-life study over one year suggests that BT-A provides progressive and sustained benefit in focal peripheral NP, supporting continued treatment beyond two cycles.

Disclosure: Nothing to disclose.

EPO-0714 | Repeated capsaicin patch therapy in elderly neuropathic pain: Progressive real-world improvements

M. Überall¹; P. Müller-Schwefe²; M. Küster³

¹IFNAP – Institute of Neurological Sciences, Nürnberg, Germany; ²Interdisciplinary Center for Pain & Palliative Care Medicine, Göppingen, Germany; ³Interdisciplinary Center for Pain & Palliative Care Medicine, Bonn, Germany

Background and aims: Localized peripheral neuropathic pain (PNP) is frequent in older adults. Systemic treatments often show limited effectiveness and are associated with relevant safety risks. Long-term real-world data on topical high-concentration capsaicin patch (HCCP) therapy in geriatric patients are limited. To assess real-world effectiveness, treatment progression, and safety of repeated HCCP applications in patients aged ≥ 75 years with localized PNP.

Methods: This retrospective cohort analysis used depersonalized 12-month routine-care data from the German Pain e-Registry (CASPAGE subgroup of CASPAR). Elderly patients receiving one to four consecutive HCCP applications were evaluated. Patient-reported outcomes included pain intensities, neuropathic pain phenotype, pain-related disability, sleep disturbance, quality of life, mood, and systemic analgesic use. The primary endpoint was a composite response defined by clinically meaningful improvement in highest pain intensity, pain-related disability, and neuropathic pain symptoms.

Results: Data from 576 patients (mean age 81.4 years) and 1576 HCCP applications were analyzed. Pain and functional outcomes improved after the first treatment and showed progressive benefits with additional applications. The composite response increased from 0.9% after one treatment to 27.5% after four. Patients receiving ≥ 3 treatments demonstrated large reductions in pain, disability, and systemic analgesic use. Adverse drug reactions were local, transient, and decreased with repeated use.

Conclusion: Repeated HCCP therapy is associated with progressive, clinically meaningful improvements and good tolerability in very elderly patients with localized PNP, supporting its role as a long-term topical treatment option.

Disclosure: The parent CASPAR registry study was supported by Grünenthal GmbH. The present CASPAGE subgroup analysis was conducted independently, without external financial support. Grünenthal had no influence on data selection, analysis, interpretation, or manuscript preparation. M.A. Überall holds leadership roles at IFNAP and O.Meany MDPM, which operate the German Pain e-Registry. Other authors declare no conflicts of interest.

EPO-0715 | Efficacy & safety of IncobotulinumtoxinA in patients with postherpetic neuralgia: Results from the PaiNT proof-of-concept phase 2 trial

N. Attal¹; I. Bicker²; I. Pulte²; R. Baron³; G. Klein²; N. Finnerup⁴; T. Geister²; U. Munzel²; E. Viel⁵

¹Paris Saclay University, Hôpital Ambroise Paré, Paris, France;

²Merz Therapeutics GmbH, Frankfurt am Main, Germany;

³University Hospital Schleswig-Holstein, Kiel, Germany; ⁴Aarhus University, Aarhus, Denmark; ⁵Nîmes University Hospital and Montpellier-Nîmes Faculty of Medicine, Montpellier, France

Background and aims: Postherpetic neuralgia (PHN) is a common peripheral neuropathic pain (PNP) and remains a major clinical challenge. Therapies often provide insufficient relief or cause systemic side effects. IncobotulinumtoxinA (incoBoNT-A, Xeomin®) may offer a promising local treatment. The PaiNT Phase 2 proof-of-concept trial evaluated incoBoNT-A in PHN and post-surgical/post-traumatic neuropathic pain (PS/PTNP).

Methods: The trial enrolled adults with moderate to severe PNP. The present results focus on PHN. Patients received subcutaneous injections of incoBoNT-A (≤ 300 U in ≤ 60 sites into painful area) or placebo and were followed for 20 weeks. The primary endpoint was the change from baseline in average daily pain (ADP) intensity (0–10 NRS) at weeks 2–12. Secondary endpoints included the change in Neuropathic Pain Symptom Inventory (NPSI, 0–100 points) total score and dimensions at weeks 2–12 and safety.

Results: 123 PNP patients including 63 with PHN were randomised. The endpoints did not significantly separate from placebo in the combined set. However, the PHN group showed a numerically greater reduction in ADP intensity from baseline throughout weeks 2–12 compared to placebo (LSM difference: -0.56 points) and statistically significantly greater reduction at week 6 (-1.14 points; $p=0.0488$). LSM difference to placebo in NPSI (total) change was -3.14. 50% of PHN patients received the maximum dose of 300 U. No new safety concerns were detected for incoBoNT-A.

Conclusion: The PaiNT proof-of-concept study demonstrated clinically meaningful results with a favourable tolerability profile in treatment of PHN with incoBoNT-A, supporting further research potentially with higher dosages in this PNP indication.

EPO-0716 | Understanding patient diversity & placebo response in post-surgical/traumatic neuropathic pain: Results from the PaiNT proof-of-concept phase 2 trial

N. Attal¹; I. Bicker²; I. Pulte²; R. Baron³; G. Klein²;

N. Finnerup⁴; T. Geister²; U. Munzel²; E. Viel⁵

¹Paris Saclay University, Hôpital Ambroise Paré, Paris, France;

²Merz Therapeutics GmbH, Frankfurt am Main, Germany;

³University Hospital Schleswig-Holstein, Kiel, Germany; ⁴Aarhus University, Aarhus, Denmark; ⁵Nîmes University Hospital and Montpellier-Nîmes Faculty of Medicine, Montpellier, France

Background and aims: Post-surgical/post-traumatic neuropathic pain (PS/PTNP) is characterised by diverse etiologies and pain therapies are often insufficient and cause systemic side effects. IncobotulinumtoxinA (incoBoNT-A, Xeomin®) may provide a promising local treatment of peripheral NP (PNP). The proof-of-concept PaiNT trial evaluated incoBoNT-A in postherpetic neuralgia (PHN) and PS/PTNP.

Methods: These results focus on the PS/PTNP subgroup. Patients received subcutaneous injections of incoBoNT-A (≤ 300 U in ≤ 60 sites into painful area) or placebo and followed for 20 weeks. The primary endpoint was the change from baseline in average daily pain (ADP) intensity (0–10 NRS) at weeks 2–12 (combined PHN & PS/PTNP). Secondary endpoints included the change in neuropathic pain symptom inventory (NPSI, 0–100 points) total score at weeks 2–12 and safety.

Results: The 60 PS/PTNP patients (28 incoBoNT-A, 31 placebo) were highly heterogeneous, with 48 distinct diagnoses (many potentially indicating mixed pain). Groups differed in diagnoses, PNP duration, pre-treatment history, and baseline characteristics. The endpoints did not significantly separate from placebo in the combined set. For PS/PTNP, LSM changes from baseline of ADP intensity and NPSI at weeks 2–12 for incoBoNT-A were -0.13 and -22.15. Placebo response was high (ADP intensity: -0.64; NPSI: -22.84), exceeding the changes for placebo observed in the PHN group (ADP intensity: -0.16; NPSI: -5.63). No new safety concerns were detected.

Conclusion: Improvements in ADP/NPSI in the PS/PTNP population were masked by very high placebo response. Treatment with incoBoNT-A is safe, but group heterogeneities make the comparison to placebo inconclusive. Careful patient selection is essential for future research.

EPO-0717 | Neuropathic pain in multiple sclerosis: Discrepancies between DN4 screening and neurophysiological measures

N. Drobinska; E. Sukockiene; M. Uginet; P. Lalive; A. Lascano
Department of Clinical Neurosciences, Division of Neurology, Geneva University Hospitals and University of Geneva, Switzerland

Background and aims: Pain is a common and disabling symptom in multiple sclerosis (MS), yet its pathophysiological mechanisms remain poorly understood. Clinical assessment of neuropathic pain relies largely on subjective screening tools such as the DN4 questionnaire. This study aimed to characterize pain phenotype in MS using the DN4 score and to determine its relationship with objective neurophysiological markers of nociceptive and non-nociceptive pathway function assessed by laser-evoked (LEPs) and somatosensory evoked potentials (SEPs).

Methods: Fifty MS patients reporting pain underwent standardized clinical evaluation, including DN4, pain intensity (VAS), fatigue (FSMC), anxiety and depression (HADS), and disability (EDSS). LEPs were recorded after laser stimulation of the hand and foot dorsum, and SEPs following median and tibial nerve stimulation. Neurophysiological parameters were compared between patients with DN4 <4 and ≥4. Logistic regression, non-parametric group comparisons, and correlation analyses were performed.

Results: Neuropathic pain phenotype (DN4 ≥4) was identified in 56% of patients. DN4 showed moderate correlation with pain intensity and fatigue, and weakly with anxiety, but showed no

significant association with LEPs or SEPs. Logistic regression confirmed that no neurophysiological measure independently predicted DN4 ≥4 status. LEP and SEP abnormalities were not significantly correlated, suggesting dissociated involvement of nociceptive and large-fiber pathways.

Conclusion: In MS, DN4-defined pain phenotype reflects subjective symptom burden rather than objective sensory pathway dysfunction. Its limited correlation with neurophysiological measures highlights pain's multidimensional nature in MS. LEPs and SEPs provide complementary mechanistic insights, supporting a multimodal, mechanism-oriented approach to pain assessment and management.

Disclosure: Natalia Drobinska, Eglė Sukockiene, Marjolaine Uginet, Patrice H. Lalive have nothing to disclose. Agustina M. Lascano received honoraria for advisory from ATC Therapeutics, Biogen, Johnson and Johnson, Roche, Argenx, Amgen and Alexion, and speakers' fees from Sanofi, CSL-Behring, UCB, Takeda non-related to the current study.

EPO-0718 | Sexually dimorphic neuroimmune pathways in chronic pain: A comprehensive systematic review of cellular and molecular mechanisms

N. Brezic¹; S. Gligorevic²; A. Sic³; V. Tseriotis⁴; N. Knezevic³

¹*Department of Medicine, NYCHH/Lincoln, Bronx, USA;*

²*Department of Medicine, NYCHH/Jacobi Medical Center – North Central Bronx Hospital, Bronx, USA;* ³*Department of Anesthesiology, Advocate Illinois Masonic Medical Center, Chicago, USA;* ⁴*Department of Neurology, Agios Pavlos General Hospital of Thessaloniki, Leoforos Ethnikis Antistaseos 161, Kalamaria, Thessaloniki, Greece*

Background and aims: Chronic pain shows marked sex differences in prevalence, severity, and persistence, suggesting underlying biological mechanisms beyond psychosocial factors. Increasing evidence indicates that sexually dimorphic neuroimmune pathways play a central role in chronic pain pathophysiology.

Methods: This systematic review was conducted according to PRISMA 2020 guidelines and synthesized human clinical and translational studies examining sex-specific neuroimmune and glial mechanisms in adult chronic pain. Multiple biomedical databases were searched from inception to December 2025, and studies reporting sex-stratified neuroimmune outcomes were included.

Results: Across pain conditions, males predominantly exhibited microglia-driven mechanisms, particularly P2X4 receptor-mediated signaling and BDNF-dependent neuronal disinhibition. In contrast, females showed greater involvement of adaptive immune pathways, including CD4⁺ and CD8⁺ T cell signaling, chemokine cascades, and astrocyte-mediated neuroimmune interactions. Cytokine profiles, immune cell phenotypes, and neuroimaging markers further distinguished sex-specific pain mechanisms. Heterogeneity and limited sex-stratified power constrained quantitative synthesis.

Conclusion: Chronic pain comprises biologically distinct, sex-dependent neuroimmune mechanisms, supporting the need for sex-informed biomarkers and precision medicine approaches in pain management.

Disclosure: Nothing to disclose

M. Sinkovic; S. Rakusa; M. Rakusa
Division of Neurology, University Medical Centre Maribor, Slovenia

Background and aims: Pain is highly prevalent in older adults. However, it may be overlooked when cognitive deficits limit self-report. Our study aimed to determine whether demographic factors and cognitive status are associated with pain.

Methods: We recruited individuals who completed two pain questionnaires (Doloplus-2 and NOPPAIN) and a cognitive evaluation. Descriptive statistics were performed, and group comparisons between cognitively impaired and cognitively preserved individuals were conducted using t-tests. Pain presence was defined as any non-zero subjective pain rating (VAS ≥ 1 , range 0–6). Factors associated with pain presence were examined using multivariable logistic regression.

Results: A total of 153 patients were included; 48 (31%) had cognitive impairment. The prevalence of pain was similar in cognitively impaired and unimpaired patients (86.0% vs 83.5%). Patients with cognitive impairment were significantly older (76.8 SD 9.5 vs 61.5 SD 15.4 years, $p < 0.001$), with higher subjective pain intensity (VAS 2.54 SD 1.47 vs 1.94 SD 1.24, $p = 0.010$), higher NOPPAIN total scores (2.54 SD 1.47 vs 1.95 SD 1.23, $p = 0.011$) and substantially higher Doloplus-2 total scores (13.6 SD 6.5 vs 7.8 SD 5.1, $p < 0.001$) compared with cognitively preserved patients. In adjusted logistic regression analysis, higher age was independently associated with pain presence (OR 1.04 per year, 95% CI 1.00–1.07, $p = 0.026$), while cognitive impairment and sex were not.

Conclusion: Pain is common across cognitive groups and increases with age. Cognitive impairment doesn't independently influence pain presence and shouldn't reduce clinical awareness of pain detection.

Disclosure: Nothing to disclose.

EPO-0720 | Restoring circadian rhythms with a citrus flavonoid to improve sleep and reduce neuropathic pain

W. Dai; V. Palada
Department of Physiology, SleepWell Research Program, Faculty of Medicine, University of Helsinki, Helsinki, Finland

Background and aims: Neuropathic pain (NP) disrupts sleep architecture and circadian regulation, impairing quality of life. Nobiletin, a polymethoxylated citrus flavonoid, amplifies molecular clock oscillations and may stabilise sleep–wake dynamics. We hypothesised that nobiletin alleviates NP by restoring circadian rhythmicity and improving sleep in mice after spared nerve injury (SNI).

Methods: Adult male and female PER2::LUC C57BL/6 mice underwent SNI. Nobiletin (10 mg/kg/day) or vehicle was continuously delivered via osmotic mini-pumps. Telemetric EEG/EMG, body temperature and locomotor activity were recorded at baseline and post-injury. Mechanical allodynia was assessed with von Frey filaments and dynamic brush testing. Ex vivo bioluminescence from DRG, spinal cord and prefrontal cortex explants was monitored to quantify Per2-driven

rhythmicity; circadian metrics were analysed using cosinor and CircaCompare. Procedures complied with institutional animal-care guidelines.

Results: SNI induced robust ipsilateral mechanical hypersensitivity. Continuous nobiletin significantly attenuated dynamic brush allodynia ($p < 0.01$) but did not alter von Frey thresholds. At day 7 post-SNI, REM sleep was reduced in both sexes, while NREM exhibited phase-dependent changes (increase during dark phase; reduction in males during light phase). In female DRG, Per2::Luc bioluminescence rhythms showed altered mesor, reduced amplitude and shifted acrophase versus sham (all $p < 0.001$). Ongoing analyses test whether nobiletin rescues REM sleep and tissue-clock amplitude.

Conclusion: Preliminary data support nobiletin as a chronotherapeutic candidate that selectively mitigates NP-related behavioural hypersensitivity and stabilises sleep and circadian oscillations. If confirmed, this non-opioid, clock-targeting approach could inform timed interventions to improve sleep and reduce NP.

Disclosure: Nothing to disclose.

EPO-0721 | Headache during IVF treatment: A comparative evaluation of GnRH agonist and antagonist protocols

Z. Kalı¹; F. Algül²; Y. Kablan³

¹Obstetrics and Gynecology Department, Gozde Hospital, Malatya, Türkiye; ²Department of Neurology, Inonu University, Malatya, Türkiye; ³Department of Neurology, Inonu University, Malatya, Türkiye

Background and aims: Controlled ovarian hyperstimulation during in vitro fertilization (IVF) involves marked hormonal changes. GnRH agonist and antagonist protocols differ in the timing and dynamics of hypothalamic–pituitary axis suppression, yet headache during IVF treatment remains poorly investigated. This study aimed to compare headache frequency between GnRH agonist and antagonist protocols and to assess the temporal association between headache occurrence and antagonist administration.

Methods: Infertile women undergoing IVF/ICSI were retrospectively evaluated by protocol, with recombinant FSH stimulation and recorded headache reports, including post-cetorelix events

Results: A total of 46 women undergoing IVF were included in the analysis (GnRH agonist: $n = 18$; GnRH antagonist: $n = 28$). Headache was reported more frequently in patients treated with the GnRH antagonist protocol compared with those receiving the agonist protocol (53.6% vs. 22.2%). In the GnRH antagonist group, headache symptoms were most commonly reported within the first 24 hours following cetorelix administration, with 9 of 15 patients (60.0%) experiencing headache during this period. The temporal distribution of headache episodes was evaluated descriptively. Headache frequency appeared to increase across rising estradiol categories, being reported in 25.0% of patients at 250–1000 pg/mL, 43.8% at 1001–2000 pg/mL, 64.3% at 2001–3000 pg/mL, and 87.5% at levels above 3000 pg/mL; this pattern may reflect a descriptive trend rather than a causal association.

TABLE 1 Clinical characteristics and headache features according to ovarian stimulation protocol.

Parameter	GnRH Agonist (n = 18)	GnRH Antagonist (n = 28)
Age (years), mean ± SD	31.4 ± 4.8	32.1 ± 5.2
Duration of infertility (years), median (range)	4 (1–9)	5 (1–11)
Primary infertility, n (%)	11 (61.1)	18 (64.3)
Secondary infertility, n (%)	7 (38.9)	10 (35.7)
Any headache during IVF, n (%)	4 (22.2)	15 (53.6)
Migraine-like headache, n (%)	3 (16.7)	8 (28.6)
Tension-type headache, n (%)	1 (5.6)	5 (17.9)
Non-specific headache, n (%)	0 (0)	2 (7.1)
Headache severity (VAS), median (IQR)	4 (3–5)	6 (5–7)
Headache onset within 24 h after Cetrotide®, n (%)	—	9/15 (60.0)
Nausea, n (%)	1 (5.6)	7 (25.0)
Photophobia, n (%)	0 (0)	1 (3.6)
Dizziness, n (%)	1 (5.6)	6 (21.4)
Paresthesia, n (%)	0 (0)	2 (7.1)
Persistent neurological deficit	None	None

TABLE 2 Temporal distribution of headache occurrence in the GnRH antagonist protocol.

Headache Type	Before Cetrotide®	Within 24 Hours After Cetrotide®	24–48 Hours After Cetrotide®
Migraine-like	1	5	5
Tension-type	2	3	3
Non-specific	1	1	1

Headache timing was evaluated descriptively in relation to cetrotide administration. More than one headache episode could be reported by the same patient.

FIGURE 1 Descriptive distribution of headache frequency across estradiol level categories.

Conclusion: Headache is more frequently reported during IVF cycles using GnRH antagonist protocols compared with agonist protocols. The early onset of symptoms following antagonist administration may be related to acute hormonal changes, rather than the ovarian stimulation process itself.

Disclosure: The authors declare no financial or non-financial conflicts of interest related to this study.

Peripheral Nerve Disorders 1

EPO-0722 | Reliability of predicted outcomes by modified Erasmus Guillain Barre outcome score mEGOS versus followup outcomes in Guillain Barré syndrome patients

A. Pai¹; N. Mukhi¹; D. Varma²
¹Department of Neurology, Kasturba Medical College Manipal Academy Of Higher Education, Manipal, India; ²Department of Infectious Diseases, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India

Background and aims: Neuroprognostication in GBS relies on clinical assessments and neurophysiological evaluations. The mEGOS score, determined at hospital admission, predicts the likelihood of GBS patients achieving independent ambulation during follow-up.

Methods: This study aimed to evaluate the reliability of predicted outcomes based on the mEGOS score at hospital admission by comparing them to actual follow-up outcomes assessed using the Hughes Disability Scale at three months. A Hughes Disability Scale score of 0–2 was stratified as a good outcome and 3–6 as a poor outcome. A mEGOS score of 0–3 indicated a good outcome and 4–9 indicated a poor outcome.

Results: Among the 113 patients analysed from records of a GBS cohort admitted to our tertiary hospital, 64% were male, and 72% presented within one week of symptom onset. Nineteen per cent required mechanical ventilation. Nerve conduction studies at admission were demyelinating in 21%, axonal in 14%, equivocal in 44%, and normal in 13%. Among the 88 patients with all parameters, the mEGOS score at admission had a sensitivity of 45.5% and a specificity of 50.6% for predicting a poor outcome at three months. The positive predictive value was 11.6% while the negative predictive value was 86.7%.

Conclusion: The mEGOS score, therefore, is primarily an early triage and reassurance tool rather than a robust predictor of disability. Its high negative predictive value emphasises its clinical utility in identifying patients who are unlikely to experience poor outcomes, but since it tends to overestimate the risk of poor outcome it has a low positive predictive value.

Disclosure: Nothing to disclose.

EPO-0723 | Safety profile of tanruprubart (ANX005) in patients with Guillain-Barré syndrome: A randomised, placebo-controlled phase 3 study

E. McCracken; H. Kroon; G. Morrison; E. Pulkstenis; A. Johnson
Annexon Biosciences, Brisbane, USA

Background and aims: Guillain-Barré syndrome (GBS) is a rare, life-altering, neuromuscular emergency, where classical complement activation contributes to progressive muscle weakness. Tanruprubart (ANX005), a humanised monoclonal IgG4 antibody, selectively inhibits complement component C1q. Infections with encapsulated bacteria and systemic autoimmunity were events of interest.

TABLE 1 Summary of TEAEs.

TEAE, n (%)	Tanruprubart 30 mg/kg (N=79)	Tanruprubart 75 mg/kg (N=81)	Placebo (N=81)
TEAEs	79 (100)	80 (98.8)	79 (97.5)
Related to study drug	24 (30.4)	34 (42.0)	5 (6.2)
Grade ≥3 TEAEs*	32 (40.5)	36 (44.4)	35 (43.3)
SAEs	15 (19.0)	9 (11.1)	15 (18.5)
Related to study drug	1 (1.3)	5 (6.2)	1 (1.3)
TEAEs of special interest	30 (38.0)	36 (44.4)	15 (18.5)
IRRs	24 (30.4)	32 (39.5)	4 (4.9)
Severe (Grade 3)†	3 (3.8)	4 (4.9)	0
Life-threatening (Grade 4)†	1 (1.3)	5 (6.2)	1 (1.3)
Fatal (Grade 5)†	0	0	0
Rash	18 (22.8)	12 (14.9)	2 (2.5)
Infection with encapsulated bacteria	13 (16.5)	10 (12.3)	12 (14.8)

*Severity based on National Cancer Institute Common Terminology Criteria for Adverse Events Version 5.0

†After unblinding of data, it was found that 1 patient in the placebo group had apparently received tanruprubart and had treatment-related SAEs of Grade 3 myocardial infarction and Grade 4 IRR.

GBS, Guillain-Barré Syndrome; IRR, infusion-related reaction; SAE, serious adverse event; TEAE, treatment-emergent adverse event.

Methods: In GBS-02 (Phase 3), participants ≥16years with a recent GBS diagnosis without planned plasma exchange or intravenous immunoglobulins were randomised to receive a single intravenous dose of tanruprubart 30 or 75 mg/kg or placebo. Antihistamine and acetaminophen were administered pre-infusion to mitigate for infusion related reactions (IRRs). Vaccinations and prophylactic antibiotics were not mandated. Safety over 6 months included treatment-emergent adverse events (TEAEs), serious adverse events (SAEs), investigator-assessed treatment-related TEAEs, and events of special interest (IRRs; encapsulated-bacteria infections; systemic immune disorders other than GBS).

Results: The safety set comprised 241 participants; 95% did not receive prophylactic antibiotics. 98.8% reported ≥1 TEAE (Table 1). Treatment-related TEAEs were mostly IRRs (rash), which were generally mild/moderate and transient without infusion interruption. One participant per group discontinued due to an IRR; none withdrew due to TEAEs. Encapsulated-bacteria infection rates were similar across groups. TEAEs and SAEs were consistent with GBS morbidity. No systemic autoimmune diseases other than GBS occurred. Three non-treatment related deaths occurred in each group.

Conclusion: Single-dose tanruprubart was generally well-tolerated. Common TEAEs were associated with disease course. Tanruprubart did not increase risk of infections with encapsulated bacteria, despite most participants not receiving prophylactic antibiotics. Findings support the promising potential of tanruprubart in GBS.

Disclosure: The study was sponsored by Annexon Biosciences (Brisbane, CA, USA). EM, H-AK, GM, EP, AJ: Employment with and shareholder of Annexon Biosciences.

EPO-0724 | Tanruprubart, anti-C1q therapy, accelerates recovery and reduces ventilation in severe Guillain-Barré Syndrome: Results from the phase 3 GBS-02 trial

H. Kroon¹; G. Morrison¹; E. Pulkstenis¹; Q. Deen Mohammad²; K. Gorson³

¹Annexon Biosciences, Brisbane, USA; ²National Institute of Neuroscience (NINS), Dhaka, Bangladesh; ³Tufts University School of Medicine, Boston, USA

Background and aims: Guillain-Barré syndrome (GBS) is a severe, autoimmune, life-altering disorder mediated by classical

complement affecting peripheral nerves, resulting in muscle weakness and often prolonged recovery. The safety and efficacy of tanruprubart, a C1q inhibitor designed to treat patients with GBS, was evaluated in the randomised placebo-controlled Phase 3 trial GBS-02 (NCT04701164). Here, we report on prespecified measures of clinical benefit associated with patient recovery time and resource utilisation.

Methods: Patients with GBS aged ≥16years and a baseline GBS disability score (GBS-DS) of 3, 4, or 5 were randomised 1:1:1 to a single intravenous (IV) infusion of tanruprubart (30 or 75 mg/kg) or placebo. Neither IV immunoglobulin or plasma exchange was given. Time to walking independently (GBS disability score ≤2) was analysed using time-to-event methods. Duration of mechanical ventilation and intensive care unit (ICU) stay were assessed using the zero-inflated negative binomial (ZINB) model (imputed for death).

Results: A total of 241 patients were randomised. Patients who received tanruprubart 30 mg/kg ($n=79$) could walk independently a median 31 days earlier ($p=0.0211$) compared with placebo ($n=81$). The duration of mechanical ventilation was a median 28 days less ($p=0.0356$) compared with placebo. The median ICU stay for the tanruprubart group was 7 days less than placebo ($p=0.5306$).

Conclusion: In this Phase 3 study of severe GBS, tanruprubart improved recovery-related outcomes, including earlier independent walking and shorter ventilation duration, with the possibility of shorter time in the ICU, consistent with clinically meaningful benefit.

Disclosure: The study was sponsored by Annexon Biosciences (Brisbane, CA, USA). HAK, GM, EP: Employment with and shareholder of Annexon Biosciences QDM: Consultancy/advisory role with Annexon Biosciences KCG: Consultancy/advisory role with Annexon Biosciences, argenx, Janssen, and Sanofi.

EPO-0725 | Targeted immunotherapy with Tanruprubart (ANX005) reduces ventilation requirements in Guillain-Barré syndrome: A phase 3 subgroup analysis

H. Kroon¹; Q. Deen Mohammad²; J. Navarro³; G. Morrison¹; J. Du¹; R. Gerwien¹; K. Abul Kalam Azad⁴; Z. Islam⁵; K. Gorson⁶

¹Annexon Biosciences, Brisbane, USA; ²National Institute of Neuroscience (NINS), Dhaka, Bangladesh; ³Cotabato Regional Medical Center, Cotabato City, Philippines; ⁴Dhaka Medical College and Hospital, Dhaka, Bangladesh; ⁵Gut-Brain Axis Laboratory, Infectious Diseases Division, icddr, Dhaka, Bangladesh; ⁶Tufts University School of Medicine, Boston, USA

Background and aims: Guillain-Barré syndrome (GBS) is a rare, life-altering neuromuscular emergency requiring hospitalisation, and mechanical ventilation in severe cases. Tanruprubart (ANX005) is a targeted, humanised monoclonal IgG4 antibody that rapidly and selectively inhibits classical complement component C1q. In GBS-02, a Phase 3, randomised, double-blind, placebo-controlled trial of tanruprubart 30 and 75 mg/kg (NCT04701164), a single infusion of tanruprubart 30 mg/kg led to early and sustained clinical benefit, and was well tolerated. This analysis evaluated the effect of tanruprubart on the duration of mechanical ventilation in GBS-02.

TABLE 1 Duration of ventilation by baseline disease characteristics.

	Tanruprubart 30mg/kg (N=79)		Placebo (N=82)	
	Participants ventilated, n/N	Median duration (IQI)	Participants ventilated, n/N	Median duration (IQI)
Overall	13/79	27.0 (15, 42)	14/82	48.9 (30, 220)
Baseline MRCss				
0–20	13/38	27.0 (15, 47)	9/38	125.0 (46, 181)
21–40	0/17	180.0 (35, 181)	6/33	51.4 (30, 100)
41–60	1/4	13.0 (–)	0/7	–
Baseline GBS-DI				
1	0/12	–	0/30	–
2	9/36	28.0 (15, 47)	9/36	142.0 (31, 181)
3	13/31	22.0 (14, 114)	10/33	45.5 (26, 220)
Baseline NfL (pg/mL)				
<352.64	0/31	40.5 (34, 114)	0/39	137.0 (34, 181)
≥352.64	0/47	25.0 (18, 18)	1/40	48.0 (30, 242)

IQI, Interquartile range; MRCss, Medical Research Council sum score; N, total number of participants with the given characteristic; n, participants with the given characteristic who received mechanical ventilation; NfL, neurofilament light

Methods: Individuals aged ≥16 years with a recent GBS diagnosis and a GBS-disability score (GBS-DS) of 3 (can walk 10 metres with help) to 5 (requiring ventilation) were enrolled. Ventilation duration was analysed using a zero-inflated negative binomial model; participants who died were imputed to 26 weeks (trial end). Ventilation duration was assessed overall and by baseline disease characteristics assessing muscle weakness (Medical Research Council sumscore [MRCss], 0=tetraplegic, 60=normal), a stratification factor (GBS-DS) and axonal damage (neurofilament-light [NfL] levels).

Results: Mechanical ventilation requirements were similar across treatment groups (Table 1). Among ventilated patients, approximately 75% were already ventilated at randomisation. Duration of ventilation was median 27 days shorter with tanruprubart 30 mg/kg versus placebo (Table 1). This difference was particularly notable in participants with greater muscle weakness (lowest MRCss tertile 0–20) and worse axonal damage (median NfL ≥352.64) at baseline compared with their healthier counterparts (Table 1).

Conclusion: Tanruprubart reduced the duration of mechanical ventilation in individuals with GBS, especially among those with more severe disease.

EPO-0726 | Comparison of anti-MAG antibody-associated neuropathy and distal or predominantly sensory CIDP: An analysis of the Portuguese CIDP registry

M. Henriques; S. Bernardo; D. Carapinha; S. Cruz; P. Study Consortium
Department of Neurology, Hospital Prof. Dr. Fernando Fonseca, Lisbon, Portugal

Background and aims: Distal or predominantly sensory chronic inflammatory demyelinating polyneuropathy (CIDP) and anti-myelin-associated glycoprotein (anti-MAG) neuropathy share overlapping clinical features but differ in prognosis and treatment response. Early differentiation is important, particularly when anti-MAG antibody testing is unavailable.

Methods: Patients from the Portuguese CIDP registry were retrospectively analyzed. Diagnoses were reviewed according to the 2021 EAN/PNS criteria. Anti-MAG neuropathy was defined by antibody titers >7000 BTU. Demographic data, disease duration, initial symptoms and signs, cerebrospinal fluid (CSF) findings, nerve conduction studies, and response to therapy were evaluated.

Results: Sixty patients were included: 48 with distal/sensory CIDP and 12 with anti-MAG neuropathy. Time to diagnosis was significantly longer in the anti-MAG group ($p=0.013$), while age at onset was similar. Albuminocytologic dissociation and higher CSF protein levels were more frequent in CIDP ($p<0.001$ and $p=0.014$, respectively). Muscle atrophy at presentation was more common in CIDP ($p=0.016$). Neurophysiological studies showed abnormalities predominantly restricted to the lower limbs in anti-MAG neuropathy ($p<0.001$), whereas sural sparing was exclusive to CIDP ($p=0.003$). CIDP patients also exhibited higher peroneal and tibial CMAP amplitudes and shorter distal peroneal latency. Improvement with intravenous immunoglobulin (IVIg) was observed in 45.8% of CIDP patients compared with 8.3% of anti-MAG patients ($p=0.044$). In multivariate analysis, sural sparing and response to IVIg remained independent predictors of CIDP.

Conclusion: Differentiating distal/sensory CIDP from anti-MAG neuropathy remains challenging. However, sural sparing, albuminocytologic dissociation, and particularly response to IVIg support a diagnosis of CIDP and may guide earlier therapeutic decisions.

Disclosure: Nothing to disclose.

EPO-0727 | Sensory recovery following digital nerve repair using conduits versus autologous nerve grafts: A systematic review and meta-analysis

M. Elkasaby¹; A. Omran²; Hamdeno¹; A. Hassan¹
¹Al-Azhar University, Cairo, Egypt; ²Plastic Surgery Department, Al-Azhar University, Damietta, Egypt

Background and aims: Digital nerve injuries can impair sensory function and hand performance. Autologous nerve grafting (ANG) remains the standard for repairing nerve gaps but is associated with donor site morbidity. Nerve conduits—such as collagen-based, chitosan-based, and muscle-in-vein types—are emerging alternatives that avoid these complications. This systematic review and meta-analysis compared the effectiveness and safety of nerve conduits versus ANG for sensory recovery after digital nerve repair.

Methods: A systematic search of PubMed, Embase, Scopus, and Web of Science was conducted through July 2025 following PRISMA guidelines. Included studies were randomized controlled trials and observational studies comparing conduits with ANG. Primary outcomes were static and moving two-point discrimination (S2PD and M2PD); complication rates were secondary. Data were pooled using a random-effects model with

mean differences (MD) and risk ratios (RR) and 95% confidence intervals (CI).

Results: Five studies with 214 patients were included. Sensory recovery was similar between conduits and ANG for S2PD (MD = -0.21; 95% CI: -2.25 to 1.83; $p=0.84$) and M2PD (MD = -0.67; 95% CI: -2.00 to 0.66; $p=0.84$). Chitosan-based conduits showed significantly better S2PD outcomes than ANG (MD = -2.57; 95% CI: -3.40 to -1.74; $p<0.0001$). Complication rates were comparable overall (RR = 2.36; $p=0.08$), but RCTs showed fewer complications with conduits (RR = 3.32; $p=0.03$).

Conclusion: Nerve conduits provide similar sensory outcomes to ANG and may reduce complications, especially with chitosan-based designs. They represent a promising alternative for digital nerve repair.

Disclosure: Nothing to disclose.

EPO-0728 | Tanruprubarb in GBS: Targeting early complement-associated inflammation conserved across the clinical spectrum and regions

P. Paliwal¹; H. Kroon¹; Z. Islam²; D. Lorenz³; E. Chang¹; Y. Ru⁴; T. Yednock¹; R. Artis¹; K. Sheikh⁵; C. Sommer⁶

¹Annexon Biosciences, Brisbane, USA; ²Gut-Brain Axis

Laboratory, icddr,b, Dhaka, Bangladesh; ³Excelra Inc, Boston, USA; ⁴Soley Therapeutics, South San Francisco, CA, USA; ⁵McGovern Medical School, UTHealth, Houston, USA;

⁶University Hospital Würzburg, Würzburg, Germany

Background and aims: Guillain-Barré syndrome (GBS) is an acute, immune-mediated polyradiculoneuropathy resulting in mild weakness to severe paralysis. Converging evidence supports an early pathogenic window where classical complement activation and innate immune effector mechanisms drive neuroinflammation and early nerve injury.

Methods: We conducted serum proteome-wide longitudinal profiling of acute inflammatory effectors using the Olink® Explore HT platform in GBS patients from a Ph3, randomised, placebo-controlled study of anti-C1q therapy tanruprubarb in Asia ($n=139$), an IVIg/PE-treated US cohort ($n=14$) and healthy controls ($n=10$). Prespecified prognostic and clinical strata were defined.

Results: Across the tanruprubarb Ph3 and IVIg/PE US cohorts, 352 proteins were elevated at baseline, including 81 proteins mapping to the top 3 Reactome inflammatory pathways, with ~2–4-fold higher levels versus healthy controls. In placebo-treated subjects, inflammatory signature rose/remained high, reaching a consistent peak at ~Day 8, then declining below baseline by Day 29, indicating a brief early inflammatory phase. In contrast, tanruprubarb produced rapid, broad suppression of these pathway-linked proteins by Day 8, confirmed in the top 12 marker panel spanning cytokine signaling, interferon signaling, innate immune pathways, and neutrophil associated markers. The IVIg/PE US cohort exhibited no early reduction in these markers.

Conclusion: Across geographically and clinically diverse cohorts, GBS demonstrated a conserved, complement-linked early inflammatory signature peaking at Day 8, defining a narrow window where short-duration upstream complement inhibition is most impactful. Tanruprubarb rapidly and durably suppressed this inflammatory cascade across strata and regions, highlighting C1q inhibition as a mechanism-targeted strategy for GBS

and supporting extrapolation of these biomarker effects to US patients.

Disclosure: The study was sponsored by Annexon Biosciences (Brisbane, CA, USA). EPO-0729 | Role of magnetic resonance neurography in CIDP: Experience from a single center

S. Palma¹; D. Pinto²; V. Teixeira²; C. Santos Silva^{1,3}; D. Tribovane²; P. Pereira¹

¹Department of Neurology, Garcia de Orta Hospital, Almada-Seixal Local Health Unit, Almada, Portugal; ²Department of Neuroradiology, Garcia de Orta Hospital, Almada-Seixal Local Health Unit, Almada, Portugal; ³Faculty of Medicine, Institute of Molecular Medicine, University of Lisbon, Lisbon, Portugal

Background and aims: According to the European Academy of Neurology/Peripheral Nerve Society guidelines, magnetic resonance (MR) imaging is a supportive diagnostic criterion for chronic inflammatory demyelinating polyneuropathy (CIDP). The aim of this study was to evaluate MR neurography findings in patients with suspected or confirmed CIDP and to compare them with patients with alternative diagnoses.

Methods: A longitudinal retrospective analysis included all patients who underwent MR neurography at Hospital Garcia de Orta between July 1, 2024, and June 31, 2025, excluding examinations for traumatic indications. Patients were stratified into two groups: those with suspected or confirmed CIDP and those with other diagnoses.

Results: Thirteen patients were included: eight with suspected or diagnosed CIDP and seven controls (83.3% vs. 57.1% male; median ages 64.5 and 56.7 years, respectively). Two patients with newly diagnosed CIDP/possible CIDP showed MR neurography abnormalities: a 65-year-old woman with suspected classic CIDP demonstrated a diffuse thickening of the bilateral cervical plexus; and a 79-year-old man with suspected right lower limb focal CIDP showed nerve thickening and post-gadolinium enhancement of the right lumbosacral plexus. No MR neurography

FIGURE 1 MR neurography.

FIGURE 2 MR neurography.

abnormalities were observed in clinically stable CIDP patients receiving immunoglobulin therapy ($n = 2$), patients with possible CIDP without electrophysiological criteria ($n = 2$), or in controls. **Conclusion:** MR neurography revealed structural abnormalities exclusively in patients with a newly CIDP diagnosis, supporting its utility as a diagnostic tool. The absence of abnormalities in clinically stable, treated CIDP patients, suggests that MR neurography may also reflect treatment response and disease activity, underlying its potential value as a prognostic biomarker.

Disclosure: Nothing to disclose.

EPO-0730 | Early ultrasonographic swelling ratio of the facial nerve as a prognostic threshold for functional recovery in acute facial palsy

S. Park; S. Lee; S. Kim; Y. Kim

Department of Acupuncture and Moxibustion Medicine, Kyung Hee University Medical Center, Seoul, Republic of Korea

Background and aims: Early prognostic evaluation in acute facial palsy is difficult because early clinical grading is subjective and electroneurography (ENoG) is unreliable during the first 1–2 weeks after onset. An objective marker applicable in the early stage is needed. We investigated whether early ultrasonographic measurement of facial nerve swelling predicts outcomes at 3 months.

Methods: A retrospective review was conducted in 22 patients with early peripheral facial palsy within 14 days of onset. Facial nerve ultrasonography was performed using a standardized protocol, with nerve diameter measured below the earlobe. The swelling ratio was defined as the affected-to-unaffected side diameter ratio. Outcomes at 3 months were assessed using the House–Brackmann (HB) grade and Sunnybrook Facial Grading System (SFGS). Poor outcome was defined as HB grade >1 or SFGS <90 . Prognostic performance was evaluated using receiver operating characteristic (ROC) analysis.

Results: ROC analysis showed the facial nerve swelling ratio predicted 3-month outcomes. A cut-off value of 1.27 discriminated incomplete recovery (HB grade >1 ; AUC 0.750, sensitivity 75.0%, specificity 100.0%). Functional impairment (SFGS <90) was predicted with an AUC of 0.886, sensitivity 85.7%, and specificity 100.0%. Patients with ratios ≤ 1.27 showed near-complete recovery (mean SFGS 93.2), whereas those with ratios >1.27 had poorer outcomes (mean SFGS 70.2; $p = 0.0182$). In contrast, ENoG thresholds ($\geq 85\%$ and $\geq 90\%$) showed low discriminative ability (AUC 0.21–0.33).

FIGURE 1 Receiver operating characteristic curves comparing early ultrasonographic facial nerve swelling ratio and electroneurography (ENoG) for prediction of 3-month outcomes in acute facial palsy.

Conclusion: An early facial nerve diameter ratio greater than 1.27 was associated with incomplete recovery and functional impairment at 3 months. Ultrasonography may provide a objective tool for early prognosis in facial palsy.

Disclosure: This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (RS-2022-KH127692).

EPO-0731 | Defining a standardized facial movement protocol for AI-based video analysis in facial nerve palsy: A Delphi study

S. Lee¹; S. Bae²; I. Jang²; S. Lee¹

¹Department of Acupuncture and Moxibustion, Kyung Hee University College of Korean Medicine, Kyung Hee University Medical Center, Seoul, Republic of Korea; ²Department of Computer Engineering, Hankuk University of Foreign Studies, Seoul, Republic of Korea

Background and aims: Reliable facial nerve palsy assessment is hindered by rater dependency and the limited precision of gross grading scales like House–Brackmann. Although our static image-based artificial intelligence (AI) model achieved high accuracy (Quadratic Weighted Kappa: \$0.7594\$), static analysis cannot evaluate essential dynamic features such as movement trajectories and velocity. This study aimed to define a standardized dynamic assessment framework via expert consensus, serving as a reference foundation for next-generation video-based AI applications.

Methods: A Delphi study was conducted with 10 specialists (> 3 years of clinical experience). Twenty-eight video-based assessment items—encompassing basic movements, contracture, synkinesis, and functional metrics—were derived from clinical practice and literature. Items were rated on a 9-point Likert scale. Consensus was predefined as a Median (Mdn) ≥ 7.0 , Interquartile Range (IQR) ≤ 2.0 , Content Validity Ratio (CVR) ≥ 0.62 , and an agreement rate $\geq 70\%$.

Results: In the first round, consensus was achieved for 20 of 28 proposed items by meeting all predefined statistical thresholds. Core facial movements (eye closure, smiling, and lip puckering) and primary metrics (symmetry and range of motion) demonstrated the highest consensus (Mdn: 9.0, IQR: 0.0, CVR ≥ 0.80). In contrast, items involving natural speech tasks and speech-rate variability showed lower agreement and were identified for further refinement in subsequent validation steps.

FIGURE 1 Main results of the first Delphi round for video-based facial nerve palsy assessment. Median scores and interquartile ranges are shown. Items in orange did not meet consensus criteria and require further refinement.

Conclusion: This study identifies expert-validated components for video-based assessment, addressing the functional gap between static image evidence and dynamic clinical requirements. The ongoing second Delphi round will finalize this framework, providing a critical foundation for high-precision, objective digital monitoring of facial nerve palsy in clinical and research settings.

Disclosure: This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (RS-2025-02220534). The authors declare no other conflicts of interest.

Headache 5

EPO-0732 | Epidemiology and clinical characteristics of nummular headache in observational studies: A systematic review and meta-analysis

A. Osiowski; M. Osiowski; D. Tattera
Jagiellonian University Medical College, Kraków, Poland

Background and aims: Nummular headache (NH) is a rare primary headache disorder with unknown epidemiology and prevalence of the most common clinical characteristics - this study aimed to establish all of the crucial aspects of NH.

Methods: Major databases were thoroughly searched for observational studies reporting the relevant data regarding NH.

Results: Out of initial 2441 records, 17 studies met all of the inclusion criteria. The pooled mean age of onset of NH was 46.91 (95% CI: 43.85–49.96). The PPE of NH in adult patients evaluated for a headache in a clinic-based setting was 0.7% (95% CI: 0.2–2.4), with slight female predominance (females=0.5%, 95% CI: 0.2–1.4 vs males=0.3%, 95% CI: 0.1–0.8). The majority of patients (69.4%, 95% CI: 58.1–78.8) experience chronic course of NH. The shape of the headache was round/circular in 78.4% (95% CI: 71.9–83.7) and oval/elliptical in 21.6% (95% CI: 16.3–28.1) of patients. In 7.5% (95% CI: 2.7–19.0) of individuals pain

FIGURE 1 Round/elliptical.

FIGURE 2 Pain qualities and location.

had multifocal location and 59.1% (95% CI: 49.7–68.0) of NH patients experienced pain exacerbations. The pain was most prevalent in the strictly parietal region (43.0%, 95% CI: 37.4–48.7) of the cranium and had pressing quality (51.4%, 95% CI: 41.6–61.1). **Conclusion:** The results of our study showed that NH is a very distinct and relatively rare to encounter headache disorder. Due to its unique clinical phenotype, physicians need to be aware when a patient presents with a small, well-localized round/oval headache in the cranium region. **Disclosure:** Nothing to disclose.

EPO-0733 | **Headache as the most common manifestation of giant cell arteritis? A systematic review with meta-analysis**

A. Osiowski; M. Osiowski; D. Tattera
Jagiellonian University Medical College, Kraków, Poland

Background and aims: This study aimed to assess the relative frequency of clinical features of giant cell arteritis (GCA) and to investigate the predictors of temporal artery biopsy (TAB) outcomes. **Methods:** A literature search of major electronic databases was conducted for observational studies that reported original data on clinical features of patients with GCA. A random-effects meta-analysis was performed to determine the pooled prevalence estimates. The study's design adhered closely to the MOOSE standards. The JBI appraisal tool was used to evaluate the risk of bias. The study's protocol was pre-registered on PROSPERO (ID: CRD42024584763). **Results:** Out of initial 12,628 records, 62 articles (9971 patients) met all of the eligibility criteria. Mean patients' age upon diagnosis was 74.33 years (95% CI: 74.12–74.54 years). The most prevalent clinical feature of GCA was new-onset headache (75.7%; 95% CI: 72.2–79.0; 95% PI: 0.47–0.92). Other common symptoms

FIGURE 1 Presentation of headache as the most common manifestation of GCA with comparison to other symptoms.

FIGURE 2 Forest plot presenting pooled prevalence estimate of headache in GCA.

of GCA were temporal artery abnormalities (51.5%; 95% CI: 45.2–57.7; 95% PI: 0.25–0.77), weakness/malaise (46.7%; 95% CI: 35.4–58.4; 95% PI: 0.09–0.88), and scalp tenderness (39.1; 95% CI: 35.3–43.1; 95% PI: 0.22–0.59). Positive TAB results were present in 73.8% of patients (95% CI: 68.1–78.8%; 95% PI: 0.35–0.94). The presence of headache (LogOR= −1.11; 95% CI: −1.92 to −0.29) or PMR (−0.71; 95% CI: −1.09 to −0.32) significantly decreases the chance of receiving positive TAB results. **Conclusion:** Since there is a greater likelihood of obtaining negative biopsy results, the TAB may not be required when a patient exhibits a headache along with other clinical symptoms that enable them to be diagnosed with GCA. **Disclosure:** Nothing to disclose.

EPO-0734 | **Glial neurovascular unit protein alterations and risk of idiopathic intracranial hypertension: A systematic review and meta-analysis**

B. Arora¹; A. Pandit¹; M. Nath¹; S. Shree¹; P. Tangri¹; P. Gupta²
¹Department of Neurology, AIIMS, New Delhi, India; ²Clinical Research Unit (CRU), AIIMS, New Delhi, India

Background and aims: Idiopathic intracranial hypertension (IIH) is characterized by raised intracranial pressure with incompletely understood pathophysiology. Increasing evidence implicates dysfunction of the glial neurovascular unit, including astrocytic, vascular, and neuroaxonal components, in disease development. This systematic review and meta-analysis evaluated the association between glial neurovascular unit-related protein alterations and the risk of IIH. **Methods:** A systematic search of PubMed, EMBASE, Cochrane Library, Scopus, and Web of Science was conducted up to August 2025. Studies comparing IIH patients with non-IIH controls and reporting levels of aquaporin-4, glial fibrillary acidic protein, fibrinogen, or neurofilament light chain were included. Data extraction and quality assessment using the Newcastle–Ottawa Scale were performed independently. Random-effects models

were used to calculate pooled standardized mean differences (SMDs) with 95% confidence intervals (CIs). BMI was analyzed as a secondary outcome.

Results: Ten studies comprising 327 IIH cases and 216 controls were identified, of which seven were included in quantitative synthesis. Cerebrospinal fluid NfL levels were significantly higher in IIH patients compared with controls (SMD 0.78, 95% CI 0.51–1.05), indicating neuroaxonal injury. Plasma fibrinogen levels were also elevated in IIH (SMD 0.66, 95% CI 0.08–1.23), suggesting a hypercoagulable and inflammatory state. Due to methodological heterogeneity, data on AQP4 and GFAP could not be pooled. Higher BMI was significantly associated with increased IIH risk (SMD 0.80, 95% CI 0.17–1.44).

Conclusion: Elevated NfL and fibrinogen levels are associated with IIH, supporting roles for neuroaxonal damage and

vascular–inflammatory mechanisms in disease pathophysiology. Well-designed multicentre studies are needed to validate glial neurovascular unit biomarkers and improve risk stratification.

Disclosure: Nothing to disclose.

EPO-0735 | People with migraine and two years treatment with anti-CGRP therapies. Second report from the prospective national registry “Hercules”

D. Mitsikostas¹; C. Deligianni^{1,2}; E. Giannouli³; E. Kouremenos⁴; I. Spanou⁴; T. Constantinidis⁵; T. Sagona⁶; E. Chroni⁶; Z. Tsouris⁷; E. Dardiotis⁷; C. Tsirois⁸; S. Konitsiotis⁸
¹1st Neurology Department, Aeginition Hospital, National and Kapodistrian University of Athens, Athens, Greece; ²Neurology Department, Athens Naval Hospital, Athens, Greece; ³Headache Clinic, Athens Medical Center, Athens, Greece; ⁴Neurology Department; 251 General Hospital of Air Forces; ⁵Neurology Clinic, Corinth, Greece; ⁶Department of Neurology, Patras University Hospital, Patras, Greece; ⁷Neurology Department, Medical School, University Hospital of Larissa, University of Thessaly, Larissa, Greece; ⁸Neurology Department, Medical School, University Hospital of Ioannina, University of Ioannina, Ioannina, Greece

Background and aims: To record the long-term efficacy and safety of anti-CGRP treatments in people with migraine in Hellas.

Methods: HERCULES is a 2-year, patient-centered, national, multicenter, longitudinal (5 total assessments every 6 months), prospective, observational study enrolling individuals with migraine treated with anti-CGRP agents. The primary endpoints are discontinuation of treatment due to adverse events and reduction in monthly migraine days (MDM).

Results: 425 subjects with migraine and prior failure to at least 3 repurposed anti-migraine prophylactic treatments attending 8 headache centers in Greece have been recorded so far [erenumab 41 (9.6%), galcanezumab 57 (13.4%), fremnezumab 287 (67.4%), eptinezumab 39 (9.2%) and rimegepant 2 (0.5%)], of whom 180 (42.3%) completed the 2-year treatment with anti-CGRP agents [29/180 (16.1%) subjects with erenumab; 22/180 (12.2%) with galcanezumab; and 129/180 (71.7%) with fremanezumab]. 57/425 (13.4%) participants discontinued treatment [fremanezumab 28/287 (9.7%); galcanezumab 17/57 (29.8%); erenumab 10/41 (24.4%); eptinezumab 2/39 (5.1%)], due to patient's decision [29/57 (50.9%)], failure [14/57 (24.6%)], adverse events [2/57 (3.5%)], complete remission of migraine [6/57 (10.5%)], or pregnancy [1/57 (1.7%)]. The most common AE recorded were constipation [47/425 (11%)] and injection site reactions [57/332 (13.4%)]. Only one severe AE has been recorded [1/425 (0.2%)] during infusion of eptinezumab (allergic reaction). After 24 doses a $\geq 50\%$, $\geq 75\%$, or 100% reduction in MDM compared to pretreatment was recorded in 147/180 (81.6%), 81/425 (19%), and 13/180 (7.2%) subjects, respectively.

Conclusion: Anti-CGRP mAbs are effective, safe, and well tolerated after long-term administration and should be considered as a first-line prophylactic treatment for migraine.

Disclosure: Hercules is supported by grants from Pharmaserve Lilly SACI, Pfizer Hellas AE and Teva Hellas SA. D.D.M. has received fees for participation in advisory committees and

FIGURE 1 This systematic review and meta-analysis demonstrate that elevated cerebrospinal fluid neurofilament light chain and plasma fibrinogen levels are significantly associated with idiopathic intracranial hypertension, indicating underlying neuroaxonal injury.

honoraria for lectures from AbbVie, Amgen, AstraZeneca, Bennett, Bristol-Meyers Squibb, Eli Lilly, Cross, ELPEN, Haleon, Intermed, Genesis Pharma, Lundbeck, Merck, Mylan, Orion Pharma, Novartis, Pfizer, Roche, and Teva Pharmaceuticals; has participated in clinical trials for Amgen, Eli Lilly, Lundbeck, Novartis, Pfizer, Swixx, and Teva Pharmaceuticals as principal investigator; is the president of the Hellenic Headache Society and a member of the Management Group of the Coordinating Panel for the Functional Neurological Disorders at the European Academy of Neurology. C.D. has received personal fees/ honoraria/ travel expenses from Pfizer, Merck, Astra-Zeneca, Teva, Orion Pharma, Haleon, Bennett. C.D. serves as member at large of European Headache Federation. E.G. has received travel grants, speaking fees and participated in advisory boards for AbbVie, Eli Lilly, Lundbeck, Novartis, Pfizer, and Teva/Specifar. E.K. has received travel grants and honoraria from Bristol-Meyers Squibb, Eli Lilly and Company, Innovis, Merck, Novartis, Lundbeck, Roche and Teva. I.S. has received travel grants from Lundbeck and Teva. T.S.C. received honoraria for participation in advisory boards, preparation and addressing of lectures in satellite symposia, as well as funding for congress participation from Abbvie, Teva, Sanofi, Cross, Elpen, Pharmathen-Innovis, Pharmaserv-Lilly, Novartis, Braintherapeutics Neuraxpharm, Merck, C.A. Papaellinas, Bayer, Swixx, Vianex, UCB and Genesis Pharma-Biogen. T.S. received honoraria from UCB. E. C. received travel funds and honoraria for participation in Advisory Meetings and Satellite Symposia from Merck, Sanofi Genzyme, Genesis Pharma, Teva Pharmaceuticals, UCB, ITF, Medison Pharma, Alexion, AstraZeneca, CSL Behring, and Takeda. Z. T. has received compensation for lecture honoraria and travel expenses, participation in scientific meetings, clinical trial membership, or clinical advisory board participation from Teva, Argenx, Sanofi, Novartis, Janssen, Immunovant, Roche, Lundbeck, Bayer, Shionogi, Merck, Genesis Pharma, Bristol-Myers Squibb, and UCB. E.D. has received compensation for lecture honoraria and travel expenses, participation in scientific meetings and advisory boards, clinical trial membership, from Abbvie, Astra-Zeneca, Bayer, Bristol-Myers Squibb, Elpen, Lundbeck, Merck, Mylan, Novartis, Sanofi, UCB, Teva, Tikun and Genesis. C.T. received honoraria for lecturing, travel grants for travel and participation in advisory meetings from Cross, Lundbeck and Teva. S.S.K. has received grants and honoraria from Abbvie, AstraZeneca, Bristol-Myers Squibb, Sanofi Aventis, Innovis, Ipsen, ITF Hellas, Genesis Pharma, ERKIM Pharma, Medison Pharma, Medtronic Hellas, Merck, Novartis, Pharmaserv, Rosche, Sandoz, Teva, Viatrix, and UCB.

EPO-0736 | Do European Headache Federation criteria reflect response to acute treatments in resistant and refractory migraine? The REFINE study

I. Gagnaniello
Università degli Studi dell'Aquila, L'Aquila, Italy

Background and aims: The European Headache Federation (EHF) defines resistant and refractory migraine by failure of ≥ 3 (resistant) or all (refractory) pharmacological preventive treatment classes, without considering acute treatments. This study aimed to evaluate whether these definitions also correlate with response to acute treatment.

Methods: We conducted a multicenter, prospective, international study (REFINE) to test the EHF definitions in a real-life setting in 15 European headache centers. The Headache Under Response to Treatment (HURT) Questionnaire assessed the impact of migraine on daily activities and effectiveness of acute medications in patients with resistant, refractory, and non-resistant non-refractory (NRNR) migraine.

Results: We included 689 patients, of whom 261 (37.9%) had resistant, 73 (10.6%) refractory, and 355 (51.5%) NRNR migraine. Patients with refractory migraine experienced more significant impairment in daily activities (HURT-2) and social activities (HURT-3) versus those with resistant and NRNR migraine (46 [63.0%] vs 110 [42.2%] vs 51 [14.4%], $p < 0.001$; 37 [50.7%] vs 67 [25.7%] vs 25 [7.0%], $p < 0.001$). Regarding acute medication efficacy (HURT-5), more patients with refractory migraine stated that one dose “never” relieved their headache, and delayed or avoided taking acute medication due to concerns about adverse events (HURT-7), versus those with resistant and NRNR migraine (29 [39.7%] vs 28 [10.7%] vs 25 [7.0%], $p < 0.001$; 16 [21.9%] vs 7 [2.7%] vs 11 [3.1%], $p < 0.001$).

Conclusion: Patients with refractory and resistant migraine report poorer acute treatment response compared with those with NRNR migraine, which significantly affect daily lives. Management of difficult-to-treat migraine should focus on optimizing acute treatments, alongside preventive therapies.

Disclosure: Nothing to disclose.

EPO-0737 | Longitudinal effects of CGRP monoclonal antibodies for migraine prophylaxis: Impact of treatment type and age group

I. Mattioli¹; A. Rondina²; A. Lanfranchi³; G. Ceccardi⁴; M. Di Pasquale²; E. Cresta³; A. Pilotto⁵; A. Padovani⁵; R. Rao³

¹Department of Frailty and Continuity of Care, ASST Spedali Civili, Brescia, Italy; ²NMD Experimental Medicine, University of Oxford, Oxford, UK; ³Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy; ⁴Department of Frailty and Continuity of Care, ASST Spedali Civili, Brescia, Italy; ⁵Neurology Unit, ASST Cremona, Cremona, Italy; ⁵Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy; Department of Frailty and Continuity of Care, ASST Spedali Civili, Brescia, Italy

Background and aims: Calcitonin gene-related peptide (CGRP) monoclonal antibodies (mAbs) are established preventive treatments for episodic and chronic migraine, but comparative longitudinal data across agents and age groups remain limited. This study aimed to evaluate long-term clinical responses to different CGRP mAbs, assess whether age or treatment type influences response trajectories, and characterize multidimensional patterns of treatment response.

Methods: We conducted a retrospective, single-centre observational study including 443 adults with high-frequency episodic or chronic migraine treated with erenumab, galcanezumab, fremanezumab, or eptinezumab between 2018 and 2025. Patients were stratified by age (< 50 vs ≥ 50 years). Longitudinal mixed-effects models assessed changes in monthly migraine days, acute medication use, pain intensity, disability, quality of life, and mood over 12 months. Generalized linear mixed models evaluated predictors of $\geq 50\%$ response. Principal component

analysis (PCA) was used to identify multidomain response patterns.

Results: All CGRP mAbs produced rapid and sustained improvements across migraine frequency, disability, and patient-reported outcomes over 12 months. Age did not significantly influence baseline severity, longitudinal trajectories, or responder status. Treatment differences were modest overall; however, at 12 months, fremanezumab and eptinezumab were associated with higher odds of response compared with erenumab, while galcanezumab showed consistently higher response odds

FIGURE 1 Clinical and migraine-related variables change over time across age and treatment groups.

FIGURE 2 probability of response over time across treatment groups (MMD=monthly migraine days).

FIGURE 3 Component loadings from PCA.

independent of time. PCA identified a “General improvement” component capturing multidomain benefit, which was more pronounced in patients treated with eptinezumab.

Conclusion: In real-world clinical practice, CGRP mAbs demonstrate broadly comparable and durable effectiveness across age groups. Subtle long-term differences between agents may emerge, particularly for multidimensional clinical improvement, supporting individualized treatment selection.

Disclosure: IM has received support for conference participation from Allergan/AbbVie, Pfizer, and Lundbeck; has received funding for an advanced training course from Teva; and is currently enrolled in a DPhil program funded by GlaxoSmithKline (Oxford–GSK). EPO-0738 | Work productivity and indirect cost savings of atogepant versus topiramate: Results from the TEMPLE trial

J. Díaz de Terán¹; P. Gandhi²; H. Guo²; F. Haile²; K. Nagy²; K. Carr²; J. Versijpt³; R. Gil-Gouveia⁴; D. Buse⁵; R. Lipton⁵
¹La Paz University Hospital, Madrid, Spain; Hospital La Paz Institute for Health Research; ²AbbVie Inc, North Chicago, USA; ³Department of Neurology, Universitair Ziekenhuis Brussel, Brussels, Belgium; ⁴Neurology Department, Hospital da Luz, Lisbon, Portugal; Center for Interdisciplinary Research in Health, Universidade Católica Portuguesa, Lisbon, Portugal; ⁵Department of Neurology and Headache Center, Albert Einstein College of Medicine, Bronx, USA

Background and aims: Using the Work Productivity and Activity Impairment (WPAI): Migraine, we contrasted presenteeism, absenteeism, overall work productivity, and indirect cost savings of participants who received atogepant versus topiramate for the preventive treatment of migraine.

Methods: TEMPLE was a phase 3b, randomized, multicenter, double-blind (DB), double-dummy, active-controlled trial to evaluate tolerability, safety, and efficacy of atogepant compared with topiramate for the preventive treatment of migraine. WPAI:Migraine was evaluated at each 4-week time point during the 24-week DB period. An excel-based cost calculator used WPAI data to calculate the per-patient-per-year (PPPY) work productivity cost by multiplying the percent overall work productivity loss, weeks per year, standard weekly full-time work hours (40), and the average hourly wage in Canada, Portugal, United Kingdom, and United States. Productivity benefit from using atogepant was calculated as the difference between atogepant and topiramate productivity loss PPPY.

Results: Based on WPAI data from TEMPLE, atogepant demonstrated greater improvements in presenteeism and overall work productivity (Figures 1 and 2), and lower absenteeism and activity impairment versus topiramate. The cost calculator using overall work productivity data demonstrated atogepant provided greater productivity benefits and indirect cost savings compared with topiramate across all 4 countries (Table 1).

Conclusion: Atogepant consistently demonstrated greater improvement compared to topiramate across all four WPAI domains. Using TEMPLE WPAI data, atogepant demonstrated work productivity benefit compared to topiramate in Canada, Portugal, UK, and United States.

Disclosure: Disclosures Javier Díaz de Terán declares public research funding from the Instituto de Salud Carlos III (Ministry of Health, Spain), project PI24/01254, outside the submitted work; and reports honoraria for consultant and/or advisory boards from AbbVie, Almirall, Lilly, Lundbeck, Novartis, Organon, Pfizer, Boston Scientific, and Teva. Jan Versijpt received personal fees and nonfinancial support from Teva, Pfizer and Medtronic, personal fees from Novartis and Lundbeck, and grants and non-financial support from Allergan/AbbVie. Raquel Gil-Gouveia reports honoraria for consultant and/or advisory boards from Allergan/AbbVie, Astra Zeneca, Almirall, Bial, Biogen, Bristol-Myers Squibb, CMBE, FLOAT, Lilly, Lundbeck, Merck, Novartis, Novo Nordisk, Organon, Pfizer, Roche, Sanofi, Tecnifar and Teva; research funding from Fundação Ciência e Tecnologia (Project 29675, MigN2Treat, 02/SAICT/2017); Learning-Health, Luz Saúde (LiON, Luz Innovation on Neurosciences); Novartis-Sociedade Portuguesa de Cefaleias; Bolsa-Proyecto Centro de Investigación Interdisciplinar em Saúde and UCP. Dawn Buse has received research funding from the US Food and Drug Administration, the National Headache Foundation and Amgen

TABLE 1 Work productivity benefit for Atogepant vs. Topiramate per patient per year.

	Canada	Portugal	United Kingdom	United States
Productivity Cost Benefit vs. Topiramate (PPPY)	CAD\$ 6,362	€ 2,195	£ 4,052	\$ 8,434
Productivity Cost Benefit including Treatment Costs vs. Topiramate (PPPY)	CAD\$ 419	€ 1,513	£ 1,728	\$ 2,271

Productivity cost benefit is the difference between atogepant and topiramate. Incremental values are calculated relative to topiramate. Productivity cost benefit is calculated as percent improvement in overall productivity from WPAI. Treatment costs represent the annual drug cost difference of atogepant compared with topiramate. CAD\$, Canadian dollars; PPPY, per-patient-per-year; WPAI, Work Productivity and Activity Impairment.

²Department of Psychiatry, University Hospital of Caen, Caen, France; ³Department of Neurology, Montpellier University Hospital (CHU), Gui de Chauliac Hospital, Montpellier, France

Background and aims: Reversible cerebral vasoconstriction syndrome (RCVS) is a cerebrovascular disorder characterized by acute headaches and reversible cerebral arterial narrowing. While case series suggest an association between serotonergic antidepressant use and RCVS onset, clinical and long-term outcomes data in this population remain scarce. We aimed to characterize the presentation and prognosis of antidepressant-associated RCVS.

Methods: We conducted a retrospective analysis of adult patients with RCVS and concurrent antidepressant use from the Lariboisière Hospital RCVS cohort (2004–2023). Clinical and neuroimaging features were compared with those of non-exposed patients. Long-term outcomes were assessed in the exposed group through structured telephone interviews.

Results: Among 501 RCVS patients, 56 (11.2%) were using antidepressant at RCVS onset. Exposed patients were more often female (82.1% vs. 60.7%, $p=0.002$) and older (median age: 48 vs. 41 years, $p=0.001$), with acute emotional stress more frequently reported at onset (41.1% vs. 20.2%, $p=0.001$). Focal deficits (25.0% vs. 13.0%; adjusted OR=2.62, 95% CI [1.26–5.46]) and hemorrhagic complications (32.1% vs. 16.4%; OR=2.28, 95% CI [1.15–4.52]) were more frequent in antidepressant users. Antidepressants were reintroduced in 53.6% of cases. Among the 39 patients with long-term follow-up, RCVS recurrence was

TABLE 1 Multivariate analysis of RCVS severity outcomes associated with antidepressant use. Adjusted odds ratios (OR) with 95% confidence intervals are reported for neurological deficits, hospitalization, and hemorrhagic complications.

Variable, n(OR ^a , 95% CI)	Neurological deficit	p-value	Hospitalization	p-value	Hemorrhagic complication	p-value
Antidepressant use	2.62 (1.26–5.46)	0.008	1.77 (0.95–3.28)	0.070	2.28 (1.15–4.52)	0.019

TABLE 2 Psychiatric outcomes at long-term follow-up in 39 antidepressant-associated RCVS. Values are no./total no. (%) or mean (25th–75th percentiles). Percentages are based on the subgroup with complete follow-up ($n=39$).

Psychiatric symptom assessed by the Modified Mini Screen	n (%)
Depressive features	22 (56.4)
Current anhedonia	16 (41.0)
Current depressed mood	10 (25.6)
Persistent depressive mood	13 (33.3)
Passive death wishes	6 (15.4)
Mood and hypomanic features	3 (7.7)
History of elevated mood or increased goal-directed activity	3 (7.7)
History of irritable mood	2 (5.1)
Anxiety and obsessive-compulsive spectrum symptoms	34 (87.2)
Excessive anxiety lasting at least 6 months	31 (79.5)
Excessive and persistent daily anxiety for 6 months	19 (48.7)
History of panic attacks	17 (43.6)
Current agoraphobia	13 (33.3)
Current social anxiety	5 (12.8)
Current compulsive behaviour	3 (7.7)
Trauma- and stressor-related symptoms	22 (56.4)
History of exposure to a traumatic event	22 (56.4)
Current intrusive symptoms (e.g., flashbacks, nightmares)	6 (15.4)
Psychotic symptoms	5 (12.8)
Preservatory delusions	5 (12.8)
Thought broadcasting or thought insertion	1 (2.6)
Other psychotic symptoms*	0 (0.0)
Psychiatric symptoms assessed by the Hospital Anxiety and Depression Scale	n (%)
Anxiety Scale, mean (± SD)	9.7 (± 3.4)
≥ 8: suspected anxiety	28 (71.8)
≥ 11: definite anxiety	14 (35.9)
Depression Scale, mean (± SD)	8.3 (± 3.4)
≥ 8: suspected depression	11 (28.2)
≥ 11: definite depression	4 (10.3)

FIGURE 1 Two cases of long-term recurrence in antidepressant-associated RCVS.

rare (5.1%). Persistent psychiatric symptoms, particularly stress-related disorders, anxiety and depressive features, remained highly prevalent.

Conclusion: Antidepressant-associated RCVS is associated with increased neurological severity and hemorrhagic risk. Recent serotonergic exposure and emotional stress may act synergistically. Antidepressant delayed reintroduction appears feasible with individualized risk assessment and close neurological and psychiatric monitoring.

Disclosure: Nothing to disclose.

EPO-0740 | Epidemiology of primary exercise headache: A systematic review and meta-analysis with comparison between clinic- and population-based settings

A. Osowski; M. Osowski; D. Tattera; K. Majka
Jagiellonian University Medical College, Kraków, Poland

Background and aims: Primary exercise headache (PEH) is a rare primary headache disorder that occurs specifically during or right after physical exertion and lasts up to 48 hours. This study aimed to evaluate the epidemiology of PEH in clinic- and population-based settings.

Methods: Major databases were thoroughly searched for articles that presented original data on the epidemiology of PEH. Random-effects meta-analysis was performed in order to calculate the pooled prevalence estimates (PPE). The study's structure adhered closely to the MOOSE and PRISMA requirements. The protocol of the study was pre-registered on PROSPERO (CRD42024612283).

Results: Out of the original 2083 records, 12 articles satisfied all inclusion requirements. The majority of the studies showed a low risk of bias. The headache is a rare finding in clinical-based settings (PPE=0.46%, 95% CI: 0.18–1.20, 95% PI: 0.01%–14.29%, I²=94.86), more common in population-based surveys (PPE=4.92%, 95% CI: 1.84–12.49, I²=98.73), shows a female predominance, and, moreover, typically has onset in the late twenties (27.47 years).

FIGURE 1 Forest plot presenting the prevalence of PEH in general adult population.

Conclusion: Our study showed that PEH is a rare primary headache disorder among adults evaluated for a headache in a clinic-based setting and is significantly more common in the general population. Furthermore, PEH is diagnosed within similar frequency among both sexes in headache-oriented clinics and moreover, predominantly late twenties. However, in the general population, there is a notable female preponderance.

Disclosure: Nothing to disclose.

EPO-0741 | Assessing physician and patient alignment in migraine severity: Evidence from real-world clinical practice

W. Whitton; L. Hargreaves; S. Cotton; S. Barlow
Adelphi Real World, Cheshire, UK

Background and aims: Migraine is characterised by unilateral headache pain. The burden of migraine is well established,

FIGURE 1 Physician and patient-reported migraine severity over the past 3 months (relative to time of data collection). Data are total percentages.

yet potentially equivocal across different stakeholders, such as patients with migraine (PwM) and their physicians. This study aimed to assess the alignment between physician and patient reported migraine severity in real world clinical practice.

Methods: Data were drawn from the 2022/23 Adelphi Migraine Disease Specific Programme™, a cross-sectional survey of physicians and their patients in France, Germany, Italy, Spain, the United Kingdom, China, Japan, and the United States. Physicians and their PwM reported average migraine severity over the past three months. The alignment between physician and patient reported severity was assessed by calculating Cohen's weighted kappa (κ) statistic. Interpretation of the κ value was based on Landis and Koch (1977).

Results: Overall, 938 physicians (391 PCPs, 527 neurologists, and 20 neurosurgeons) reported data for 7357 PwM, of which patient-reported data were available for 3125. Matched severity data were available for 3078 PwM. Physicians reported 55% of patients ($n=1688$) experienced very mild/mild migraine, 37% ($n=1137$) experienced moderate migraine, and 8% ($n=253$) experienced severe/very severe migraine. Conversely, 47% ($n=1443$) of PwM reported experiencing very mild/mild migraine, 38% ($n=1171$) reported moderate migraine, and 15% ($n=464$) reported severe/very severe migraine. A kappa value of 0.57 was observed, suggesting only moderate alignment between physicians and their patients (Figure 1).

Conclusion: This study indicates physicians may under-recognise the severity of migraine, highlighting the importance of open dialogue to support a shared understanding of migraine severity and guide optimal management decisions.

Disclosure: William Whitton, Lucy Hargreaves, Sarah Cotton, and Sophie Barlow are all employees of Adelphi Real World.

P. Kim Chiaw¹; S. Keshwani¹; L. Bou Khzam¹; A. Grajales¹; N. Nightingale²; I. Wang²; C. Neish²; J. Murray²

¹Pfizer Canada, Kirkland, Quebec, Canada; ²IQVIA Solutions Canada Inc, Mississauga, Ontario, Canada

Background and aims: Migraine is a leading cause of disability, yet substantial gaps in diagnosis, documentation, and treatment continue to impact care quality. Applying natural language processing (NLP) to real-world electronic medical record (EMR) data provides an opportunity to reveal these systemic challenges and pinpoint critical patient care gaps.

Methods: We performed a descriptive retrospective analysis of Accuro EMR data from one general practice (GP) (2012–2023) and one neurology clinic (2022–2023) in Ontario using the DARWEN NLP engine. Extracted variables included demographics, monthly migraine days (MMDs), migraine classification, comorbidities, acute and preventive therapies, and medication overuse headache (MOH).

Results: The cohort comprised 967 GP and 149 neurology patients, predominantly female, with mean ages 41–42 years. Psychiatric and sleep comorbidities were common in both groups - anxiety (28.9%; 27.5%), depression (11.7%; 4.0%), and insomnia (40.1%; 26.8%), respectively—underscoring migraine complexity. Migraine classification was rarely documented in GP, with 72.7% of patients having an unknown classification compared with 22.1% in neurology; MMDs were likewise underreported. Treatment patterns diverged, GP relying heavily on NSAIDs and opioids, while neurology commonly used triptans and a broader, though still limited, use of preventive therapies. MOH was rarely documented in GP (0.6%) but frequently identified in neurology (42.3%).

Conclusion: Findings highlight system level barriers—poor documentation, underdiagnosis, and inconsistent access to migraine-specific therapy—which fragment migraine care. Enhancing EMR systems, integrating AI-enabled decision support, and improving equitable access to evidence-based treatments are essential to advancing migraine care in Canada.

¹Aix-Marseille Université, AP-HM, Hôpital de La Timone, Service Pharmacie, Marseille, France; ²Aix-Marseille Université, INSERM 1263, Marseille, France; ³Aix-Marseille Université, AP-HM, Hôpital de La Timone, Centre d'Evaluation et de Traitement de la Douleur, Marseille, France

Background and aims: Cluster headache (CH) is a primary headache disorder historically considered more prevalent in men. As a chronobiological condition, it has been hypothesised CH may be influenced by seasonality or sunlight-related factors. The French open healthcare databases offer an opportunity to analyse real-world dispensing patterns of CH treatments. The aim of this study was to provide an innovative interpretation of the clinical expression of this condition through healthcare data, and to highlight the evolving economic burden of its treatments.

Methods: We extracted consumption data for the two validated attacks treatments for CH: 6 mg subcutaneous sumatriptan (SS) and oxygen therapy (OT). Treatments patterns were analysed by sex, age group, and French administrative region, and compared with climatic, demographic and economic variables.

Results: Between 2014 and 2024, the total amount for OT in CH tripled, while SS costs increased by only 1.6-fold. A consistent decrease in the male-to-female sex ratio was observed across all age group for both treatments. A distinct peak in SS dispensing was observed in July. However, no statistically significant associations were found between SS dispensing and sunshine or rainfall. Younger men exhibited significantly higher consumption than older men, and overall consumption was higher in men than in women.

Conclusion: Our findings highlight evolving treatment patterns and shifting sex ratio in the delivery of CH therapies in France. While no clear environmental drivers of treatment used were identified, the study underscores the value of open health data in monitoring prescribing trends and evaluation the economic impact of CH therapies.

Disclosure: Nothing to disclose.

Movement Disorders 8

EPO-0744 | Movement disorders in multisystem proteinopathies: A systematic review

¹Department of Rehabilitation Sciences and Physiotherapy/
Movant, Faculty of Medicine and Health Science, University
of Antwerp, Antwerp, Belgium; ²Department of Neurology,
Antwerp University Hospital, Antwerp, Belgium; ³Translational
Neurosciences, Faculty of Medicine and Health Sciences,
University of Antwerp, Belgium; ⁴Institute of Health, Jimma
University, Jimma, Ethiopia

Methods: A prospective cohort was conducted with adult CD patients attending treatment at Antwerp University Hospital, Belgium (UZA) and a specialized private physiotherapy practice. Depression and Anxiety were measured using the Beck Depression inventory (BDI-II) and the Beck Anxiety Inventory (BAI-II), respectively. Sleep quality was measured using Pittsburgh Sleep Quality Index (PSQI); and QoL was measured using EuroQoL-5 dimensions (EQ-5D) at baseline and 6-weeks

post treatment. Paired T-test and Wilcoxon signed rank was used for comparison.

Results: A total of 29 CD patients were included. The mean age was 61.6 ± 9.25 years. The mean $\pm$ standard deviation (SD) score of the global PSQI score decreased from 10.1 ± 4.6 at baseline to 7.41 ± 4.7 post treatment. The mean (SD) BAI-II score decreased slightly from 13.5 ± 9.43 at baseline to 12.52 ± 10.2 post treatment. The median (IQR) of BDI-II score changed from 7 (5–19) to 8 (2.5–20). There was significant improvement of PSQI following BoNT treatment ($MD = 2.65$, $p < 0.001$).

Conclusion: BoNT injection significantly improved sleep quality. However, no statistical difference was observed in depressive and anxiety symptoms. The persistence of psychiatric symptoms underscores the necessity of comprehensive bio-psychosocial interventions. Considering this, future studies targeting development of intervention modality is needed.

Disclosure: Nothing to disclose.

EPO-0747 | The immediate effect of peripheral stimulation on cervical dystonia disease outcomes: Single-case experimental design

S. Kassaye¹; D. Crosiers²; E. Kebede Gudina³; N. Nadjmi⁴; E. Van de Casteele⁵; J. De Pauw¹; W. De Hertogh¹

¹Department of Rehabilitation Sciences and Physiotherapy/Movant, Faculty of Medicine and Health Science, University of Antwerp, Antwerp, Belgium; ²Department of Neurology, Antwerp University Hospital, Antwerp, Belgium; ³Institute of Health, Jimma University, Jimma, Ethiopia; ⁴Department of Cranio-Maxillofacial Surgery, Antwerp University Hospital, Antwerp, Belgium; ⁵ZMACK/Associate MKA, AZ, Antwerp, Belgium

Background and aims: Limited Cervical Range of Motion (CROM) and pain are among the most common symptoms of Cervical Dystonia (CD) which are treated with Botulinum NeuroToxin injections. However, adjuvant interventions may offer additional benefit. Therefore, this study evaluated the immediate effects of peripheral stimulation comprising conventional transcutaneous electrical nerve stimulation (TENS), muscle stimulation (NMES), and muscle vibration on CROM and pain in patients with CD.

Methods: A Single-Case Experiment Design (SCED), alternating treatment design was conducted with 19 CD patients, recruited at the Antwerp University Hospital (UZA). Participants randomly received conventional TENS, NMES and muscle vibration on three different days. Main outcome measures were CROM, measured using a 3D-stereophotogrammetric scanning system (3dMD Inc, GA, USA) and pain, quantified by Visual Analogue Scale (VAS).

Results: Mean age of participants was 59.87 ± 8.9 years. Baseline CROM for rotation ranged from 87° to 137.6° and from 79° to 132.4° for flexion/extension. Improvements in neck rotation were observed in 5 (33.3%) participants after conventional TENS, 8 (42.1%) after NMES, and 8 (42.1%) after muscle vibration. Similarly, improvement in flexion and extension was observed in 10 (55.6%) after conventional TENS, 8 (53.3%) after NMES, and 7 (46.7%) after muscle vibration. Significant reductions in pain shortly after the three interventions were observed in patients experiencing pain.

FIGURE 1 Individual mean score of full range of neck rotation at baseline (0), immediately post stimulation (1), 10 min. post stimulation (2) for the different interventions.

Conclusion: These findings suggest that peripheral stimulation may provide immediate symptomatic relief in CD, particularly for improving cervical range of motion and reducing pain. While promising, these results should be considered as exploratory and warrant further investigation in larger, controlled studies.

Disclosure: Nothing to disclose.

EPO-0748 | Divergent clinical phenotypes in siblings with a shared GBA1 mutation and posterior cortical hypometabolism

T. Filidei¹; R. Malito²; L. Gallo¹; R. Calabrese³; P. Mitrotti³; L. Bandirali³; A. Samanes Gajate²; D. Perani²; C. Tassorelli¹; E. Valente¹; S. Caminiti³; M. Avenali¹

¹Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; ²IRCCS San Raffaele Scientific Institute, Milan, Italy; ³IRCCS Mondino Foundation, Pavia, Italy

Background and aims: Variants in the glucocerebrosidase gene (GBA1) are among the strongest genetic risk factors for Parkinson's disease (PD), yet disease penetrance is incomplete and marked intrafamilial heterogeneity is observed. Neuroimaging biomarkers may capture early neurobiological changes that are not reflected by clinical severity. The objective of this study was to describe the dissociation between clinical phenotype and brain metabolic patterns in siblings carrying a GBA1 mutation.

Methods: Two siblings carrying the same severe GBA1 mutation (p.H255Q) underwent a comprehensive cross-sectional evaluation. Assessments included motor and non-motor examination using the Movement Disorder Society Unified Parkinson's Disease Rating Scale, standardized cognitive testing, and brain metabolic imaging with fluorodeoxyglucose positron emission tomography (FDG-PET). Peripheral biomarkers included glucocerebrosidase enzymatic activity and monomeric

FIGURE 1 Schematic representation of the proposed pathogenic pathway linking GBA1 mutations to reduced glucocerebrosidase activity, lysosomal dysfunction, lipid accumulation, and alpha-synuclein aggregation in Parkinson's disease.

TABLE 1 Comparison of cognitive test performance between the sibling with GBA1-associated Parkinson's disease (GBA-PD) and the non-affected GBA1 carrier (GBA-nonPD) across global cognition, memory, and visuospatial domains.

FIGURE 2 FDG-PET hypometabolism patterns in a GBA1-associated Parkinson's disease patient (59-year-old male) and an unaffected GBA1 carrier (56-year-old female), obtained using single-subject SPM analysis versus 125 age-corrected healthy controls ($p < 0.05$).

alpha-synuclein levels measured in peripheral blood mononuclear cells.

Results: The proband, a 59-year-old man with Parkinson's disease, showed motor impairment, multidomain cognitive deficits consistent with Parkinson's disease-mild cognitive impairment, and a high non-motor symptom burden. His 56-year-old sister exhibited only minimal motor signs, preserved cognition, and negligible non-motor symptoms. Despite the marked

clinical divergence, FDG-PET demonstrated a similar pattern of bilateral posterior cortical hypometabolism in both siblings. Glucocerebrosidase activity was comparable, while monomeric alpha-synuclein levels were higher in the affected sibling.

Conclusion: This intrafamilial observation highlights a dissociation between cortical hypometabolism and clinical expression in carriers of a severe GBA1 mutation. These findings suggest that metabolic brain changes may precede or evolve independently of overt clinical manifestations, supporting the potential role of FDG-PET in the phenotypic characterization of genetic Parkinson's disease.

Disclosure: Nothing to disclose.

EPO-0749 | Intrafamilial biochemical correlates of disease expression in GBA1 mutation carriers discordant for Parkinson's disease

T. Filidei¹; L. Gallo¹; R. Calabrese²; P. Mitrotti²; L. Bandirali¹; R. Stiuso²; C. Tassorelli¹; E. Valente¹; S. Caminiti¹; M. Avenali¹
¹Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; ²IRCCS Mondino Foundation, Pavia, Italy

Background and aims: Pathogenic variants of the glucocerebrosidase gene (GBA1) are a major genetic risk factor for Parkinson's disease, yet disease penetrance is incomplete. Discordant sibling designs allow intrafamilial comparisons that control for shared genetic background and early-life environment. The objective of this study was to investigate intrafamilial differences in peripheral glucocerebrosidase activity and total alpha-synuclein levels in siblings carrying the same GBA1 variant but discordant for Parkinson's disease.

Methods: We conducted a family-based cross-sectional study including sibling pairs carrying identical GBA1 variants and discordant for Parkinson's disease. The most recent peripheral blood mononuclear cell sample with available biochemical data was selected for each subject. Glucocerebrosidase activity and total alpha-synuclein levels were quantified and normalized to total protein content. Intrafamilial paired differences were calculated as values in the Parkinson's disease-affected sibling minus those in the non-manifesting carrier. Analyses focused on paired descriptive statistics and resampling approaches.

Results: Five discordant sibling pairs were available for analysis. Glucocerebrosidase activity showed heterogeneous intrafamilial differences without a consistent directional pattern. In contrast, total alpha-synuclein levels were higher in the Parkinson's disease-affected sibling in most pairs. Resampling analyses supported a positive intrafamilial difference for alpha-synuclein despite limited statistical power. Larger intrafamilial

TABLE 1 Demographic characteristics of discordant sibling pairs carrying the same GBA1 variant. Each couple includes one Parkinson's disease-affected sibling (GBA-PD) and one non-manifesting GBA1 carrier.

Couple	Group	Age (years)	Sex	Education (years)	GBA1 variant

Couple 5	GBA-NC	61	M	17	T369M

FIGURE 1 Within-family paired comparison of total alpha-synuclein and glucocerebrosidase activity in peripheral blood mononuclear cells from GBA1 discordant sibling pairs. Each line represents one family, comparing non-manifesting carriers and Parkinson.

FIGURE 2 Exploratory association between intrafamilial differences in total alpha-synuclein (Parkinson's disease minus carrier) in peripheral blood mononuclear cells and motor severity, assessed by MDS-UPDRS Part III, in GBA1 discordant sibling pairs.

differences in alpha-synuclein tended to associate with greater motor and non-motor burden.

Conclusion: In this discordant sibling design, the Parkinson's disease-carrier difference captures biological processes associated with disease expression beyond shared genetic risk. While peripheral glucocerebrosidase activity appears variable within families, total alpha-synuclein emerges as a more consistent downstream readout associated with Parkinson's disease manifestation in GBA1 mutation carriers.

Disclosure: Nothing to disclose.

EPO-0750 | RTA-408 enhances Nrf2 activation and mitochondrial function to improve SCA3 cell and drosophila models

C. Liu¹; W. Lin²; F. Leng²; W. Cheng²; W. Lin³; S. Pan²; J. Chang⁴
¹Department of Neurology, Changhua Christian Hospital, Changhua, Taiwan; ²Department of Vascular and Genomic Center, Institute of ATP, Changhua Christian Hospital, Changhua, Taiwan; ³Graduate Institute of Integrated Medicine, College of Chinese Medicine, China Medical University, Taichung, Taiwan; ⁴Center of Regenerative Medicine and Tissue Repair, Institute of ATP, Changhua Christian Hospital, Changhua, Taiwan

FIGURE 3 Material and methods.

FIGURE 2 MJD26 and MJD78 cells were treated with RTA-408 at 0.1, 0.3, and 0.5 μ M for 24 hours.

FIGURE 3 Effects of RTA408 treatment in ELAV-SCA3tr-Q78 and GMR-SCA3tr-Q78 Drosophila.

Background and aims: Spinocerebellar ataxia type 3 (SCA3) is a polyglutamine neurodegenerative disorder characterized by mutant ataxin-3 aggregation, oxidative stress, mitochondrial dysfunction, and progressive neuronal degeneration. Dysregulation of the Nrf2 antioxidant pathway contributes to SCA3 pathogenesis. RTA-408 (omaveloxolone), a potent Nrf2 activator, has therapeutic potential in Friedreich's Ataxia. This study evaluated the effects of RTA-408 on Nrf2 signaling, mitochondrial integrity, and disease-related phenotypes in SCA3 cellular and Drosophila models.

Methods: Human SK-N-SH neuroblastoma cells expressing normal (MJD26) or expanded polyglutamine (MJD78) ataxin-3 were treated with RTA-408 (0.1–0.5 μ M) for 24 hours. Cell viability, apoptosis, Nrf2 nuclear translocation, antioxidant enzyme

expression, mutant ataxin-3 protein levels, mitochondrial morphology, and mitochondrial copy number were assessed. In vivo efficacy was examined in ELAV- and GMR-driven SCA3 transgenic Drosophila treated with RTA-408 (1–4 μ M), assessing survival, locomotor performance, and retinal degeneration.

Results: MJD78 cells showed reduced viability, increased apoptosis, impaired Nrf2 nuclear localization, elevated mutant ataxin-3 levels, and fragmented mitochondria. RTA-408 significantly improved cell viability, enhanced Nrf2 nuclear translocation, increased antioxidant enzyme expression, reduced mutant ataxin-3 protein levels, and partially restored mitochondrial morphology and copy number. In SCA3 transgenic Drosophila, RTA-408 significantly prolonged survival, improved climbing activity, and ameliorated retinal degeneration.

Conclusion: RTA-408 confers neuroprotection in SCA3 models by activating Nrf2 signaling and improving mitochondrial function. The reduction of mutant ataxin-3 likely reflects decreased protein accumulation or enhanced clearance secondary to improved cellular redox homeostasis, supporting Nrf2-targeted mitochondrial modulation as a potential disease-modifying strategy for SCA3.

Disclosure: Nothing to disclose.

EPO-0751 | Sensor-based extended timed up and go parameters and cognitive performance in idiopathic Parkinson's disease

D. Almonti¹; R. Zangari²; L. Brighina³; A. Pilotto⁴; G. Cairolì²; V. D'Agostino³; A. Oppo³; A. Rizzardi⁴; A. Padovani⁵; F. Birolì²

¹Department of Neurology, Papa Giovanni XXIII Hospital, Bergamo, Italy; ²FROM Research Foundation, Papa Giovanni XXIII Hospital, Bergamo, Italy; ³Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy; ⁴Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Italy; ⁵Brain Health Center, University of Brescia, Italy

Background and aims: This study investigated whether Extended Timed Up and Go (eTUG) parameters capture global and composite cognitive impairment in Parkinson's disease (PD).

Methods: Sixty-two PD patients (Hoehn-Yahr 2–3, age 55–74, MMSE >24) underwent sensor-based eTUG assessment using a single lumbar inertial measurement unit. Temporal (duration, turning time) and kinematic (velocity, trunk acceleration) parameters were extracted. Cognitive assessment included Montreal Cognitive Assessment (MoCA), MMSE, Frontal Assessment Battery (FAB) and composite scores reflecting attentive-executive functions. Motor severity was evaluated using Unified Parkinson's Disease Rating Scale Part III (UPDRS-III) and Postural Instability and Gait Difficulty (PIGD scores), and functional endurance was assessed with the six-minute walk test (6MWT). Spearman's correlations examined associations among eTUG, cognitive, motor, and 6MWT measures, considering $|r| \geq 0.3$ and $p < 0.05$ as significant.

Results: Turning time showed moderate correlations with global cognition (MoCA: $r = -0.39$) and attentive-executive function ($r = -0.38$), $p < 0.01$ (Figure 1). eTUG duration correlated with motor severity (UPDRS-III: $r = 0.51$, and PIGD: $r = 0.37$, $p < 0.01$) and 6MWT parameters (distance: $r = -0.76$; gait speed: $r = -0.40$, $p < 0.01$). Kinematic parameters of eTUG showed

FIGURE 1 TUG turning time according to attentive-executive cognitive performance.

weaker cognitive associations but correlated moderately-to-strongly with motor impairment and sustained walking performance (6MWT).

Conclusion: Sensor-based eTUG turning metrics showed greater sensitivity to global and attentive-executive cognitive performance compared to straight-walking measures, highlighting the added value of turning analysis. Total eTUG duration captured both motor impairment and functional endurance. Overall, these findings support eTUG as a feasible motor-cognitive marker for clinical stratification and research applications in PD.

EPO-0752 | Switching to CREXONT/IPX203 improves good on time and reduces motor fluctuations: Interim real-world results from the first 100 patients in ELEVATE-PD

R. Hauser¹; S. Isaacson²; S. Bette²; A. Richmond³; M. Jay⁴; G. Banisadr⁴; S. Fisher⁴; H. Visser⁴

¹University of South Florida Parkinson's Disease and Movement Disorders Center, USA; ²Parkinson's Disease and Movement Disorders Center of Boca Raton, Boca Raton, USA; ³University of Kansas Medical Center, Kansas, USA; ⁴Amneal Pharmaceuticals, Evanston, USA

Background and aims: CREXONT (IPX203), a novel extended-release carbidopa-levodopa formulation containing a mucoadhesive polymer, is designed to improve levodopa delivery and absorption. Here, we evaluate interim outcomes from the real-world study of CREXONT, assessing its impact to extend "Good On" time and reduce "Off" time in PD patients after switching from other levodopa-based therapies.

Methods: ELEVATE-PD is an ongoing, open-label phase 4 study where PD patients are converted from prior levodopa-based therapies (IR CD/LD, IR+COMT inhibitors, Rytary) to CREXONT. Following a 5-week dose-optimization period and a 1-week stable dosing, patients are followed for 12 months. Eligible participants had ≥ 2.5 hours of daily "Off" time at baseline. The primary endpoint is change in daily "Good On" time from baseline/Visit 1 to Day 42/Visit 4. This interim analysis includes 111 patients who completed Day 42.

Results: At baseline, mean daily "Good On" time was 9.39 ± 2.53 hours, "Off" time was 6.21 ± 2.31 hours. • CREXONT treatment increased daily "Good On" time: +3.40 hours for patients switching from IR CD/LD ($n = 74$), +2.91 hours from IR+COMT inhibitors ($n = 9$), +3.07 hours from Rytary ($n = 22$).

Corresponding reductions in “Off” time were: -3.18, -3.09, -2.90 hours, respectively. CREXONT increased “Good On” time per dose by: +2.09, +0.91, +0.98 hours, respectively. CREXONT also improved MDS-UPDRS total scores: -15.3, -10.0, -10.3 points, respectively. Majority of TEAEs were mild-to-moderate; most common ($\geq 3\%$) were dizziness (9.0%), nausea (7.2%), fall (7.2%), dyskinesia (4.5%), hallucination (3.6%), headache (3.6%).

Conclusion: Switching from other levodopa-based therapies to CREXONT significantly improved daily symptom control by increasing “Good On” time, decreasing “Off” time, and enhancing motor function across all treatment groups.

Disclosure: Supported by Amneal Pharmaceuticals.

EPO-0753 | Effect of cognitive and motor dual-task activities on balance in patients with PPPD, FGD, and healthy controls

I. Klopotovska¹; E. Finegan²; M. Bancroft³; D. Shivji¹; Z. Gunes⁴; M. Bautista⁵; L. Flix Diez⁶; D. Kaski³

¹University College London Hospitals NHS Foundation Trust, UK; ²Dublin Neurological Institute, The Mater Misericordiae University Hospital, Dublin, Ireland; ³UCL Queen Square Institute of Neurology, London, UK; ⁴Bezmialem Vakif University, Istanbul, Türkiye; ⁵Hospital Universitario Royo Villanova, Zaragoza, Spain; ⁶Clinica Universidad de Navarra, Madrid, Spain

Background and aims: Balance control relies on integrating sensory inputs and motor responses and can be challenged by simultaneous cognitive or motor tasks, known as the dual-task effect. This study investigated balance under cognitive and motor dual-task conditions in individuals with FGD, PPPD, and healthy controls.

Methods: In this observational cross-sectional study, 15 participants with PPPD (61.7 ± 12.5 years [mean $\pm$ SD]), 16 with FGD (56.1 ± 15.5 years), and 15 healthy controls (55.3 ± 12.5 years) were assessed. Diagnoses followed Bárány Society criteria (PPPD) and Gupta and Lang criteria (FGD). Postural sway was measured using force plate during three 20-second conditions: eyes closed, eyes closed with a motor dual task (dominant-hand

FIGURE 2 Sway across conditions in FGD, PPPD, and healthy control groups.

prono-supination), and eyes closed with a cognitive dual task (listing months backward) (Figure 1).

Results: FGD participants showed significantly higher sway than PPPD ($p=0.035$) and healthy controls ($p<0.001$) across all conditions. Healthy controls and PPPD did not show changes in sway during the dual-task. A small, non-significant reduction in sway was observed in the FGD group during the cognitive dual-task. (Figure2) Dual-task performance, measured by task completion time ($p=0.996$) and months-backward errors ($p=0.491$), did not differ between groups. No learning or adaptation effects were detected.

Conclusion: FGD and PPPD demonstrate distinct postural control profiles, with higher sway in FGD under all conditions. Dual-tasking did not significantly influence performance, although a trend toward reduced sway during cognitive dual-tasking was noted in FGD. Additional analyses will examine balance changes across monthly intervals during the cognitive task.

Disclosure: Nothing to disclose.

EPO-0754 | Features of the cerebellar fMRI connectivity in Parkinson's disease patients with cognitive decline, REM sleep behavior disorder and freezing of gait

O. Alenikova¹; A. Chumak¹; L. Parhach¹; E. Mikitchuk²

¹Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus; ²Belarusian State University, Minsk, Belarus

Background and aims: Sleep disturbances like RBD, postural instability (PI), freezing of gait (FOG) and cognitive decline in Parkinson's disease (PD) are closely linked, and often untreatable. These symptoms are caused by disturbances in brain networks involving the cerebellum, which determines the nature and severity of the motor and non-motor PD manifestations. We investigated the altered cerebellar functional connections (FC) in relation to RBD, PI, FOG severity and cognitive impairment in PD.

Methods: We used questionnaires and tests for assessment sleep problems, gait disturbances and cognition. Rs-fMRI data were analyzed using the SPM12 with the CONN toolbox. The PD patients were divided into 2 groups according to REM Sleep Behavior Disorder scoring (Table 1).

FIGURE 1 Task description.

TABLE 1 Comparative assessment of the PD patient's groups and the control group.

Parameters	PD Group 1 n = 19	PD Group 2* n = 14	Control group n = 80
	Median (IQR)		
Age, years	61 (55 – 68)	59 (52 – 68)	60 (55 – 70)
H & Y stage	1.5 (1–3)	1.5 (1–3)	–
Disease duration (years)	8 (6 – 15)	5 (4 – 13)*	–
UPDRS (part I)	21 (16 – 27)	10 (14 – 28)	–
UPDRS (part II)	17 (10 – 49)	17 (18 – 48)	–
Freezing of Gait Questionnaire	11 (5–29)	11 (13–18)	–
Postural instability (from 0 to 4, where 0 is the norm; 4 = cannot stand without help)	2 (1 – 3)	2 (1 – 3)	–
Parkinson's Disease Sleep Scale-2	28 (10 – 80)	25 (19 – 81)	–
REM Sleep Behavior Disorder rating scales (RBDs)*	8 (0 – 20)	2 (1–3)*	2 (1–8)
MMSE	28 (27 – 29)	28 (27 – 29)	29 (28 – 30)
MoCA	23 (22 – 26)	25 (22 – 28)	27 (26 – 28)

* Patients with a RBDs score of 5 or higher are included in Group 1. PD patients with an RBDs score of 4 or less are included in Group 2.
IQR = p < 0.05: Significant differences between Group 1 and Group 2 (Mann-Whitney test).
MMSE = Mini-mental State Examination
MoCA = Montreal Cognitive Assessment

Results: PD patients both groups demonstrated altered FC between cerebellum (lobule VI, Crus I-II, vermis) and Somatomotor, Default Mode (DMN), Central Executive Network (CEN) nodes. The 1stgroup had a longer PD duration and increased FC within the cerebellar network and between the cerebellum and the Salience Network (SN) compared to 2ndgroup. A significant negative correlation was found between the RBDs score and pedunculopontine nucleus (PPN)-cerebellum FC. In addition to reduced PPN-cerebellum FC, FOG and PI severity negatively correlated with cognitive impairment and reduced PPN – CEN FC.

Conclusion: The cerebellum is the key structures involved in the large-scale functional network, which is compromised by neurodegeneration, contributing to sleep problems, gait disturbances, and cognitive decline in PD. These clinical manifestations have their own specific patterns of the «brainstem (PPN)-cerebellum-cerebrum» FC alteration, what can be considered as a target for neuromodulation.

Disclosure: Nothing to disclose.

EPO-0755 | Clinical decision-making for patients with Friedreich ataxia: Real-world insights from a survey of health care providers in four European countries

A. Adarmes-Gomez¹; M. Graf²; I. Brewer²; N. Land²; J. Chou²; R. Lawson³; M. Urbich⁴; P. Guaraldi⁵

¹Nerology, Unidad de Trastornos del Movimiento, Neurology Service, Instituto de Biomedicina de Sevilla, IBI/Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Seville, Spain; ²HEOR, Precision AQ, Bethesda, USA; ³Biogen, Inc, Cambridge, USA; ⁴Biogen International GmbH, Baar, Zug, Switzerland; ⁵Nerology, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy

Background and aims: Friedreich ataxia (FA) is a rare genetic neurological disease. This study assessed knowledge of FA disease characteristics and clinical decision-making practices of European health care providers (HCPs) in real-world clinical settings.

Methods: Between May-October 2025, we conducted a cross-sectional survey of HCPs in France, Italy, Poland, and Spain to

assess disease knowledge and decision-making practices in the management of patients with FA. HCPs were asked about prior experience with diagnosing and managing patients with FA.

Results: The sample included 549 HCPs comprising 135 pediatricians, 155 primary care physicians, 216 adult neurologists, and 43 pediatric neurologists. 75% of HCPs reported experience managing ≥1 patient with FA and 36% of all HCPs indicated being confident or very confident with identifying the symptoms of FA, while 36% and 25% were somewhat or not at all confident, respectively. 48% of all HCPs estimated confirming an FA diagnosis takes a minimum of 7 months, and a majority of HCPs indicated delayed FA diagnosis has an above average or very high impact on worse quality of life (QoL, 69%), delays in treatment initiation (63%), worse survival outcomes (56%), and disease progression (53%). Improving QoL was the most important treatment objective (mean rank = 2.9 out of 6), followed closely by delaying loss of ambulation (3.2) and improving function (3.4).

Conclusion: In our sample of HCPs, confidence with FA disease characteristics and management was limited, potentially contributing to delayed diagnoses and treatment. Across all four European countries and HCP specialties, improving QoL was seen as the most important treatment objective.

Background and aims: Long-term follow-up data in advanced Parkinson's patients receiving Device-Aided Therapy (DAT) remain limited, our objective is to assess survival and determinants over up to 15 years of therapy.

Methods: Clinical and demographic data of all patients who underwent DAT implantation (Deep Brain Stimulation (DBS) or Levodopa-Carbidopa Intestinal Gel (LCIG)) at the Advanced Therapies for Movement Disorders Clinic, Neurology Department of Ferrara, from 2000 to 2023, were retrospectively analysed and compared.

Results: A total of 207 patients underwent DAT implantation during the observation period, 141 with DBS and 66 with LCIG. LCIG patients were older at implantation and had more advanced PD, with higher dropout at follow-up, whereas the DBS group showed a higher proportion of mortality from

FIGURE 1 Kaplan–Meier survival analysis over a 15-year follow-up comparing patients receiving Deep Brain Stimulation (DBS) and Levodopa–Carbidopa Intestinal Gel (LCIG/Duodopa). Censored observations are indicated on the curves.

TABLE 2 Results of Cox proportional hazards models at 10- and 15-year follow-up, number of events (deaths) shown in parentheses.

10-year survival (35)	B	SE	P value	HR	95% CI
DAT (LCIG)	0.50	0.41	0.23	1.64	0.73–3.69
Age at implant	0.08	0.03	0.003*	1.08	1.03–1.15
Sex (Male)	-0.35	0.38	0.36	0.70	0.33–1.50
H&Y at implant	-0.31	0.39	0.43	0.73	0.34–1.59
Years of disease at implant	0.02	0.03	0.44	1.02	0.97–1.08
15-year survival (47)					
DAT (LCIG)	0.52	0.36	0.17	1.67	0.80–3.52
Age at implant	0.08	0.03	0.004*	1.08	1.02–1.14
Sex (Male)	0.32	0.33	0.34	1.37	0.72–2.62
H&Y at implant	0.05	0.37	0.90	1.05	0.51–2.15
Years of disease at implant	0.04	0.03	0.24	1.04	0.98–1.10

cardiopulmonary and infection-related complications. Fifteen-year Kaplan–Meier analysis showed similar mean and median survival (DBS: mean 10.99 years, median 12.0 years; Duodopa:

mean 10.62 years, median 13.17 years, $\chi^2 = 0.021$, $p = 0.884$). Age at implantation was the only independent predictor of mortality at 10- and 15-year follow-up (10-year: HR 1.09 per year, 95% CI 1.03–1.15, $p = 0.003$; 15-year: HR 1.08 per year, 95% CI 1.02–1.14, $p = 0.004$) by Cox models, while DAT type, sex, preoperative Hoehn–Yahr, and time from disease onset to implantation were not significantly associated with mortality.

Conclusion: Although causes of death differ between groups, overall long-term survival is comparable across DAT types. Age at implantation is the only factor exerting a stable long-term effect on survival, independent of device type.

Disclosure: Nothing to disclose.

EPO-0757 | Sensor-based kinematic markers of subthalamic deep brain stimulation efficacy in Parkinsonian tremor

A. Babakhani¹; A. Papp¹; L. Halász²; L. Erőss²; A. Szilágyi¹; G. Miklós²; G. Fekete³; L. Bognár³; M. Muthuraman⁴; G. Tamás¹

¹Department of Neurology, Semmelweis University, Budapest, Hungary; ²Department of Neurosurgery and Neurointervention, Semmelweis University, Budapest, Hungary; ³Department of Neurosurgery, University of Debrecen, Debrecen, Hungary; ⁴Department of Neurology, Julius-Maximilians-Universität of Würzburg, Würzburg, Germany

Background and aims: Subthalamic nucleus deep brain stimulation (STN-DBS) improves tremor in Parkinson's disease, but objective kinematic outcome markers remain limited. We quantified STN-DBS-related changes in tremor frequency, amplitude, and rhythmicity in tremor-dominant Parkinson's disease as objective outcome measures.

Methods: Thirty-one patients with tremor-dominant Parkinson's disease underwent bilateral STN-DBS. Resting and postural tremor of the more affected hand were recorded with a three-dimensional gyroscope preoperatively and at follow-up (≥ 6 months). Fourier-based analysis extracted peak tremor frequency, peak amplitude, rhythm (coefficient of variation), and tremor frequency range. Motor symptoms were assessed with the Movement Disorder Society Unified Parkinson's Disease Rating Scale (MDS-UPDRS) part III. Active contact locations were measured relative to the subthalamic nucleus center.

Results: Mean age was 63.2 years (standard deviation, SD 7.67). Disease duration at surgery was 8.1 years (SD 4.37). MDS-UPDRS part III scores improved from 15.8 (SD 10.85) to 8.3 (SD 7.07) with stimulation ON. Resting tremor scores decreased from 1.9 (SD 1.16) to 0.26 (SD 0.51). Postural tremor scores decreased from 1.3 (SD 1.14) to 0.2 (SD 0.42). Peak tremor frequency increased for resting (4.8–7.2 Hz) and postural tremor (5.3–8.0 Hz). Peak amplitude decreased by 56.2% for resting and 87.4% for postural tremor. Rhythmicity became less regular, with a 55% reduction for resting and 42% for postural tremor.

Conclusion: STN-DBS in Parkinson's disease shifts tremor toward higher-frequency, less rhythmic oscillations and improves tremor scores, especially for postural tremor. Quantitative kinematic measures provide objective markers of STN-DBS efficacy and may support sensor-based outcome assessment and adaptive DBS programming.

Disclosure: Nothing to disclose.

Background and aims: Non-motor symptoms (NMS) in Parkinson's disease (PD), particularly those fluctuating with motor states (non-motor fluctuations, NMF), significantly impact patient's quality of life but are often underrecognized and undertreated. The aim of the study is to evaluate the effect of adjunctive therapy with the COMT inhibitor Opicapone (OPC) on static and fluctuating NMS in PD patients with motor fluctuations.

Methods: In this prospective observational study we enrolled twenty-one PD patients with motor fluctuations who initiated OPC 50 mg/day as add-on therapy to levodopa. Clinical evaluations at baseline (T0) and after 8–10 weeks (T1) included the MSD-UPDRS part III-IV and the Non-Motor Fluctuation Assessment (NoMoFA) Questionnaire, including the subscores pertaining to fluctuating symptoms (NoMoFA NMF), non-fluctuating symptoms (NoMoFA NoDif). Pre/post-treatment comparisons were analyzed using the Wilcoxon signed-rank test.

Results: We observed a significant reduction in the severity of nonmotor symptoms reported in OFF and in the severity of nonmotor symptom fluctuations (NoMoFA NMF) at T1 ($p < 0.001$). No significant changes were found in the 'static' non-motor symptoms (NoMoFA NoDif subscore; $p = 0.936$). The total NoMoFA score showed a trend toward improvement (median 18 to 14; $p = 0.083$).

Conclusion: Adjunctive OPC therapy was associated with a significant reduction in fluctuating NMS, particularly during OFF periods, in PD patients with motor fluctuations. These real-world findings support the hypothesis that improved dopaminergic

TABLE 2 NoMoFA scores at T0 and T1.

	T0	T1	P
NoMoFA ON	0 (0-0)	0 (0-0)	0.773
NoMoFA OFF	2 (0-4)	0 (0-3)	0.005**
NoMoFA NoDif	14 (9-19)	14 (8-21)	0.936
NoMoFA NMF	2 (0-3)	0 (0-3)	0.005**
NoMoFA TOT	18 (11-20)	14 (8-21)	0.083*

The p-values of the Wilcoxon test are presented and the level of significance is indicated by asterisks as follows: * = $p < 0.05$; ** = $p < 0.01$; *** = $p < 0.001$.
NoMoFA: Non-Motor Fluctuation Assessment Questionnaire; NoDif: No Difference; NMF: Non-motor fluctuations.

EPO-0759 | Somatosensory timing captures early disease heterogeneity and predicts disease trajectory in Parkinson's disease

F. Aiello¹; M. De Bartolo²; M. Costanzo³; C. Cutrona⁴; G. Leodori¹; F. Marchet¹; G. Vivacqua⁵; G. Ferrazzano¹; G. Fabbrini¹; A. Berardelli⁶; A. Conte¹; D. Belvisi¹
¹Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy; ²Department of Radiological Sciences, Oncology and Anatomical Pathology, Sapienza University of Rome, Rome, Italy; ³Department of Neuroscience, Istituto Superiore di Sanità, Rome, Italy; ⁴Department of Neurology and Stroke Unit, San Giovanni Addolorata Hospital, Rome, Italy; ⁵Department of Experimental Morphology and Microscopy Integrated Research Center (PRAAB), Campus Biomedico University of Rome, Italy; ⁶IRCCS Neuromed, Pozzilli (IS), Italy

Background and aims: The somatosensory temporal discrimination threshold (STDT) is a neurophysiological parameter reflecting the shortest time interval between two tactile stimuli required to perceive them as temporally separate. STDT is a stage-, severity- and disease duration-dependent parameter, possibly reflecting dopaminergic degeneration. However, its long-term evolution and predictive value remain underexplored. We aimed to investigate longitudinal STDT changes and its potential to predict clinical progression in PD and discriminate divergent disease trajectories.

FIGURE 1 Differences in Somatosensory Discrimination Threshold among groups: (A) Comparison of STDT values between early PD patients and HC; (B) Longitudinal changes of STDT in PD patients.

Baseline STDT predicting motor worsening

FIGURE 2 Baseline STDT values predict motor symptom progression in Parkinson's disease. Scatter plot showing the relationship between STDT z-scores at baseline and changes in UPDRS III scores (delta_UPDRS III) over a 4-year follow-up in PD patients.

FIGURE 3 Significant clinical differences between PD clusters. Box and violin box illustrate significant differences between PD cluster 1 and cluster 2 patients in clinical scores at baseline, follow-up and in the progression rate.

Methods: We conducted a 4-year longitudinal study involving 60 early-stage PD patients and 50 healthy controls (HC). In PD patients, clinical and STDT assessments were performed at baseline and follow-up. STDT was measured at the distal phalanx of the index finger using an ascending stepwise paradigm. Longitudinal changes, correlations between STDT and clinical measures, regression analyses for progression prediction, and k-means clustering based on baseline STDT were performed.

Results: At baseline, STDT values were similar between patients and HC, but significantly worsened over time in PD. Initially associated with REM sleep behaviour disorder (RBD) symptoms, STDT later correlated with cognitive decline and predicted motor progression. STDT-based clustering identified two subtypes: cluster 1, defined by higher baseline STDT and more severe RBD, exhibited greater motor and non-motor burden and faster progression at 4-year follow-up than cluster 2.

Conclusion: Early STDT differentiates patients with distinct clinical profiles and divergent disease trajectories, capturing early inter-individual variability and predicting long-term motor outcomes in PD. STDT-based clustering aligns with brain-first vs body-first models, supporting its value in early PD stratification.

EPO-0760 | Longitudinal assessment of smartphone-based motor and speech biomarkers in isolated REM sleep behaviour and Parkinson's disease

V. Illner¹; M. Novotny¹; T. Kouba¹; T. Tykalova¹; M. Simek¹; P. Sovka¹; J. Svihlik¹; E. Ruzicka²; K. Sonka²; P. Dusek²; J. Rusz¹

¹Department of Circuit Theory, Faculty of Electrical Engineering, Czech Technical University in Prague, Prague, Czech Republic;

²Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic

Background and aims: The sensitivity of smartphone assessments to disease progression in isolated rapid eye movement sleep behaviour disorder (iRBD) and Parkinson's disease (PD) remains unexplored.

Methods: Participants completed a set of active smartphone tasks every 14 days over a two-year period in their home environments. The cohorts included 23 patients with iRBD, 24 patients with early PD, and 26 healthy controls. The tasks comprised (i) speech assessments (sustained vowel phonation, rapid syllable repetition, and reading a passage), (ii) psychomotor assessments (tapping speed, alternating tapping, and word typing), (iii) a tremor assessment (holding the phone with an outstretched arm), and (iv) a walking turnaround task.

Results: Most tasks, including sustained vowel phonation, rapid syllable repetition, tapping speed, alternating tapping, and the tremor task, demonstrated strong learning effects, limiting their ability to differentiate between groups or detect progression. Word typing with the dominant hand showed group

differentiation (iRBD and PD vs. controls; $p < 0.05$). Measures of monopitch during reading and turnaround walking performance exhibited significant longitudinal worsening in the iRBD group ($p < 0.05$).

Conclusion: Measures capturing monotone speech and walking turnaround performance show potential for inclusion in future clinical trials in iRBD. Most simple active tasks demonstrated limited sensitivity to disease progression due to pronounced learning effects.

EPO-0761 | Assessing dysarthria severity via long-term average spectrum in neurological diseases

M. Simek¹; T. Tykalova¹; J. Klempir²; J. Rusz¹; J. Svihlik³

¹Department of Circuit Theory, Faculty of Electrical Engineering, Czech Technical University in Prague, Prague, Czech Republic;

²Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic; ³Faculty of Electrical Engineering, CTU Prague, Faculty of Chemical Engineering, UCT Prague, Czech Republic

Background and aims: Speech is one of the most complex quantitative markers of motor function and is often affected already in most progressive neurological diseases. This study aimed to evaluate sensitivity of long-term averaged spectrum (LTAS) descriptors computed for reading passage in a broad range of neurological diseases and various types and severities of dysarthria.

Methods: Four spectral moments (spectral mean, spectral standard deviation, spectral skewness and spectral kurtosis) based on LTAS were computed for reading passage collected from 462 speakers, including 306 healthy controls and 156 neurological patients secondary to multiple sclerosis, Parkinson's disease, supranuclear palsy, multiple-system atrophy, Huntington's disease, essential tremor, cerebellar ataxia, and amyotrophic lateral sclerosis. One-way analysis of covariance with post hoc Fisher's least significant difference test was applied.

Results: Compared to controls, Parkinson's disease showed lower mean ($p=0.015$) and higher skewness ($p=0.014$) and kurtosis ($p=0.01$). Among parkinsonian groups, multiple system atrophy also had lower mean ($p=0.042$). Conversely, mean was higher ($p=0.006$) and skewness lower ($p=0.036$) for cerebellar ataxia. Multiple sclerosis demonstrated only a lower mean ($p=0.023$). Among diseases, mean ($p<0.001$), skewness ($p<0.001$) and kurtosis ($p=0.008$) were able to separate cerebellar ataxia and multiple system atrophy.

Conclusion: Our results confirmed LTAS as a suitable approach to objectively describe speech changes due to neurological diseases. Furthermore, spectral moments were able to significantly separate diseases with similar clinical manifestations, which could have important implications for differential diagnosis.

Disclosure: The project was supported by the Czech Ministry of Health, project number NW24-04-00211 and by the ERC-CZ program from the Ministry of Education Youth and Sports, project number LL2504.

EPO-0762 | Artificial intelligence-driven identification of Parkinson's disease using oculometrics

E. Han¹; A. Coito²; H. Fadavi³; B. Hauser²; P. Massatsch²; V. Stozitzky⁴; D. Li⁴; B. Balint¹; H. Dawes³; K. Weber¹

¹University Hospital of Zurich, Switzerland; ²machineMD, Switzerland; ³University of Exeter, UK; ⁴gaitQ, UK

Background and aims: Parkinson's disease (PD) diagnosis remains largely clinical, motivating the search for objective biomarkers to support diagnosis, early detection, and disease monitoring. Eye movement and pupillary abnormalities in PD can be quantified as oculometrics and provide objective features for data-driven analysis. We aimed to develop and evaluate artificial intelligence (AI) models for PD detection using quantitative ocular motor and pupillary measurements acquired with a virtual reality (VR)-based medical eye-tracker.

Methods: Eighty-one individuals with idiopathic PD were recruited at clinical centres in Zurich (Switzerland) and Exeter (UK). Participants completed two study visits including standardized VR-based ocular motor assessments and routine clinical examinations. The analysis included 132 PD examinations and 148 examinations from an independent healthy control cohort. Each PD examination was matched to an age- and sex-matched control using a globally optimal matching algorithm. Group differences were assessed using standardized mean differences (SMDs) and Welch's t-tests. A supervised machine learning classifier was trained using the most discriminative oculometric features, with site-specific performance evaluation.

Results: The largest PD-control differences were observed in saccadic parameters (accuracy, peak velocity, and main sequence), vergence measures, ocular alignment, and pupillary dynamics (constriction and dilation velocity and latency). Classification performance was high across sites: Zurich—AUC 0.96 (sensitivity 0.96; specificity 0.89); Exeter—AUC 0.91 (F1-score 0.84; sensitivity 0.89; specificity 0.79).

Conclusion: VR-derived oculometrics can help differentiate individuals with PD from healthy controls, supporting the potential of an oculometrics-based framework as an objective biomarker approach for PD. Further work focuses on cohort expansion, cross-site data integration, and correlation with clinical disease measures.

²Medical University of Innsbruck, Department of Neurology, Innsbruck, Innsbruck, Austria; ³University of Luxembourg, Luxembourg Centre for Systems Biomedicine, Esch-sur-Alzette, Luxembourg

Background and aims: Parkinson's disease (PD) has a prodromal phase characterized by non-motor symptoms and clinical features that can be integrated into probabilistic risk estimates. Data on medical and neurological comorbidities across levels of estimated prodromal PD risk remain limited.

Methods: We conducted a cross-sectional analysis within the Healthy Brain Aging (HeBA) study, an online population-based cohort. Prodromal PD risk was estimated using the Movement Disorder Society probabilistic research criteria. Participants were classified as high (MDS score >30%) or low (MDS score <1%) risk and matched 1:1 by age, sex, and recruitment site ($n = 326$ total; 163 high-risk and 163 low-risk participants). Type II Diabetes mellitus and depression/anxiety were excluded from the risk calculation and analyzed separately. Medical and neurological conditions and clinical symptom scores were compared between high and low risk groups.

Results: High-risk participants had more medical conditions, including hypertension (58.9% vs. 30.1%), depression/anxiety (55.8% vs. 14.1%), hypercholesterolemia (52.1% vs. 30.1%), diabetes mellitus (20.2% vs. 8.0%), and peripheral vascular disease (14.1% vs. 3.1%) (all $p < 0.01$). Restless legs syndrome (17.8% vs. 0.6%) and essential tremor (8.6% vs. 1.2%) were also more frequent. Multimorbidity increased the odds of high-risk classification (odds ratios: 3.47 for two conditions, 12.38 for three, and 19.50 for >4). Clinical symptom scores including NMS total, GDS, UPDRS-II, and Quality of Life (VAS), differed significantly between groups (all $p < 0.001$).

Conclusion: Higher estimated prodromal PD risk was associated with increased multimorbidity and worse clinical symptom profiles, according to the scales used, in individuals without a PD diagnosis.

FIGURE 1 Morbidity phenotype associated with prodromal Parkinson's disease risk. (A) Prevalence of selected medical conditions by risk group. (B) Dose-response association between morbidity burden and High-Risk status, expressed as odds ratios.

Disclosure: The HeBA study is supported by a grant from The Michael J. Fox Foundation for Parkinson's Research (grant MJFF-PI047794). All authors report no disclosures related to this work.

EPO-0764 | Language as an early indicator of cognitive impairment in Parkinson's disease: Development and validation of an AI-based application

L. Justi; L. Uhlemann; S. Brodoehl
 Biomagnetic Center, Department of Neurology, Jena University Hospital, Jena, Germany

Background and aims: Parkinson's disease (PD) is not only defined by motor symptoms but also by early changes in speech that affect linguistic, semantic and executive functions. Because speech production engages widespread neural networks, subtle alterations can signal early cognitive decline. With recent advances in artificial intelligence (AI), these patterns can now be captured and analyzed automatically, making speech a promising non-invasive marker of cognitive impairment in PD.

Methods: We developed an automated pipeline that records speech, transcribes it using Whisper AI, and analyzes linguistic and semantic features with spaCy and an OpenAI large language model. Extracted markers included word count, sentence structure, verb-noun ratios, semantic coherence and content complexity. These features were used to train three machine-learning models—Support Vector Classifier, Random Forest Classifier and Logistic Regression—to differentiate patients with cognitive impairment (MoCA <24) from those without impairment (MoCA ≥24). The entire workflow was implemented in a web-based application for standardized and scalable data processing.

Results: Automated linguistic measures showed a high degree of concordance with manually obtained reference values, confirming the validity of the pipeline. All machine-learning models demonstrated good discriminative performance. Logistic

FIGURE 1 Screenshot of the web-based application prototype showing audio input, automated transcription, feature extraction, and model output.

FIGURE 2 ROC curves for all ML models, with Logistic Regression achieving the highest AUC (0.804).

TABLE 1 Performance metrics of the trained Support Vector Machine, Random Forest, and Logistic Regression models. Shown are accuracy, precision, recall, specificity, F1-score, AUC-ROC, and the mean AUC values from the stratified 5-fold cross-validation.

Model	Performance Metrics					Cross-Validation AUC (M ± SD)
	Accuracy	Precision	Recall	Specificity	F1-Score	
SVM	0.705	0.708	0.871	0.792	0.832	0.709
RF	0.807	0.800	0.810	0.708	0.834	0.764
LR	0.798	0.727	0.762	0.790	0.744	0.804

Regression performed best, achieving an AUC-ROC of 0.804 and showing the most robust classification across repeated evaluations. The integrated web application processed recordings reliably and consistently.

Conclusion: Our study suggests that AI-based speech analysis can reliably detect speech alterations that indicate cognitive impairment in Parkinson's disease. The validated pipeline and its integration into a web application support its potential as a scalable, non-invasive screening tool.

EPO-0766 | Cortical oscillatory and connectivity profiles of stimulation-induced bradykinesia in dystonia

A. Mak¹; B. Tenge-Bahners²; D. Aravitska²; H. Voss¹; L. Feldmann¹; L. Goede¹; A. de Almeida Marcellino¹; W. Neumann¹; T. Sander³; E. Florin²; A. Kühn¹; R. Lofredi¹
¹Charité – Universitätsmedizin, Berlin, Germany; ²Heinrich-Heine-Universität, Düsseldorf, Germany; ³Physikalisch Technische Bundesanstalt, Berlin, Germany

Background and aims: Pallidal neuromodulation is an established treatment for dystonia, likely acting through modulation of distributed brain networks and their oscillatory dynamics. However, in some patients, pallidal deep brain stimulation (DBS) induces bradykinesia. While this adverse effect has been linked to local stimulation sites and oscillatory changes, its network-level correlates remain unclear.

Methods: We recorded whole-head magnetoencephalography (MEG) in 16 dystonia patients with pallidal DBS at rest with stimulation ON and after a ≥30-minute washout (DBS OFF). In both conditions, patients performed a video-recorded finger-tapping task. Kinematics were extracted using computer vision-based pose estimation. DBS electrodes were localized using Lead-DBS, and functional connectivity from active contacts was estimated using a normative fMRI connectome ($n=1000$). Connectivity profiles were correlated with DBS-induced changes in tapping frequency. To assess oscillatory network effects, we computed cortical spectral power (theta 4–8 Hz, alpha 8–12 Hz, beta 13–30 Hz, gamma 40–90 Hz) and related whole-cortex power changes to movement slowing.

Results: At the group level, DBS did not significantly alter tapping frequency, indicating marked interindividual variability. Across patients, however, the connectivity profile of the active contact predicted DBS-induced slowing ($R=0.45$, $p=0.04$): stronger connectivity to sensorimotor and supplementary motor areas was associated with greater bradykinesia. Cortical modulation in the alpha and gamma bands explained 50% ($R=0.77$, $p=0.001$) and 31% ($R=0.56$, $p=0.01$) of the variance, respectively. These signatures were spatially and spectrally distinct from those associated with therapeutic DBS effects, suggesting separable network mechanisms.

Conclusion: Integrating connectivity and oscillatory profiling may support individualized DBS programming to minimize motor side effects.

Disclosure: Nothing to disclose.

EPO-0768 | Efficacy and safety of magnetic resonance-guided focused ultrasound thalamotomy in essential tremor: A systematic review and meta-analysis

A. Shiramba¹; S. Lane²; N. Ray³; T. Gilbertson⁴; R. Srinivasiah⁵; J. Panicker⁵; M. Radon⁵; J. Osman-Farah⁵; A. Macerollo⁶

¹School of Medicine, University of Liverpool, Liverpool, UK; ²Institute of Data Health Sciences, University of Liverpool, Liverpool, UK; ³Department of Psychology, Manchester Metropolitan University, Manchester, UK; ⁴Department of Neurology, Ninewells Hospital & Medical School, Dundee, UK; ⁵The Walton Centre NHS Foundation Trust for Neurology and Neurosurgery, Liverpool, UK; ⁶Institute of Systems, Molecular and Integrative Biology, The University of Liverpool, Liverpool, UK

Background and aims: Magnetic resonance-guided focused ultrasound is a surgical intervention for medication-refractory essential tremor, however, meta-analyses have been limited in their exploration of the durability of the treatment effect. This study aimed to assess the treatment effect and safety of this procedure over time. Different to other meta-analyses, this study assessed treatment effect durability over time from 1 month to 5 years follow-up, as well as tremor recurrence.

Methods: A systematic search of the literature using set criteria was conducted via PubMed, Scopus, Web of Science, and Cochrane library databases, in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Data analysis was conducted in R, utilising a random-effects model for meta-analysis and a mixed-effects model for meta-regression.

Results: 45 studies met the inclusion criteria, with 42 included in analyses. Significant changes in hand tremor, total tremor, disability scores, and quality of life scores were demonstrated across the time points investigated, the pooled standardized mean differences were -2.36 ($p < 0.0001$), -2.08 ($p < 0.0001$), -2.85 ($p < 0.0001$), and -1.41 ($p < 0.0001$) 1 year post-operation. Sensory symptoms and unsteadiness adverse events were frequently observed, with pooled proportions of 22% (95% CI 15%; 31%) and 23% (95% CI 16%; 31%) 1 month post-operation.

Conclusion: Although the procedure demonstrated efficacy and safety across the studies evaluated, meta-regression analysis suggests a decrease in treatment effect over time that requires further investigation.

Disclosure: Nothing to disclose.

EPO-0769 | Multi-target deep brain stimulation for dystonia and complex tremor syndromes: A single-centre case series and literature review

A. Shiramba¹; J. Panicker²; D. Damodaran²; D. Bhargava²; J. Osman Farah²; A. Macerollo³

¹School of Medicine, University of Liverpool, Liverpool UK;

²The Walton Centre NHS Foundation Trust for Neurology and Neurosurgery, Liverpool, UK; ³Institute of Systems, Molecular and Integrative Biology, The University of Liverpool, UK

Background and aims: Deep Brain Stimulation (DBS) is an established neurosurgical procedure for pharmacologically refractory dystonia and complex tremor syndromes. Multiple target stimulation, such as internal globus pallidus (GPi) and ventral intermediate nucleus (VIM) stimulation, can be used to achieve the control of dystonic features as well as the severe tremor at the same time. This clinical study aims to highlight 10 cases treated at the Walton Centre NHS Foundation Trust (Liverpool, UK) wherein DBS has been implemented beyond unilateral and singular target procedures. It describes the immediate and long-term response and effects of multiple-target DBS in patients with dystonia and complex tremor syndromes (including Holmes tremor).

Methods: Case notes were reviewed retrospectively for the included patients. Data were collected from baseline and subsequent appointments, including treatment details, quantitative and qualitative findings, and side effects. Metrics included the cervical dystonia scale TWSTRS, Fahn-Marsden dystonia scale, FTM scale for tremor, EQ-5D for quality of life, and HADS Anxiety and HADS Depression scores.

Results: Our cohort experienced symptom relief following multi-target DBS, with varying levels of symptom suppression and stimulation-related side effects (i.e. slurred speech, gait disturbance); stimulation adjustments were made accordingly. Importantly, there were discrepancies in objective clinical improvement and perceived symptom relief by the patients.

Conclusion: Multi-target DBS can be useful in managing dystonia and complex tremor cases; it requires balancing symptoms improvement with side effects through continued follow-up and setting adjustments. Tremor suppression and side effect profiles are patient dependent, with varying levels of success demonstrated in our case series.

EPO-0770 | Early COMT inhibition improves motor stability and real-world mobility in Parkinson's disease: A randomized single-blind study with digital biomarkers

A. Zampogna¹; E. Fusco²; M. Patera²; M. Falletti²; V. Bellia²; L. Longo²; C. Pauletti²; A. Suppa¹

¹Department of Human Neurosciences, Sapienza University of Rome, Italy; ²Department of Human Neurosciences, Sapienza University of Rome, Italy

Background and aims: Whether early COMT inhibition provides superior real-world mobility compared with levodopa dose escalation in patients with Parkinson's disease (PD) and emerging motor fluctuations remains unclear. This study compared the efficacy of early add-on therapy with Opicapone versus an additional levodopa dose, using clinician-rated outcomes (CROs), patient-reported outcome measures (PROMs), and digital biomarkers.

Methods: Forty-six PD patients were randomized into two clinically-matched groups ($n=23$ each) receiving either add-on Opicapone 50 mg or an additional levodopa/carbidopa dose (100/25 mg). Single-blind clinical evaluations were performed at baseline and after one month using CROs (MDS-UPDRS III, CGI-C) and PROMs (WOQ-19, PDQ-9, PGI-C). Also, home monitoring with a validated waist-worn wearable sensor provided digital biomarkers of daily steps, step length, gait velocity, cadence, their coefficients of variation (CV), and estimated ON/OFF time.

Results: While CROs did not show between-group differences after treatment, PROMs and digital biomarkers consistently indicated that patients receiving Opicapone had reduced fluctuation severity (WOQ-19), greater perceived improvement (PGI-C),

FIGURE 1 Main findings from clinician-rated outcomes (CROs), patient-reported outcome measures (PROMs), and digital biomarkers.

FIGURE 2 Main clinical-behavioural correlations.

longer objective daily ON time, and more stable gait performance (step length, gait velocity, and cadence CVs) than those taking an additional levodopa dose (Figure 1). MDS-UPDRS III scores correlated with daily ON/OFF time and objective gait measures, indicating worse real-world mobility with increasing motor severity (Figure 2).

Conclusion: Early add-on therapy with Opicapone appears more effective than an additional levodopa dose in improving motor stability and patient-perceived well-being in PD patients with emerging motor fluctuations. While CROs may fail to capture changes in long-term motor phenomena, digital biomarkers provide an ecologically valid assessment of real-world motor behaviours.

Disclosure: Nothing to disclose.

EPO-0771 | Cognitive performances are associated with subclinical gait alterations in drug-naïve cognitively unimpaired patients with Parkinson's disease

C. Cabato¹; V. Sant'Elia¹; N. Piramide¹; R. De Micco¹; O. Ciaramaglia¹; M. Siciliano¹; M. Siciliano²; F. Ambrosio¹; L. Donisi¹; F. Esposito¹; A. Tessitore¹

¹Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy;

²Neuropsychology Laboratory, Department of Psychology, University of Campania "Luigi Vanvitelli", Caserta, Italy

Background and aims: Gait impairment is the most disabling symptom in Parkinson's disease (PD) patients and is associated with high falling risk, worse disease progression and reduced survival. Cognitive impairment has been consistently associated with impaired walking ability and higher fall risk in PD. Detection of subclinical gait alterations could identify early PD patients at risk to develop cognitive impairment.

Methods: Thirty-four drug-naïve cognitively unimpaired PD patients (disease duration ≤ 3 years, Hoehn & Yahr ≤ 2.5) and

20 age- and sex-matched healthy controls were consecutively enrolled. All patients underwent a II-level neuropsychological assessment to exclude cognitive impairment. Motor symptoms were evaluated using the Unified Parkinson's Disease Rating Scale part III (UPDRS-III). Gait and balance parameters were acquired using six Opal V2R wearable sensors when performing the Timed up and go test in single and dual task (ST/DT) conditions. Bivariate correlation analysis between clinical and wearable sensors metrics was performed.

Results: Worse gait and postural parameters detected by wearable sensors in ST/DT conditions significantly correlated with cognitive tests exploring visuo-spatial processing, psychomotor coordination and executive functions involved in retrieving words and information recalling. No correlations have been found between cognitive tests and UPDRS-III scores.

Conclusion: Subclinical gait and postural changes are already associated with cognitive performances in PD patients with normal cognition. Wearable sensors could provide useful information to characterize early PD patients, even when gait and postural disturbances are not clinically detectable. Integrating clinical, neuropsychological and digital data may identify patients more prone to develop clinical overt cognitive impairment useful for prevention strategies.

longitudinal clinical and TMS changes in early PD with unilateral motor signs, comparing stable versus progressive patients.

Methods: Following our previous study [1], 16 PD patients with unilateral motor signs and bilateral putaminal DAT-SPECT loss, and 28 healthy controls (HC), were assessed at baseline; 13 completed follow-up. Clinical scales and bilateral TMS measures of corticospinal excitability, intracortical excitability, interhemispheric inhibition, and paired associative stimulation were collected.

Results: Motor disability increased with reduced asymmetry [2]; 5 out of the original 13 patients with unilateral motor signs converted to bilateral involvement (defined as 'progressors'; presymptomatic-side MDS-UPDRS-III ≥ 3), while others remained unilateral ('non-progressors'). Compared with HC, PD showed increased corticospinal excitability in both hemispheres and reduced intracortical facilitation. In the total PD cohort, presymptomatic hemispheres showed longitudinal motor worsening, accompanied by increased corticospinal excitability (RMT reduction $p=0.003$) and reduced intracortical facilitation (ICF $p=0.013$; slope $p=0.039$). In progressors, presymptomatic hemispheres converting to symptomatic showed increased RMT ($p=0.042$), reduced ICF ($p=0.043$), flattening of the intracortical slope ($p=0.043$), and loss of long-interval IHI ($p=0.043$). In non-progressors, the presymptomatic hemisphere showed increased excitability (RMT reduction $p=0.018$) with SICI enhancement ($p=0.050$), while ICF, IHI, and motor scores remained stable.

PAS average	135.600 (64.542-213.788)	97.144 (91.906-125.027)	181.839 (122.538-188.913)	208.384 (139.858-288.295)	0.275	0.347	0.686

Conclusion: Corticospinal hyperexcitability reflects PD state and progression, whereas preserved intracortical and inter-hemispheric inhibition supports compensation. Loss of facilitation and interhemispheric control marks maladaptive changes linked to clinical conversion. TMS measures appear promising biomarkers of compensatory capacity and motor progression in early PD.

EPO-0773 | Real-world post-market outcomes of magnetic resonance-guided focused ultrasound in movement disorders

G. Schiff¹; A. Sanchez Fraga²; A. Sokolov¹; K. Gant³; C. Ferrer²; A. Grinspan³

¹Insightec Ltd, Tirat Carmel, Israel; ²Insightec Europe GmbH, Munich, Germany; ³Insightec Inc, Miami, USA

Background and aims: MR-guided focused ultrasound (MRgFUS) is an established, CE-approved therapy for unilateral Parkinson's disease (PD), unilateral and staged-bilateral essential tremor (ET) and neuropathic pain (NP). Over 30,000 procedures, including 8000 in Europe, have been performed. This analysis reports updated safety outcomes based on accumulated clinical experience.

FIGURE 1

phases, respectively (Table 2). Daily OFF time was reduced from Vpre to Vpost in 3.2 ± 1.9 hours ($p=0.002$). PwP improved significantly from Vpre to Vpost in motor symptoms, whereas a trend of significance was found for non-motor symptoms burden and quality of life (Figure 1).

Conclusion: LECIG could be a good therapeutic option in PwP who failed fLD/fCD.

Disclosure: Nothing to disclose.

EPO-0775 | Low-income settings, low dyskinesia? A treatment paradox in Parkinson's disease care

I. Teacă¹; M. Gavriliuc¹; A. Arabadji¹; E. Costru-Tașnic²; M. Cebuc¹; N. Ribac²; O. Gavriliuc²

¹Neurology Department no.1, Nicolae Testemițanu University, Chișinău, Republic of Moldova; ²Diomid Gherman Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova

Background and aims: Levodopa-induced dyskinesia (LID) is a common complication of long-term dopaminergic therapy in Parkinson's disease (PD) in high-income countries. In contrast, low-resource settings report a paradoxically lower prevalence. This study evaluated whether limited access to optimized dopaminergic treatment and a conservative approach is linked to a distinct motor complication profile in PD patients from a low-income country.

Methods: We conducted an observational study of 113 adults with idiopathic PD at a tertiary neurological center in Moldova during 2025. Data collected included disease duration, diagnostic delay, Hoehn and Yahr stage, current dopaminergic therapy (dose, frequency, duration), use of adjunctive and anticholinergic medications, and dyskinesia presence. Access to advanced and dyskinesia-specific therapies was described.

Results: Despite a median disease duration of 3 years (IQR 1.55–6) and advanced stages at presentation (Hoehn & Yahr stage 2: 50%; stage 3: 36%; stage 4: 9%; stage 5: 1%), dyskinesia was rare (8%). Levodopa was often started late (median 1.775 years, IQR 0.6–3.5) and given at relatively low doses (median LEDD

600 mg, IQR 375–750), reflecting limited availability and concern over complications. Individual dose adjustment was restricted by the absence of alternative formulations and adjunct therapies. Effective dyskinesia treatments, such as amantadine (2 patients) or device-aided therapies, were seldom accessible. Anticholinergics were commonly used (17%), indicating compensatory strategies in a resource-limited setting.

Conclusion: In conclusion, the low prevalence of dyskinesia in this low-income setting likely reflects chronic underexposure to dopaminergic therapy rather than disease-related protection, highlighting the need for earlier diagnosis and improved access to diversified PD treatments.

Disclosure: This study was funded by the National Agency for Research and Development (NARD) of the Republic of Moldova, research project no. 25.80012.8007.04TC.

EPO-0776 | Brain-heart interaction in patients with Parkinson's disease treated by STN-DBS

M. Lamoš¹; A. Žáčková²; J. Haláček³; P. Jurák³; V. Kincl⁴; M. Bočková⁵

¹Brain and Mind Research Program, Central European Institute of Technology, Masaryk University, Brno, Czech Republic;

²Faculty of Medicine, Masaryk University, Brno, Czech Republic;

³Institute of Scientific Instruments, Czech Academy of Sciences, Brno, Czech Republic; ⁴Department of Internal Medicine/

Cardiology, Masaryk University School of Medicine, St. Anne's Hospital, Brno, Czech Republic; ⁵First Department of Neurology,

Masaryk University School of Medicine, St. Anne's Hospital, Brno, Czech Republic

Background and aims: Parkinson's disease (PD) is recognized as a multisystem disorder with a variety of symptoms including autonomic dysfunctions. There is increasing evidence of cardiovascular symptoms including altered heart rate variability (HRV) compared to healthy controls. Deep brain stimulation of the subthalamic nucleus (STN-DBS) is an established therapy for motor symptoms. This study used simultaneous EEG and ECG recordings to examine the effects of STN-DBS on cortical-autonomic interactions.

Methods: EEG and ECG were recorded in 24 PD patients treated with STN-DBS at rest in DBS OFF and ON condition. For ECG, HRV metrics, SD1 and SD2 were computed from Poincaré plots. In EEG, spectral parameterization (FOOOF) was performed to extract oscillatory power (delta, theta, alpha, beta, low/high gamma) and aperiodic features (offset, exponent). DBS-induced change was defined as $\Delta = \text{ON} - \text{OFF}$. Associations between ΔEEG and ΔHRV were assessed using Spearman correlations.

Results: Short-term HRV (ΔSD1) was positively correlated with Δalpha power, strongest at F4 ($r=0.54$, $p=0.011$). Overall autonomic flexibility, reflected by ΔSD2 , was negatively associated with $\Delta\text{exponent}$. This coupling was most prominent in central and temporoparietal areas, with significant effects in C4 ($r=-0.59$, $p=0.005$), T8 ($r=-0.46$, $p=0.038$), and Cz ($r=-0.44$, $p=0.048$).

Conclusion: DBS exerts no coherent autonomic effect. However, our main findings reveal a structured pattern underlying this heterogeneity. Increases in SD2, reflecting increased autonomic flexibility considered beneficial, were associated

with shifts toward cortical excitation, while reductions in SD2 corresponded to increased cortical inhibition.
Disclosure: Nothing to disclose.

EPO-0777 | Interpretable digital gait biomarkers for multiclass screening of Parkinson's disease, Alzheimer's disease, and healthy controls

S. Kim¹; J. Jung¹; M. Son²
¹Department of Neurology, Busan Paik Hospital, Busan, Republic of Korea; ²Research Institute, JEIOS Inc, Busan, Republic of Korea

Background and aims: Parkinson's disease (PD) and Alzheimer's disease (AD) are prevalent neurodegenerative disorders that present with overlapping gait impairments, limiting the utility of clinical observation for differential screening.
Methods: We investigated whether shoe-embedded inertial measurement units (IMUs) can support multiclass classification of PD, AD, and healthy controls while revealing interpretable, disease-specific digital gait biomarkers. Ninety-four participants (41 PD, 26 AD, 27 controls) performed 10-meter walking tasks (196 trials total). From bilateral tri-axial acceleration and angular velocity signals (100 Hz), 373 gait features spanning spatiotemporal, time-domain, frequency-domain, and entropy measures were extracted. To prevent information leakage from repeated trials, we applied nested cross-validation with GroupKFold at the participant level.
Results: Among 11 classifiers, Linear Discriminant Analysis achieved optimal performance (test macro-F1 0.840, 95% CI: 0.77–0.92; AUC 0.946; balanced accuracy 0.843) using only 20 features with the smallest generalization gap (0.040). Class-wise sensitivity was 0.99 for controls, 0.82 for PD, and 0.73 for AD. SHAP analysis revealed distinct pathophysiological signatures: PD classification was driven by increased variability in inversion-eversion angular velocity and double-support phase duration, consistent with basal ganglia-mediated motor control deficits; AD classification relied on entropy measures, gait velocity reduction, and timing alterations, reflecting impaired cognitive–motor integration.
Conclusion: These findings demonstrate that shoe-embedded IMU gait analysis combined with explainable machine learning can effectively differentiate neurodegenerative conditions while providing clinically interpretable biomarkers aligned with established disease mechanisms, supporting scalable screening and hypothesis-driven biomarker discovery.
Disclosure: Nothing to disclose.

EPO-0778 | Prevalence of nocturnal hypertension and pathological nocturnal dipping profile in patients with synucleinopathies in a tertiary care center

S. Loueslati¹; A. Gandhi²; B. Thompson³; N. Hankov⁴; M. Castro-Jimenez⁵; C. Hubsch⁶; G. Courtine⁷; J. Bloch⁸; G. Wuerzner⁹; J. Bally¹⁰
¹Service of Neurology, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; ²NeuroX Institute, School of Life Sciences, Swiss Federal Institute of Technology, Lausanne, Switzerland; ³Service of Nephrology and Hypertension and University of Lausanne, Lausanne University Hospital, Lausanne Switzerland; ⁴NeuroX Institute, School of Life Sciences, Swiss Federal Institute of Technology, Lausanne, Switzerland; ⁵Service of Neurology, Lausanne University Hospital and University of Lausanne, Lausanne Switzerland; ⁶Service of Neurology, Lausanne University Hospital and University of Lausanne, Lausanne Switzerland; ⁷NeuroX Institute, School of Life Sciences, Swiss Federal Institute of Technology, Lausanne, Switzerland; ⁸Department of Neurosurgery, Lausanne University Hospital (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland; ⁹Service of Nephrology and Hypertension and University of Lausanne, Lausanne University Hospital, Lausanne Switzerland; ¹⁰Service of Neurology, Lausanne University Hospital and University of Lausanne, Lausanne Switzerland

Background and aims: Nocturnal hypertension and pathological nocturnal dipping profiles are adverse prognostic factors in α synucleinopathies (Parkinson's Disease and Multiple System Atrophy), yet they remain under diagnosed because they are usually asymptomatic. This study evaluated their prevalence in a cohort of synucleinopathy patients followed at a tertiary centre.
Methods: Forty adults (26M/14F) with synucleinopathies and history of orthostatic hypotension were recruited from the CHUV-Movement Disorders Unit. All underwent 24 hour Ambulatory Blood Pressure Monitoring (ABPM). Nocturnal hypertension was defined as mean nighttime SBP ≥ 120 mmHg or DBP ≥ 70 mmHg. Dipping status was classified as dippers (10–20% night time fall), non dippers (<10%) and risers (night time BP higher than daytime). Isolated nocturnal hypertension meant elevated night time BP with normal daytime BP (<135/85 mmHg). Association between variability indices and

FIGURE 1 Dipping status classification and their prevalence.

FIGURE 2 Association between daytime variability and nocturnal blood pressure levels.

mean nocturnal BP were assessed using Pearson correlation coefficients and linear regression.

Results: 80.0 % percent of participants had nocturnal hypertension, and 81.3% of those met criteria for isolated nocturnal hypertension. Pathological nocturnal BP profiles were present in 82.5% of the cohort (Figure 1), more severe in male than in female. Higher daytime BP variability was moderately associated with higher nocturnal mean SBP ($r=0.44$) and DBP ($r=0.47$) (Figure 2).

Conclusion: Nocturnal hypertension and abnormal dipping are highly prevalent in synucleinopathy patients, supporting routine 24 hour ABPM—especially in those with orthostatic hypotension complaints—to enable early cardiovascular management and improve quality of life. Larger prospective studies are needed to confirm these findings and assess their impact on disease morbidity and mortality.

Disclosure: Nothing to disclose.

Treatment in MS and Related Disorders 2

EPO-0779 | Efficacy and safety of fenebrutinib vs ocrelizumab in primary progressive multiple sclerosis: Primary results of the phase III FENTrepid study

A. Bar-Or¹; J. Oh²; G. Giovannoni³; M. Sormani⁴; M. Weber⁵; S. Stoll⁶; J. Nicholas⁷; H. von Büdingen⁸; J. Lopez⁹; L. Roberts⁹; M. Triyatni⁸; Q. Qi⁹; J. Ratchford⁹; J. Napieralski⁹; A. Goodyear⁹; S. Hauser¹⁰; L. Kappos¹¹

Hoffmann-La Roche Ltd, Basel, Switzerland; ⁹Genentech, Inc, South San Francisco, USA; ¹⁰University of California San Francisco, San Francisco, USA; ¹¹University Hospital and University Basel, Research Center for Clinical Neuroimmunology and Neuroscience (RC2NB), Basel, Switzerland

Background and aims: Bruton's tyrosine kinase inhibitors (BTKi) have the potential to meet the need for multiple sclerosis

(MS) treatments targeting both relapsing and progressive disease biologies. The Phase II FENopta study (NCT05119569) showed rapid reduction of acute inflammatory disease activity in relapsing MS with fenebrutinib, an oral, highly selective, non-covalent, reversible, central nervous system-penetrant BTKi. The effect of fenebrutinib on progressive MS subtypes has not been demonstrated. FENTrepid (NCT04544449) is the first clinical trial of fenebrutinib in primary progressive MS (PPMS), using ocrelizumab (the only approved treatment for PPMS) as an active comparator.

Methods: FENTrepid is a Phase III, multicentre, randomised, double-blind, double-dummy, parallel-group study evaluating the noninferiority of fenebrutinib vs ocrelizumab in people with PPMS (2017 McDonald criteria), age 18–65 years and Expanded Disability Status Scale [EDSS] score 3.0–6.5. Participants (randomised 1:1) received 200-mg oral fenebrutinib twice daily or 600-mg intravenous ocrelizumab every 24 weeks. The primary endpoint was time to onset of 12-week composite confirmed disability progression via worsening on EDSS, Timed 25-Foot Walk Test and 9-Hole Peg Test.

Results: PwPPMS ($N=985$) had a mean (SD) age of 48.9 (10.3) years and median baseline EDSS score of 5.0. Half were female (49.5%) and most (84%) had no recent exposure to prior disease-modifying therapies. Mean (SD) durations since MS symptom onset and diagnosis were 9.0 (6.7) and 4.7 (5.4) years, respectively. Primary efficacy and safety results will be presented.

Conclusion: FENTrepid will provide evidence on the benefits and risks of fenebrutinib vs ocrelizumab on disability progression in PPMS.

EPO-0780 | Long-term frexalimab treatment modulates the activity of immune networks

B. Djukic¹; R. Gandhi¹; G. Boldina²; V. Truong³; N. Ternes⁴; B. Zhang¹; M. Levit¹; P. Krishnaswami¹; S. S. Geertsens¹; S. Saubadu⁵; P. Truffinet⁵; H. Wiendl⁶; T. Chitnis⁷; A. Bar-Or⁸
¹Sanofi, Cambridge, USA; ²Sanofi, Vitry-sur-Seine, France; ³Ivadata Life Sciences, Paris, France; ⁴Sanofi, Montpellier, France; ⁵Sanofi, Gentilly, France; ⁶Department of Neurology and Neurophysiology, University of Freiburg, Freiburg, Germany; ⁷Brain & Mind Institute, University of Sydney, Sydney, Australia; ⁸Department of Neurology, Mass General Brigham, Harvard Medical School, Boston, USA; ⁹Department of Neurology, University of Pennsylvania, Philadelphia, USA

Background and aims: Frexalimab, a second-generation anti-CD40L monoclonal antibody, inhibits the costimulatory CD40/CD40L pathway, and may recalibrate immune networks involving adaptive and innate immunity. During the double-blind-period of the phase-2 trial (NCT04879628) in participants with relapsing multiple sclerosis (pwRMS), frexalimab-1200mg/intravenous (IV) reduced new gadolinium-enhancing T1-lesions

FIGURE 1 Proposed mechanism of action of frexalimab (anti-CD40L antibody) in multiple sclerosis.

by 89% vs placebo at Week (W) 12. Proteomic and transcriptomic analyses revealed modulation of B-cell activation and antibody production, and reduced plasma levels of innate immune cell-secreted chemokines and cytokines implicated in MS. Here, we explore frexalimab's long-term effects through W120 of the open-label-extension (OLE) using plasma proteomics.

Methods: 129 pwRMS were randomised (4:4:1:1) to frexalimab-1200mg/intravenous (IV) every-4-weeks (q4w), frexalimab-300mg/subcutaneous (SC)-q2w, or matching placebo. After W12, placebo recipients switched to frexalimab and entered the OLE. All SC participants switched to 1800mg-q4w for pharmacokinetic comparability with 1200mg/IV-q4w. Plasma proteomic analysis from frexalimab-1800mg/SC ($n=26$) and 1200mg/IV ($n=30$) arms was performed using NULISaseq with 249-plex-Inflammation panel, and analysed by a paired t-test and Benjamini-Hochberg correction.

Results: At W120, frexalimab treatment yielded 79 differentially abundant soluble proteins (76 downregulated, 3 upregulated) vs baseline, primarily involved in cytokine-receptor interactions, immune-cell communication, and chemotaxis. Frexalimab significantly downregulated adaptive and innate immune cell receptors/co-receptors, cytokines, chemokines, antigen-presentation and adhesion-molecules (CXCL13, CD27, BCMA, GZMA, CSF1R) associated with MS pathophysiology, including progressive disease.

Conclusion: Long-term frexalimab treatment exerts comprehensive immunomodulatory effects by downregulating inflammatory mediators associated with disease progression. These findings support understanding of frexalimab's mechanism of action, which targets immune networks involving adaptive and innate immunity, and holds the potential to mitigate acute and chronic neuroinflammation in MS.

¹⁵Department of Neurology, Christian Doppler Medical Center, Salzburg, Austria

Background and aims: The non-interventional KRONOS study investigates effects of early versus late treatment with Ofatumumab in RMS patients in real-world Austrian clinical practice. Current evidence suggests patients benefit from early highly effective therapy. KRONOS aims to support this evidence for Ofatumumab.

Methods: KRONOS (NCT05776888) is an ongoing 24-month, non-interventional study collecting retrospective and prospective data. Eligible RMS patients received Ofatumumab for ≥ 3 and ≤ 12 months at baseline. The primary endpoint is the proportion of patients with NEDA-3 in the second year after starting Ofatumumab, comparing early (Cohort1) versus late use

Disability-free	No	6	10.9%	5	9.3%	11	19.1%	6	10.9%	11	19.1%
Disability-free	Total	61	100%	9	100%	65	100%	54	100%	119	100%

TABLE 1 KRONOS EDSS change.

(Cohort 2). Secondary endpoints include demographics, individual NEDA-3 components, and safety.

Results: A total of 106 patients were enrolled at 15 centers. Cohort 1 includes treatment-naïve patients or those on disease-modifying therapy (DMT) <3 years; Cohort 2 includes patients with ≥3 years of prior DMT. Mean age was 34.3 years in Cohort 1 and 41.0 years in Cohort 2; overall, 37.5 years. Gender distribution was 40% male/60% female in Cohort 1 and 23.5%/76.5% in Cohort 2. Since disease onset, 79.5% in Cohort 1 and 40.5% in Cohort 2 had <2 relapses. Since starting Ofatumumab, 94.5% in Cohort 1 and 92.2% in Cohort 2 had no relapses. Most patients had EDSS 0.0–1.0. Overall, 13.2% showed a change in EDSS, mainly reductions (64.3% –1.0 point; 7.1% –2.0 points).

Conclusion: KRONOS patients were predominantly female with low baseline disability. Most remained relapse-free after starting Ofatumumab, and a minority showed improved EDSS. Longitudinal data will clarify longer-term outcomes and effects of early versus late Ofatumumab use.

Disclosure: This study is fully funded by Novartis Pharma GmbH, Austria.

Background and aims: Real-world data directly comparing efficacy outcomes among RRMS patients treated with high-efficacy disease modifying treatments remain limited. In this retrospective single centre study, we compared the efficacy of natalizumab (NTZ) and ocrelizumab (OCR).

Methods: We analysed relapse-free survival (RFS), MRI activity-free survival (MFS), progression-free survival (PFS – 6-month confirmed increase EDSS score) and evidence of disease activity (NEDA-3), among RRMS patients treated with OCR ($n = 677$) and NTZ ($n = 368$) at Imperial College Healthcare Trust between 2008 and 2024. After propensity score matching (1:1), outcomes were compared by using Log-rank tests. Cox model regressions were performed across pre-specified subgroups.

Results: After matching ($n = 276$ per group), 394 (71.3%) patients were females, at treatment start median age was 38 years (IQR 30–47), disease duration 4 years (IQR 1–9), and median EDSS score 2.5 (IQR 2.0–5.0). At 4 years follow up, RFS (NTZ: 89% vs OCR: 85%, $p = 0.064$) and MFS (NTZ: 86% vs OCR: 82%, $p = 0.120$) were similar between the groups, while higher proportions of NTZ-treated patients were free of progression (89% vs 85%, $p = 0.050$) and maintained NEDA-3 (74% vs 62%, $p = 0.002$) status. In subgroup analyses, NTZ was associated with a lower risk of losing NEDA 3 than OCR in patients ≤45 years (HR 0.54, 95% CI 0.37–0.78), with EDSS <4 (HR 0.60, 95% CI 0.42–0.87), and with disease duration ≤5 years (HR 0.52, 95% CI 0.35–0.76).

Conclusion: In our cohort, NTZ was superior to OCR in achieving sustained disease remission, driven by more effective prevention of disability progression

Disclosure: Nothing to disclose.

EPO-0783 | FCGR3A V158F affects ocrelizumab binding to natural killer cells and B cell repopulation during extended dosing

G. Abbadessa¹; U. Chianese¹; C. Russo²; G. Miele¹; E. Maida¹; G. Esposito³; G. Lus¹; G. Romano¹; F. Bile¹; E. Signoriello¹; R. Benedetti¹; C. Procaccini³; G. Matarese⁴; L. Altucci¹; S. Bonavita¹

¹University of Campania Luigi Vanvitelli, Naples, Italy; ²AOU Federico II, Naples, Italy; ³Istituto degli Endotipi in Oncologia, Metabolismo e Immunologia (IEOMI) – CNR, Naples Italy;

⁴University of Naples Federico II, Naples, Italy

Background and aims: Ocrelizumab is highly effective in multiple sclerosis (MS). We tested whether FCGR3A (CD16) V158F variant (rs396991) modifies B cell kinetics and outcomes during ocrelizumab and whether ocrelizumab binding to natural killer (NK) cells differs by genotype.

FIGURE 1 FCGR3A polymorphism effects on B cell kinetics and clinical outcomes under ocrelizumab treatment in MS subjects.

FIGURE 2 FCGR3A polymorphism effects on ocrelizumab and rituximab binding to NK cells.

Methods: We enrolled 101 people with MS receiving ocrelizumab (at least two cycles). B cell repopulation (BR) was defined as CD19 positive B cells at least 10 cells/ul. Genotype was modelled dominantly (F carriers vs VV) and as a genotype by interval interaction, adjusted for age, sex, baseline disability, disease

duration, and prior therapy class. Flow cytometry binding assays tested whether rs396991 affects ocrelizumab binding to NK cells using fluorescein labelled ocrelizumab and rituximab in eight donors (four FF, four VV).

Results: While the polymorphism did not affect B cell kinetics under standard dosing, interval extension increased early B cell repopulation in F carriers (odds ratio 2.17; p equals 0.04), and no effects were observed on disease activity or progression outcomes; per month, the odds were 3.08 in F carriers (p equals 0.00026) and 1.42 in VV (p equals 0.195). Ocrelizumab binding to NK cells was lower in FF than VV (p less than 0.001), with the same pattern for rituximab (positive control). No genotype effect was seen in monocytes or B cells, supporting a CD16 specific effect.

Conclusion: FCGR3A V158F identifies patients with earlier B cell repopulation when ocrelizumab intervals are extended, consistent with genotype dependent ocrelizumab binding on NK cells.

Disclosure: Nothing to disclose.

EPO-0784 | Switching natalizumab to cladribine: A monocentric observational trial in multiple sclerosis

G. Borriello¹; M. Peresson¹; F. Gurreri¹; V. Panetta²

¹Multiple Sclerosis Center, San Pietro Fatebenefratelli Hospital, Rome, Italy; ²Altrastatistica SRL -Consultancy & Training-Biostatistics office, Rome, Italy

Background and aims: To test the feasibility of transitioning patients from Natalizumab to Cladribine tablets, an open-label, single-arm, one year, phase IV, research study has been performed to obtain data on safety and efficacy in Multiple Sclerosis (MS).

Methods: patients with Relapsing Remitting (RR) or Secondary Progressive MS were included. All patients were discontinued because of JCV high positivity at both STRATIFY JCV™ and IMMUNOWELL™ Anti-JCV assay. Concomitant administration of corticosteroid therapy was administered orally at the dosage of prednisone 50mg/day, tapered over 30 days or Betametasone 4 mg/day intramuscular for two weeks. Cladribine tablets were administered with the first dose given between days 3 to day 7 after last Natalizumab infusion.

Results: Sixty-five patients mean age of 42.0 years (min-max: 23.0–64.0), 80.0% female were included and all completed the study at 1 year. Most patients had RRMS (66.2%). The mean time from diagnosis was 15.0 years (SD 7.22). At baseline, none of the patients reported relapse in the previous 12 months with the mean EDSS of 3.0. All patient tested for JCV Index resulted positive above 1.5 cut-off. Three patients (4.6%) experienced a relapse at days 110, 180 and 240 after the switch. The median EDSS score was 3.0 at both 6 and 12 months. During Natalizumab treatment in the previous year, infections occurred in 30.8% of patients and 10.8% experienced an infection during Cladribine treatment.

Conclusion: Cladribine maintains disease stability and is well tolerated in patients discontinuing Natalizumab. The study provides real-world evidence supporting Cladribine as a successor therapy.

Disclosure: Nothing to disclose.

Background and aims: Frexalimab is a second-generation anti-CD40L monoclonal antibody that inhibits the costimulatory CD40/CD40L pathway and may recalibrate immune networks involving adaptive and innate immunity. During the double-blind-period of the phase-2 trial (NCT04879628) in participants with relapsing multiple sclerosis (pwRMS), frexalimab-1200mg/intravenous (IV) reduced new gadolinium-enhancing (Gd+) T1-lesions by 89% vs placebo and was well-tolerated at Week (W) 12. Here, we report W144 (3-year) results of the open-label-extension (OLE).

Methods: 129 participants were randomised (4:4:1:1) to frexalimab-1200 mg/IV every-4-weeks (q4w) or frexalimab-300 mg/subcutaneous (SC)-q2w or matching placebo. After W12,

placebo recipients switched to frexalimab and 125 participants entered the OLE. All SC participants switched to 1800mg-q4w for pharmacokinetic comparability with 1200mg/IV-q4w. By W112, all SC participants switched to 1800mg-q4w, with W144 imaging data available for 55/57 participants. Key endpoints included efficacy (Gd+ T1-lesions, new/enlarging T2-lesions, annualised relapse rate [ARR]) and safety.

Results: 100 participants (78%) remained on treatment at the W144 cut-off. The total number of Gd+ T1-lesions (mean [SD]) remained low in all treatment groups (IV: 0.1 [0.3], placebo»IV: 0.3 [1.0]; SC: 0.0 [0.0], placebo»SC: 0.1 [0.3]). New/enlarging T2-lesions monthly count also remained low through W144. Further, ARR (baseline–W144) was low in the frexalimab-1200mg/IV arm; 86% of participants were relapse-free. Frexalimab was well-tolerated through W144, with stable lymphocyte counts, immunoglobulin levels and no new safety signals.

Conclusion: Frexalimab continues to exert sustained reduction in disease activity with favourable safety in pwRMS over 3 years, supporting its further development in phase-3 trials for RMS (FREXALT) and non-relapsing secondary progressive MS (FREVIVA) as a potential high-efficacy, non-lymphocyte-depleting therapy.

Background and aims: The main goal was to analyze the efficacy and safety in MS patients treated with ofatumumab.
Methods: Retrospective, multicentre cohort study including patients treated with ofatumumab from the EMCAM cohort (Multiple Sclerosis Study Group of Madrid). Demographic and clinical characteristics were collected, and effectiveness and safety outcomes were evaluated during the first two years of treatment.
Results: A total of 473 patients were included. The clinical and demographic characteristics are shown in Table 1. 20% of patients have been undergoing treatment for more than a year, and 13% for more than two years. 19.4% of patients switched to ofatumumab due to relapse, 31% due to radiological activity and 13.5% for both reasons. 36.1% switched for other reasons such as safety concerns or adverse events. Two pregnancies have been reported, one full-term and one that ended in miscarriage. 4.8% Patients have discontinued treatment. After one year of treatment with ofatumumab, the ARR decreased significantly to 0.02 and gadolinium-enhancing lesions decreased to 0.04.

Clinical and demographic characteristics of the study	N= 473
Demographic characteristics	
Mean age at inclusion (range)	40.0 (18-72)
Sex (percentage)	100% M
Clinical features	
Baseline EDSS	2.2 (0-8)
Previous relapse	14%
Baseline annualized relapse rate (ARR)	0.28
Baseline gadolinium-enhancing lesions	0.36
Patients with previous pregnancy	4.8%
Patients with relapse prior to treatment	19.4%
Patients previously treated with high or very high efficacy modifying therapies	11.8%

TABLE 1 Clinical and demographic characteristics.

EDSS remained stable at one year 2.2 (0–8). Adverse events were reported in 46% of patients after the first dose, and all were mild. One patient experienced a pulmonary thromboembolism shortly after treatment initiation; this event was deemed unrelated to therapy and did not require discontinuation. One patient suffered an ischemic stroke secondary to vertebral artery dissection three months after starting ofatumumab and has remained on treatment to date.
Conclusion: Ofatumumab was well-tolerated, with no moderate or severe adverse events. two years Significant reductions in ARR and Gd+ lesions were observed at 1 and 2 years supporting its effectiveness and safety in relapsing multiple sclerosis.
Disclosure: Nothing to disclose.

EPO-0787 | Effectiveness and safety of ponesimod in relapsing multiple sclerosis: Results from an Italian multicenter real-world observational study

Background and aims: In 2021, the phase III OPTIMUM trial demonstrated the efficacy of Ponesimod (PON) - a sphingosine-1-phosphate receptor modulator - over teriflunomide in treating Relapsing Multiple Sclerosis (RMS). However, real-world evidence on its effectiveness and safety is still limited.

Methods: We conducted a retrospective, multicenter observational study across 12 Italian MS centers, including adult patients with RMS treated with PON. Effectiveness was evaluated in patients with at least 12 months of follow-up (FU), assessing relapse rate, MRI activity, and disability progression. Safety and tolerability were investigated by reviewing patients' clinical records, focusing on adverse events (AEs), lymphocyte counts and treatment discontinuation.

Results: We included 106 patients treated with PON. Twenty-two patients did not reach the minimum 12-month FU period: 16 for a shorter FU, 6 for treatment discontinuation (4 for AEs and 2 for breakthrough disease activity). Eighty-four (79.2%) patients completed ≥ 12 months follow-up, and 40 (37.7%) reached 24 months. During the first 12-months of FU, disease activity/PIRA occurred in 5 patients (5.8%), while 81 (94.2%) achieved NEDA-3 status. Lymphopenia developed within the first 3-months in most (90%) patients: 23% grade 1, 42% grade 2, 25% grade 3, 0% grade 4. No severe opportunistic infections were observed. Over the entire FU period, treatment discontinuation occurred in 10 patients (9.4%), most commonly due to AEs ($n=7$), with no unexpected safety signals.

Conclusion: In this Italian real-world study, PON showed high effectiveness in controlling clinical and radiological disease activity, with a favourable safety and tolerability profile.

EPO-0788 | Long-term efficacy and safety of ponesimod in females and males: Post-hoc analysis of the ponesimod long-term extension trial

K. Hellwig¹; K. Dost-Kovalsky¹; S. Vignali²; S. Sliepen²; A. Sarfati²; S. de Guitaut²; A. Atallah²; M. Heubl²

¹Department of Neurology, St. Josef-Hospital, Bochum, Germany; ²Medical Affairs Department, Juvisè Pharmaceuticals, Paris, France

Background and aims: Potential sex-related differences in response to disease-modifying therapies in relapsing-remitting multiple sclerosis (RRMS) are not well characterized. We assessed long-term efficacy and safety of ponesimod in females versus males in the OPTIMUM trial and its long-term extension (LTE).

Methods: After 108 weeks of double-blind treatment with ponesimod 20 mg (P) or teriflunomide 14 mg (T) in the core OPTIMUM study, participants were offered ponesimod 20 mg in the OLE for up to 5 years. Outcomes were analyzed by sex subgroups.

Results: 735 females and 398 males were included. Baseline characteristics were comparable. In the core study, mean annualized relapse rate (ARR) was 0.21 (95% CI 0.18–0.26) vs 0.31 (95% CI 0.26–0.37) in females and 0.23 (95% CI 0.18–0.29) vs 0.31 (95% CI 0.25–0.38) in males for P vs T, respectively. ARR remained low in the extension period (0.11 females; 0.12 males) and the 24-week Confirmed Disability Accumulation at Week 360 was similar for female and male patients (22.0%, 21.2%) in patients continuously treated with Ponesimod. Safety patterns across the combined (core + OLE) period were broadly similar between sexes and consistent with previously reported OPTIMUM findings. Sex-related differences were observed, with urinary tract infection more common in females (14% vs <5% males), while alanine aminotransferase elevation occurred

more often in males (32% vs 22%). Headache, fatigue and nausea were more frequent in females.

Conclusion: Ponesimod demonstrated sustained long-term efficacy and safety with comparable outcomes in both sexes. These results support consistent use of ponesimod across both sub-populations.

Disclosure: K.DK has nothing to disclose K.H. has received speaker honoraria and research support from Bayer, Biogen, Merck, Novartis, Sanofi-Genzyme, Roche and Teva, has received support for congress participation from Bayer, Biogen, Merck, Roche, Sanofi Genzyme and Teva, and has served on scientific advisory boards for Bayer, Biogen, Sanofi, Teva, Roche, Novartis and Merck M.H, S.G, A.A and A.S are employees of Juvise Pharmaceuticals.

EPO-0789 | **Efficacy and safety of ponesimod in patients aged 50years or older in OPTIMUM and its long-term extension**

P. Vermersch¹; A. Atallah²; M. Heubl²; S. de Guitaut²; A. Sarfati²
¹Univ. Lille, Inserm U1172 LilNCog, CHU Lille, FHU Precise, Lille, France; ²Medical Affairs Department, Juvise Pharmaceuticals, Paris, France

Background and aims: OPTIMUM was a 2-year phase 3 trial comparing ponesimod with teriflunomide in relapsing multiple sclerosis. In the 5years extension period, all participants received ponesimod 20 mg. This post-hoc analysis evaluated the efficacy and safety of ponesimod in patients aged 50years or older.

Methods: This post-hoc analysis included participants aged 50years or older at core study entry enrolled in OPTIMUM. Clinical efficacy outcomes include Annualized relapse rate (ARR) and disability accumulation. Imaging efficacy was assessed using cumulative combined unique active lesions (CUAL), defined as T1 gadolinium-enhancing lesions plus new or enlarging T2 lesions. Safety assessments included adverse events (AE).

Results: 68 patients were aged 50years or older (34 ponesimod and 34 teriflunomide in the core study). During the core period, ARR was numerically lower with ponesimod (0.11 vs 0.23) compared with teriflunomide [rate ratio 0.47 (95% CI 0.16 to 1.35)] (Table 1). 96.4% of ponesimod patients remained CUAL free

TABLE 1 Annualized relapse rate (ARR) estimates by randomization group and study period in patients aged over 50years; CL, confidence level; RR, rate ratio.

Period	Statistic	Randomization Group	
		Ponesimod 20 mg	Teriflunomide 14 mg
Core	Mean ARR estimate	0.108	0.229
	95% CI	(0.047, 0.252)	(0.122, 0.429)
	Treatment Effect (RR)	0.573	
	95% CI	(0.166, 1.864)	
	Number of subjects	34	34
	Number of relapses	7	16
Combined (Core + Extension) Ponesimod 20mg for all patients	Mean ARR estimate	0.094	0.130
	95% CI	(0.048, 0.185)	(0.073, 0.256)
	Treatment Effect (RR)	0.689	
	95% CI	(0.273, 1.728)	
	Number of subjects	34	34
	Number of relapses	15	22
	Total time (years)	597	582

TABLE 2 Adverse events by randomization group during combined period (core + extension) in patients aged over 50years; AE: adverse events.

Subjects with at least one:	Randomization group	
	Ponesimod 20 mg n = 33	Teriflunomide 14 mg n = 34
AE	31 (93.9%)	33 (97.1%)
Severe AE	3 (9.1%)	6 (23.5%)
Drug related AE	19 (57.6%)	29 (85.3%)
AE leading to discontinuation	6 (18.2%)	6 (17.6%)
Serious AE	7 (21.2%)	8 (23.5%)
Fatal AE	0 (0.0%)	1 (2.9%)

at the end of OPTIMUM compared to 86.2% of teriflunomide patients. During the combined period, ARR remained lower in patients receiving continuous ponesimod compared with those switching from teriflunomide (0.09 versus 0.14). At extension week 240 visit, none of the patients treated continuously with ponesimod presented CUALs. 9.1% of patients treated continuously with ponesimod during the combined period experienced severe AE and no fatal AE were reported. (Table 2).

Conclusion: In this post-hoc analysis of patients aged 50years or older, ponesimod demonstrated sustained clinical and imaging efficacy with a favorable safety profile. These findings require confirmation in larger real-world cohorts.

Disclosure: P.V. received honorarium, contributions to meetings from Biogen, Sanofi-Genzyme, Novartis, Merck, Roche, AB Science, Janssen, Ad Scientiam and Juvise Pharmaceuticals. Research supports from Novartis, Sanofi-Genzyme and Merck. M.H, S.G, A.A and A.S are employees of Juvise Pharmaceuticals.

EPO-0790 | **Long-term treatment effects of frexalimab on NFL, CXCL13, and brain volume loss in relapsing multiple sclerosis**

C. Granziera¹; P. Vermersch²; B. Djukic³; S. S. Geertsens³; A. T. Shafer³; P. Truffinet⁴; G. Giovannoni⁵
¹Translational Imaging in Neurology (ThInk) Basel, Department of Biomedical Engineering, Faculty of Medicine; Neurologic Clinic and Policlinic, MS Center and Research Center for RC2NB, University Hospital Basel and University of Basel, Basel, Switzerland; ²University of Lille, Inserm U1172, Lille Neuroscience and Cognition, CHU Lille, FHU Precise, Lille, France; ³Sanofi, Cambridge, MA, United States; ⁴Sanofi, Gentilly, France; ⁵Queen Mary University of London, London, UK

Background and aims: Frexalimab, a second-generation anti-CD40L monoclonal antibody, inhibits the costimulatory CD40/CD40L pathway, and may recalibrate immune networks involving adaptive and innate immunity. During the double-blind-period of the phase-2 trial (NCT04879628) in participants with relapsing multiple sclerosis (pwRMS), frexalimab-1200mg/intravenous (IV) reduced new gadolinium-enhancing T1-lesions by 89% vs placebo at Week (W) 12, with 24% and 21% reductions in plasma neurofilament light chain (NfL) and chemokine (C-X-C motif) ligand-13 (CXCL13) levels, respectively. Here, we report W144 (3-year) results of NfL, CXCL13, and brain volume loss (BVL) during the open-label-extension (OLE).

Methods: 129 pwRMS were randomised (4:4:1:1) to frexalimab-1200 mg/IV every-4-weeks (q4w), frexalimab-300 mg/subcutaneous (SC)-q2w, or matching placebo. After W12, placebo

FIGURE 1 Incidence of de novo tension-type headache ($n=260$ participants).

FIGURE 2 Average reduction in sleep duration (study sample: $n=260$).

FIGURE 3 The prevalence of night time digital cravings (68 percent) as a behavioral marker identified in sleep architecture disorder participants.

insomnia. Participants participated in two hours of evening video-based short-form for 60 days. Data were collected through headache diaries and sleep records. Statistical analysis has been carried out with SPSS 26.0.

Results: 27 percent ($n=70$) developed de novo tension headache (TTH) after 60 days ($p<0.01$). The mean total amount of sleep has decreased by 52 minutes a night. The sleep latency

ranged from 15 to 60 minutes ($p<0.001$). A specific behavioural marker, night-time digital cravings (compulsive use of a smartphone when waking up in the night) was identified in 68 percent of sleep-deprivation patients. A comparative analysis showed that the effect of digital stimulation on sleep latency was greater than that of caffeine and nicotine.

Conclusion: Results Regular consumption of short-form video content is a self-reinforcing trigger of TTH and severe sleep architecture disorder. These findings support the inclusion of digital silence protocols (at least 60 minutes before bedtime) in the clinical guidelines for the management of headache and insomnia. The night time digital cravings serve as a key indicator of the behavioural addiction of this population.

Disclosure: Nothing to disclose.

EPO-0793 | Psychiatric and affective: Behavioural profile in patients with isolated REM sleep behaviour disorder

F. Di Laudo¹; L. Baldelli¹; L. Sambati²; D. Cimatti²; M. Binda¹; P. Guaraldi²; A. Cerere¹; G. Loddo³; G. Mainieri²; F. Mignani¹; G. Calandra-Buonaura¹; F. Provini¹

¹Department of Biomedical and NeuroMotor Sciences (DiBiNeM), University of Bologna, Italy; ²IRCCS - Istituto delle Scienze Neurologiche di Bologna, Italy; ³Department of Primary Care, Azienda AUSL di Bologna, Italy

Background and aims: Isolated REM sleep behaviour disorder (iRBD) is considered a prodromal stage of overt synucleinopathies. Increasing interest has focused on identifying biomarkers of iRBD and predictors of phenoconversion. Psychiatric comorbidities in this population remain poorly investigated. This study aimed to describe the prevalence of psychiatric comorbidities in isolated iRBD and to evaluate differences in clinical features.

Methods: Eighty-nine patients with polysomnography-confirmed isolated RBD were enrolled. Clinical history was collected; patients underwent neuropsychological testing, cardiovascular reflex tests and olfactory function assessment. Affective-behavioural features were assessed using Beck Depression Inventory-II (BDI-II), State-Trait Anxiety Inventory (STAI-S, STAI-T), Apathy Evaluation Scale (AES) and Neuropsychiatric Inventory (NPI).

Results: Among 89 patients (66 males, 23 females), 29 (32.6%) had a psychiatric diagnosis, mainly depressive and anxiety disorder; in 31% psychiatric diagnosis preceded iRBD. In the whole cohort, depressive symptoms were present in 39.3% and anxiety symptoms in 14.6%; 18.3% of patients without psychiatric diagnosis reported at least one psychiatric symptom. Patients with psychiatric comorbidity showed higher affective symptom burden for depression, anxiety and apathy (all except AES, $p=0.061$). NPI data showed significant differences in anxiety and irritability domains ($p<0.05$). No differences were observed in hyposmia, neurogenic orthostatic hypotension or mild cognitive impairment. Seventeen patients converted to a synucleinopathy, 31.1% of patients with psychiatric diagnosis vs 13.3% without ($p<0.05$).

Conclusion: Psychiatric comorbidities are common in iRBD, and psychiatric symptoms may occur even in the absence of a formal diagnosis. The presence of a psychiatric diagnosis seems associated with phenoconversion, but larger studies are needed to further characterize this clinical phenotype.

Disclosure: Nothing to disclose.

F. Colò¹; B. Viberti¹; S. Bellini¹; A. Chancel²; P. Luppi²; P. Fort²; M. Schmidt¹

¹Center for Experimental Neurology, Department of Neurology, Bern University Hospital (Inselspital) and University Bern; Bern, Switzerland; ²Université Claude Bernard Lyon 1, CNRS, INSERM, Lyon Neuroscience Research Center CRNL UMR 5292 U1028, SLEEP, Bron, France

Background and aims: REM sleep is preferentially expressed under thermoneutral conditions, likely due to reduced thermoregulatory demands. Recent evidence suggests that skin temperature (T_{skin}) and hypothalamic circuits critically modulate REM sleep. Here, we investigated how T_{skin} and melanin-concentrating hormone (MCH) neurons regulate REM sleep and cataplexy in a mouse model of narcolepsy, considering sex, thermal dynamics, and afferent thermoregulatory inputs.

Methods: Using hypocretin-knockout mice, we selectively manipulated T_{skin} during the active phase while monitoring sleep–wake states and cataplexy. To assess causality, we optogenetically inhibited or activated MCH neurons in MCH-Cre; Hcrt-KO mice. Fiber photometry was used to assess MCH neuronal activity during thermal manipulation. Monosynaptic rabies tracing combined with cFos mapping was employed to identify thermoregulatory afferent inputs to MCH neurons.

Results: Thermoneutral skin warming robustly increased REM sleep and reduced cataplexy, whereas skin cooling produced opposite effects; these dissociating effects were observed in both sexes. Non-state-specific MCH inhibition reduced REM sleep and increased cataplexy, while state-specific inhibition during cataplexy prolonged episode duration. Thermoneutral warming overrode the pro-cataplectic effect of MCH inhibition, suggesting parallel temperature-dependent mechanisms partially independent of MCH signaling. Conversely, optogenetic activation of MCH neurons increased REM sleep and decreased cataplexy. Monosynaptic rabies tracing combined with cFos mapping identified thermoregulatory inputs to MCH neurons, with the median preoptic nucleus (MnPO) showing the strongest warm-activated connectivity.

Conclusion: These findings identify skin temperature as a key physiological variable that dissociates REM sleep and cataplexy and highlight MnPO–MCH circuits as a critical interface between thermoregulation and behavioral state control.

Disclosure: Nothing to disclose.

Background and aims: Excessive daytime sleepiness (EDS) and insomnia (IN) are common sleep–wake complaints with substantial personal and societal burden, yet they are often underrecognized in primary care. This pilot study evaluated the feasibility of 12-month recruitment and follow-up and estimated the prevalence and correlates of EDS/IN with health-related quality of life (HRQoL), health status, and economic burden using standardized definitions and validated tools.

Methods: Adult patients were recruited from five general practices and five community pharmacies in Switzerland. A two-step approach was used: consecutive identification of self-reported sleep complaints, followed by screening with validated questionnaires. Participants exceeding clinical cutoffs (ESS >10 and/or ISI >7) were enrolled. Baseline measures included PSQI, HRQoL (SF-12, EQ-5D-5L), and a validated cost-of-illness questionnaire. Follow-up lasted 12 months.

Results: Of 821 pre-screened patients, 757 had complete data. Overall, 38% reported EDS/IN (IN 32%, EDS 19%, both 13%), and 82% had symptoms >3 months. Self-medication was reported by 22% and prescribed therapy by 28% (benzodiazepines, Z-drugs, antidepressants). Among 92 screened for follow-up, 15% did not meet questionnaire cutoffs despite subjective complaints. HRQoL was lowest in those with both EDS and IN, with mental domains more affected than physical. Health-related costs were reported by 74% (median CHF 5340). After 12 months, symptoms largely persisted, with only modest improvements in PSQI and ISI.

Conclusion: This study demonstrates feasibility and highlights the chronicity, clinical impact, and economic burden of EDS/IN in primary care, underscoring the need for improved guideline-based management.

Disclosure: Funded by the European Academy of Neurology.

M. Schmidt¹; Y. Dauvilliers²; R. Del Rio Villegas³; G. Lammers⁴; E. Mignot⁵; G. Plazzi⁶; A. Cai⁷; Y. Du⁷; M. Etherton⁷; T. Olsson⁷

Background and aims: Narcolepsy type 1 (NT1) is caused by loss of orexin producing neurons. We report a pooled analysis of data from two randomized, double-blind, phase 3 studies (The First Light: NCT06470828; The Radiant Light: NCT06505031) that evaluated the effect of oreporexton (TAK-861) on NT1 symptoms and their severity.

Methods: Participants were aged 16–70 years, had an established diagnosis of NT1, and were randomized to twice daily oral oreporexton 1 mg (The First Light only), 2 mg, or placebo, ≥ 3 hours apart for 12 weeks. The primary endpoint was change from baseline to week 12 in mean sleep latency on the Maintenance of Wakefulness Test (MWT). Key secondary endpoints included changes from baseline in Epworth Sleepiness Scale (ESS) and Narcolepsy Severity Scale for Clinical Trials scores to week 12, weekly cataplexy rate at week 12, and Patient Global Impression of Change (PGI-C) in overall narcolepsy symptoms at week 12.

Results: Overall, 273 participants were randomized to oreporexton 1 mg/1 mg ($n = 61$), 2 mg/2 mg ($n = 136$), or placebo ($n = 76$). At week 12, the least square mean differences from placebo (95% CI) for change from baseline in MWT mean sleep latencies were 15.90 (12.65, 19.15) minutes (1 mg/1 mg oreporexton) and 19.16

(16.65, 21.68) minutes (2 mg/2 mg; both unadjusted $P < 0.0001$). Results for the other endpoints are shown in Table 1.

Conclusion: In this pooled analysis, oreporexton treatment improved measures of wakefulness, sleepiness, and cataplexy frequency and reduced the severity of narcolepsy symptoms over 12 weeks vs placebo.

EPO-0797 | A hospital-based, retrospective analysis of the characteristics of periodic limb movements in sleep in children

M. İriş¹; D. Onar¹; D. Karadeniz¹; L. DelRosso²; G. Benbir Şenel¹
¹Neurology, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Türkiye; ²Sleep Medicine, University of California, San Francisco, Fresno, USA

Background and aims: Periodic limb movements in sleep (PLMS) plays a growing role in screening patients for sleep disorders, as it is commonly associated with other sleep-related diagnoses, deteriorates nighttime sleep quality and sleep architecture. While well-studied in adults, pediatric data remains scarce. We investigated PLMS characteristics in children in our hospital-based retrospective study.

Methods: We reviewed medical records and polysomnography (PSG) of 286 patients (<18 years). 109 (38.1%) children had a PLMS index ≥ 5 /hour. Among these, 22 (20.2%) had PLMS only, and were diagnosed with Periodic Leg Movement Disorder (PLMD) due to associated symptoms. Additionally, 48 (44.0%) had pediatric obstructive sleep apnea (pOSA), and 19 (17.4%) had NREM parasomnias (NP). Overlapping diagnoses were excluded. Controls had normal PSG and no clinical sleep disorders.

Results: Demographics showed 52.8% of controls were boys, compared to 40.9% in PLMD ($p = 0.272$), 72.3% in pOSA and PLMS ($p = 0.030$), and 63.2% in NP and PLMS ($p = 0.093$). Mean age was significantly lower in pOSA+PLMS group (6.6 ± 4.3 years, $p = 0.010$) versus others (11.1 ± 4.7 in controls; 7.3 ± 3.6 in PLMD; 9.6 ± 3.0 in NP+PLMS groups). Regression

TABLE 1 Secondary endpoint data at week 12.*

Endpoint	Oreporexton 1 mg/1 mg	Oreporexton 2 mg/2 mg	Placebo
ESS Total Score; least square mean difference (95% CI) for change from baseline vs placebo	-8.27 (-10.82, -5.73)	-6.71 (-10.82, -2.60)	—
P value	<0.0001	<0.0001	—
Weekly Cataplexy Rate; incidence rate ratio (95% CI) vs placebo	0.28 (0.10, 0.41)	0.32 (0.20, 0.48)	—
P value	<0.0001	<0.0001	—
Narcolepsy Severity Scale for Clinical Trials total score; placebo adjusted least square mean (95% CI) change from baseline	-14.75 (-17.51, -11.99)	-17.40 (-19.57, -15.23)	—
P value	<0.0001	<0.0001	—
Patient Global Impression of Change; number and proportion of participants rating narcolepsy symptoms as much or very much improved	42 (72.7%)	123 (92.9%)	13 (18.8%)

FIGURE 1 Ferritin levels across groups.

analysis adjusted for age and sex. Aside from PLMS and apnea-hypopnea indexes, PSG parameters (latency, efficiency, stages) showed no significant differences between groups. Mean ferritin levels were below 50 µg/L in all groups except pOSA, with the lowest levels in NP+PLMS (26.8 ± 16.1 µg/L, $p=0.059$).

Conclusion: PLMS is quite common in pediatric sleep center populations (~33%), frequently co-existing with pOSA and NREM parasomnias. Low ferritin levels in groups except pOSA emphasize the importance of iron deficiency. Furthermore, a 20% hospital-based PLMD prevalence is striking, suggesting this group is underestimated and warrants larger prospective studies.

Disclosure: Nothing to disclose.

EPO-0798 | Effect of the oral orexin receptor 2 agonist oreporexton (TAK-861) on functional impacts of narcolepsy type 1: Pooled data from two phase 3 studies

TABLE 1 Least square mean change (95% CI) from baseline to week 12 versus placebo for the 6 FINI domains.*

Domain	Oreporexton 1 mg/1 mg	Oreporexton 2 mg/2 mg
Tiredness	-33.3 (-45.7, -25.3)	-43.7 (-60.4, -26.0)
Cognitive Functioning	-30.4 (-37.7, -23.3)	-34.1 (-50.8, -28.5)
Cataplexy	-18.5 (-24.6, -12.4)	-25.8 (-35.3, -16.3)
Social Activities	-20.4 (-26.2, -14.7)	-33.4 (-49.5, -27.4)
Everyday Activities	-34.5 (-41.1, -27.8)	-43.0 (-60.3, -25.6)
Everyday Responsibilities	-30.4 (-36.1, -24.8)	-36.9 (-53.7, -20.1)

Background and aims: Narcolepsy type 1 (NT1), a central hypersomnolence disorder with deficiency of hypothalamic orexin signaling, affects functioning and quality of life. We conducted a pooled analysis of data from two randomized, double-blind, oreporexton (TAK-861) phase 3 studies (The First Light: NCT06470828; The Radiant Light: NCT06505031) to investigate its effect on functional impacts using the Functional Impacts of Narcolepsy Instrument (FINI).

Methods: Eligible participants were aged 16–70 years and had a confirmed NT1 diagnosis. Participants were randomized to twice daily oral oreporexton 1 mg (The First Light only), 2 mg, or placebo, ≥3 hours apart for 12 weeks. Change from baseline to week 12 in FINI domain scores was a secondary endpoint in both trials. The FINI comprises 6 independent domains scored from 0 (best functioning) to 100 (worst functioning): Tiredness, Cognitive Functioning, Cataplexy, Social Activities, Everyday Activities, and Everyday Responsibilities.

Results: Improvements with oreporexton were observed across all FINI domains. Mean (SD) change from baseline at week 12 with oreporexton (overall) was -44.6 (23.7) for the Tiredness domain, -33.6 (25.0) for Cognitive Functioning, -24.5 (22.6) for Cataplexy, -33.8 (27.1) for Social Activities, -45.9 (23.0) for Everyday Activities, and -40.0 (28.5) for Everyday Responsibilities; corresponding changes with placebo were -5.1 (22.2), -2.4 (24.4), -5.5 (18.5), -2.6 (23.8), -6.6 (21.5), and -7.7 (28.5). Comparisons versus placebo showed improvements with oreporexton across all domains and doses (Table 1).

Conclusion: In this pooled analysis of data from two phase 3 trials, oreporexton showed improvements in narcolepsy-specific functioning versus placebo.

EPO-0799 | Differential effects of digital self-monitoring and multimodal training on sleep and psychological outcomes in adults with sleep difficulties

S. Shelly¹; T. Tamir²; M. Catalogna³; N. Saporta²; A. Amedi³

¹Department of Neurology, Rambam Medical Center, Haifa, Israel; ²Remepy Health Ltd, Ramat Gan, Israel; ³The Baruch Ivcher Institute for Brain, Cognition, and Technology, Reichman University, Herzliya, Israel

Background and aims: Sleep difficulties and insomnia are widespread conditions that impair emotional well-being, daily functioning, and overall quality of life. Although digital tools are increasingly used to address sleep difficulties, the specific contribution of individual intervention components remains unclear.

Methods: We conducted a 4-week randomized study in 63 adults with sleep complaints, comparing a digital sleep diary (DSD) to a multimodal app combining self-monitoring, psychological training, and a cognitive multisensory task. Sleep and psychological outcomes were assessed pre- and post-intervention. A subsample completed resting-state fMRI to explore neural mechanisms.

Results: Both groups showed improvements in PSQI, indicating better subjective sleep quality. However, only the multimodal group showed significant ISI reductions and broader gains in depression, anxiety, stress, and attention scores. Neuroimaging revealed shared increases in nucleus accumbens (NAc) connectivity with default mode regions across groups. Unique to the multimodal group were reductions in NAc-insula and NAc-anterior cingulate connectivity, key salience network regions involved in both emotion regulation and attentional processing. Improvements in insomnia severity correlated with psychological improvements only in the multimodal group.

Conclusion: While self-monitoring improved sleep quality, only the multimodal intervention significantly reduced insomnia

FIGURE 2 Significant improvements in affective symptoms following the Multimodal intervention.

severity and emotional symptoms. These findings highlight the value of incorporating targeted psychological and multisensory tools within digital sleep platforms and suggest that such multimodal interventions may offer a scalable and effective solution for addressing both sleep disturbance and its associated emotional symptoms in real-world settings.

Disclosure: The authors of this abstract are employees or consultants of Remepy Health Ltd, the company who developed the app and the sponsor of the study.

EPO-0800 | A multimodal neurophysiological signature of REM sleep behavior disorder: A pilot study

A. Quercia¹; G. Lanza²; A. Galeano¹; A. Garifoli¹; B. Lanuzza¹; M. Manuela¹; M. Tripodi¹; A. Palmigiano²; M. Figorilli³; F. Ginatempo⁴; C. Liguori⁵; R. Ferri¹

¹Department of Neurology and Sleep Research Centre, Oasi Research Institute-IRCCS, Troina, Italy; ²Department of Surgery and Medical-Surgical Specialties, University of Catania, Catania, Italy; ³Sleep Disorder Research Center, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy; ⁴Department of Biomedical Sciences, University of Sassari, Sassari, Italy; ⁵Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy

Background and aims: REM Sleep Behavior Disorder (RBD) is a strong prodrome of alpha-synucleinopathies. Although brainstem dysfunction explains the loss of REM atonia, the interaction between sleep architecture, cortical activity, and motor excitability remains poorly understood. We aimed to map these multimodal interactions to clarify how cortical source signals from wake EEG relate to sleep macrostructure and daytime motor control.

Methods: Seven patients with RBD (6 males, 72.86 ± 4.01 years) underwent clinical evaluation (MMSE, MoCA, UPDRS-I, UPDRS-III), 5 minutes of resting-state High-Density EEG, full-night Polysomnography (PSG), and Transcranial Magnetic Stimulation (TMS). Cortical current density was reconstructed via eLORETA. To mitigate statistical bias from the limited sample size, we applied a Domain-Specific PCA to extract the main variance factors: EEG-Source Activity, PSG indices, TMS inhibitory metrics (Silent period, contralateral and ipsilateral), and Clinical Outcomes. Interactions were mapped using Graph Theory and Hierarchical Clustering.

Results: Source analysis revealed significant cortical hypoactivity within the Salience and the Default Mode networks

FIGURE 1 Effects of the digital interventions on sleep outcomes across groups.

FIGURE 1 eLORETA statistical maps of source activity differences in RBD. Three-dimensional maps showing the log-F ratio distribution for reconstructed sources averaged across frequency bands (Delta, Theta, Alpha, Gamma).

FIGURE 2 Integration of multimodal biomarkers via Graph Theory. Correlation network representing the interactions between the main variance factors extracted through Domain-Specific PCA. The nodes include the EEG-Source Activity (EEG Network), PSG indice.

(Figure 1). The PCA identified an Insular-Source Factor as a central hub. This cortical node showed a strong coupling with Sleep Efficiency ($\rho=0.83$) and a secondary association with inhibition Motor Latencies ($\rho=-0.60$) (Figure 2). In contrast, the network revealed a striking dissociation of both REM atonia and clinical motor symptoms (UPDRS-III), which exhibited the lowest centrality.

Conclusion: RBD may involve a systemic failure of cortical integration between the Salience and Default mode networks, a neurophysiological substrate for both sleep instability and slowed motor inhibitory processing. This multimodal approach provides a preliminary but promising window into the cortical network reorganization underlying RBD pathophysiology.

Disclosure: This research was supported by the following institutional grants: Italian Ministry of University and Research (MUR), BANDO PRIN 2022, project title “Caratteristiche neurofisiologiche multimodali e rischio di fenocconversione nell’iRBD” (grant number: MUR 20228XKKCM_001) to Claudio Liguori, Giuseppe Lanza, and Aurora Palmigiano; Italian Ministry of Health (MinSal), BANDO RF 2021, project title “Translational correlates of multimodal electrophysiological

markers of disease process in REM Sleep Behavior Disorder (RBD) and its progression into neurodegenerative disorders: diagnostic hints and therapeutic implications” (grant number: GR-2021-12372863) to Giuseppe Lanza, Michela Figorlli, and Francesca Ginatempo.

EPO-0802 | Leveraging a unified electronic health records system through community outreach centres to deliver tele-neurology services in Kenya: A pilot study

C. Chirchir; J. Shah; D. Sokhi

Department of Medicine, Aga Khan University Medical College of East Africa (Nairobi Campus), Nairobi, Kenya

Background and aims: Access to neurologists in Sub-Saharan Africa is significantly below global recommendations; Kenya has ~20 neurologists for 55 million people. While our 2021 study demonstrated tele-neurology consultations (TNCs) were feasible, critical limitations included the inability to use private insurance or access onsite investigations and/or prescriptions. We aimed to address these gaps by leveraging our tertiary hospital’s (TH) network of 55 community outreach centres (COCs)—the country’s largest, with half spread across the capital—all interlinked by a unified electronic health record (EHR) implemented in 2023.

Methods: Prospective patients booked in the TH neurology clinic were offered TNC at their nearest COC. The new integrated workflow permitted insurance processing and direct ordering of investigations/prescriptions via EHR after the TNC. We undertook a post-TNC survey after consenting participants and present our interim results.

Results: We surveyed 30 participants [median (IQR) age 45 (37.0–51.0) years, 73.3% (22/30) female]; the majority of conditions for TNC were epilepsy and migraine [53.3% (16/30), equal weighting]. 90% (27/30) reported “high satisfaction” including for accessing investigations/prescriptions at COCs. Median (IQR) savings in travel, time and overall cost were 17 (11.5–216.0) km, 3 (2.0–48.0) hours and €16.5 (IQR 7–70) per encounter respectively, and total carbon emissions saved were 2.36 tCO_{2e}.

FIGURE 1 Visual Abstract. Summary of the pilot study demonstrating the feasibility, economic impact, and high acceptability of tele-neurology delivered via Community Outreach Centres (COCs) in Kenya.

Conclusion: Our enhanced workflow, utilizing the TH's vast COC network and EHR, proved highly acceptable and successfully overcame previous insurance and investigation barriers. Interim data confirm significant reductions in travel burden, costs, and carbon emissions, supporting the integration of this model into routine specialist care.

Disclosure: Nothing to disclose.

EPO-0803 | The International Hospital Federation Geneva Sustainability Centre Toolkit to improve the sustainability of neurology services

C. Gericke

School of Medicine, Australian National University, Canberra, Australia & International Hospital Federation (IHF) Geneva Sustainability Centre, Geneva, Switzerland

Background and aims: Climate change is the biggest threat to human health in the 21st Century. As a systemic issue that impacts all aspects of the healthcare sector, a common understanding of key sustainability terms and concepts is essential. Many hospitals and doctors, including neurologists, are interested in reducing their department or hospital's carbon footprint.

Methods: Presentation of the GSC Toolbox to improve the sustainability of healthcare services and practical case studies on how this can be used in clinical services.

Results: Many hospitals and health organisations around the world have now implemented the GSC Toolbox and other GSC tools. After a brief overview of all GSC tools to improve sustainability (sustainability accelerator tool, accreditation and certification, action planning, capacity strengthening), several international case studies of hospitals that have successfully implemented the GSC Toolbox will be presented.

Conclusion: Participants will learn practical tools to reduce their department or hospital's carbon footprint through case studies presented by a practising neurologist and public health physician.

Disclosure: CG is a member of the Steering Committee of the IHF Geneva Sustainability Centre.

EPO-0804 | Effectiveness of mobile stroke (MSUs) in acute ischemic stroke: An updated systematic review and meta-analysis of the five "T-Letter"

¹⁰Faculty of Medicine, Minya University, Minya, Egypt

FIGURE 1 Graphical abstract.

FIGURE 2 Outcome analysis.

Background and aims: Mobile stroke units may accelerate acute ischemic stroke management, but updated evidence comparing their effectiveness and safety with standard emergency medical services (EMS) remains limited, necessitating a contemporary, comprehensive meta-analysis.

Methods: This PRISMA-compliant systematic review (PROSPERO CRD420251273498) searched 5 databases for comparative studies of MSUs versus standard EMS. Random-effects models pooled treatment time, functional, mortality, and safety

FIGURE 3 Comparison between MSU and ESU.

outcomes, with risk of bias assessed using RoB-2, ROBINS-I, and NOS tools.

Results: Across thirty three eligible studies identified, pooled analyses showed substantial reductions in treatment delays, with alarm-to-IVT/IAC time shortened by 29.1 minutes (95% CI –33.7 to –24.6; $I^2 = 97.6\%$) and time to thrombolysis reduced by 36.0 minutes (95% CI –47.4 to –24.7; $I^2 = 89.9\%$). Functional outcomes favored MSUs care across multiple thresholds: the likelihood of excellent outcome (mRS 0–1) increased by 18% (RR 1.18), good outcome (mRS 0–2) by 13% (RR 1.13), and mRS 0–3 by 10% (RR 1.10). MSUs management increased IV tPA use by 17% (RR 1.17) and markedly improved golden-hour thrombolysis (RR 4.64). While 7-day mortality did not differ (RR 0.93), 90-day mortality was reduced by 16% (RR 0.84, 95% CI 0.74–0.94). Safety outcomes, including intracranial hemorrhage (RR 1.01), seizures (RR 0.99), stroke mimics (RR 1.03), and TIA (RR 0.84),

showed no significant differences, supporting the numerical efficacy and safety profile of MSU-based stroke care.

Conclusion: MSUs care significantly reduced treatment times, increased thrombolysis rates, improved functional outcomes, and lowered 90-day mortality without increasing adverse events, demonstrating superior effectiveness and comparable safety versus standard EMS.

Disclosure: Nothing to disclose.

EPO-0805 | Dementia burden in Europe, 1990–2023: Evidence from the global burden of disease study

D. Urso¹; E. Nichols²; S. Giannoni-Luza³; C. Brayne⁴; N. Ray¹; G. Logroscino³

¹GeoHealth group, Institute of Global Health, Faculty of Medicine, University of Geneva, Geneva, Switzerland; ²Leonard Davis School of Gerontology, University of Southern California, Los Angeles, USA; ³Department of Translational Biomedicine and Neuroscience (DiBrain), University of Bari ‘Aldo Moro’, Bari, Italy; ⁴Cambridge Public Health, University of Cambridge, Cambridge, UK

Background and aims: Dementia is a leading cause of disability and mortality in Europe, yet no recent harmonised assessment has described its burden across the European Union (EU-27) and the WHO European Region.

Methods: We used data from the Global Burden of Disease Study 2023 (GBD 2023) to estimate prevalence, mortality, and disability-adjusted life years (DALYs) for Alzheimer’s disease and other dementias from 1990 to 2023. Estimates were produced for the EU-27 and the WHO European Region, by age and sex. Non-fatal outcomes were modelled using DisMod-MR 2.1, and dementia-attributable mortality was estimated using an excess-mortality framework. We also quantified DALYs attributable to six modifiable risk factors.

Results: In 2023, 7.76 million people were living with dementia in the EU-27 and 12.28 million in the WHO European Region, representing ~90% increases since 1990 despite modest declines in age-standardised prevalence. Prevalence was nearly twice as high in women as in men. Dementia rose from the eighth to the third leading cause of death in the EU-27. Dementia accounted for 5.49 million DALYs in the EU-27. An estimated 41% of DALYs in the EU-27 were attributable to modifiable risk factors, particularly ambient particulate matter pollution, high fasting plasma glucose, and high body-mass index, which are disproportionately concentrated in socioeconomically disadvantaged populations.

Conclusion: Despite modest declines in age-standardised rates, the absolute burden of dementia in Europe continues to rise, driven by population ageing. The substantial contribution of modifiable risk factors highlights major opportunities for prevention. Robust, country-specific estimates are essential to guide integrated strategies combining prevention and care planning.

Background and aims: Large registries with real-world clinical data are essential for understanding long-term health trajectories. Large language models (LLM) reliably extract binary-coded diagnoses from clinical text (Dennstadt et al, 2024). Little is known about their ability to capture the temporal structure of diagnoses, including repeated instances. Classification of diagnostic trajectories is essential for prognostic modeling, with particular relevance for preventive medicine. **Methods:** This interim analysis is part of the ongoing “Sleep and Longevity” project within the Bern Sleep-Wake Registry (Figure 1). Six ICD-11 comorbidities with 25 subcategories were selected. They were manually scored in 1000 randomly selected

TABLE 1 LLM performance evaluated descriptively against the ground truth for exact matches.

Cohen's kappa for all records with identified dates	0.84	0.80	0.30	0.00	0.68	0.78	0.78	0.78

plain-text diagnostic records by two independent medical doctors. Disagreements were resolved by a third medical doctor to define the ground truth. For each diagnosis, scorers recorded its presence, type, and date, allowing up to five instances per diagnosis. LLM-based extraction was performed using the data-element-extractor Python package (v0.2.0) with GPT-OSS-20B. Only basic prompting was applied. LLM performance was evaluated descriptively against the ground truth for exact matches. **Results:** Interrater agreement between scorers was high (Cohen's kappa: median 0.96, IQR [0.79–0.98]). The LLM reliably identified diagnoses but struggled to differentiate repeated instances and their dates, occasionally returning no date (Table 1). For instances with an identified date, agreement with the ground truth was moderate to high. **Conclusion:** This is the first study to extract diagnostic trajectories from clinical text in patients with neurologic disorders using LLM. We will improve the extraction through optimized prompting, constrained outputs, and computational strategies (e.g. use of a larger model). **Disclosure:** Nothing to disclose.

FIGURE 1 (A) Study design. (B) Simplified structure of Python script.

EPO-0807 | Risk and causes of hospitalization in persons with Parkinson's disease or atypical parkinsonism: The ParkLink Bologna cohort

L. Vignatelli¹; C. Zenesini¹; M. Marinelli¹; F. Baccari¹; L. Apollonio²; L. Baldelli³; C. Calabrò²; I. Cani³; P. Guaraldi¹; G. Giannini³; G. Loddo¹; R. Pantieri¹; E. Sancisi²; C. Scaglione¹; C. Stipa²; V. Tontini²; E. Baldin¹; G. Calandra-Buonaura³; F. Nonino¹
¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; ²Azienda USL di Bologna, Bologna, Italy; ³Department of Biomedical and NeuroMotor Sciences (DiBiNeM), Alma Mater Studiorum – University of Bologna, Italy

Background and aims: Parkinson's disease is among the leading neurological causes of global burden in the elderly. Risk of hospitalization in people with Parkinson's disease (PPD) is an essential aspect to consider for improving healthcare strategies.

TABLE 1 Incidence Rate Ratios (IRR) with 95% Confidence Intervals (95% CI) for the significant hospital clinical features, comparing the Parkinson's disease and atypical Parkinsonism cohorts with their respective control cohorts.

	Parkinson's disease IRR (95% CI)	Atypical parkinsonism IRR (95% CI)
All hospital admissions	1.60 (1.45–1.76)	1.61 (1.28–2.02)
Infections	2.35 (1.50–3.66)	2.51 (1.67–3.96)
Dematitis	2.28 (1.51–3.43)	2.38 (1.32–4.32)
Metabolic imbalances	1.86 (1.13–3.06)	6.25 (2.46–15.9)
Unlaid cerebrovascular disease	1.88 (1.36–2.62)	2.08 (0.99–4.01)
Myocarditis	1.79 (1.18–2.68)	0.64 (0.29–2.06)
Thromboembolism	1.27 (0.54–3.06)	3.96 (1.24–12.2)
Disorders of thyroid gland	0.38 (0.12–2.09)	6.42 (1.51–26.91)
Psychiatric events	0.38 (0.04–2.22)	1.19 (1.19–42.76)

We aimed to investigate the risk and causes of hospitalization admission in 2-year observation in PPD or people with atypical parkinsonism (PAPS) compared to a matched general population cohort.

Methods: Prospective cohort of PPD or APS compared to a general population sample, matched for sex, age, residence, and comorbidity index within the ParkLink Bologna record linkage system, an ongoing project started in February 2015 in the Local Health Care Trust of Bologna, Northern Italy. PPD/PAPS were diagnosed and recruited by neurologists during routine outpatient clinical practice. Clinical data were linked to administrative health data. Hospitalization at 2-year after recruitment was reported as Incidence Rate Ratio (IRR) between PPD/PAPS and controls.

Results: 816 PPD, 148 PAPS and 9447 controls were included. A higher risk of hospitalization was observed among PPD (IRR 1.60, 95% CI 1.45–1.76) and PAPS (IRR 1.61, 95% CI 1.28–2.02). The acute leading causes of hospitalisation were infections and metabolic imbalances for both groups, while severe trauma specifically affected PPD and thromboembolism specifically affected PAPS (Table).

Conclusion: Linking administrative data with reliable clinical data allow exploring relevant outcomes of the clinical course of PPD. Over a 2-year period, PPD and PAPS had an approximately 60% higher risk of hospitalization, respectively, mainly due to a doubled risk of infections and metabolic imbalances, compared to a matched general population cohort.

Disclosure: The study is funded by IRCCS ISNB (Bando Ricerca Corrente 2025).

EPO-0808 | 5q-associated spinal muscular atrophy in Austria: Epidemiology and co-morbidities

Background and aims: Spinal muscular atrophy (SMA) is a genetic motor neuron disease caused by homozygous deletions or other pathogenic variants in the SMN1 gene, resulting in the degeneration of lower motor neurons associated with progressive weakness and muscle wasting. The development and approval of disease-modifying therapies (DMT) in recent years has fundamentally transformed the management, as well as the clinical and epidemiological landscape of patients with SMA.

Methods: In this study, hospitalisation and prescription databases together with the capture-recapture method are utilised to estimate the prevalence of SMA in Austria and to identify co-morbidities associated with SMA. Patients were matched to healthy controls (1:10) by sex, age and district of residence.

Results: We estimated a total population of 236 patients (95% CI 231–241) with SMA in Austria and a corrected prevalence of 2.5/100,000 persons in the year 2023. Patients with SMA showed significantly higher use of several medication classes, particularly therapies related to respiratory and infectious conditions. Healthy controls, by contrast, exhibited higher prescribing rates of cardiovascular medications, including beta-blockers and ACE inhibitors, as well as lipid-lowering agents and muscle relaxants.

Conclusion: Our findings provide a robust nationwide estimate of SMA prevalence in Austria and highlight a distinct pattern of co-morbidities in the era of disease-modifying therapies, supporting informed healthcare planning and long-term management of patients with SMA.

Disclosure: This study was financially supported by Biogen, Novartis and Roche.

¹Department of Neurology, Medical University of Vienna, Vienna General Hospital, Vienna, Austria; ²Austrian Federation of Social Insurances, Vienna, Austria

Background and aims: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder characterised by the progressive loss of motor neurons, ultimately leading to death within a few years of disease onset. Although recent studies suggest that the global burden of the disease has increased over past decades, the trajectory of epidemiological metrics in Austria remain unknown.

Methods: Hospital discharge records and riluzole prescription databases were used to identify ALS cases between 2016 and 2023. The capture–recapture method was applied to estimate the incidence and prevalence of ALS in Austria. The relationship between disease prevalence and the ratio of deaths to prevalent cases (death-to-case ratio) in a given year was analysed using Pearson's correlation.

Results: A total of 3344 patients were identified during the study period, of whom 44.3% were female. While the corrected annual incidence remained stable (5.2/100,000 person-years in 2016 and 4.8/100,000 person-years in 2023), the prevalence increased steadily over the same period, rising from 8.6 to 14.5/100,000 individuals. Median survival was 605 days (95% CI 569–638). The death-to-case ratio decreased during the study period, from 0.32 in 2016 to 0.22 in 2023, which correlated negatively with the corresponding prevalence numbers ($r = -0.85$, $p = 0.0019$).

Conclusion: In this study, we report on the epidemiology of ALS in Austria between 2016 and 2023. Notably, while the annual incidence remained stable over the study period, our findings indicate an increase of prevalence, most likely due to reduced mortality rates. Our results underscore the need for national healthcare policies to address the challenges posed by the growing disease burden.

Disclosure: This study was not financially supported.

¹Department of Neurology and Stroke, Saint John's Central Hospital of North Buda, Budapest, Hungary; ²BiomTeam@MiND Brain-Gut Center, Budapest, Hungary; ³National Public Health and Pharmaceutical Center, Budapest, Hungary; ⁴Faculty of Economics and Business, University of Debrecen, Debrecen, Hungary; ⁵Institute of Preventive Medicine and Public Health Faculty of Medicine, Semmelweis University, Budapest Hungary

Background and aims: Hungary has one of Europe's highest obesity rates (72.5% of adults). Excess weight is a major risk factor for stroke, contributing to substantial health burden (~€1 billion annual stroke care costs). We aimed to examine BMI

FIGURE 1 Sex-specific prevalence of hypertension across BMI.

FIGURE 2 BMI-related prevalence of diabetes by sex.

FIGURE 3 Prevalence of hypertriglyceridemia by BMI and sex.

associations with cardiometabolic risk factors in Hungarian adults and identify optimal thresholds for stroke prevention.

Methods: Cross-sectional study of 868 Hungarian adults assessing BMI associations with hypertension, type 2 diabetes, dyslipidemia, and atherosclerosis. BMI was calculated from measured height and weight; cardiometabolic conditions determined via clinical examination and laboratory-based point-of-care tests. Sex-stratified logistic regression identified BMI cut-offs for elevated cardiometabolic risk, compared to WHO standards.

Results: Higher BMI significantly associated with hypertension, diabetes, hypertriglyceridemia, and atherosclerosis ($p < 0.05$), but not hypercholesterolemia. Hungarian adults exhibited lower BMI thresholds than international standards. Women showed elevated risk at BMI ~21.8–22.3 kg/m² (normal range) and further elevation at ~25–27.8 kg/m². Men demonstrated risk inflection points at BMI ~23.8–24.3 and ~28.8–29.9 kg/m².

Conclusion: BMI thresholds for cardiometabolic risk are lower in Hungarians than WHO definitions. Hungary-specific cut-offs improve identification of high-risk individuals and enable timely intervention to prevent stroke, substantially reducing incidence and burden.

Disclosure: Nothing to disclose.

EPO-0811 | A nationwide analysis: Memantine in the treatment of dementia in Hungary

P. Halmos¹; D. Bereczki²; B. Dobi³; P. Vinnai³; A. Ajtay²; T. Kovács²

¹Doctoral College János Szentágothai Neurosciences Division, Semmelweis University, Budapest, Hungary; ²Department of Neurology, Semmelweis University, Budapest, Hungary; ³HUN-REN SE Neuroepidemiological Research Group, Semmelweis University, Budapest, Hungary

Background and aims: Dementia is a leading cause of dependency and disability, placing a substantial burden on patients, caregivers and healthcare. The aim of this study was to provide a comprehensive overview of the use of anti-dementia drugs (ADD) – especially memantine – and their association with survival outcomes.

Methods: Using the NEUROHUN database, we analyzed health data covering the entire population of Hungary between 2010 and 2020. Descriptive statistics were calculated to assess disease incidence and prevalence, followed by Kaplan–Meier survival analyses and Cox proportional hazard regression to evaluate survival outcomes.

Results: We identified 398,584 patients with a diagnosis of dementia between 2010 and 2020. Of the total cohort, only 13.3 % of the patients were treated with at least one of the ADDs examined (memantine, donepezil or rivastigmine). Among the medication-fillers, 24.04 % patients were treated with memantine only. Kaplan–Meier analysis demonstrated that the untreated group had the shortest median survival (3.105 years, 95% CI: 3.083–3.129), whereas among patients on medication, those treated with memantine monotherapy had the shortest median survival (3.704 years, 95% CI: 3.606–3.784). In the Multivariable Cox proportional hazards model, patients receiving a combination of memantine and donepezil had the lowest mortality risk (HR: 0.581, 95% CI: [0.566–0.597]) compared to the untreated group.

Conclusion: These findings suggest a high proportion of delayed diagnoses, as memantine is typically prescribed only in advanced dementia stages. Timely diagnosis—particularly in the era of emerging disease-modifying therapies—along with prevention programs and evidence-based healthcare planning is therefore essential.

Disclosure: Nothing to disclose.

Neuroimmunology 4

EPO-0812 | Efficacy of eculizumab in the severe acute attacks of aquaporin-4 IgG-positive neuromyelitis optica spectrum disorder

K. Zeng; W. Chen; A. Lin

Department of Neurology, the First Affiliated Hospital, Fujian Medical University, Fuzhou, China

Background and aims: To compare the therapeutic efficacy of intravenous methylprednisolone (IVMP) versus IVMP combined with eculizumab in patients with neuromyelitis optica spectrum disorder (NMOSD) experiencing severe acute attacks.

Methods: The study performed a retrospective analysis of 25 severe acute attacks occurring in 17 patients with NMOSD during the acute phase. Treatment outcomes were evaluated using the Expanded Disability Status Scale (EDSS) and changes in visual acuity.

Results: Thirteen of the 17 patients received adjunctive eculizumab during the acute phase. The IVMP plus eculizumab group exhibited substantial clinical improvement at discharge and follow-up, with a mean Δ EDSS (defined as discharge EDSS minus attack EDSS) of -1.5, in contrast to a mean Δ EDSS of -0.1 in the IVMP monotherapy group.

Conclusion: The combination of IVMP and eculizumab provides superior clinical benefit over IVMP for patients with NMOSD presenting with severe acute attacks.

Disclosure: Nothing to disclose.

EPO-0813 | Impact of blood-brain barrier integrity on the clinical interpretation of serum neurofilament light as a biomarker of neuroaxonal damage

A. Imeri-Merseli¹; M. Haindl²; R. Demjaha²; C. Tafrali²; M. Martinez Serrat²; D. Pinter²; R. Bichler²; S. Wurth²; S. Hochmeister²; C. Enzinger²; A. Lass³; E. Hofer⁴; M. Khalil²

¹Diagnostic & Research Institute of Human Genetics, Medical University of Graz, Austria; ²Department of Neurology, Medical University of Graz, Austria; ³Institute of Molecular Biosciences, University of Graz, Austria; ⁴Department of Neurology, Medical University of Graz, Austria; Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Austria

Background and aims: Neurofilament light chain (NfL) is an established biomarker of neuroaxonal damage. Despite its relevance in disease monitoring and treatment follow-up, the influence of BBB integrity on serum NfL levels, however, remains insufficiently investigated. This study aimed to assess the impact of BBB integrity on serum NfL concentrations and its clinical relevance.

Methods: NfL concentrations were analyzed in paired cerebrospinal fluid (CSF) and serum samples. BBB integrity was assessed using the CSF/serum albumin quotient (QAlb). 109 patients were included in correlation and regression analyses, 79 patients were classified by BBB integrity (intact BBB: $n=35$; disrupted BBB: $n=44$). NfL was measured using HD-X (single molecule array assay) and Lumipulse G600 II (chemiluminescent enzyme immunoassay).

Results: Patients with a disrupted BBB showed higher NfL concentrations compared to patients with an intact BBB: HD-X CSF 453 [276–1268] pg/mL vs. 1252 [569–4622] pg/mL ($p < 0.001$); HD-X serum 9.98 [6.26–28.58] pg/mL vs. 25.46 [11.51–53.56] pg/mL ($p = 0.005$). Lumipulse CSF 334 [213–1191] pg/mL vs. 1060 [544–4260] pg/mL ($p = 0.001$); Lumipulse serum 12.33 [9.24–40.79] pg/mL vs. 35.60 [15.26–64.96] pg/mL ($p = 0.006$). CSF/serum correlations were stronger in patients with an intact BBB (HD-X: $r_s = 0.84$; Lumipulse: $r_s = 0.87$; both $p < 0.001$) than with a disrupted BBB (HD-X: $r_s = 0.73$; Lumipulse: $r_s = 0.71$; both $p < 0.001$). In the overall cohort ($N = 109$), strong CSF/serum correlations were observed (HD-X: $r_s = 0.80$, $p < 0.001$; Lumipulse: $r_s = 0.83$, $p < 0.001$). Linear regression showed no significant influence of QAlb on this relationship (interaction $p > 0.9$).

Conclusion: BBB integrity influences absolute serum NfL concentrations but not the CSF/serum NfL relationship, supporting serum NfL as a valid biomarker of neuroaxonal damage, even in BBB dysfunction.

EPO-0814 | Diagnostic performance and pitfalls of a commercial assay for CASPR2 autoantibodies

C. Milano¹; L. Naranjo²; R. Ruiz Garcia²; L. Arlettaz³; C. Papi¹; L. Marmolejo¹; T. Armangué⁴; M. Guasp¹; J. Dalmau¹; F. Graus¹; M. Spatola⁵

¹Neuroimmunology Program, Fundació de Recerca Clínica Barcelona-Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), University of Barcelona, Spain; La Caixa Research Institute, Barcelona, Spain; ²Neuroimmunology Program, Fundació de Recerca Clínica Barcelona-Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), University of Barcelona, Spain; Immunology Service, Biomedical Diagnostic Center, Hospital Clínic, Barcelona, Spain; ³Service d'Immuno-Allergologie, Institut Central des Hôpitaux, Sion, Switzerland; ⁴Neuroimmunology Program, FRCB-IDIBAPS, University of Barcelona, Spain; La Caixa Research Institute, Barcelona, Spain; Pediatric Neuroimmunology Unit, Neurology Department, Sant Joan de Déu Children's Hospital, University of Barcelona, Barcelona, Spain; ⁵Neuroimmunology Program, FRCB-IDIBAPS, University of Barcelona, Spain; La Caixa Research Institute, Barcelona, Spain; Service d'Immuno-Allergologie, Institut Central des Hôpitaux, Sion, Switzerland

Background and aims: Widespread use of commercial cell-based assays (cCBA) has enhanced detection of contactin-associated protein-like 2 antibodies (CASPR2-abs) but has also raised concerns about false positive results, particularly when testing is limited to serum or antibody titres are low. However, their diagnostic performance has not been systematically validated.

Methods: We analysed serum and CSF samples from patients referred to our Neuroimmunology laboratory (Barcelona) for suspected autoimmune neurological disorders who tested positive for CASPR2-abs by cCBA (Euroimmun). Samples were re-tested using in-house rat brain immunohistochemistry and CBA.

Results: Of 105 patients with CASPR2-abs detected by cCBA, 74 (71%) were confirmed by in-house techniques (true-positive) and 31 (29%) were not (false-positive). Compared to true-positive, false-positive results occurred more frequent in females (4% vs. 52%, $p < 0.0001$) and younger patients (median age 68 vs. 58 years, $p = 0.02$). Among patients with false positive results, 23 (74%) presented with symptoms initially compatible with CASPR2 autoimmunity (although most had a final alternative diagnosis). However, only 1/20 (5%) had clinico-radiological evidence of limbic encephalitis, compared with 19/64 (30%) patients with confirmed CASPR2-abs ($p = 0.03$). False positive results occurred exclusively in serum (31 samples available). All paired CSF (21 available) from these patients were negative by both CBAs and in-house testing. In contrast, all the available CSF (37/37) from patients with true-positive serum results were also positive by cCBA.

Conclusion: CASPR2-abs detected exclusively in serum by cCBA, in the absence of CSF positivity, should be interpreted with caution, particularly in younger patients and females. CSF antibody testing is essential to minimize false-positive diagnoses.

Disclosure: Nothing to disclose.

D. Omar¹; T. Arun¹; C. Rice²; H. Mehta¹; B. Quirk³; P. Fernandes⁴; P. Brex⁵; A. Gontsarova⁶; J. Mathews⁷; V. Singh-Curry⁸

¹University Hospitals Coventry Warwickshire NHS Trust, UK; ²North Bristol NHS Trust, UK; ³Royal Free London NHS Foundation Trust, UK; ⁴University Hospital Southampton NHS Foundation Trust, UK; ⁵King's College Hospital NHS Foundation Trust, UK; ⁶Imperial College Healthcare NHS Trust, UK; ⁷Barts Health NHS Trust, UK; ⁸Chelsea And Westminster Hospital NHS Foundation Trust, UK

Background and aims: Neurosarcoidosis (NS) is a diagnosis of exclusion, with significant clinical and radiological overlap with infectious, neoplastic, and neuroinflammatory conditions. We report outcomes from the UK NS multidisciplinary team (MDT) meeting, focusing on cases where the diagnosis of NS was not confirmed.

Methods: Twenty-eight cases of suspected NS were reviewed since the MDT launch (May 2025). Clinical presentation, imaging features, diagnostic consensus, recommended investigations, onward referrals, and treatment decisions were reviewed.

Results: The primary reason for referral was diagnostic uncertainty (19/28), and, in 6/28 (21%), the MDT found insufficient evidence to confirm a diagnosis of NS. Differential diagnoses included vasculopathy and tuberculosis (6/28 each), IgG4-related disease (4/28), neoplastic and demyelinating conditions (3/28 each) and Progressive multifocal leukoencephalopathy and fungal infection (2/28 each). Of those, MDT suggested unlikely to be NS (4/6) had radiological evidence of recurrent infarcts. The most frequent clinical manifestations were brainstem symptoms (7/28), seizures, and headache (5/28 each). Frequently recommended investigations included cardiac assessment (MRI/PET), additional CSF analysis, vascular imaging, ophthalmological evaluation and full-thickness skin biopsy. Suggested management changes included discontinuation of immunosuppressive treatment (5/28), initiation of tuberculosis therapy (2/28), escalation to infliximab (7/28), cyclophosphamide (3/28), tocilizumab or adalimumab.

Conclusion: National MDT review frequently identified opportunities for additional work-up with the aim of increasing diagnostic confidence and treatment outcomes, including the rationalisation of immunosuppression. These early data highlight the importance of the national MDT in supporting neurologists managing neurosarcoidosis and other complex neuroinflammatory conditions.

Disclosure: Nothing to disclose.

¹Neurological Department A. Perrino's Hospital Brindisi Italy; ²Department of Radiology, A. Perrino's Hospital, Brindisi, Italy; ³Hematological Department, A. Perrino's Hospital, Brindisi, Italy

Background and aims: Chimeric antigen receptor (CAR) T-cell therapy has profoundly changed the therapeutic landscape of relapsed/refractory B-cell lymphoma. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) represent relevant adverse events. Rare manifestations, including severe leukoencephalopathy, and non-ICANS complications such as myelopathy and peripheral neuropathy, have been reported.

Methods: We report the clinical course, neuroimaging findings, and treatment of a patient who developed acute leukoencephalo-myelo-radiculopathy after anti-CD19 CAR T-cell therapy.

Results: A 28-year-old woman with stage IVB diffuse large B-cell lymphoma resulted refractory to first-line chemotherapy. She underwent cyclophosphamide/fludarabine lymphodepletion and axicabtagene ciloleucel infusion. On day 1, she developed grade 2 CRS, treated with tocilizumab and corticosteroids. On day 4, she developed grade 2 ICANS, progressing to grade 4 on day 5. High-dose intravenous methylprednisolone was initiated. Brain magnetic resonance imaging (MRI) revealed diffuse leukoencephalopathy extending to the upper cervical spinal cord. On day 7, the patient was awake, but severe tetraparesis was evident. Spinal MRI demonstrated longitudinally extensive acute myelitis and thickening of the cauda equina nerve root with faint contrast enhancement. Lumbar puncture was not performed due to severe thrombocytopenia. Polymerase chain reaction testing for neurotropic viruses on peripheral blood was negative. High-dose intravenous methylprednisolone was continued, and intravenous immunoglobulin was administered, with mild neurological improvement. By day 23, clinical and radiological evidence of abdominal mass progression emerged. The patient died on day 45.

Conclusion: CAR T-cell therapy may rarely cause severe neurotoxicity affecting both the central and peripheral nervous systems. Systematic reporting is needed to improve risk stratification and management.

Disclosure: Nothing to disclose.

FIGURE 1 Leukoencephalopathy changes on magnetic resonance imaging: T2-weighted fluid attenuation inversion recovery axial image of the brain demonstrate symmetrical T2 hyperintensity of the deep white matter, most pronounced in the centrum semiovale.

FIGURE 3 Conus medullaris involvement in acute inflammatory myelopathy. Sagittal T2-weighted lumbar spine magnetic resonance imaging demonstrates hyperintense signal changes and mild enlargement of the conus medullaris, with associated thickening of the cauda equi.

FIGURE 2 Acute inflammatory myelopathy: Sagittal T2-weighted fat-suppressed MRI spinal magnetic resonance imaging demonstrates a longitudinally extensive intramedullary hyperintense signal involving the cervical and thoracic spinal cord, associated with mild cord.

Matteo, University of Pavia, Pavia, Italy; ⁵Unit of Child Neuropsychiatry, EpiCARE Network, IRCCS Istituto Giannina Gaslini, Genova, Italy; ⁶Child Neurology Unit, Buzzi Children's Hospital, Milan, Italy; ⁷Neuroimmunology Laboratory and Neuroimmunology Research Section, IRCCS Mondino Foundation, Pavia, Italy

Background and aims: Acute disseminated encephalomyelitis (ADEM) is a rare CNS demyelinating disease, in some cases associated with antibodies to the myelin oligodendrocyte glycoprotein (MOG-IgG). Recently, antibodies to the proteolipid protein-1 (PLP1-IgG) has recently been identified in a subset of ADEM patients, though its frequency remains unknown. We aim to define the ADEM serological and clinical/paraclinical features in children versus adults.

Methods: We retrospectively screened patients with suspected ADEM referred to our laboratory and included those meeting the International Pediatric Multiple Sclerosis Study Group criteria. We collected clinical and radiological information from the clinical charts. In patients with available samples, we performed serological screening including MOG-IgG and PLP1-IgG.

Results: Ninety-eight ADEM patients were included in the study. The median age at onset was 7 years (0.03–76.27), and 71% were pediatric (≤ 16 years). Adults presented more frequently myelitis ($p = 0.002$), PNS involvement ($p < 0.001$), and sensory/sphincter symptoms ($p < 0.001$). Among 78 of 98 patients tested for anti-myelin autoantibodies, 28/78 were MOG-IgG+ (mostly children; $p = 0.054$); 10/78 were PLP1-IgG+ (mostly adults; $p < 0.001$); 34/78 were double-negative; and 6/78 were double-positive. PLP1-IgG+ patients showed more frequently PNS involvement ($p < 0.001$) and higher mRS at follow-up ($p = 0.002$). Over a median follow-up of 1.35 years, 30/98 patients relapsed without correlation with auto-antibody profile. Good recovery (mRS < 3) was associated with younger age ($p < 0.001$), myelitis ($p = 0.006$), MOG-IgG+ ($p = 0.030$) and PLP1-IgG- ($p < 0.001$).

Conclusion: Adult-onset ADEM exhibits distinct clinical/para-clinical and serological profile compared to pediatric cases. Further studies are needed to better define the relevance of PLP1-IgG in this subgroup.

Disclosure: Nothing to disclose.

FIGURE 1 Map showing thalamic nuclei significantly decreased in MOGAD compared to healthy controls.

Background and aims: As multiple analytical platforms for serum NfL (sNfL), an established biomarker of neuroaxonal damage, are now available, assay comparability and harmonization are critical for clinical and research use. This study compared sNfL measurements across three assays—NF-light Advantage V2/Plus (Quanterix), Lumipulse G NfL blood (FujiRebio), and Elecsys NfL (Roche Diagnostics) and suggested conversion formulas to support standardization.

Methods: Serum samples from healthy donors ($n = 303$) and patients with multiple sclerosis (MS; $n = 181$) were analyzed. Inter-assay agreement was assessed using Passing–Bablok regression and correlation analyses. Assays were further evaluated for their ability to detect MS disease activity. In addition to original data, this poster will integrate and compare published conversion formulas and provide data on NfL levels across neurological diseases.

Results: All assays demonstrated strong correlations (Pearson $r > 0.98$; Spearman $\rho > 0.90$; $p < 0.001$). Fourteen of 484 samples (2.9%) showed stable, platform-specific deviations (> 4 SD). After excluding outliers, conversion equations to the NF-light Advantage scale were derived: $NfL = 6.31 \times [Elecsys] + 2.33$ ng/L; $NfL = 0.94 \times [Lumipulse] + 1.30$ ng/L. All platforms detected significant differences between MS relapse and remission ($p < 0.001$). Age-adjusted Z scores values yielded the largest effect sizes.

Conclusion: The three platforms show high concordance and comparable clinical performance. However, rare but marked assay-specific deviations underscore the need for continued harmonization. Age-adjusted Z scores may further enhance interpretability. The consistency and generalizability of published conversion formulas across broader NfL ranges warrant further investigation.

Disclosure: Assay kits were provided by Roche Diagnostics and FujiRebio; all analyses were conducted independently.

Background and aims: Cognitive impairment is increasingly recognized as a relevant clinical manifestation of neuromyelitis optica spectrum disorders (NMOSD), but its underlying mechanisms and early predictors remain poorly understood. Alterations in cortical excitability, measurable through transcranial magnetic stimulation (TMS), may reflect subclinical cortical dysfunction and represent a potential biomarker of future cognitive decline.

Methods: Forty-eight patients with newly diagnosed NMOSD and twenty-five matched healthy controls underwent baseline neurophysiological assessment using TMS, including measures of resting motor threshold, short-interval intracortical inhibition (SICI), and intracortical facilitation (ICF). Comprehensive neuropsychological testing was performed at baseline and at 5 years. Cognitive impairment was defined as performance ≥ 1.5 SD below controls on ≥ 2 cognitive domains. Multivariate regression analyses were used to identify baseline predictors of cognitive decline, adjusting for age, education, disease duration, and relapse rate.

Results: At diagnosis, NMOSD patients showed significantly reduced SICI and increased ICF compared with controls ($p < 0.01$), indicating early cortical disinhibition. After 5 years, 37.5% of patients developed cognitive impairment, primarily affecting attention, executive function, and processing speed. Baseline SICI reduction independently predicted cognitive decline ($\beta = -0.42$, $p = 0.004$), even after controlling for demographic and clinical covariates. No association was found between relapse frequency or EDSS progression and cognitive outcomes.

Conclusion: Early alterations in cortical excitability, reflecting GABAergic dysfunction, are strong predictors of long-term cognitive deterioration in NMOSD. TMS-derived measures may serve as valuable biomarkers to identify patients at higher risk for cognitive decline and guide early neuroprotective interventions.

Background and aims: International evaluation of rapid iDOT aquaporin-4 assay

Methods: Sera from centres in China, France, Italy, Korea, Spain, UK were sent coded to the coordinating centre in Italy from four patient groups (1. AQP4 antibody positive NMOSD patients 2. MOG-IgG clear positive MOGAD patients 3. Clinically definite pwMS 4. Sera difficult on any assay). iDOT kits from China were sent to Italy. All samples were recoded and shipped with kits to 8 testing centres (Austria, Brazil, India, Sri Lanka, France, China, Korea, UK). iDOTs were performed at all centres; ICBA in Korea and UK; fCBA in China. Test sensitivity was based on positive results in group 1; specificity was based on negative results in groups 2–4.

Results: Unblinding revealed 381 sera were tested: Group 1: 126, Group 2: 106, Group 3: 93, Group 4: 56. Kits were employed close to/after expiry date in seven centres. The median sensitivity was 84.9% (range 39.7–92.9%); median specificity was 99.2% (range 98.8–99.6%). 72% of group 1 samples were positive on all iDOTs across 7 centres with only 7 (6%) samples positive in fewer than 4/7 centres. The China team performed the assay on iDOT kits 2 months old with a sensitivity of 100% and specificity of 98.8%. The fCBA was 91.2% sensitive. ICBA were 83.7% and 100% sensitive. All three were 100% specific.

Conclusion: The iDOT kit performed well despite being near the end of their shelf-life. A relatively new kit performed in-house had equal sensitivity to the best ICBA and highlights great promise for this system.

EPO-0822 | Efficacy and safety analysis of efgartigimod in patients with very-late-onset myasthenia gravis

Y. Zhao; M. Qu; X. Rong; X. Sun; L. Wang; M. Liu
Department of Neurology, the Affiliated Hospital of Qingdao University, Qingdao, China

Background and aims: Myasthenia gravis (MG) is an autoimmune disorder caused by pathogenic IgG autoantibodies disrupting the neuromuscular junction. Very-late-onset MG (VLOMG, onset ≥ 65 years) poses greater management challenges, with scarce data on efgartigimod (a novel FcRn antagonist) in this population.

Methods: Retrospective analysis of 62 AChR antibody-positive VLOMG patients treated with efgartigimod (10 mg/kg IV weekly for 4 weeks, repeated after 4-week intervals) at Affiliated Hospital of Qingdao University (Nov 2023–Sep 2025), assessing MSE rate, corticosteroid reduction, MG-ADL/MG-QoL15r scores, muscle function, and adverse events (AEs).

Results: A total of 62 eligible VLOMG patients were enrolled, of these, 15 completed 3 or more treatment cycles, 10 completed 2 cycles, and 37 completed 1 cycle. At the study endpoint, 41.9% (26/62) of patients had achieved MSE. MG-ADL/MG-QoL15r scores and corticosteroid doses significantly decreased across subgroups (1, 2, ≥ 3 cycles, all $P < 0.05$). MG-ADL/MG-QoL15r

Background and aims: Current guidelines for immune-related neurotoxicities recommend discontinuation of immune checkpoint inhibitors (ICIs) and steroid therapy in severe cases. However, the management of ICI-related neuropathies remains less standardised, with intravenous immunoglobulin (IVIg) frequently combined with steroids despite limited evidence.

Methods: We conducted a retrospective analysis of patients with ICI-related neuropathies from six French centers. Clinical, biological and electrophysiological data were collected at baseline, 3 months, and 6 months. The outcome was defined by changes in the modified Rankin Scale (mRS) and the Inflammatory Neuropathy Cause and Treatment (INCAT) disability scores between baseline and follow-up visits.

Results: Forty-eight patients with ICI-related neuropathies were identified including 24 demyelinating neuropathies, 18 axonal neuropathies, and 6 multifocal radiculopathies. Most presented with subacute onset and predominant sensory symptoms. Immunomodulatory therapy was initiated for severe cases, primarily steroids alone ($n=25$) or steroids combined with IVIg ($n=14$). 90% of patients achieved a favourable and rapid outcome: 11 experienced complete recovery, 32 partial or subtotal improvement. No significant advantage was observed in adding IVIg to steroids. In the analysis of other variables, a higher baseline disability score (INCAT) was the only factor significantly associated with poorer outcomes. ICIs were reintroduced in ten patients, with good tolerance observed.

Conclusion: Our study does not support the routine use of IVIg in addition to steroids as first-line treatment for ICI-related neuropathies, even in demyelinating cases. Reintroduction of ICIs after resolution of neurological impairment appears safe and feasible.

EPO-0824 | **Imaging-informed cerebral hemodynamic insights into Moyamoya disease and stroke risk: A systematic review**

A. Shrivastava¹; R. Singh²; A. Garg³; S. Sanghi¹; A. Suri²; S. Roy¹

¹Department of Applied Mechanics, Indian Institute of Technology Delhi, New Delhi, India; ²Department of Neurosurgery, All India Institute of Medical Sciences New Delhi, Delhi, India; ³Department of Neuroimaging and Interventional Neuroradiology, All India Institute of Medical Sciences New Delhi, Delhi, India

Background and aims: Moyamoya disease (MMD) is a progressive cerebrovascular disorder characterized by intracranial arterial stenosis, leading to impaired cerebral perfusion and increased risk of ischemic and hemorrhagic stroke. Although advanced imaging is routinely used for diagnosis and follow-up, the hemodynamic mechanisms underlying disease progression, stroke risk, and post-revascularization outcomes remain incompletely understood. This systematic review synthesizes imaging-informed hemodynamic evidence to support pathophysiological understanding and clinical decision-making in MMD.

Methods: This systematic review followed PRISMA guidelines. A comprehensive literature search of PubMed, Scopus,

FIGURE 1 Overview of the systematic review methodology for computational bio-fluid mechanics studies in Moyamoya disease: (A) keyword cloud illustrating the literature search strategy, (B) temporal trend of publications and citations.

FIGURE 2 Multimodal clinical imaging approaches for evaluating cerebrovascular structure, perfusion, and hemodynamics in Moyamoya disease. Shown are representative MRI sequences and angiographic techniques (DSA, TOF-MRA, CTA), functional MRI, 4D flow MRI.

Web of Science, and IEEE Xplore was conducted up to March 2024 using the keywords “Moyamoya disease” AND “computational fluid dynamics.” Original computational studies investigating cerebral hemodynamics, cerebrovascular biomechanics, patient-specific blood-flow modeling, stroke prediction, or relevant idealized models were included. Eighteen studies were selected for qualitative synthesis.

Results: Eighteen imaging-informed computational studies were analyzed. Neuroimaging modalities, including digital subtraction angiography, CT perfusion, ASL-MRI, and phase-contrast MRI, were frequently integrated with computational fluid dynamics to quantify flow redistribution, perfusion deficits, and vascular remodeling. Consistent findings revealed abnormal flow patterns, elevated wall shear stress, pressure drops, and impaired distal perfusion in stenotic internal carotid and middle cerebral arteries. Pressure- and shear-based metrics emerged as potential biomarkers for disease progression, surgical outcome assessment, and stroke risk stratification.

Conclusion: Patient-specific modeling integrated with clinical imaging shows promise for disease assessment, surgical planning, and postoperative evaluation. Future work should emphasize physiologically realistic fluid–structure interaction frameworks, standardized boundary condition calibration, and integration with advanced imaging and physics-guided AI to enable robust, non-invasive, personalized clinical decision-making.

Disclosure: Nothing to disclose.

Hospital Universitario de La Princesa, Madrid, Spain; ⁸Neurology, Hospital Universitario 12 de Octubre, Madrid, Spain; ⁹Neurology, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain

Background and aims: To evaluate functional outcomes and mortality in patients aged ≥ 85 years with large vessel occlusion (LVO) ischemic stroke managed with endovascular therapy (EVT).

Methods: We conducted a prospective, multicenter observational study including patients aged ≥ 85 years with LVO treated in seven Stroke Centres in Madrid over one year (from February 2024). Patients treated with EVT were compared with those managed without EVT. Inverse probability of treatment weighting (IPTW) based on propensity scores was applied to adjust for baseline differences between groups.

Results: A total of 277 patients were included (71% women), with a mean age of 89.2 ± 3.11 years and a median baseline mRS of 1 (IQR 0–4). EVT was performed in 188 patients (67.8%). Patients treated with EVT had less pre-stroke cognitive impairment and higher NIHSS scores. After IPTW adjustment, there were no significant differences in functional independence at 3 months (mRS 0–2) between EVT and non-EVT patients (31.1% vs 24.7%; $p = 0.31$; OR = 1.41, 95% CI 0.72–2.72). However, EVT was associated with a higher proportion of favorable outcomes when considering the mRS 0–3 (50.0% vs 31.9%; $p = 0.035$; OR = 1.92, 95% CI 1.05–3.52) and with lower 3-month mortality (29.3% vs 50.9%; $p = 0.038$; OR = 0.51, 95% CI 0.27–0.96).

Conclusion: In our cohort, EVT did not significantly increase the likelihood of full independence or mild disability (mRS 0–2) at 3 months. However, EVT was associated with reduced mortality and a lower degree of disability among dependent patients.

Disclosure: Nothing to disclose.

EPO-0826 | Two circulations, different outcomes?
Clinical and paraclinical results of mechanical thrombectomy in anterior and posterior circulation strokes

B. Moutinho¹; A. Fernandes¹; S. Vedor²; M. Silva²; D. Ferro¹
¹Neurology Department, Unidade Local de Saúde São João, Porto, Portugal; ²Neuroradiology Department, Unidade Local de Saúde São João, Porto, Portugal

Background and aims: Mechanical thrombectomy (MT) is the standard of care for acute ischemic stroke due to large vessel occlusion (LVO). The outcomes of thrombectomy for anterior circulation infarction (ACI) and posterior circulation infarction (POCI) may differ due to inherent clinical and paraclinical particularities of the respective vascular territories. Objective: To compare technical and clinical outcomes of MT in patients with POCI versus ACI.

Methods: Retrospective analysis of consecutive patients who underwent MT for POCI between July/2023-July/2025, and for ACI between January-July/2025. Demographic, clinical, and procedural variables were systematically collected.

Results: A total of 148 patients were included (49 POCI, 99 ACI), 78 (52.7%) female. No significant differences were found in age ($p=0.321$) or interhospital transfer rates ($p=0.666$). POCI patients more frequently presented with Glasgow Coma Scale (GCS) score ≤ 8 at admission than ACI patients (17/49 vs. 4/99, $p<0.001$). Compared with ACI, POCI was associated with lower neurological improvement at 24 hours (38.8% vs. 69.7%, $p<0.001$), longer median onset-to-puncture time (627 vs. 416 minutes, $p=0.001$), and higher two-month mortality (16/49 vs. 9/99, $p<0.001$). Puncture-to-recanalization time (31.9 ± 24.6 vs. 36.4 ± 22.1 minutes, $p=0.324$) and successful reperfusion rates (TICI ≥ 2 C; 63.3% vs. 59.6%, $p=0.720$) were similar between groups. However, procedure-related complications occurred more frequently in POCI (8/49 vs. 2/99, $p=0.001$).

Conclusion: Despite similar technical performance regarding time to recanalization and rate of successful reperfusion, POCI patients exhibited distinct clinical trajectories, which may be associated with lower admission GCS and delayed symptom-to-puncture times.

Disclosure: Nothing to disclose.

EPO-0827 | Early evolocumab reduces early neurological deterioration in acute non-cardioembolic stroke: A real-world retrospective cohort study

D. Jeong
Department of Neurology, Veterans Health Service Medical Center, Seoul, Republic of Korea

Background and aims: Early neurological deterioration (END) complicates 15–20% of acute ischemic strokes despite standard care. The acute neuroprotective potential of PCSK9 inhibition, mediated by rapid lipid-lowering and anti-inflammatory mechanisms, remains unexplored.

Methods: This retrospective cohort study at Central Veterans Hospital, Republic of Korea (2022–2025) enrolled consecutive patients with acute non-cardioembolic ischemic stroke (large artery atherosclerosis or small vessel occlusion) presenting

Characteristic	Evolocumab (n=96)	Control (n=120)	p-value
Age (mean $\pm$ SD)	72.1 $\pm$ 10.5	72.3 $\pm$ 10.2	0.98
Sex (male, %)	58.3	57.5	0.92
NIHSS (mean $\pm$ SD)	5.2 $\pm$ 3.1	5.4 $\pm$ 3.3	0.63
LDL-C (mg/dL)	149 $\pm$ 32	145 $\pm$ 35	0.85
hs-CRP (mg/L)	5.2 $\pm$ 2.1	5.0 $\pm$ 2.3	0.89
Time to puncture (min)	627	416	0.001
Time to recanalization (min)	31.9 $\pm$ 24.6	36.4 $\pm$ 22.1	0.324
TICI ≥ 2 C (%)	63.3	59.6	0.720
Successful reperfusion (%)	63.3	59.6	0.720
Neurological improvement at 24h (%)	38.8	69.7	<0.001
Two-month mortality (%)	32.7	9.1	<0.001

Outcome	Evolocumab (n=96)	Control (n=120)	p-value
END (≥ 2 points) (%)	8.3	18.3	0.04
Adjusted OR	0.41	0.38	0.03
Functional independence at 90 days (%)	71	63	0.31
No symptomatic intracranial hemorrhage (%)	100	100	1.00
No serious adverse events (%)	100	100	1.00

FIGURE 1 Baseline characteristics, primary outcome.

within 48 hours. The evolocumab group ($n=96$, 100% Korean Asian, mean age 72 ± 10 years, 58% male) received subcutaneous evolocumab 140mg within 24 hours plus moderate-to-high-intensity statins (atorvastatin 40–80mg or rosuvastatin 20–40mg). Historical controls ($n=120$) received high-intensity statins alone, matched 1:1.25 for age (± 5 years), sex, and baseline NIHSS (± 2 points). The primary endpoint was END (NIHSS increase ≥ 2 points) within 7 days, assessed daily by certified neurologists blinded to treatment allocation.

Results: Baseline characteristics were balanced (baseline NIHSS 5.2 ± 3.1 vs 5.4 ± 3.3 , $p=0.63$). Evolocumab achieved superior LDL-C reduction versus controls ($149 \pm 32 \rightarrow 61 \pm 18$ mg/dL [59% reduction] vs $145 \pm 35 \rightarrow 89 \pm 24$ mg/dL [39% reduction]; between-group difference -32 mg/dL, 95% CI -40 to -24 , $p<0.001$) and greater hs-CRP reduction ($5.2 \pm 2.1 \rightarrow 2.8 \pm 1.5$ mg/L [46% reduction] vs $5.0 \pm 2.3 \rightarrow 4.1 \pm 1.9$ mg/L [18% reduction], $p<0.001$). END occurred in 8/96 (8.3%) versus 22/120 (18.3%) patients (unadjusted OR 0.41, 95% CI 0.17–0.95, $p=0.04$; adjusted OR 0.38, 95% CI 0.15–0.91, $p=0.03$), representing 55% relative risk reduction and a number-needed-to-treat of 10. Functional independence at 90 days was 71% versus 63% ($p=0.31$). No symptomatic intracranial hemorrhage or serious adverse events occurred.

Conclusion: Early evolocumab demonstrated potent dual lipid-lowering and anti-inflammatory effects, independently associated with reduced END.

Disclosure: Nothing to disclose.

EPO-0828 | Predictors and clinical impact of incomplete recanalization from endovascular treatment in acute ischemic stroke: A single-centre cohort study

E. Maslias¹; D. Strambo¹; S. Hajdu²; F. Puccinelli²; B. Bartolini²; G. Saliou²; P. Michel¹

¹Stroke Center, Neurology Service, Department of Clinical Neurosciences, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; ²Service of Diagnostic and Interventional Radiology, Interventional Neuroradiological Unit, Lausanne University Hospital and University of Lausanne, Switzerland

Background and aims: Poor recanalization at the end of endovascular treatment (EVT) despite successful catheter access

Disclosure: Nothing to disclose.

Neurology, Balıkesir University Health Practice and Research Hospital, Balıkesir, Türkiye

Results: Clinically relevant thrombophilia testing was positive in 57/112 (50.9%). Management changed in 27/112 (24.1%) and was more frequent in thrombophilia-positive than thrombophilia-negative patients (46% vs 2%, $p < 0.001$). Thrombophilia-positive patients were younger (42.4 (4.9) vs 45.9 (6.1) years, $p = 0.001$)

Figure 1 consists of two bar charts. The top chart, titled 'Feedback Change Rate by Positive Item', shows the relationship between the number of positive feedback items (1 to 5) and the change rate. The y-axis is 'Feedback Change Rate (%)' ranging from 0 to 30. The x-axis is 'Number of Positive Items'. The change rate increases from approximately 18% for 1 item to 28% for 5 items. The bottom chart, titled 'Frequency Rate of (Nonnegative Item) (N=121)', shows the relationship between the number of nonnegative items (1 to 5) and the frequency rate. The y-axis is 'Frequency Rate (%)' ranging from 0 to 30. The x-axis is 'Number of Nonnegative Items'. The frequency rate increases from approximately 15% for 1 item to 25% for 5 items.

Spearman korelasyon matrisi

	WHSS	TG/HDL	HDL	LDL	TG	Thrombophilic_pos_count	APS_ang_pos	SI_high
WHSS	1.00	0.80	-0.01	0.63	0.77	0.07	0.05	0.79
TG/HDL	0.80	1.00	-0.01	0.76	0.90	0.06	0.05	0.73
HDL	-0.01	-0.01	1.00	-0.01	-0.06	-0.12	-0.27	-0.01
LDL	0.63	0.76	-0.01	1.00	0.79	0.04	0.09	0.73
TG	0.77	0.90	-0.06	0.79	1.00	0.06	0.05	0.68
Thrombophilic_pos_count	0.07	0.06	-0.12	0.04	0.06	1.00	0.05	0.66
APS_ang_pos	0.05	0.05	-0.27	0.09	0.05	0.05	1.00	0.39
SI_high	0.79	0.73	-0.01	0.73	0.68	0.66	0.39	1.00

and had higher National Institutes of Health Stroke Scale (NIHSS) scores (7.8 (7.9) vs 1.8 (3.7), $p < 0.001$), more frequent SII-high status (40% vs 7%, $p < 0.001$), and higher TG/HDL-C

(11.7 (11.0) vs 4.2 (4.9), $p < 0.001$). Very high TG/HDL-C risk level was more common in the thrombophilia-positive group (53% vs 15%, $p < 0.001$). TG/HDL-C correlated strongly with NIHSS (Spearman correlation coefficient 0.85, $p < 0.001$).

Conclusion: In young cryptogenic ischemic stroke, clinically relevant thrombophilia findings were frequent and were associated with higher NIHSS and adverse atheroinflammatory profiles (SII and TG/HDL-C). The management impact of thrombophilia testing was higher than prior reports, suggesting a more favorable benefit-harm balance when testing is focused on selected young cryptogenic patients.

Disclosure: Nothing to disclose.

Background and aims: Endovascular treatment (EVT) is an effective treatment for patients with acute ischemic stroke (AIS). However, it is unclear if treatment with intravenous thrombolysis (IVT) prior to EVT confers any benefit in octogenarians and older. This study aimed to address if bridging tPA has improved functional outcomes or complications in patients 80years

Methods: This multicentre retrospective cohort study included patients 80years old and above who underwent endovascular therapy for large vessel occlusion acute ischaemic stroke in 10 compressive stroke centres across China and Singapore between 2018 and 2024. Clinical and procedural factors of patients in Singapore and China were compared using multivariate binary logistic regression. The primary outcome measured was achieving successful recanalization. Secondary outcomes included 3-month functional independence defined as modified rankin

TABLE 2 Comparing recanalization, safety and outcomes between elderly patients who underwent bridging thrombolysis and those who did not.

		Without Thrombolysis	Thrombolysis	P value
Successful recanalization		163 (87.63)	84(89.36)	0.672
Complete recanalization		121 (65.05)	57(60.64)	0.468
Parenchymal haematoma		23 (12.37)	13(13.83)	0.730
Any haemorrhage		49 (26.34)	36(38.30)	0.048
3-month functional independence (mRS 0-2)		39 (20.97)	23(24.47)	0.505
3-month independent ambulation (mRS 0-3)		61 (32.88)	39 (41.49)	0.512
3-month mortality		63(33.33)	34(36.17)	0.637
3-month mRS	0	17(9.14)	30(10.64)	0.298
	1	8(4.30)	5(5.32)	
	2	14(7.53)	8(8.51)	
	3	22(11.83)	30(17.02)	
	4	40(21.51)	8(8.51)	
	5	23(12.37)	13(13.83)	
	6	62(33.33)	34(36.17)	

scale (mRS) 0–2, 3-month independent ambulation as defined as mRS 0–3, and 3-month mortality rates. Data on complications such as parenchymal haematoma and any haemorrhage was also collected.

Results: Bridging IVT was not associated with increased rates of successful recanalisation (89.36% vs 87.63%; $p=0.672$), improvement in 3-month functional independence, improvement in 3-month independent ambulation or 3-month mortality rates. Instead, patients who underwent bridging IVT had higher rates of haemorrhage compared to patients who did not undergo bridging IVT even after adjusting for confounding factors (OR=1.921; 95% CI 1.026–3.596; $p=0.041$).

Conclusion: In patients over 80years old with AIS, bridging IVT is not associated with improved functional independence or reduced mortality at three months. However, it is associated with increased risk of hemorrhage.

Disclosure: Nothing to disclose.

EPO-0831 | Anticoagulation and stroke risk in dialysis patients with atrial fibrillation: A single-centre study in Malta

J. Darmanin; M. Schembri
Mater Dei Hospital, Malta

Background and aims: Anticoagulation is central to stroke prevention in atrial fibrillation (AF), but its use in end-stage renal failure (ESRF) patients on dialysis is challenging. Warfarin has traditionally been used, though it is associated with labile INR, drug interactions, vascular calcification, and increased bleeding risk. Direct oral anticoagulants (DOACs), particularly apixaban, are increasingly prescribed off-label due to predictable pharmacokinetics and no need for routine monitoring, but evidence of their safety and efficacy in ESRF is limited and conflicting.

Methods: This single-centre retrospective study included all ESRF patients on chronic dialysis in Malta with documented AF. Data collected included demographics, comorbidities,

anticoagulation type (warfarin, DOAC, or none), and major bleeding events. Patients were followed for one year to assess cerebrovascular outcomes, including ischaemic stroke or transient ischemic attack (TIA).

Results: Of 358 ESRF patients, 43 (12%) had AF: 7 (16.3%) received apixaban, 30 (69.8%) warfarin, and 5 (11.6%) no anticoagulation. Preliminary findings show 3 patients (60%) without anticoagulation experienced a cerebrovascular event, while no events occurred in warfarin or apixaban groups. Labile INR was noted in 11 warfarin patients (36.7%), and 4 experienced major bleeding; no major bleeding occurred with apixaban.

Conclusion: These results suggest warfarin and apixaban may be similarly effective for stroke prevention in ESRF patients with AF, but warfarin carries a higher bleeding risk. Although limited by small sample size, this audit included the entire ESRF population in Malta, providing valuable insight into real-world anticoagulation practices in this high-risk group.

Disclosure: Nothing to disclose.

EPO-0832 | Diagnostic value of microbiological analysis of cerebral thrombi in infective endocarditis-related stroke: A tertiary-center descriptive study

L. García-Granados¹; C. Villar Rodríguez¹; D. Villagrán Sancho¹; M. Medina Rodríguez¹; J. Cabezas Rodríguez¹; A. de Albóniga-Chindurza Barroeta²; M. Aguilar Pérez²; M. Poyato Borrego³; A. González García²; E. Zapata Arriaza²; F. Moniche Álvarez¹

¹Department of Neurology, Hospital Universitario Virgen del Rocío, Sevilla, Spain; ²Department of Radiology, Hospital Universitario Virgen del Rocío, Sevilla, Spain; ³Infectious Diseases Unit, Department of Internal Medicine, Hospital Universitario Virgen del Rocío, Sevilla, Spain

Background and aims: Infective endocarditis (IE) is an uncommon but severe cause of cardioembolic ischemic stroke. Since 2023, a positive microbiological analysis of the retrieved thrombus has been recognized as a pathological criterion for definite IE, enabling diagnosis to be established based on a single microbiological isolation.

Methods: Patients with ischemic stroke secondary to IE were included and divided into two groups according to the clinical sequence of diagnosis. Clinical, radiological, microbiological and prognostic characteristics were compared between groups (Table 1). The primary objective was to assess the diagnostic value of microbiological analysis of thrombi retrieved during mechanical thrombectomy.

Results: Seventeen patients were included (8 presenting with stroke as the first manifestation and 9 with a previous diagnosis of IE). The median age was 67years and 82.4% were male. Thrombus microbiological analysis was performed in 13 cases. In patients presenting with stroke as the first manifestation, thrombus cultures were positive in 100% of cases compared with 33.3% in patients with prior infective endocarditis ($p=0.021$), with 100% concordance with blood culture isolates (Table 2). Patients with stroke as the initial manifestation showed a higher proportion of favorable functional outcome at 3 months (mRS 0–2: 87.5% versus 44.4%), showing a trend toward statistical significance ($p=0.05$).

Conclusion: Microbiological analysis of cerebral thrombi may provide relevant diagnostic value in IE, particularly when stroke

TABLE 1 Characteristics of patients with ischemic stroke associated with infective endocarditis, stratified by study group: Group A (stroke as first clinical manifestation) and Group B (infective endocarditis diagnosed before stroke).

Baseline characteristics			
Variable	Group A	Group B	P
Age	63.5 (IQR 58.2–65.8)	69.0 (IQR 67.8–74.0)	0.194

TABLE 2 Comparison of thrombus and blood culture microorganisms in endocarditis-related stroke by group (A: stroke first, B: endocarditis first). In Group A, thrombus culture showed 100% concordance with blood cultures.

	Thrombus culture	Blood culture
#01 – Group A	<i>Streptococcus equinus</i>	<i>Streptococcus equinus</i>
#02 – Group A	<i>Staphylococcus epidermidis</i>	<i>Staphylococcus epidermidis</i>
#03 – Group A	<i>Enterococcus faecalis</i>	<i>Enterococcus faecalis</i>
#04 – Group A	<i>Staphylococcus epidermidis</i>	<i>Staphylococcus epidermidis</i>
#05 – Group A	<i>Staphylococcus epidermidis</i>	<i>Staphylococcus epidermidis</i>
#06 – Group A	<i>Streptococcus faecalis</i>	<i>Streptococcus faecalis</i>
#07 – Group A	<i>Streptococcus gordonii</i>	<i>Streptococcus gordonii</i>
#08 – Group B	<i>Staphylococcus aureus</i> methicillin sensible	<i>Staphylococcus aureus</i> methicillin sensible
#09 – Group B	Negative	<i>Aerococcus urinae</i>
#10 – Group B	<i>Candida parapsilosis</i>	<i>Candida parapsilosis</i>
#11 – Group B	Negative	<i>Enterococcus faecalis</i>
#12 – Group B	Negative	<i>Streptococcus galloyticus</i>
#13 – Group B	Negative	<i>Staphylococcus aureus</i> methicillin sensible

is the first clinical manifestation. Early diagnosis of IE supported by thrombus analysis may enable earlier targeted treatment and be associated with improved long term functional outcomes.

Disclosure: Nothing to disclose.

EPO-0833 | Development of the GLaSSES score for predicting neurological deterioration after acute ischaemic stroke

M. De Sampaio; M. Grecco; A. Carrá; G. Di Fonzo; P. Guillermo; J. Pozo
Neurology Department, Hospital Churrucua Visca, Buenos Aires, Argentina

Background and aims: Patients with acute ischaemic stroke (AIS) may experience neurological deterioration (ND) within the first seven days, defined as an increase in the National Institutes of Health Stroke Scale (NIHSS) score. ND incidence ranges from 5% to 40% and is linked to increased morbidity and mortality. Despite ongoing research, no practical predictive tool is currently available.

Methods: We conducted a retrospective observational study of patients aged >18 years hospitalised for AIS (excluding reperfusion therapies). ND occurrence, causes, and associated mortality were recorded. A multivariable logistic regression model with forward stepwise selection identified independent predictors. Model performance was evaluated using receiver operating characteristic (ROC) curve analysis.

Results: Of 444 patients (mean age 71.3 years), ND occurred in 20.3%, mainly due to ischaemic core progression (46%). Five independent risk factors were identified: hyperglycaemia (OR 15.9, 95% CI 8.1–33.2), leukocytosis (OR 10.1, 95% CI 4.8–23.1), baseline NIHSS severity (OR 3.3, 95% CI 1.3–8.9), symptomatic intracranial stenosis (OR 3.8, 95% CI 2.5–5.5), and extracranial stenosis (OR 6.0, 95% CI 1.6–8.9). The GLaSSES score stratified patients into four risk categories: ND incidence 1.9% (very low),

FIGURE 1 Receiver operating characteristic (ROC) curve of the predictive model.

FIGURE 2 Distribution of the modified Rankin Scale score at 7 days in patients with neurological deterioration.

17.7% (low), 47.5% (moderate), 85.7% (high). The model showed good discrimination (AUC 0.85, 95% CI 0.82–0.88). Mortality was 47.8% in ND patients.

Conclusion: The GLaSSES score is a promising, simple tool for predicting ND risk in AIS patients. External validation in larger, prospective cohorts is warranted to confirm its clinical utility and improve outcomes.

Disclosure: Nothing to disclose.

EPO-0834 | Mechanical thrombectomy in patients with low ASPECTS: Real-world outcomes compared with SELECT-2 and LASTE

P. Diaz-Corta; B. Lara-Rodríguez; A. Paipa-Merchan; H. Quesada-García; A. Núñez-Guillén; P. Cardona-Portela
Neurology, Hospital Universitario Bellvitge, Barcelona, Spain

Background and aims: Randomised trials (SELECT-2, LASTE) support mechanical thrombectomy (MT) in patients with large ischaemic core infarction defined by low ASPECTS (≤ 5). Real-world safety and functional outcomes remain less well described.

Methods: We conducted a retrospective observational study including consecutive patients with acute ischemic stroke and low ASPECTS treated with MT at a tertiary hospital.

Results: Sixty-six patients were included (mean age 67 years; 56.1% women). Median baseline NIHSS was 20 and median ASPECTS was 4. Intravenous fibrinolysis was given in 22.7%. Successful reperfusion (mTICI 2b-3) was achieved in 83.3%. sICH occurred in 10.6%. Median 90-day mRS was 4 and 18.8% achieved mRS 0–2. Baseline characteristics and functional outcomes were broadly comparable to SELECT-2 and LASTE, with similar reperfusion rates and functional status (both, median 90-day mRS of 4).

Conclusion: In routine practice, MT in patients with ASPECTS ≤ 5 achieved high reperfusion rates with functional outcomes consistent with trial populations, supporting external validity and ongoing implementation in carefully selected patients.

Disclosure: Nothing to disclose.

EPO-0835 | Cerebral hemodynamic signatures linking mild cognitive impairment and late-life depression: A multimodal transcranial doppler and MRI Study

S. Arnautu¹; D. Jianu²; D. Arnautu¹

¹Department V Internal Medicine, “Victor Babes” University of Medicine and Pharmacy, Timisoara, Romania; ²Department of Neurosciences, “Victor Babes” University of Medicine and Pharmacy, Timisoara, Romania

Background and aims: Late-life depression (LLD) and mild cognitive impairment (MCI) frequently coexist in older adults and share common neurovascular mechanisms. Cerebral small vessel dysfunction has been implicated in both cognitive and affective decline, yet clinically accessible markers linking these conditions remain limited. We investigated whether cerebral hemodynamic parameters assessed by transcranial Doppler (TCD), combined with MRI markers, identify shared neurovascular signatures between MCI and LLD.

Methods: In this cross-sectional study, 96 older adults with depressive symptoms underwent standardized cognitive assessment (MMSE-2, MoCA), affective evaluation (GDS-15), brain MRI with Fazekas scoring of white matter lesions (WMLs), and TCD examination of the middle cerebral artery. Hemodynamic parameters included mean blood flow velocity (MBFV), end-diastolic velocity (EDV), pulsatility index (PI), and resistive index (RI). Logistic regression and receiver operating characteristic (ROC) analyses identified independent predictors of MCI.

Results: Compared with cognitively unimpaired participants, individuals with MCI showed significantly lower MBFV and EDV and higher PI and RI (all $p < 0.05$). In multivariable analysis, altered MBFV, EDV, PI, and RI remained independently associated with MCI. RI demonstrated the highest discriminative accuracy (AUC=0.919), followed by MBFV (AUC=0.879). PI correlated with depressive symptom severity, while RI was associated with greater WML burden.

FIGURE 1 Transcranial Doppler ultrasound recording of the middle right cerebral artery (MCA). The spectrum shows peak systolic velocity (PSV), end-diastolic velocity (EDV), and mean blood flow velocity (MBFV) used for the calculation of the pulsatility index (PI) and resistivity index (RI).

TABLE 1 Predictors for MCI.

Univariate Logistic Regression	Odds Ratio	95% CI	p Value
Age (years)	0.88	0.79–0.97	0.01
GDS-15	1.66	1.04–2.66	0.03
MRI Fazekas visual scale	2.17	1.07–4.41	0.03
MBFV (cm/s)	0.64	0.49–0.84	<0.01
PSV (cm/s)	1.32	1.03–1.69	0.02
EDV (cm/s)	0.78	0.66–0.91	<0.01
PI (%)	0.79	0.63–1.00	0.04
RI (%)	5.4	2.97–9.88	0.02
Multivariate Logistic Regression	Odds Ratio	95% CI	p Value
MBFV (cm/s)	0.64	0.43–0.94	0.02
EDV (cm/s)	0.70	0.53–0.91	0.03
PI (%)	3.2	0.74–13.9	<0.01
RI (%)	1.9	0.22–2.66	<0.01

Abbreviations: MRI, magnetic resonance imaging; GDS-15, 15-item Geriatric Depression Scale; MBFV, mean blood flow velocity; PI, pulsatility index; RI, resistivity index; PSV, peak systolic blood flow velocity; EDV, end-diastolic blood flow velocity.

FIGURE 2 A comparative ROC curve of all four predictors.

Conclusion: Altered cerebral hemodynamics represent a shared neurovascular substrate linking MCI and late-life depression. Integrating TCD-derived indices with MRI markers offers a clinically feasible multimodal approach for early identification of vascular cognitive and affective vulnerability in older adults.

Neuro-Ophthalmology/Neuro-Otology 2

EPO-0836 | The vertigo challenge: Diagnostic variability across acute referral pathways

A. Heatley¹; I. Zia¹; E. Cortese¹; J. Tierney¹; M. Mahmud¹; S. Haider¹; A. Chandratheva¹; R. Simister¹; D. Kaski¹; N. Koohi¹
 NHNN and NeuroSDEC at UCLH, London, UK

Background and aims: Acute vertigo, a common emergency presentation, places considerable strain on acute care resources. Stroke-focused pathways drive extensive investigations, despite a low likelihood of a central cause. We evaluated diagnostic agreement between the emergency, stroke referral services, and specialist neuro-otology in acute vertigo patients to identify gaps and inform targeted strategies.

Methods: This single-centre retrospective cohort included new referrals with acute vertigo between August 2023 and July 2025. Of approximately 300 adult patients, 151 were analyzed. Data included referral source (ED, Acute Medicine Unit (AMU), Stroke Unit, TIA clinic, Neurology SDEC), vascular risk factors, imaging, and initial versus specialist diagnosis based on clinical history and imaging as a gold standard.

Results: Referrals originated from the ED/AMU (42.4%) and neuro-SDEC/stroke/TIA services (57.6%). Overall diagnostic agreement was 32% higher for neurology-led services (39.8%) than emergency services (23.5%). Overall, agreement was highest for stroke/TIA (75%) and lowest for chronic cardiovascular causes (6.7%). Additionally, 27.8% had no referral diagnosis, and most (65.56%) underwent neuroimaging.

Conclusion: Neurology-led teams showed higher diagnostic accuracy than emergency services, which have limited neurology expertise, and this may explain the variability. Structured triage systems are essential to reduce misclassification, avoid unnecessary imaging, and support frontline teams.

Disclosure: Nothing to disclose.

EPO-0837 | Tolosa-Hunt syndrome versus its mimics: Comparative analysis of clinical and radiological characteristics for accurate diagnosis

E. Patricio¹; C. Peralta¹; P. Miranda¹; J. Pineda¹; E. Reyes¹; K. Yorro¹; A. Tejada¹; C. Pérez Lizardo¹; A. Reyes¹; M. Rodríguez²

¹Synaptic Research League, Santo Domingo, Dominican Republic; ²Neurology Department, Hospital Universitario Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic

Background and aims: Tolosa-Hunt syndrome (THS) is a rare cause of painful ophthalmoplegia, diagnosed by its steroid response [1]. However, its presentation is mimicked by serious pathologies, often leading to initial misdiagnosis. This study analyzes the key differences between true THS and its clinical mimics to improve diagnosis accuracy.

Methods: A systematic review was performed following PRISMA guidelines. Out of 22 studies, 15 were included. PubMed and BVS were searched using the keywords “Tolosa-Hunt syndrome,” “painful ophthalmoplegia,” and “cavernous sinus syndrome.” Data was extracted for comparative analysis of clinical and diagnostic variables.

Results: 222 patients, 125 females and 97 males, were included, with a mean age of 35.87 years. True THS accounted for 168 patients (75%). The other 58 cases were diagnosed with conditions including Rosai-Dorfman Disease and neoplastic conditions involving cavernous sinus and orbit. True THS has slight predominance in females (86, 52.4%) than in male (78, 47.6%). True THS was involved unilaterally (>90%), more frequent on the left side in majority of patients. MRI abnormalities identified in 90% of cases with true THS predominant to isolated cavernous sinus

FIGURE 1 Initial diagnosis versus final diagnosis in clinical suspicion of Tolosa-Hunt Syndrome.

FIGURE 2 Prisma-P flowchart of the process of inclusion of studies in the systematic review.

inflammation; >95% of false TSH showed mass-like infiltrative lesions extending beyond the cavernous sinus. 85–90% of false cases demonstrated partial improvement after corticosteroid therapy, true cases showed >95% response and pain relief.

Conclusion: Most cases labeled as THS are true THS; but some represent neoplastic disorders. Persistent or bilateral symptoms, mass-like MRI lesions beyond the cavernous sinus, and incomplete steroid response suggest false-positive THS, supporting early reassessment and targeted testing.

Disclosure: Nothing to disclose.

EPO-0838 | Brain MRI abnormalities along the visual pathways in subacute leber hereditary optic neuropathy

C. La Morgia¹; G. Amore²; M. Carbonelli¹; M. Romagnoli²; C. Tonon¹; R. Lodi¹; R. Liguori¹; V. Carelli¹

¹Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy; ²IRCCS Institute of Neurological Sciences of Bologna, Bologna, Italy

Background and aims: Brain MRI abnormalities along the visual pathways are historically considered an uncommon feature of LHON at difference with inflammatory optic neuritis. We aimed at describing the prevalence of such MRI abnormalities in subacute LHON patients, correlating with clinical and genetic characteristics.

Methods: We retrospectively analysed clinical, genetic and ophthalmological data from 40 genetically-confirmed LHON patients. MRI data performed within 6 months from onset were collected. Best corrected visual acuity (BCVA), retinal nerve fiber layer (RNFL) thickness and visual fields parameters were compared between patients with and without MRI abnormalities at time of MRI execution and at follow-up (≥ 24 months). Linear mixed models were applied to account for inter-eye correlation, with clinical and genetic predictors as covariates.

Results: MRI abnormalities along the visual pathways were found in 20/40 (50%) patients. Optic nerve hyperintensity was

present in 45%, chiasm and optic tract involvement in 20%, and contrast enhancement of the optic nerve in 22%. At time of MRI execution, optic nerve hyperintensity resulted significantly associated with worse BCVA and visual field parameters, while optic nerve contrast enhancement was selectively associated with thinner temporal RNFL. At follow-up (25 patients), long-term BCVA was significantly influenced by mutation type, with rare mutations showing better outcomes, while MRI abnormalities were not prognostic. As exploratory analysis, high-dose steroid therapy at onset showed mild influence on functional parameters at follow-up.

Conclusion: MRI abnormalities are frequent in LHON and likely reflect early axonal damage and possibly an ongoing inflammatory component, but their independent prognostic value is still under evaluation.

Disclosure: Nothing to disclose.

EPO-0839 | Saccadic velocity dynamics abnormalities and levodopa-induced dyskinesia in Parkinson's disease: An exploratory study

C. Terravecchia¹; A. Rufa²; C. Cicero¹; G. Donzuso¹; G. Mostile¹; A. Nicoletti¹

¹University of Catania, Department "G.F. Ingrassia", Section of Neurosciences, Catania, Italy; ²Eye tracking and Visual Application Lab (EVA Lab), Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy

Background and aims: Oculomotor abnormalities were described in Parkinson's disease (PD) as an expression of disease-related basal ganglia dysfunction, showing coherent relations with the disease's clinical features. Nevertheless, the possible relation between saccadic performances and levodopa-induced dyskinesia (LID) has never been addressed to date. This exploratory study aimed to investigate possible associations between saccadic eye movements features and LID in PD.

Methods: Horizontal and vertical visually-guided saccades (VGS) were analysed through Eyelink 1000 Plus in healthy controls (HCs), PD without LID (PD-LID-) and PD with LID (PD-LID+) in their OFF motor state. The following VGS metrics were assessed: latency, amplitude, duration, mean and peak velocity, gain. VGS dynamics were also assessed by: peak velocity/amplitude ratio, reflecting main sequence linear relation, and Q-ratio (peak/mean velocity ratio), used to quantify and detect abnormalities of VGS velocity profile (i.e. higher Q-ratio).

Results: Thirty-two HCs, $N=16$ PD-LID- and $N=26$ PD-LID+ were enrolled. After adjusting by possible confounders, lower horizontal and vertical VGS amplitude, mean, peak velocity and gain were found in PD-LID- as compared to HCs while no significant differences on VGS dynamics were found. On the other hand, reduced amplitude and gain as well as increased peak velocity/amplitude and Q-ratios were shown in PD-LID+ as compared to HCs. Significantly higher peak velocities, peak velocity/amplitude and Q-ratios were demonstrated in PD-LID+ as compared to PD-LID-.

Conclusion: This exploratory study firstly highlights the association between saccadic velocity dynamics abnormalities as assessed in the OFF motor state and LID in PD. Clinical applications should be further investigated.

Disclosure: Nothing to disclose.

K. Koçoğlu¹; H. Eraslan Boz¹; P. Özçelik¹; M. Akkoyun¹; I. Tüfekci¹; G. Halmágyi²; G. Akdağ³

¹Department of Neurosciences, Institute of Health Sciences, Dokuz Eylül University, İzmir, Türkiye; ²Department of Neurology, Royal Prince Alfred Hospital, Sydney, NSW Australia; ³Department of Neurology, Faculty of Medicine, Dokuz Eylül University, İzmir, Türkiye

Background and aims: This study investigated vestibular function in Alzheimer's disease (AD) and amnesic mild cognitive impairment (aMCI), to examine the prevalence of vestibular impairment and its association with domain-specific cognitive decline.

Methods: The study included 91 participants: 30 AD, 30 aMCI, and 31 controls. All participants underwent neuropsychological testing and vestibular assessments using video Head Impulse Test (vHIT) for semicircular canals (SCCs) and vestibular-evoked myogenic potentials (VEMPs) for otolith function. Overall vestibular scores were defined as abnormal results on ≥ 2 of 10 subtests. Cognitive domains assessed included memory, executive function, attention, visuospatial, and language (Table 1).

Results: (1) Abnormal vHIT results were significantly higher in AD and aMCI (50% each) versus controls (12.9%; $p=0.002$)

TABLE 1 The descriptive statistics of the demographics and neuropsychological tests.

Demographics	HCA (n = 31)	aMCI (n = 30)	AD (n = 30)	
Age	67.77 $\pm$ 7.08	71.39 $\pm$ 5.55	71.43 $\pm$ 7.57	[F(2,88) = 2.846, $p=0.062$]
Sex (F/M)	20/11	18/12	15/15	[$\chi^2(2) = 3.378$, $p=0.302$]
Education	12.42 $\pm$ 3.24	9.27 $\pm$ 3.53	9.03 $\pm$ 3.44	[H(2) = 9.909, $p=0.007$]
yGDS	6.48 $\pm$ 4.99	9.10 $\pm$ 3.29	6.56 $\pm$ 3.87	[H(2) = 3.132, $p=0.076$]
BAI	4.13 $\pm$ 4.07	4.30 $\pm$ 4.79	2.46 $\pm$ 3.08	[H(2) = 3.319, $p=0.070$]
Disease duration (mo)	-	25.97 $\pm$ 22.47	23.00 $\pm$ 13.75	[U = 411.000, $z=-0.389$, $p=0.550$, $r=-0.08$]

HCA, healthy controls; aMCI, amnesic mild cognitive impairment; AD, Alzheimer's disease; F, female; M, male; yGDS, Yesavage Geriatric Depression Scale; BAI, Beck Anxiety Inventory; mo, month.

TABLE 2 The proportions of subjects with abnormal responses in vestibular tests.

All vestibular tests	HCA (n = 31)	aMCI (n = 30)	AD (n = 30)	
Overall vestibular impairment score	14 (45.16%)	20 (66.67%)	19 (63.33%)	$\chi^2(2) = 3.796$, $p=0.183$
Video Head Impulse Test				
Overall vHIT	4 (12.9%)	15 (50%)	15 (50%)	$\chi^2(2) = 11.819$, $p=0.002$
Adjusted residual	3.47	1.75	1.78	
p	0.009	0.062	0.062	significant at $p < 0.009$
Lateral vHIT	0 (0%)	6 (20%)	4 (13.3%)	$\chi^2(2) = 6.086$, $p=0.049$
Adjusted residual	2.8	1.9	0.3	
p	0.098	0.089	0.517	significant at $p < 0.009$
Anterior vHIT	2 (6.3%)	7 (23.3%)	6 (20%)	$\chi^2(2) = 3.598$, $p=0.169$
Posterior vHIT	6 (19.3%)	9 (30%)	12 (40%)	$\chi^2(2) = 5.762$, $p=0.056$
Vestibular-evoked myogenic potentials				
VEMPs total	17 (54.8%)	23 (76.7%)	19 (63.3%)	$\chi^2(2) = 3.206$, $p=0.199$
cVEMP total	13 (41.9%)	16 (53.3%)	17 (56.7%)	$\chi^2(2) = 0.423$, $p=0.808$
cVEMP AC	14 (45.2%)	19 (63.3%)	10 (33.3%)	$\chi^2(2) = 3.223$, $p=0.074$
cVEMP BC	23 (74.2%)	25 (83.3%)	22 (73.3%)	$\chi^2(2) = 1.042$, $p=0.599$
sVEMP total	11 (35.5%)	17 (56.7%)	11 (36.7%)	$\chi^2(2) = 2.807$, $p=0.245$
sVEMP AC	13 (41.9%)	20 (66.7%)	20 (66.7%)	$\chi^2(2) = 3.596$, $p=0.169$
sVEMP BC	28 (90.3%)	22 (73.3%)	21 (70%)	$\chi^2(2) = 0.569$, $p=0.752$

HCA, healthy controls; aMCI, amnesic mild cognitive impairment; AD, Alzheimer's disease; vHIT, video Head Impulse Test; VEMPs, vestibular-evoked myogenic potentials; cVEMP, cervical VEMP; AC, air-conducted; BC, bone-conducted; sVEMP, ocular VEMP; VEMPs total indicates overall cVEMP total and sVEMP total responses. cVEMP total indicates overall cVEMP AC and BC responses. sVEMP total indicates overall sVEMP AC and BC responses.

while VEMPs and overall vestibular scores showed no group differences; (2) Specific vestibular impairments were associated with distinct cognitive domains; (2a) in AD with vestibular impairment (ADwVi), memory linked to posterior SCC impairment and visuospatial to overall vestibular scores ($p=0.029$). In aMCI with vestibular impairment (aMCIwVi), visuospatial associated with abnormal ocular VEMP (oVEMP; $p=0.046$); (2b) oVEMP showed contrasting associations: language in aMCIwVi ($p=0.009$) versus, Mini-Mental State Examination (MMSE) and executive function in AD without vestibular impairment ($p=0.033$ and $p=0.023$, respectively); and (3) the overall vestibular scores, though not differing between groups ($p=0.063$), correlated with memory, visuospatial, language performance, and age (Table 2).

Conclusion: These findings indicate subclinical vestibular impairment, particularly involving SCCs, is prominent in AD and aMCI. Specific vestibular-cognitive associations suggest vestibular assessment could serve as a valuable supplementary tool for identifying and monitoring cognitive decline in at-risk populations.

Disclosure: Nothing to disclose.

EPO-0841 | Can perfusion-weighted imaging improve diagnostic accuracy in transient vascular vertigo?

H. Lee; H. Park

Department of Neurology and Institute of Wonkwang Medical Science, Wonkwang University School of Medicine, Wonkwang University Hospital, Regional Cardiocerebrovascular Center, Iksan, Republic of Korea

Background and aims: Transient vestibular syndrome (TVS) is a frequent manifestation of transient ischemic attacks (TIA) in the vertebrobasilar territory. However, the underlying etiology often remains unidentified in more than half of these patients, even with detailed neuro-otological examinations and standard MRI, including diffusion-weighted imaging (DWI). The aim of this study is to evaluate the clinical utility of perfusion-weighted imaging (PWI) in diagnosing acute transient vascular vertigo (TVV).

Methods: We retrospectively reviewed patients with recurrent transient vertigo/dizziness between October 2023 and November 2025. Inclusion criteria were: no alternative vestibular diagnosis, negative findings on initial brain MRI/DWI, and evaluation within 7 days of onset. Comprehensive neuro-otological assessments (VOG, vHIT, cVEMP, SVV/SVH), lipid profiles, and PWI were analyzed.

Results: Thirty-one patients were included (mean age 67 ± 13 years; 14 males). While all patients were DWI-negative, PWI revealed perfusion deficits in 18 patients (58%). Posterior circulation vascular stenosis or hypoplasia was identified in 24 patients (77%). Regarding neuro-otological findings, none showed spontaneous nystagmus or skew deviation, though apogeotropic nystagmus was observed in 12 patients. Abnormal cVEMP and vHIT were found in 13% and 22.5% of patients, respectively. All patients possessed at least three vascular risk factors, most commonly diabetes and dyslipidemia. Notably, 7 patients (22.6%) progressed to cerebral infarction within one week.

Conclusion: PWI is a valuable diagnostic tool for identifying transient vascular vertigo, especially when DWI is negative. The

presence of posterior circulation stenosis and multiple vascular risk factors should raise clinical suspicion of TVV to prevent subsequent stroke.

Disclosure: Nothing to disclose.

EPO-0842 | Interpretation of HINTS findings in idiopathic sudden sensorineural hearing loss with vertigo

J. Choi¹; H. Kim¹; S. Choi¹; Y. Lee¹; S. Choi²; K. Choi²; M. Kim²; W. Hwang²; S. Lee³

¹Department of Neurology, Pusan National University School of Medicine, Research Institute for Convergence of Biomedical Science and Technology, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; ²Department of Neurology, Pusan National University Hospital, Pusan National University School of Medicine and Biomedical Research Institute, Busan, Republic of Korea; ³Department of Neurology, Chonnam National University Hospital, Chonnam National University Medical School, Gwangju, Republic of Korea

Background and aims: The head impulse-nystagmus-test of skew (HINTS) examination is widely used to distinguish peripheral from central causes of acute vestibular syndrome, but its diagnostic performance in idiopathic sudden sensorineural hearing loss (SSNHL) with vertigo remains uncertain. This study aimed to assess the accuracy and clinical utility of the HINTS examination in patients with idiopathic SSNHL accompanied by vertigo.

Methods: We prospectively evaluated 121 patients with idiopathic SSNHL and vertigo at two university hospitals. The patients underwent detailed neuro-otological examinations, including nystagmus assessment, caloric testing, head impulse tests (HITs), and, as well as brain MRI to exclude central lesions. HINTS findings were classified as “peripheral” or “central” according to established criteria, and false-positive and true-negative rates were calculated.

Results: Spontaneous nystagmus (SN) was present in 59 patients (49%), with no cases of direction-changing nystagmus and only one case of skew deviation. Abnormal caloric responses were observed in 34/71 (48%), whereas abnormal horizontal HIT findings occurred in 35/119 (29%). Concordance between the two tests was noted in 80% of patients, while 17% showed abnormal caloric responses despite normal horizontal HIT. Among 59 patients with SN, 36 (61%) demonstrated “central” HINTS patterns despite normal brain MRI findings, indicating a high false-positive rate. Misclassification was significantly more frequent in patients with ipsilesional SN than in those with contralesional SN (89% vs 31%, $p < 0.001$).

Conclusion: In idiopathic SSNHL with vertigo, the HINTS examination frequently yields central patterns despite peripheral pathology, reflecting limited specificity. Thus, careful interpretation with complementary audiovestibular testing is required for accurate diagnosis.

Disclosure: Nothing to disclose.

EPO-0843 | When LHON mimics demyelination: Area postrema syndrome in Biallelic DNAJC30 variant

K. Dzwilewski; M. Krygier; J. Szymarek; M. Zawadzka; M. Mazurkiewicz-Beldzińska
Department of Developmental Neurology, Medical University of Gdańsk, Gdańsk, Poland

Background and aims: Biallelic pathogenic variants in a nuclear-encoded gene DNAJC30 cause autosomal recessive form of Leber hereditary optic neuropathy (arLHON), commonly considered to be mitochondrially inherited. Although most affected individuals present with isolated optic neuropathy, further research expanded phenotypic spectrum of diseases linked to DNAJC30. We report a patient with LHON and area postrema syndrome (APS).

Methods: 13-year-old patient was referred due to blurred vision with central scotoma of the left eye, recurrent vertigo, and vomiting for 2 months. He presented horizontal gaze-evoked nystagmus and convergence insufficiency of the left eye. Ophthalmological evaluation showed bilateral papilledema with telangiectatic vessels and significant vision impairment of the left eye. Laboratory tests did not detect any specific antibodies. MRI identified brain stem T2 high-signal lesions of suspected inflammatory etiology. Thus, intravenous steroids were commenced, followed by immunoglobulin therapy, without significant vision improvement. Follow-up MRI showed T2 high-signal lesions in AP and optic nerves enhancement, indicative for NMOSD. Despite further immunosuppressive treatment visual function did not improve. On the contrary, progressive vision impairment was observed. Hence, whole exome sequencing was performed, identifying homozygous pathogenic DNAJC30 variant c.152A>G, p.(Tyr51Cys).

Results: The patient was diagnosed with arLHON with symptoms of APS and provided with idebenone, resulting in significant vision improvement.

Conclusion: DNAJC30-associated disease may mimic neuromyelitis optica spectrum disorder (NMOSD). We highlight the need of early genetic diagnosis in patients with optic neuropathy and APS who do not respond to immunotherapy, as targeted treatment with idebenone may lead to significant clinical and radiological improvement.

Disclosure: Nothing to disclose.

EPO-0844 | When atypical is common: Rethinking optic neuritis in multiple sclerosis

L. Silva; B. Silva; A. Martins; I. Monteiro; R. Machado; I. Correia; C. Nunes; C. Macário; A. Jorge; S. Batista; J. Lemos
Neurology Department, Coimbra University Hospital Centre, Coimbra, Portugal

Background and aims: Optic neuritis (ON) is a classic manifestation of multiple sclerosis (MS). If atypical features are present (AON), these generally suggest a distinct underlying etiology from MS. We aimed to ascertain the prevalence of AON in MS and to further investigate it as a subgroup.

Methods: A retrospective analysis of clinical/paraclinical data from MS patients who presented with acute optic neuritis in our department was conducted. All patients underwent

neuro-ophthalmic observation, retinography, optical coherence tomography, and perimetry at baseline, and 1- and 6-month follow-ups. These were further separated into typical (TON) and AON groups.

Results: We included 62 patients (47 females [75.8%]; mean age 38.9 ± 11.9). AON was present in 62.9% patients. If not considering lack of pain as an atypical feature, AON was still present in 40.3%. Visual acuity was $\leq 20/400$ at baseline, $\leq 20/200$ at 1-month and $\leq 20/100$ at 6-months, in 21%, 4.8% and 4.8% patients, respectively. Ten (16.1%) patients were ≥ 50 years old at the time of optic neuritis. There was no pain in 35.5% patients. There was severe optic disc edema in 3.2%, and peripapillary hemorrhages in 1 (1.6%) patient. Four (6.5%) patients had bilateral involvement. In 3.2% patients, chiasmal involvement was documented. EDSS score, disease duration and number of relapses in the last two years did not significantly differ between groups.

Conclusion: Approximately 40% of MS patients show ≥ 1 atypical feature at the time of their optic neuritis. While AON still requires the active exclusion of an alternative diagnosis, atypical optic neuritis is not uncommon in MS.

Disclosure: Nothing to disclose.

EPO-0845 | **Pupillodynamics: A potential indicator of autonomic dysfunction in Parkinson disease**

L. Lehner; G. Laudes; L. Schwach; A. Jäck; S. Christoph; L. Marth; F. Schöberl; F. Hopfner; G. Höglinger; M. Strupp
Department of Neurology, LMU University Hospital, LMU Munich, Germany

Background and aims: The pupillary light reflex is an important metric of autonomic function. In Parkinson's disease (PD) autonomic function is often impaired, even in early stages of the disease. Therefore, we aimed to identify disease specific alterations by dynamic pupillometry.

Methods: Dynamic pupillometric parameters were assessed in 116 patients with PD and 188 healthy controls (HC) using

TABLE 1 Group differences in pupillometric parameters between Parkinson's disease and healthy controls adjusted for age and sex. *F*, *F* statistic from the general linear model; η^2 , partial eta squared (effect size); SE, standard error.

Parameter	Healthy controls Mean $\pm$ SE	Parkinson disease Mean $\pm$ SE	<i>F</i> (1, df)	<i>p</i>	η^2
Baseline pupil size after dark adaptation (mm)	3.689 $\pm$ 0.047	3.648 $\pm$ 0.053	4.254	.040	0.015
Pupil size after light exposure (mm)	2.329 $\pm$ 0.028	2.384 $\pm$ 0.033	28.133	<.001	0.093
Minimal pupil size at 10 s (mm)	2.887 $\pm$ 0.032	2.870 $\pm$ 0.043	28.178	<.001	0.093
Minimal pupil size at 15 s (mm)	2.681 $\pm$ 0.021	2.833 $\pm$ 0.039	66.965	<.001	0.137

FIGURE 1 Age-stratified comparison of minimal pupil size at 10 and 15 s in HC and PD. Bars represent estimated marginal means $\pm$ SE. Group sizes: 51–60 years: HC *n* = 27, PD *n* = 29; 61–70 years: HC *n* = 37, PD *n* = 37; 71–80 years: HC *n* = 29, PD *n* = 31.

FIGURE 2 Age-stratified comparison of constriction dynamics (8–10 s and 13–15 s) in HC and PD. Bars represent estimated marginal means $\pm$ SEM. Group sizes: 51–60 years: HC *n* = 27, PD *n* = 29; 61–70 years: HC *n* = 37, PD *n* = 37; 71–80 years: HC *n* = 29, PD *n* = 31.

BulbiCamTM. Group differences were analyzed with univariate general linear models for each pupillometric parameter, including diagnosis as the between-subject factor and age and sex as covariates. Additional age-stratified analyses were performed within the 51–60, 61–70, and 71–80 years subgroups.

Results: Patients with PD showed larger baseline pupil size after dark adaptation and after light exposure, as well as significantly larger minimal pupil size at 10 and 15 s, indicating reduced and less sustained pupillary constriction (medium to large effect sizes, η^2 up to 0.137). In PD pupillary dynamics were selectively altered, with markedly reduced late phase constriction (8–10 and 13–15 s). Peak velocity of dilatation was modestly reduced in PD, whereas peak acceleration and pupillary latencies did not differ significantly between groups (Table). Age-stratified analyses demonstrated that group differences in tonic pupil size and minimal pupil diameter were preserved or enhanced in older age groups (Figure 1), while impaired late phase pupillary constriction were consistently present across all age strata (Fig. 2).

Conclusion: PD is associated with selective alterations of pupillary control, predominantly affecting pupil size regulation and late-phase pupillary constriction. These findings support disease-specific autonomic pupillary dysfunction in PD.

EPO-0846 | Translating RNFL thickness into papilledema grades in idiopathic intracranial hypertension

Y. Huang-Link¹; S. Eriksson¹; J. Schmiauke¹; G. Yang²
¹Department of Neurology, Linköping University Hospital, Linköping, Sweden; ²Huizhou Aier Eye Hospital, Huizhou, China

Background and aims: The Frisén scale is widely used to grade papilledema, but it remains subjective with notable inter-observer variability. Quantitative OCT provides objective and reproducible assessment of papilledema with micrometer-level precision. This study aimed to define retinal nerve fiber layer (RNFL) thickness thresholds that correspond to modified Frisén papilledema grades.

Methods: A total of 49 patients with newly diagnosed idiopathic intracranial hypertension (98 eyes) were followed for up to two years. 64 healthy controls were included. RNFL thickness was compared across papilledema grades, and ROC was applied to identify cut-off values.

Results: RNFL thickness correlated strongly with papilledema levels according Frisén grading and moderately with intracranial pressure. RNFL thickness increased progressively with higher papilledema grades and differed significantly between all grade groups ($p < 0.001$). Threshold values of approximately 105, 140, 232, and 400 μm distinguished Grade 0 from I, I from II, II from III, and III from IV, respectively, with AUCs ranging from 0.77 to 0.95.

Conclusion: The results demonstrate that RNFL measurements can be translated into clinically meaningful papilledema severity levels. Defining RNFL-based cut-offs offers a more objective, sensitive, precise and reproducible approach to grading papilledema, supporting improved monitoring and management in IIH.

Disclosure: Nothing to disclose.

Figure 1. Mean retinal nerve fiber layer (RNFL) thickness in eyes with idiopathic intracranial hypertension (IIH) across different papilledema grades (0-IV) and in healthy controls (HC). RNFL thickness increased progressively with papilledema severity, with significant differences observed between grade groups. Statistical comparisons were performed using one-way ANOVA with post hoc Bonferroni correction. Error bars indicate 95% confidence intervals. ** $p < 0.01$ versus HC.

Spinal Cord and Root Disorders

EPO-0847 | Spinal cord compression due to plexiform neurofibromas in NF1

A. Elsaddig
Neurology Department, Sheikh Tahnoon Bin Mohammed Medical City, Al Ain, United Arab Emirates

Background and aims: Neurofibromatosis type 1 (NF1) is an autosomal dominant neurocutaneous disorder caused by mutations in the NF1 gene. It is characterised by Schwann cell proliferation, leading to cutaneous neurofibromas and plexiform neurofibromas, which may cause neurological complications due to mass effect.

Methods: We present the case of a 26-year-old male with a known diagnosis of NF1 who presented with a six-month history of intermittent, sudden-onset jerking sensations affecting the chest and upper limbs, associated with pins and needles and tingling. Clinical examination and neuroimaging findings were reviewed.

Results: Neurological examination revealed multiple cutaneous neurofibromas, particularly over both wrists, with bilateral thenar eminence wasting. Muscle tone was normal, with preserved power except for weakness of thumb abduction. Upper limb reflexes were brisk. In the lower limbs, there was pyramidal-pattern weakness with an absent left ankle reflex. MRI of the brain and spine demonstrated extensive cervical plexiform neurofibromas causing compression of the cervical spinal cord at the C2–3 level, with no radiological evidence of malignant transformation.

FIGURE 1 Sagittal T2 and axial T2 showing distortion and compression of cervical cord.

FIGURE 2 Brachial plexus STIR view showing huge large plexiform neurofibromas.

Conclusion: NF1 is an important cause of nerve root hypertrophy and spinal cord compression. Plexiform neurofibromas can result in significant cervical cord compromise, highlighting the need for early recognition and surveillance imaging in symptomatic patients.

Disclosure: Nothing to disclose.

EPO-0848 | A systematic review of the natural history of degenerative thoracic myelopathy

E. Koubeh; S. Möbus; T. Rujeedawa; O. Mowforth; M. Kotter
Department of Clinical Neurosciences, University of Cambridge, Cambridge, UK

Background and aims: Degenerative thoracic myelopathy (DTM), a recently proposed term, encompasses a spectrum of degenerative spine conditions that cause thoracic spinal cord compression and progressive neurological dysfunction. The natural history of DTM is poorly characterised, hindering prompt diagnosis and management. This systematic review aimed to assess the initial symptoms, progression, and prognostic factors. Studying DTM as a unified condition provides a larger body of evidence to draw conclusions from, analogous to Degenerative Cervical Myelopathy.

Methods: A systematic literature search was performed in Embase and MEDLINE, identifying papers assessing DTM. Relevant outcomes included initial symptoms, symptom progression, duration of disease and prognostic factors. This review followed PRISMA guidelines.

Results: Sixteen studies met the inclusion criteria. Sensory disturbances were more common than motor symptoms in the early stages of DTM, with all 8 studies reporting initial symptoms finding that numbness, tingling or pain were most common. Gait disturbances and motor symptoms such as weakness were commonly reported later in disease progression. The prevalence of symptoms increased over time. Symptom progression was highly variable, with a mean duration from symptom onset to surgery of 25.5 months. Risk factors for progression include the underlying aetiology, age and the presence of T2 hyperintensity on spinal MRI.

Conclusion: Despite a paucity of literature on the natural history of DTM, this review identifies several patterns which provide actionable guidance for clinicians. Recognising early symptoms may reduce diagnostic delay, prognostic features can inform risk-stratified surveillance and understanding progression may inform treatment thresholds. Importantly, diagnostic delay is associated with poorer post-operative outcomes in DTM.

Disclosure: Nothing to disclose.

EPO-0849 | Abstract withdrawn

EPO-0850 | Clinical characteristics of toxocara canis myelitis in Lebanon: Largest single center cohort study

K. Eid; N. El Ayoubi; T. El Halabi; S. F. Atweh
Neurology Department, American University of Beirut Medical Center, Beirut, Lebanon

Background and aims: Neurotoxocariasis is a rare manifestation of human toxocariasis presenting as myelitis and literature is limited to small case series. This study describes the clinical characteristics, diagnostic findings, treatment results, and prognostic factors of Toxocara-associated myelitis.

Methods: This is a retrospective cohort study conducted at a tertiary center, including 44 patients diagnosed with Toxocara myelitis between 1998 and 2025. Diagnosis was based on clinical presentation, magnetic resonance imaging (MRI), serology, cerebrospinal fluid (CSF), eosinophilia, and treatment response. Clinical improvement was defined as $\geq 50\%$ or $< 50\%$ from baseline. Predictors of outcome were obtained by bivariate and multivariate analyses.

Results: Majority of patients were males (84%) with median age 41 years. All patients were ambulatory at baseline with sensory symptoms, however autonomic dysfunction and motor weakness were present in 59% and 57% of cases, respectively. Peripheral eosinophilia was in 46%, CSF pleocytosis in 21%, CSF eosinophilia in 5% and CSF oligoclonal bands in 44%. 95% had positive serology in blood and/or CSF. All patients were treated with Albendazole, 82 % also received corticosteroids. Of the 41 reevaluated patients: 71% improved, and 51% attained $\geq 50\%$ recovery. Early Albendazole initiation was the only predictor of a favorable outcome (median 10 vs. 32 weeks from symptom onset; $p=0.012$), confirmed controlling for age, sex, and treatment with corticosteroids. Importantly, demographic characteristics, clinical presentation, laboratory data, and corticosteroid use were not associated with recovery.

Conclusion: Toxocara myelitis is considered a potentially reversible subacute myelitis. The most important factor for neurological recovery is the early diagnosis and administration of albendazole.

Disclosure: Nothing to disclose.

EPO-0851 | Paraneoplastic sensory ganglionopathy as the initial manifestation of a small pancreatic neuroendocrine tumor

M. Henriques; J. Almada Silva; D. Carapinha; M. Saraiva; R. Pinheiro; A. Rêgo
Department of Neurology, Hospital Prof. Dr. Fernando Fonseca, Lisbon, Portugal

Background and aims: Paraneoplastic neurological syndromes (PNS) are rare immune-mediated disorders, affecting fewer than 1% of patients with cancer, and may precede the diagnosis of an underlying malignancy. Sensory ganglionopathy is a severe and disabling manifestation, classically associated with small-cell lung carcinoma but also described in other tumors, including neuroendocrine neoplasms. The frequent absence of detectable onconeural antibodies may delay diagnosis, emphasizing the importance of systematic malignancy screening in unexplained sensory neuronopathies.

Methods: We report a 56-year-old woman presenting with subacute progressive sensory ataxia, marked proprioceptive loss, generalized areflexia, postural instability, and functional dependence. Motor weakness was predominantly secondary to sensory deafferentation. Cranial nerve examination were normal.

Results: Brain and spinal MRI showed no structural abnormalities. Cerebrospinal fluid analysis revealed mild protein elevation

without pleocytosis, oligoclonal bands, or infectious markers. Extensive metabolic, infectious, toxic, and autoimmune investigations, including neuronal surface antibodies, were negative. Neurophysiological studies were consistent with moderate sensory ganglionopathy. Given the unexplained progressive course, systemic malignancy screening was pursued. Abdominal imaging identified a small lesion in the pancreatic head. Functional imaging with PET-DOTANOC confirmed a somatostatin receptor-positive pancreatic neuroendocrine tumor. The patient underwent pancreaticoduodenectomy following multidisciplinary discussion. While awaiting surgery, recurrent hypoglycaemic episodes occurred, consistent with hormonally active disease, requiring glucagon therapy. Histopathological examination confirmed a well-differentiated, low-grade pancreatic neuroendocrine tumor (WHO grade 1). Despite tumor resection and immunomodulatory therapy, neurological deficits persisted, consistent with irreversible dorsal root ganglion damage.

Conclusion: Sensory ganglionopathy may be the initial manifestation of pancreatic neuroendocrine tumors, supporting early comprehensive oncological screening in unexplained subacute sensory neuronopathy.

Disclosure: Nothing to disclose.

EPO-0852 | Spontaneous spinal epidural hematoma secondary to a dural arteriovenous fistula as a cause of acute myelopathy

M. Serrano Alarcón¹; A. Trondin³; E. Huertas Muñoz¹; L. Guirao Guillen¹; L. Centeno Pons¹; C. Gómez-Escalonilla Escobar¹; L. Franco Rubio¹; A. López-Frías López-Jurado²

¹Neurology Department, Hospital Clínico San Carlos, Madrid, Spain; ²Neurointerventional Radiology Department, Hospital Clínico San Carlos, Madrid, Spain; ³Neurosurgery Department, Hospital Clínico San Carlos, Madrid, Spain

Background and aims: Spinal dural arteriovenous fistulas are vascular malformations that typically cause slowly progressive myelopathy. However, a rare but severe complication in this setting is spontaneous spinal epidural hematoma, which may present as acute spinal cord compression.

Methods: We report the case of an 81-year-old man who presented to the emergency department with acute lumbar pain followed by sudden bilateral lower-limb weakness. Neurological examination revealed paraparesis with muscle strength graded as follows: hip flexion/extension 3-/2, knee flexion/extension 1/1, ankle dorsiflexion/plantarflexion 3+/0. Patellar and Achilles reflexes were absent, with bilateral indifferent plantar responses. Sensory examination showed bilateral hypoesthesia to pain and touch below the knees. Acute myelopathy was suspected, and urgent spinal MRI demonstrated an extensive extradural collection compatible with spinal epidural hematoma from T7 to L3, with maximal compression and myelopathy associated at T11–T12. Tortuous perimedullary vessels of uncertain significance were also observed. Emergency D11–D12 laminoplasty with hematoma evacuation was performed by the Neurosurgery ward.

Results: Given the suspicion of an underlying vascular malformation, the case was discussed with the Neurointerventional Radiology service, and spinal angiography was performed 48 hours later, identifying a dural arteriovenous fistula at the left D6 neural foramen. Neurological outcome was favorable, with

FIGURE 1 Sagittal STIR spinal MRI demonstrating an extensive hyperintense extradural collection consistent with an acute spinal epidural hematoma extending from T7 to L3, with maximal spinal cord compression and associated myelopathy at T11–T12.

FIGURE 2 Sagittal STIR spinal MRI showing postoperative changes at the level of the previous hematoma, with persistent but reduced extent of myelopathy. Engorged perimedullary vessels surrounding the spinal cord are observed, raising suspicion of an underlying vas.

muscle strength improving to 5/5 in the right lower limb and 2/5 in the left lower limb within 24 hours. Assisted ambulation was achieved after two weeks.

Conclusion: Dural arteriovenous fistula should be considered in cases of acute myelopathy secondary to spontaneous spinal epidural hematoma. Spinal angiography is essential for diagnosis and enables definitive treatment.

Disclosure: Nothing to disclose.

FIGURE 3 Spinal angiography demonstrating an arteriovenous shunt between radiculomedullary arteries and perimedullary veins, consistent with a dural arteriovenous fistula at the left D6 neural foramen.

EPO-0853 | Isolated seronegative longitudinally extensive transverse myelitis in children: A Tunisian case series

M. Elloumi; A. Zioudi; Z. Miladi; M. Jamoussi; T. Ben Younes; M. Ben Hafsa; H. Ben Rhouma; H. Klaa; I. Kraoua
LR18SP04 and Department of Pediatric Neurology, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia

Background and aims: Pediatric longitudinally extensive transverse myelitis (LETM) classification has evolved with antibody discovery. These cases are heterogeneous with variable clinical features and outcomes.

Methods: We retrospectively reviewed eight Tunisian children diagnosed with isolated seronegative inflammatory LETM from 2020 to 2025. Demographics, clinical presentation, neuroimaging, cerebrospinal fluid (CSF) findings, treatments, and outcomes were collected. Functional status and follow-up MRI findings were analyzed. All patients were tested for serum and CSF myelin oligodendrocyte glycoprotein antibodies and serum anti-aquaporin 4.

Results: Eight patients (five females, three males) had a median age of 13.5 years (range 5–17). A history of a preceding infection was noted in three patients. All presented with paraparesis. Six had sensory symptoms. Four had urinary dysfunction. CSF pleocytosis was present in six patients. CSF oligoclonal bands were positive in three. MRI showed cervical cord involvement in seven and conus medullaris involvement in two. Two patients had tumefied lesions. Two showed multifocal contrast

enhancement. All received intravenous methylprednisolone. Six continued oral corticosteroids for 3–8 months. One received intravenous immunoglobulin. Five patients improved clinically. Two patients relapsed. One patient worsened. At a median follow-up of two years, five had improved motor function. Follow-up MRI showed spinal cord atrophy in two, stable myelitis in two, and lesion enlargement in one.

Conclusion: Seronegative pediatric LETM presents with variable clinical and radiological features. Despite early corticosteroid therapy, many patients have incomplete recovery. Careful long-term follow-up is required to better understand this entity. Further studies are needed to identify prognostic factors and optimize treatment strategies.

Disclosure: Nothing to disclose.

EPO-0854 | Spinal dural arteriovenous fistula as a diagnostic pitfall: A case report and literature

O. Cibuku¹; V. Leka²; E. Xhukellari¹; V. Thimjo¹; E. Enesi³; A. Rroji³

¹Neurovascular Service, University Hospital “Mother Teresa” Tirane, Albania; ²Stroke Center, American Hospital, Tirane, Albania; ³Neuro radiology Department, University Hospital “Mother Teresa” Tirane, Albania

Background and aims: Spinal dural arteriovenous fistulas (sDAVFs) are rare but potentially reversible vascular causes of progressive myelopathy resulting from venous hypertensive congestion of the spinal cord. Because of their insidious onset and nonspecific clinical and radiological features, they are frequently misclassified in acute and pre-hospital settings, leading to delayed neurology referral and preventable neurological disability.

Methods: We report a 61-year-old man with several months of progressive gait impairment, lower limb numbness, and urinary retention. Examination showed spastic paraparesis (Aminoff–Logue G4 U3). Spinal MRI demonstrated longitudinal T2 hyperintensity from T7 to L1 with dilated perimedullary flow voids. Cerebrospinal fluid showed elevated protein, initially suggesting inflammatory or degenerative etiologies. However, progressive symptoms with sphincter dysfunction and characteristic imaging raised suspicion for a vascular cause. Digital subtraction angiography confirmed a right-sided dural arteriovenous fistula at L2. Endovascular embolization resulted in clinical improvement with recovery of motor function and resolution of urinary symptoms (Aminoff–Logue G3 U1).

Results: A brief literature review indicates that median diagnostic delays range from 12 to 44 months, primarily due to

FIGURE 1 MRI shows medullary edema (red arrow) from T7 to L1 with the presence of perimedullary vessels (blue arrow).

O. Cibuku¹; V. Leka²; E. Ranxha¹; E. Enesi³; A. Rroji³

¹Neuro Vascular Service, University Hospital “Mother Teresa” Tirane, Albania; ²Stroke Center, American Hospital, Tirane, Albania; ³Neuro Radiology Department, University Hospital “Mother Teresa”, Tirane, Albania

Background and aims: Spinal dural arteriovenous fistulas (sDAVF) are the most common intradural spinal vascular malformations, yet they remain frequently underdiagnosed. Incidious clinical onset and misinterpretation of initial MRI can lead to delayed recognition and progressive venous hypertensive myelopathy. Using statistical techniques, this research analyzes the clinical features, diagnostic delay, and short-term outcomes following endovascular therapy to investigate disability predictors.

Methods: A retrospective observational study including 9 patients diagnosed with sDAVF from 2022–2025. All patients underwent complete spinal MRI and selective spinal angiography. Functional status was assessed using the Aminoff–Logue (AL) gait and sphincter scores and the modified Rankin Scale (mRS). Associations between diagnostic delay and disability scores were explored with Pearson or Spearman correlation, as appropriate. A simple linear regression model evaluated diagnostic delay as a predictor of AL scores (β -coefficient, 95% CI, p -value). Statistical significance was set at $p < 0.05$, outcomes before and after treatment compared using paired t -tests.

Results: Mean age was 54.5 years; 7/9 were male. Median diagnostic delay was 7.11 months. Common comorbidities included degenerative spine disease (56.4%), hypertension (35.6%), and type 2 diabetes (23.4%). Post-treatment analysis demonstrated significant improvement in AL gait and sphincter scores (Wilcoxon $p < 0.05$). Linear regression showed a positive β -trend between longer diagnostic delay and worse baseline AL scores, although not statistically significant ($p > 0.05$), likely due to the small sample size.

FIGURE 2 Medullary angiography reveals aright lateral dural arteriovenous fistula at the L2 level (yellow arrow), with hypertrophic perimedullary vessels (orange arrow).

FIGURE 3 Post-embolization arteriography demonstrates reduced hypertrophic plexuses.

misinterpretation of MRI, attribution of symptoms to nonvascular spinal disorders, and low awareness during stroke-mimic triage and early neurological assessment. Prolonged delays are consistently associated with poorer neurological outcomes.

Conclusion: This case emphasizes the importance of including sDAVF in stroke-mimic algorithms and neurology referral pathways for patients with unexplained progressive myelopathy, to enable timely angiographic confirmation and definitive treatment.

Disclosure: Nothing to disclose.

FIGURE 1 Statistical results of the study.

Conclusion: Diagnostic delays in sDAVF remain common and correlate with greater neurological disability. Endovascular treatment achieved marked functional improvement. Incorporating structured MRI protocols and multidisciplinary evaluation is essential to reduce delays and improve outcomes. **Disclosure:** Nothing to disclose.

EPO-0856 | Peripheral arteriovenous fistula and non-traumatic myelopathy: Diagnostic challenges in a case of acute tetraparesis

P. Tavares de Almeida¹; L. Carvalho Rosas²; M. Rodrigues³; P. Pires³; T. Lima²; J. Novo¹
¹Neurology Department, Local Health Unit of Gaia and Espinho, Vila Nova de Gaia, Portugal; ²Neurosurgery Department, Local Health Unit of Gaia and Espinho, Vila Nova de Gaia, Portugal; ³Cerebrovascular Intervention Neuroradiology Unit, Radiology Department, Local Health Unit of Gaia and Espinho, Vila Nova de Gaia, Portugal

Background and aims: Acute tetraparesis is a neurological emergency requiring prompt diagnostic evaluation. While traumatic or intrinsic spinal cord vascular causes are more frequent, rarer conditions such as hemodynamic changes induced by peripheral arteriovenous fistulas (AVFs) should be considered in selected patients.

Methods: Retrospective review of a patient's clinical file.

Results: A 57-year-old man presented with severe back pain followed by sudden tetraparesis evolving over 1 hour. He had no history of trauma. Past medical history included chronic kidney disease and prior hemodialysis via a right elbow AVF. Neurological examination revealed tetraparesis with lower limb plegia and MRC 3/5 upper limbs weakness, sensory level at C4, and absent reflexes. Cervical MRI revealed a posterior epidural collection from C3-D10, suggestive of acute hemorrhage, and spinal cord hyperintensity from C5–C7 with diffusion restriction, compatible with ischemic injury. Emergent C5–C7 laminectomy and drainage of the epidural collection were performed, however follow-up MRI revealed progression of spinal cord hyperintensity from C4–D1. Dural AVF was suspected and the patient underwent diagnostic angiography, excluding this hypothesis, but revealing an AVF of the elbow with a broad thrill and exuberant development of the right brachial territory and cervical collaterals, associated with subclavian-steal syndrome. The elbow AVF was considered the likely cause of cervical vascular ectasia and consequent spinal ischemia. The patient underwent elbow AVF ligation and was discharged after 40 days, referred for rehabilitation.

Conclusion: This rare case highlights the importance of considering peripheral vascular causes as a potential etiology of non-traumatic myelopathies, especially in patients with a history of hemodialysis.

Disclosure: Nothing to disclose.

Pain 2

EPO-0857 | From peripheral hemodynamics to central connectivity: A multi-modal framework towards precision medicine in trigeminal neuralgia

C. Cao¹; A. Oswal²; H. Chen³; X. Jiang¹; Y. Wang¹
¹Department of Neurosurgery, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, China; ²MRC Brain Networks Dynamics Unit, University of Oxford, Oxford, UK; ³Department of Radiology, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, China

Background and aims: Trigeminal neuralgia (TN) management is evolving towards precision medicine, necessitating biomarkers that delineate pathological neurovascular conflict

FIGURE 1 Effective vs. ineffective surgical outcomes in CFD analysis. (A, B) Intraoperative views. (C, D) Key hemodynamic parameters (PSP, PSF, WSS, OSI). (E) ROC curve comparison of predictive models.

FIGURE 2 (A) Trigeminal ganglion lead placement. (B) TGS reduces thalamo-somatosensory hyperconnectivity. (C) Classification performance metrics. (D) ROC curves with AUC and optimal threshold.

(NVC) and its central consequences. We propose a multi-modal framework integrating peripheral hemodynamics and central connectivity to guide treatment.

Methods: In Study 1 (CFD-MVD), In 56 classical TN patients, computational fluid dynamics (CFD) quantified hemodynamic parameters (e.g. peak systolic flow-PSF, max wall shear stress) at neurovascular conflict (NVC) sites to predict microvascular decompression (MVD) efficacy. In Study 2 (TGS-fMRI), In 29 TN patients, longitudinal resting-state fMRI assessed thalamo-somatosensory functional connectivity (FC) changes before and after trigeminal ganglion stimulation (TGS). Machine learning evaluated FC as a treatment-response biomarker.

Results: Study 1 revealed that “effective” NVC for MVD was characterised by significantly lower PSF (0.202 ± 0.136 vs. 0.306 ± 0.142 mL/s, $p=0.007$) and higher Max WSS (3.231 vs. 2.197 Pa, $p=0.024$). A prediction model incorporating these parameters achieved an AUC of 0.920 for MVD efficacy. Study 2 demonstrated that TN patients exhibited pathological hyperconnectivity within the thalamo-somatosensory circuit compared to healthy controls. Successful TGS significantly normalised this aberrant FC in a region-specific manner. The SVM classifier reliably distinguished pre- from post-TGS states (AUC = 0.74), validating these FC patterns as stable neuromodulation biomarkers.

Conclusion: This framework links peripheral CFD biomarkers (guiding MVD selection) with central fMRI biomarkers (assessing TGS response), enabling personalised TN therapy based on distinct pathophysiological profiles.

Disclosure: Nothing to disclose.

EPO-0858 | Clinical features distinguishing fibromyalgia from small fiber neuropathy

F. Masciarelli¹; D. Dell'Aversana¹; F. Vitale¹; G. Ciccarelli¹; S. Tozza¹; G. Caporaso²; V. Provitera²; L. Santoro¹; F. Manganeli¹; M. Nolano¹

¹University of Naples Federico II, Department of Neurosciences, Reproductive Sciences, and Odontostomatology, Naples, Italy;

²Neurology Department – Skin Biopsy, Lab Istituti Clinici Scientifici Maugeri, Spa SB Institute of Telesse Terme – IRCCS, Italy

Background and aims: Fibromyalgia syndrome (FMS) has been described associated with small fiber pathology and it manifests with a distinct clinical picture compared with pure small fiber neuropathy (SFN). However, some severe fibromyalgic patients may present with overlap phenotypes. We compared sensory and autonomic symptoms and signs across FMS, FMS associated with SFN and pure SFN.

Methods: We retrospectively analyzed 115 patients with FMS and 67 with biopsy-confirmed SFN without FMS. Within FMS, 91 patients were classified as FMS+SFN, when associated with SFN symptoms and signs, otherwise as FMS ($n=24$). We collected pain descriptors and distribution, sensory signs (allodynia, hyperalgesia, hypoesthesia to pinprick/touch), autonomic symptoms and comorbidities.

Results: Our population (mean age 46.1 ± 14.3 years) was mainly composed of women (FMS+SFN 90.1%; FMS 79, 2%; SFN 68,7%). Compared with FMS, FMS+SFN more often reported burning pain (91.2% vs 58.3%), hyperalgesia (23.1% vs 0%) and allodynia (47.3% vs 0%) and less frequently was associated

with dysmetabolic comorbidities (15.4% vs 37.5%). Compared with SFN, FMS+SFN more frequently reported excruciating pain (91.2% vs 67.2%), painful cold (19.8% vs 7.5%), pins and needles (19.8% vs 7.5%), tingling (54.9% vs 32.8%), pinprick hyperalgesia (23.1% vs 3.0%), mechanical allodynia (47.3% vs 29.9%), itch (65.9% vs 38.8%), hypoesthesia to pinprick (82.4% vs 54.0%) and widespread pain distribution (95.6% vs 40.2 %). Overall, FMS+SFN presented more frequently autonomic symptoms (mostly urinary) and autoimmune comorbidities.

Conclusion: Patients with FMS/SFN phenotype overlap show a more severe sensory/autonomic burden than FMS and should prompt evaluation for the search of potentially treatable causes.

Disclosure: Nothing to disclose.

EPO-0859 | Sympathetic skin response in fibromyalgia patients with small fibers pathology

G. Paparella¹; E. Ammendola¹; E. Ladisa¹; G. Paparella¹; G. Devigili²; M. Delussi³; K. Ricci¹; L. Clemente¹; M. de Tommaso¹

¹Neurophysiopathology Unit, Department of Translational Biomedicine and Neuroscience (DiBrain), University of Bari Aldo Moro, Bari, Italy; ²Movement Disorders Unit, Clinical Neurophysiology Unit Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; ³Department of Education, Psychology, Communication (For.Psi.Com.), University of Bari Aldo Moro, Bari, Italy

Background and aims: Fibromyalgia (FM) is a chronic disease characterised by small fibre pathology and autonomic dysfunction. Sympathetic Skin Response (SSR) is easily obtained in clinical practice as a marker of autonomic dysfunction. The present study aims to assess SSR abnormalities in small fibre pathology associated with the disease.

Methods: This was a retrospective, observational, monocentric, cross-sectional study including 393 patients with FM, who underwent skin biopsy from the thigh and ankle, SSR obtained with a standard electromyographic active electrode attached to the right palm and sole, and clinical evaluation.

Results: SSR at the hand and foot was similarly absent in the three FM groups: those with normal skin biopsy, proximal denervation, and proximal and distal denervation. Latency at the foot was significantly prolonged in patients with proximal denervation ($z=2.33$, $p=0.019$). Amplitude was reduced in patients with distal denervation compared with the normal skin biopsy group ($z=2.30$, $p=0.020$). SSR had low predictive performance with respect to skin biopsy results ($r^2=0.04$). Latency of SSR at the foot and intraepidermal nerve fibre density (IENFD) correlated with the score for associated symptoms. Amplitude of SSR at the foot also negatively correlated with anxiety, depression, and fatigue scores.

Conclusion: SSR abnormalities did not correspond with small fibre impairment as shown by skin biopsy in FM patients, but instead appear to reflect different aspects of the complex clinical picture, including psychopathological features and fatigue, as distinct biomarkers of the symptom constellation.

Disclosure: Nothing to disclose.

Background and aims: Differential diagnosis of somatoform pain disorder (SPD) from other chronic pain (CP) conditions presents significant diagnostic challenges due to the overlap in symptoms. It is known that CP leads not only to anxiety, depression and sleep disturbances, but also to a specific neurochemical imbalance in the brain. In addition, sleep disorders and CP negatively affect brain homeostasis by reducing glymphatic clearance. To identify differences in neurochemical imbalance and glymphatic clearance using MRI spectroscopy (MRS) and MRI tractography in patients with SPD and CP.

Methods: 27 patients were diagnosed with SPD according to DSM-5 criteria (1st group), and 32 patients with chronic secondary musculoskeletal pain according to ICD-11 criteria (2nd group). We used MRS and MRI with DTI-ALPS index analysis, questionnaires and scales to assess pain characteristics, anxiety levels, depression and quality of life (table).

Results: No differences were found in anxiety, depression, VAS, or quality of life. 1st group had the worst scores in the mental health component and the distress subscale. The 2nd group showed a decrease in the DTI-ALPS index and NAA with an increase of the glial metabolites, which was expressed in NAA/

4DSQ – Four-Dimensional Symptom Questionnaire
MFI-36 – Multidimensional Fatigue Inventory
GAD-7 – Generalized Anxiety Disorder 7
SP-36 – 36-Item Short-Form Survey
DTI-ALPS – Diffusion tensor image analysis along the perivascular space
NAA – N-acetylcholine, Cr – Creatine, MI – Myo-Inositol, Cho – Choline
^Δ – Statistically significant difference (p < 0.05) between the 1st group and 2nd group (Mann-Whitney)
^Δ – Statistically significant difference (p < 0.05) between controls, 1st group and 2nd group (Kruskal-Wallis test)

Cr, NAA/MI and NAA/Cho ratio reduced in the thalamus, amygdala, prefrontal region compared to the 1st group and the controls (Table).

Conclusion: Despite the fact that both types of pain disorders are characterized by disturbances in the functional relationship between the affective and cognitive systems, the present study shows that SPD does not lead to significantly metabolic changes and glymphatic dysfunction characteristic of CP, which can be used to differentiate these conditions.

Disclosure: Nothing to disclose.

EPO-0861 | **Immune activity in skull bone marrow and the periphery in chronic pain: A TSPO PET/MRI and LPS-stimulated cytokines study**

M. Menduni De Rossi¹; M. Mohammadian³; L. Brusaferrri⁶; J. Cooper-Hohn³; M. Kim³; J. P. Murphy³; Z. Alshelhi³; G. Grmek³; J. Schnieders³; C. Chane³; T. Carmichael³; D. Yang³; V. Napadow⁴; M. Loggia³
¹Department of Translational Research on New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy; ³Department of Radiology, Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Harvard Medical School, Boston, USA; ⁴Spaulding Rehabilitation Hospital, Boston, MA, United States; ⁶Department of Computer Science and Digital Technology, College of Technology and Environment, London South Bank University, London, UK

Background and aims: Chronic pain is increasingly recognized as a neuroinflammatory condition involving interactions between peripheral immune processes and the central nervous system. The skull bone marrow (SBM) is a critical interface in this peripheral-central immune axis, yet cytokine signatures and SBM activation patterns in distinct chronic pain conditions remain unclear.

FIGURE 1 3D mapping of voxels in patients with chronic pain showed a voxel-wise positive correlation between skull bone marrow [11C]PBR28 TSPO signal and IL-1Ra fold change (LPS-stimulated/base-line), overlaid onto a 3D skull model in standard MNI152 space.

FIGURE 2 Scatter plots of the partial linear regression and 95% confidence interval showing associations between PROMIS-29 scores and cytokine fold change (LPS-stimulated/baseline) in cLBP and KOA patients. All analyses were adjusted for baseline cytokine levels.

FIGURE 3 Bar plots showing group differences in IL-10 and IL-4 fold change (LPS-stimulated/baseline) between healthy controls, KOA, and cLBP. Bars represent group means $\pm$ SEM. Group comparisons were assessed using *t*-tests

Methods: We assessed lipopolysaccharide (LPS)-induced cytokine reactivity in peripheral blood cells from patients with chronic lower back pain (cLBP; $n = 13$) and knee osteoarthritis (KOA; $n = 17$), alongside healthy controls ($n = 10$). Cytokine fold changes were analyzed in relation to pain intensity, pain interference, depression, and anxiety using partial linear regression adjusting for baseline cytokine levels. SBM immune cell density was quantified via [^{11}C] PBR28 PET/MRI, indexing 18 kDa translocator protein (TSPO) expression.

Results: Compared to controls, only cLBP patients exhibited significantly reduced LPS-induced IL-4 and IL-10 reactivity ($p < 0.05$). In cLBP, pain intensity showed associations with IL-1 β , TNF- α , GM-CSF, and IFN- γ reactivity ($p < 0.05$), with a trend for IL-6. In contrast, KOA demonstrated broader clinical associations, with both pain intensity and pain interference correlating with IL-1 β , IL-6, MCP-1, and MIP-1 α ($p < 0.05$). Notably, depressive and anxiety symptoms correlated with IL-1 receptor antagonist (IL-1RA) reactivity exclusively in cLBP ($p < 0.001$). Voxelwise analyses revealed significant associations between SBM TSPO signal and IL-1RA, IL-6, IL-8, and GM-CSF reactivity ($p < 0.01$).

Conclusion: These findings reveal condition-specific peripheral immune signatures in chronic pain and provide in vivo evidence linking SBM activation with peripheral cytokine reactivity, supporting a functional skull-immune-brain axis in human pain pathophysiology.

Disclosure: Nothing to disclose.

EPO-0862 | Characteristics of migraine patients who successfully discontinued anti-CGRP monoclonal antibodies: A single-center retrospective study

N. Imai¹; R. Narita¹; A. Moriya¹; R. Suzuki¹; E. Kitamura²
¹Department of Neurology and Headache Center, Japanese Red Cross Shizuoka Hospital, Japan; ²Department of Neurology, Kitasato University School of Medicine, Japan

Background and aims: Randomized controlled trials have established anti-CGRP monoclonal antibodies (mAbs) as effective for migraine prevention. While some patients discontinue treatment following substantial improvement—a process termed “graduation”—the clinical characteristics associated with success remain poorly understood. This study investigated factors associated with successful graduation from anti-CGRP mAbs in a real-world setting.

Methods: We retrospectively evaluated 257 migraine patients (ICHD-3 criteria) treated with anti-CGRP mAbs at our institution. Clinical characteristics, including medication overuse headache (MOH), baseline monthly migraine days (MMDs), and MIDAS/HIT-6 scores, were compared between “graduates” and “non-graduates.” Multivariable logistic regression analysis was performed to identify independent factors associated with graduation.

Results: The anti-CGRP mAbs administered included galcanezumab ($n = 96$), erenumab ($n = 66$), and fremanezumab ($n = 95$). Thirty patients (11.7%) successfully graduated. Univariate analyses showed graduates had a significantly lower prevalence of MOH (20% vs. 66%, $p = 0.015$) and fewer baseline MMDs (median 11 vs. 16, $p = 0.042$). In multivariable logistic regression, absence of MOH (adjusted OR: 0.22; 95% CI: 0.05–0.89; $p = 0.034$) and lower baseline MMDs (adjusted OR: 0.93; 95% CI: 0.87–0.99; $p = 0.048$) were independently associated with successful graduation. No significant interaction was observed between MOH and MMDs.

Conclusion: Successful discontinuation of anti-CGRP mAbs was independently associated with fewer baseline MMDs and absence of MOH. Early initiation of preventive therapy—before high frequency and medication overuse develop—may enhance the likelihood of successful treatment withdrawal, supporting a treat-to-target strategy aimed at eventual treatment graduation.

Disclosure: Noboru Imai reports being an advisor for Sawai and received speaker fees from Daiichi Sankyo, Eli Lilly, Otsuka, and Amgen; however, these companies had no relation to the study.

Background and aims: Pain is a common and disabling symptom in multiple sclerosis (MS), but the clinical and functional impact of neuropathic pain (NP) versus musculoskeletal pain (MSP) is not well defined in large real-world cohorts.

Methods: In this cross-sectional study, 1,503 people with MS attending a tertiary MS center were assessed. Pain subtypes were classified using PainDETECT and the Nordic Musculoskeletal Questionnaire into no pain, MSP, or NP. Disability was measured with the Expanded Disability Status Scale (EDSS). Health-related quality of life (HRQoL) was evaluated with EQ-5D-3L and EQ-VAS.

Results: Pain was reported by 68.2% of participants; 50.5% had MSP and 17.7% had NP. The NP group had higher disability (median EDSS 2.0) than MSP or no-pain groups ($p < 0.001$). HRQoL was poorest in NP, with significantly worse EQ-5D domain scores and EQ-VAS compared with MSP and no pain (all $p < 0.001$). MSP most frequently involved the lower back (33.4%), neck (31.3%), knees (31.0%), and ankles/feet (29.4%).

Conclusion: In MS, NP is associated with greater disability and markedly worse HRQoL than MSP or no pain, supporting routine screening for pain subtypes and early, targeted management to reduce functional and psychosocial burden.

FIGURE 1 Anatomical distribution of musculoskeletal pain in people with multiple sclerosis (pwMS).

EPO-0864 | Microstructural changes at the trigeminal root entry zone and their role in classical trigeminal neuralgia: A systematic review

S. Nelson
Barts London Health, Whitechapel, UK

Background and aims: Classical trigeminal neuralgia is linked to neurovascular compression at the root entry zone. This review aimed to summarise evidence on structural and physiological mechanisms contributing to pain generation.

Methods: A systematic search of PubMed, Scopus, and Web of Science was conducted (2000–2024). Eligible studies included human clinical, neuroimaging, neurophysiological, or histopathological investigations examining the REZ in classical TN. Data were extracted on REZ morphology, diffusion tensor imaging (DTI) findings, electrophysiological abnormalities, and correlations with pain severity or treatment outcomes. Screening and qualitative synthesis followed PRISMA guidelines.

Results: A total of 47 studies met inclusion criteria. Neurovascular compression was consistently associated with focal demyelination at the REZ, with 78% of imaging studies reporting reduced fractional anisotropy in the affected nerve. Electrophysiological data demonstrated abnormal trigeminal reflex latencies consistent with impaired axonal conduction. Across clinical studies, greater structural or electrophysiological disruption was associated with higher pain intensity, increased attack frequency, and reduced responsiveness to sodium-channel blockers. Evidence also showed that patients with severe REZ distortion were more likely to benefit from microvascular decompression compared with medical therapy alone.

Conclusion: Across diverse methodologies, current evidence supports a shared mechanism in TN centred on REZ demyelination, abnormal impulse generation, and ectopic cross-talk between trigeminal fibres. These mechanistic insights reinforce

FIGURE 1 Educational infographic illustrating the role of MRI in identifying neurovascular compression in trigeminal neuralgia. Included to contextualise the diagnostic relevance of imaging referenced in this review.

the value of integrating neuroimaging and neurophysiology into routine evaluation to improve treatment selection. A unified mechanistic framework may also guide future biomarker development for personalised TN management.

Disclosure: Nothing to disclose.

EPO-0865 | An artificial intelligence-based decision-support tool to predict outcomes in low back pain

S. Singh; P. Kumar
Department of Neurosurgery, AIIMS, Raebareli, India

Background and aims: The study aimed to create a predictive tool (an artificial intelligence-based decision-support tool), which merges Clinical Intelligence and Radiomics to generate customized therapy plans for LBP patients.

Methods: The tool uses deep learning models to perform automated segmentation which enables the extraction of geometrical parameters including disc height and width, vertebrae height and width, canal diameter, disc height index, signal intensity, and disc volume. A total of 402 patient's mid-sagittal T2-weighted MRIs have been utilized for the segmentation model while 4260-disc slice with radiological geometric parameters for spondylosis grading. The creation of a labeled dataset utilized

FIGURE 1 The workflow of our study.

expert-verified Pfirrmann and spondylosis severity gradings (11 grades, shown in fig. 2) to address the clinical issues stemming from manual grading variability and subjectivity. The machine learning algorithms use this combined dataset to predict results and combined with clinical scores (Oswestry Disability Index and Numerical Rating Scale) to recommend personalized treatment plans.

Results: The DeepLabV3+ segmentation model with ResNet50 encoder reached 95.5% accuracy, which increased to 98.7% after 8-fold cross-validation and simultaneously improved precision (96.95%), recall (97.1%), Dice coefficient (96.9%), and IoU (94.8%). The CNN with MobileNetV2 achieved 97.84% accuracy and 96.76% IoU for spondylosis severity prediction after cross-validation. The Gradient Boost classifier demonstrated the best results with geometrical data by achieving 91.65% accuracy and 84.59% IoU.

Conclusion: The tool introduces an innovative method to customize LBP treatment through the combination of AI technology with radiological data and clinical expertise.

Disclosure: The study was sponsored by DHR-MRU grant. Nothing to disclose Part of work is published (doi:10.1007/s10278-025-01517-3).

EPO-0866 | A role for glycine transporter 2-inhibitors in modulating levels of dopamine in the nucleus Accumbens

Y. Olsson¹; K. Danielsson²; A. Domi²; H. Lidö²; L. Engström Ruud³; M. Ericson²; B. Söderpalm²

¹Department of Neurology, Sahlgrenska University Hospital, Gothenburg, Sweden; ²Addiction Biology Unit, Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Sweden; ³Department of Physiology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Sweden

Background and aims: Impaired glycinergic neurotransmission in the spinal cord which disinhibits nociceptive signaling to higher cortical centers is implicated in states of pathological pain. Glycine transporter 2 (GlyT2)-inhibition, which augments glycine receptor (GlyR) signaling has emerged as a novel

FIGURE 1 Overview of hypothesized glycinergic signaling in the nAc. Enhanced glycinergic tone in the nAc, produced by e.g. GlyT1- or GlyT2-inhibition disinhibits VTA-nAc dopaminergic projections, thereby slightly elevating accumbal dopamine output.

FIGURE 2 Systemic treatment with partial but not full GlyT2-inhibitors slightly elevate extracellular dopamine but not glycine levels in vivo in the nAc. Combined GlyT1- and GlyT2-inhibition did not produce any statistically significant additive effects.

pharmacological treatment concept for pain, devoid of adverse effects and effective in achieving allodynia in a phase III-trial. In rats, GlyRs also regulate dopamine (DA) levels in the nucleus Accumbens (nAc), a pivotal region for motivational processes. Recently, the presence of GlyT2-expressing glycinergic axons in the mouse nAc has been established.

Methods: This study in rats examined if GlyT2-inhibition alters accumbal DA and glycine content as measured by in vivo microdialysis. The presence of GlyT2-expressing axons and GlyRs in the nAc was examined by immunohistochemistry (IHC).

FIGURE 3 Immunoreactivity for GlyT2 and GlyR was confirmed in the nAc at the A/P level of probe insertion for microdialysis (bregma +1.85 mm) and more caudally (+0.7), although with a higher signal for GlyT2 in e.g. septal regions.

Results: The partial GlyT2-inhibitors NAGly (10mg/kg i.p.) and Opiranserin (20 mg/kg i.p.), but not the full GlyT2-inhibitor Org 25543, slightly elevated accumbal DA levels, while no effects on extrasynaptic glycine levels were observed. The reversible GlyT1-inhibitor Bitopertin (10mg/kg p.o.) produced a pronounced glycine and DA elevation but combined GlyT1- and GlyT2 inhibition did not yield any statistically significant additive effects. The IHC study confirmed the presence of GlyT2 and GlyRs in the nAc.

Conclusion: To conclude, this study indicates that GlyT2-expressing glycinergic neurons are involved in regulating nAc DA levels, albeit to a lesser extent than extrasynaptic GlyRs situated nearby GlyT1s. The extraspinal effects mediated by systemic treatment with GlyT2-inhibitors, i.e. involvement of the mesolimbic DA system, should be further explored.

Disclosure: Nothing to disclose.

EPO-0867 | Central mechanisms and therapeutic interventions in trigeminal neuralgia: A systematic neuroimaging and neuromodulation study

Y. Wang; C. Cao; H. Chen; X. Jiang

The First Affiliated Hospital of USTC, Hefei, China

Background and aims: Microvascular decompression (MVD) targets peripheral neurovascular conflict in trigeminal neuralgia (TN), yet its variable efficacy highlights the critical role of central nervous system adaptations. Vascular compression pathophysiology, central sensitization neuroimaging correlates, and their treatment response predictive value remain unclear. This study combined multimodal neuroimaging with MVD, rTMS and TGS interventions to elucidate TN central mechanisms and explore personalized therapeutic strategies.

FIGURE 1 (a) rs-fMRI workflow: acquisition→preprocessing→ROI extraction→FC matrix construction; (b) NE vs E: enhanced thalamo-somatosensory FC ($p < 0.05$); (c) Subcortical somatomotor FA ↓ with longer disease duration ($FDR \leq 0.05$); (d) SVM MVD prediction performance.

FIGURE 2 rTMS neural mechanisms. (a) Study design: randomization to active M1-rTMS, sham, active DLPFC-rTMS; (b) Post-intervention VAS pain reduction in all groups; (c) Divergent activation: M1-rTMS ↓ insula recruitment, sham/DLPFC ↑ prefrontal activity.

Methods: Three complementary studies: ① 60 TN patients (30 MVD responders/non-responders) and 30 HCs underwent pre-operative rs-fMRI and DTI, with thalamo-S1 FC analyzed (pipeline: Fig. 1a) and an SVM prediction model constructed; ② 34 early TN patients were randomized to active M1-rTMS, sham stimulation, active DLPFC-rTMS (Fig. 2a), with clinical scales and rs-fMRI assessed pre-/post-intervention for network reorganization; ③ 29 TN patients received longitudinal rs-fMRI before/after TGS (30 HCs as controls, electrode placement: Fig. 3a), with FC dynamics analyzed and feature stability verified via SVM.

Results: ① MVD non-responders showed enhanced thalamo-somatosensory FC (Fig. 1b), milder vascular compression, and reduced subcortical FA with structural-functional decoupling (Fig. 1c); ② SVM predicted MVD outcomes with 67.33% accuracy (Fig. 1d); ③ All rTMS groups achieved pain relief (Fig. 2b), with active M1-rTMS suppressing insula activation and sham/

FIGURE 3 TGS study: (a) Electrode placement; (b) Pre-/post-TGS connectivity normalization; (c) SVM validation of treatment response (71.17% accuracy).

DLPFC groups enhancing prefrontal activity (Fig. 2c, targeted vs placebo-mediated); ④ TGS normalized aberrant thalamo-somatosensory hyperconnectivity (Fig. 3b, with regional heterogeneity), and SVM distinguished pre-/post-TGS states with 71.17% accuracy (Fig. 3c).

Conclusion: This study confirms TN as a spectrum disorder from peripheral compression to central sensitization, with thalamo-somatosensory FC as a core biomarker. It enables pre-operative MVD patient stratification, guides neuromodulation target optimization, and advances TN management from empirical surgery to circuit biomarker-informed personalized therapy.

Peripheral Nerve Disorders 2

EPO-0868 | Atherogenic lipid indices and electrophysiological severity in Carpal Tunnel Syndrome

A. Aksoy Gündoğdu¹; D. Kotan²; E. Çiçekli²

¹Department of Neurology, Tekirdağ Namık Kemal University Faculty of Medicine, Tekirdağ, Türkiye; ²Department of Neurology, Sakarya University Faculty of Medicine, Sakarya, Türkiye

Background and aims: Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy, yet the role of metabolic and vascular factors in disease severity is not fully understood. Composite lipid indices may better reflect microvascular and metabolic alterations than conventional lipid fractions. This study compared atherogenic lipid indices between CTS patients and healthy controls and evaluated their association with electrophysiological severity.

Methods: In this cross-sectional case-control study, 124 CTS patients and 113 age- and sex-matched controls were enrolled. Electrophysiological grading followed the Padua classification. Fasting total cholesterol, high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), triglycerides (TG), and remnant cholesterol (RC) were measured. Composite indices included the TG/HDL, non-HDL/HDL, and atherogenic index of plasma (AIP). Between-group comparisons

TABLE 1 Demographic and baseline biochemical characteristics of patients with carpal tunnel syndrome and healthy controls.

	CTS (n = 124)	Controls (n = 113)	p value
Age, years (mean ± SD)	46.3 ± 8.6	48.0 ± 12.8	0.098
Female sex, n (%)	92 (74.2)	81 (71.7)	0.664
Fasting glucose, mg/dL	96 (20.3)	93 (13)	0.001
HbA1c, %	5.7 (0.10)	5.5 (0.30)	<0.001
HDL-cholesterol, mg/dL	53 (2)	45 (14)	<0.001
LDL-cholesterol, mg/dL	116.6 (16.9)	100 (31.9)	<0.001
Total cholesterol, mg/dL	201 (17)	175 (40)	<0.001
Triglycerides, mg/dL	117 (11.5)	139 (10.2)	0.293
Remnant cholesterol, mg/dL (RC)	30 (9)	26 (20.5)	0.029
Atherogenic index of plasma (AIP)	0.35 (0.06)	0.44 (0.44)	0.100
TG/HDL ratio	2.21 (0.35)	2.76 (2.81)	0.100
Non-HDL/HDL ratio	2.78 (0.45)	2.72 (1.12)	0.125

Values are presented as mean ± SD or median (IQR). Between-group comparisons were performed using t-test or Mann-Whitney U test. CTS: carpal tunnel syndrome; RC: remnant cholesterol; AIP: atherogenic index of plasma.

TABLE 2 Biochemical parameters according to carpal tunnel syndrome severity.

	Mild CTS (n = 37)	Moderate CTS (n = 47)	Severe CTS (n = 40)	p value
Fasting glucose, mg/dL	98.5 (22.5)	96 (20)	99 (16)	0.202
HbA1c, %	5.65 (0.10)	5.70 (0.10)	5.60 (0.30)	<0.001
HDL-cholesterol, mg/dL	53 (1)	52 (3)	54 (2)	<0.001
LDL-cholesterol, mg/dL	107 (11.5)	116.6 (12.4)	120.9 (6.45)	<0.001
Total cholesterol, mg/dL	190 (6)	201 (10)	204 (7)	0.001
Triglycerides, mg/dL	117 (1)	115 (13)	121 (24)	0.010
Remnant cholesterol, mg/dL (RC)	30 (0.4)	32.4 (10)	29.1 (4.67)	0.023
Atherogenic index of plasma (AIP)	0.34 (0.01)	0.35 (0.10)	0.35 (0.06)	0.004
TG/HDL ratio	2.24 (0.33)	2.87 (0.71)	2.78 (0.15)	0.028
Non-HDL/HDL ratio	2.58 (0.37)	3.10 (0.78)	2.80 (0.46)	<0.001

Values are presented as median (IQR). Comparisons across CTS severity groups were performed using the Kruskal-Wallis test with Bonferroni-corrected post hoc analyses. CTS: carpal tunnel syndrome; AIP: atherogenic index of plasma; RC: remnant cholesterol.

FIGURE 1 Correlation heatmap and hierarchical clustering of lipid parameters in CTS.

and correlations with severity were analyzed using non-parametric tests and Spearman correlation.

Results: Compared with controls, CTS patients had higher fasting glucose, HbA1c, total cholesterol, LDL-C, HDL-C, and remnant cholesterol (all $p < 0.05$). Composite indices (TG/HDL, non-HDL/HDL, AIP) were similar between groups. Electrophysiological severity showed significant associations with multiple lipid measures, with total cholesterol, LDL-C, TG, TG/HDL, non-HDL/HDL, AIP, and remnant cholesterol increasing progressively from mild to moderate and severe CTS (all $p < 0.05$). No significant sex-related differences were observed.

Conclusion: Composite atherogenic indices and RC were associated with electrophysiological severity rather than CTS presence, supporting a severity-focused metabolic framework. Atherogenic burden may contribute to progressive median nerve dysfunction beyond mechanical compression. Routine lipid-derived indices may aid risk stratification and enhance understanding of CTS pathophysiology.

Disclosure: Nothing to disclose.

EPO-0869 | Autonomic dysfunction in hereditary transthyretin amyloidosis: Real-world experience of stabilization under vutrisiran therapy

C. Fasano¹; M. Gianoli¹; S. Longhi²; I. Ruotolo³; R. D'Angelo¹; R. Rinaldi¹; F. Provini¹; G. Calandra Buonauro¹; P. Guaraldi¹

¹IRCCS Istituto delle Scienze Neurologiche di Bologna, University of Bologna, Bologna, Italy; ²Cardiology Unit, Cardiac Thoracic and Vascular Department, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; ³University of Bologna, Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy

Background and aims: Hereditary transthyretin amyloidosis (ATTRv) is a systemic disease caused by the deposition of misfolded transthyretin (TTR), frequently affecting both peripheral nerves and the heart. Amyloid deposition prematurely involves autonomic ganglia, leading to early and often progressive autonomic dysfunction. Vutrisiran (Amvuttra), an RNA interference therapeutic targeting TTR, is approved for the treatment of hATTR and has demonstrated benefits on both neurological and cardiac outcomes.

Methods: We retrospectively analysed 57 patients with ATTRv treated with vutrisiran and followed within the Emilia-Romagna regional network. Demographic and clinical data were collected from 9 months before treatment initiation through 18 months of follow-up. Autonomic symptoms were assessed using the Composite Autonomic Symptom Score-31 (COMPASS-31), and disability was evaluated with the Norfolk Quality of Life-Diabetic Neuropathy (Norfolk QOL-DN) questionnaire.

Results: Repeated measures analyses of COMPASS-31 domains demonstrated overall longitudinal stability across follow-up, with particular regard to the gastrointestinal domain, which exhibited a directional trend toward improvement. Norfolk QOL-DN scores

Longitudinal distribution of COMPASS-31 gastrointestinal domain scores at baseline (T0), 9 months (T9), and 18 months (T18). Box plots show median, interquartile range and overall distribution of scores over time.

The figure shows the association between baseline orthostatic intolerance (COMPASS-31 domain) at T0 and Norfolk Quality of Life–Diabetic Neuropathy (Norfolk QOL-DN) at T9, with both variables adjusted for baseline Norfolk QOL-DN.

displayed a descriptive reduction from baseline to 18 months. Baseline COMPASS-31 domains were not independently associated with Norfolk QOL-DN at 9 months after adjustment for baseline disability; however, orthostatic intolerance showed a positive directional trend, suggesting that higher autonomic symptom burden at baseline may contribute to worse outcome.

Conclusion: Our real-world findings highlight the role of autonomic dysfunction in determining clinical disability in ATTRv and suggest that treatment with vutrisiran may be effective in stabilizing autonomic symptom progression. These results support the relevance of targeting dysautonomia as a key component of disease management in ATTRv.

Disclosure: Alnylam Pharmaceuticals.

EPO-0870 | Sensory neuronopathy in chronic alcohol users: A retrospective bicentric cohort study

E. Louis¹; G. Beaudonnet²; B. Bardel³; C. Cauquil⁴; C. Labeyrie⁴; G. Fargeot⁴; I. Iliescu²; J. Lefaucheur³; A. Creange¹; T. Gendre¹

¹AP-HP, Henri Mondor University Hospital, Department of Neurology, Créteil, France; ²AP-HP, Bicêtre University Hospital, Unit of Clinical Neurophysiology, Le Kremlin-Bicêtre, France; ³AP-HP, Henri Mondor University Hospital, Unit of Clinical Neurophysiology, Créteil, France; ⁴AP-HP, Bicêtre University Hospital, Department of Neurology, Le Kremlin-Bicêtre, France

Background and aims: Chronic alcohol misuse typically causes length-dependent axonal polyneuropathy. Purely sensory ataxic presentations have been reported, but data are limited. We aimed to characterise sensory neuronopathy (SNN) associated with chronic alcohol misuse.

Methods: In a retrospective two-centre cohort (2008–2024), we analysed adults meeting clinical and electrophysiological criteria for SNN, reporting chronic alcohol misuse (≥ 100 g ethanol/week for ≥ 3 months), without any alternative aetiology. Severity was assessed using the modified Rankin Scale and a neurophysiological sensory score based on ten sensory nerves. Patients with and without a favourable outcome (mRS improvement ≥ 1) were compared.

Results: Twenty-five patients were included (median age 50 years; 64% female). They presented pure sensory non-length-dependent ataxic neuropathy (100%), of acute/subacute onset (88%), highly disabling (mRS ≥ 3 : 76%), painful (68%), asymmetrical (44%), with central nervous system involvement (32%). Precipitating events included unintentional weight loss (64%) and alcohol intake escalation (32%). Reported weekly consumption did not correlate with baseline severity. Markers of malnutrition (11/23, 48%) and vitamin deficiencies (18/23, 78%) were frequently observed, mostly involving B1, B9, and B12 pathways. Outcome was favourable in 16/21 (71%) and was more frequent among patients receiving B1 supplementation ($p=0.047$).

Conclusion: Our findings are consistent with an association between chronic alcohol misuse and a distinct SNN phenotype marked by rapid onset, pain, and favourable outcomes despite high baseline disability. Findings support a predominantly nutritional contribution, without ruling out direct alcohol neurotoxicity. Rapid-onset SNN should prompt assessment of alcohol exposure and nutritional status, with early vitamin supplementation when misuse is identified.

EPO-0871 | The electrophysiology of disease remission in chronic inflammatory demyelinating polyneuropathy

J. Freiha¹; Y. Rajabally²; R. Iqbal²; D. Allen¹; C. Osman¹

¹Wessex Neurological Centre, University Hospital Southampton, Southampton, UK; ²Inflammatory Neuropathy Service, Department of Neurology, University Hospitals Birmingham, Birmingham, UK

Background and aims: Whether serial electrophysiology may be useful in chronic inflammatory demyelinating polyneuropathy (CIDP), is unknown.

Methods: We retrospectively studied electrophysiological findings during active disease and after remission off-treatment, in subjects with CIDP, at 2 UK neuropathy centres.

Results: We included 24 consecutive subjects. Eighteen subjects (75%) had typical CIDP, 3 (12.5%) had motor CIDP and 3 (12.5%) had distal CIDP. Mean age was 61.3 years. Mean interval between electrophysiological study during active disease and post-remission, was 63.25 months (SD: 52.0). Mean distal motor latency improved for median ($p<0.001$), ulnar ($p<0.001$), fibular ($p=0.01$) and tibial ($p=0.002$) nerves. Mean motor conduction velocity improved for median ($p<0.001$), ulnar ($p<0.001$) and fibular ($p=0.012$) nerves. Mean minimum F-wave latency improved for median ($p=0.003$), ulnar ($p=0.002$), and tibial ($p=0.027$) nerves. The proportion of nerves showing conduction block was reduced post-remission compared to during active disease (10/67 vs. 26/66; $p=0.002$). Demyelinating criteria were fulfilled by all subjects during active disease vs. 14/24 (58.3%) after remission ($p=0.006$). Electrophysiological quasi-normalization correlated with shorter pre-treatment disease duration ($p=0.002$). Amplitude of functional improvement correlated with fibular nerve CMAP amplitude at the first study ($p=0.024$).

Conclusion: Electrophysiological quasi-normalisation may occur in a third of subjects with CIDP in remission off-treatment and may be more likely with prompt diagnosis/treatment. Amelioration of most commonly studied parameters may be

observed in all tested nerves. Pre-treatment fibular nerve axonal loss may predict clinical improvement amplitude.

EPO-0872 | Comparative efficacy of treatments for chronic inflammatory demyelinating polyneuropathy: A network meta-analysis

O. Uwishema

Department of Research and Education, Oli Health Magazine Organization, Kigali, Rwanda

Background and aims: Chronic inflammatory demyelinating polyneuropathy is an immune-mediated neuropathy with multiple therapeutic options but limited head-to-head randomized comparisons. This study aimed to systematically compare and rank the efficacy and safety of available treatments for chronic inflammatory demyelinating polyneuropathy using a network meta-analysis of randomized controlled trials.

Methods: A systematic literature search was conducted across PubMed, EMBASE, Scopus, CENTRAL, and ClinicalTrials.gov from inception to January 14, 2025. Randomized controlled trials evaluating pharmacological treatments for chronic inflammatory demyelinating polyneuropathy were included. Outcomes assessed were disability measured by the Inflammatory Neuropathy Cause and Treatment score, functional independence measured by the Inflammatory Rasch-built Overall Disability Scale, muscle strength measured by the Medical Research Council sum score, grip strength, and safety outcomes. A frequentist network meta-analysis with random-effects modeling was performed, with Bayesian sensitivity analyses conducted to assess ranking consistency.

Results: Seventeen randomized controlled trials involving 1,079 participants were included. Subcutaneous immunoglobulin at 0.4g per kilogram demonstrated the greatest improvement in disability. Intravenous immunoglobulin at 1.0g per kilogram showed the strongest improvement in muscle strength. Efgartigimod significantly improved functional independence and ranked consistently across analyses. Plasma exchange showed the largest improvement in grip strength but was supported by a single trial. Corticosteroids ranked lowest across efficacy outcomes. Treatment rankings were consistent between frequentist and Bayesian analyses.

Conclusion: Intravenous immunoglobulin, subcutaneous immunoglobulin, and efgartigimod are the most effective therapies for improving disability, function, and strength in chronic inflammatory demyelinating polyneuropathy. These findings support individualized treatment selection based on patient-specific clinical goals.

EPO-0873 | Burden of Guillain-Barré syndrome in the United States in 2025

S. Rinaldi¹; M. Kim²; S. Vaghela³; E. Brouwer⁴; L. Bloudek⁴; B. Turner⁵; J. Duchon⁵; J. Allen⁶

¹Oxford University Hospitals NHS Foundation Trust, Oxford, UK; ²Annexon Biosciences, Brisbane, USA; ³Annexon Biosciences, Brisbane, USA, and HealthEcon Consulting, Inc, Ancaster, Canada; ⁴Curta Inc, Seattle, USA; ⁵Magnolia Market Access, Bridgewater, USA; ⁶University of Minnesota, Minneapolis, USA

Background and aims: Guillain-Barre Syndrome (GBS) imposes substantial disability and economic burden, extending well beyond the initial hospitalisation. Real-world data quantifying this burden remain limited. This study characterised real-world GBS incidence, healthcare resource utilisation (HCRU), and costs in the US.

Methods: We analysed 2017–2023 data from a large US commercial claims database and Medicare Fee-for-Service (FFS) 5% sample to identify patients with GBS (Figure 1). Annual incidence rates were projected to the 2025 US population, and costs were adjusted for age and sex. Direct medical costs were estimated with paid amounts during the index hospitalisation and subsequent year, adjusted to 2024 USD. HCRU was measured during the 12 months following discharge from index hospitalisation.

Results: An estimated 8,039 GBS cases [95% CI: 7,734–8,364] occurred in the US in 2025, corresponding to an incidence of 2.39 per 100,000. During the index hospitalisation, 28.0% of commercial and 34.9% of Medicare patients required ICU care [mean (SD) ICU stay of 7.8 (14.2) and 9.1 (13.3) days, respectively] (Table 1), and age/sex-adjusted GBS-related medical costs averaged \$77,096 and \$50,429 for commercial and Medicare patients, respectively (Table 2). During the 12-month follow-up, GBS-related and all-cause medical costs averaged \$32,786 and \$67,822 for commercial and \$62,322 and \$104,919 for Medicare

EPO-0874 | Premature death as a major driver of total societal cost of Guillain-Barré syndrome in the United States

S. Rinaldi¹; M. Kim²; S. Vaghela³; S. Katsandres⁴; L. Bloudek⁴; B. Bloudek⁴; E. Brouwer⁴; B. Turner⁵; J. Duchan⁵; J. Allen⁶
¹Oxford University Hospitals NHS Foundation Trust, London, UK; ²Annexon Biosciences, Brisbane, USA; ³Annexon Biosciences, Brisbane, USA and HealthEcon Consulting, Inc, Ancaster, Canada; ⁴Curta Inc, Seattle, USA; ⁵Magnolia Market Access, Bridgewater, USA; ⁶University of Minnesota, Minneapolis, USA

Background and aims: Guillain-Barre Syndrome (GBS) is associated with substantial economic burden, including direct costs (hospitalisation and rehabilitation) and indirect costs (lost productivity and increased risk of premature death). We present the indirect cost of premature deaths among US patients hospitalised with GBS (USD 2025).

Methods: Incidence and mortality rates for patients hospitalised with GBS, derived from a claims analysis of commercially insured and Medicare Fee-For-Service 5% standard analytical files from 2017–2023, were projected to the 2025 US populations aged <65 and ≥65 years (average age: 45 and 70, respectively). Excess mortality was estimated using age-adjusted background mortality (Centers for Disease Control and Prevention Life Tables). A value of statistical life (VSL) was applied to excess deaths ≤12 months post-hospitalisation to estimate total premature mortality cost.

Results: 8,039 US GBS cases (95% CI: 7,734–8,364) were projected for 2025 (<65 years: 67%, ≥65: 33%). Excess mortality rates ≤12 months from hospitalisation were 4.98% (<65) and 22.1% (≥65) (including inpatient mortality: 1.8% vs 7.7%). Premature mortality costs (using the US Department of Health and Human Services age-agnostic 2025 central VSL estimate; \$13.2M) were \$3.446B (<65) and \$7.669B (≥65). The total annual estimate was \$11.114B for deaths ≤12 months from hospitalisation. Applying age-specific central estimates for VSL (age-specific US EQ-5D scores, Hamner 2026. 45yr: \$10.8M; 70yr: \$5.6M), resulted in premature mortality costs of \$6.086B (<65: \$2.812B, ≥65: \$3.274B). Results were robust regardless of statistical method.

Conclusion: Premature death in patients hospitalised with GBS is a major driver of GBS total costs from a US societal perspective.

EPO-0875 | De novo mutations in charcot-marie-tooth disease of Korean origin

S. Nam¹; A. Lee²; K. Chung²; B. Choi³

¹Cell and Gene Therapy Institute, Samsung Medical Center, Seoul, Republic of Korea; ²Department of Biological Sciences, Kongju National University, Gongju, Republic of Korea; ³Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background and aims: Charcot–Marie–Tooth disease (CMT), a genetically and clinically heterogeneous group of peripheral neuropathies, is characterized by progressive muscle weakness and significant limb deformities. De novo mutations are an important source of pathogenic variation in autosomal dominant CMT, yet their overall frequency, parental origin, and clinical implications beyond recurrent copy number variants remain poorly defined. The aim of this study was to systematically identify de novo mutations in autosomal dominant CMT and to investigate their genetic features, parental origin, and associated clinical phenotypes.

Methods: We examined 151 genetically diagnosed Korean parent–offspring trio families with autosomal dominant CMT, excluding cases with CMT1A duplication. Pathogenic variants were identified using Sanger sequencing, whole-exome sequencing, or targeted gene panels, and de novo status was confirmed by parental testing and paternity verification. Parental origin, CpG methylation status, mutation spectra, and clinical characteristics were analyzed.

Results: We identified 49 de novo point or small insertion/deletion mutations in 61 patients, corresponding to a de novo frequency of 40.4%. De novo mutations showed marked gene-specific differences, with high frequencies in INF2, MORC2, PMP22, and KIF5A. Most mutations were paternally derived and preferentially occurred at highly methylated CpG sites. Clinically, affected children carrying de novo mutations demonstrated significantly earlier disease onset compared with their parental founders, consistent with phenotypic anticipation.

Conclusion: De novo mutations contribute substantially to autosomal dominant CMT and exhibit distinct molecular and clinical patterns. These findings emphasize the value of trio-based analyses for genetic diagnosis and provide insights into mutational mechanisms and disease progression in inherited peripheral neuropathies.

Disclosure: Nothing to disclose.

EPO-0876 | Phenotypic severity in patients with hereditary motor and sensory neuropathy with somatic mosaic mutations

S. Nam¹; A. Lee²; K. Chung²; B. Choi³

¹Cell and Gene Therapy Institute, Samsung Medical Center, Seoul, Republic of Korea; ²Department of Biological Sciences, Kongju National University, Gongju, Republic of Korea; ³Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background and aims: Hereditary motor and sensory neuropathies (HMSN) are inherited peripheral neuropathies characterized by progressive muscle weakness and sensory dysfunction. Although somatic mosaicism in HMSN-associated genes has been reported, most cases show asymptomatic or mild phenotypes. However, some mosaic cases resemble patients with germline mutations. This study aimed to characterize somatic mosaicism and its clinical impact in a Korean HMSN family.

Methods: Whole exome sequencing (WES) followed by variant filtering was used to identify genetic causes. The degree of somatic mosaicism was quantified by analyzing approximately 100 cloned sequences per mutation site and calculating variant ratios. Clinical phenotypes were compared with those of patients carrying typical germline mutations.

Results: Two cases of somatic mosaicism were identified: p.Cys104Tyr in INF2 and p.Ser729Arg in TRPV4. The estimated mosaicism levels in blood were approximately 24% and 30%, respectively. The individual with the INF2 mutation exhibited mild peripheral neuropathy, whereas the individual with the TRPV4 mutation showed severe clinical manifestations. The INF2 case was considered gonadal mosaicism. Notably, the p.Cys104Tyr mutation in INF2 was associated with demyelinating peripheral neuropathy without focal segmental glomerulosclerosis (FSGS), expanding the known phenotype of INF2-related disease.

Conclusion: This study represents one of the first reports describing somatic mosaicism involving INF2 and TRPV4 in HMSN. The severity of clinical phenotypes in mosaic cases appears to depend on both the mutation site and the proportion of mutant alleles in affected tissues. These findings suggest that somatic mosaicism may play an important role in inter- and intra-familial phenotypic heterogeneity in HMSN.

Disclosure: Nothing to disclose.

Background and aims: Multifocal motor neuropathy (MMN) is a rare, chronic, predominantly complement-driven neuropathy, causing axonal degeneration and progressive, disabling, asymmetric limb weakness. Empasiprubart binds C2, blocking the classical and lectin complement pathways while leaving the alternative pathway intact. The phase 2 ARDA study (NCT05225675) assessed safety and efficacy of empasiprubart in adults with MMN.

Methods: Enrolled participants had probable/definite MMN (2010 European Federation of Neurological Societies/Peripheral Nerve Society guidelines) and proven intravenous immunoglobulin (IVIg) dependency and were on a stable IVIg regimen before randomisation. Participants were assigned to 1 of 2 dosing cohorts, each randomised 2:1 to empasiprubart or placebo. Efficacy endpoints included patient-reported outcomes (PROs) measured by the Chronic Acquired Polyneuropathy Patient-Reported Index (CAP-PRI), the Fatigue Severity Scale (FSS), the Patient Global Impression of Change (PGI-C), the Treatment Satisfaction Questionnaire for Medication (TSQM-14), and the Health-Related Productivity Questionnaire (HRPQ). Safety and tolerability were evaluated throughout the study.

Results: Overall, 27 participants (empasiprubart, $n=18$; placebo, $n=9$) were randomised per cohort (total $N=54$). Participants in cohort 2 were older, with longer duration of disease and time since first IVIg treatment versus cohort 1. Overall, empasiprubart was generally well tolerated. Most adverse events

were mild/moderate. Improvements in PROs were generally observed with empasiprubart compared with placebo in both cohorts, including CAP-PRI (Figure 1A), FSS (Figure 1B), PGI-C (improvement: 94% vs 11% in cohort1; 83% vs 44% in cohort 2), TSQM-14 (Figure 2A–C), and HRPQ (Table 1).

Conclusion: Empasiprubart improved PROs versus placebo, with patients consistently reporting less fatigue and better quality of life.

⁴Department of Neuro-Radiology, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; ⁵The Paris Brain Institute, Sorbonne University, Paris, France; ⁶Sorbonne University - AP-HP, Pitié-Salpêtrière Hospital, Department of Neurology, INSERM U974, Paris, France; ⁷Clinical Research Unit, Saint Louis-Lariboisière-Fernand Widal Hospital, and Paris Cité Université, Paris, France

Background and aims: Radiation-induced leukoencephalopathy (RIL) is a known late complication of brain radiotherapy in glioblastoma (GBM) survivors, whereas early-onset RIL remains poorly described. This ancillary study of the phase III ASTER trial evaluated the incidence of early-onset RIL and explored associated risk factors, including exposure to losartan, a peroxisome proliferator-activated receptor gamma (PPAR γ) agonist.

Methods: We retrospectively analyzed ASTER trial participants treated with standard radiotherapy plus temozolomide (STUPP protocol). Brain MRI performed before radiotherapy and at six months post-treatment was centrally reviewed. Early-onset RIL was defined by new or progressive confluent T2/FLAIR white-matter hyperintensities with associated cortico-subcortical atrophy and no contrast enhancement, quantified using a simplified Scheltens scale. Cognitive function and quality of life were assessed using the Montreal Cognitive Assessment (MoCA) and EORTC QLQ-C30/BN20 questionnaires. Clinical, treatment-related, and genetic factors (PPAR γ) were analyzed.

Results: Thirty-one patients were evaluable. Early-onset RIL was identified in 29% ($n=9$), with high inter-rater diagnostic agreement. No significant associations were observed with age, MGMT promoter methylation, IDH1 mutation, or PPAR γ polymorphism. Losartan exposure was not associated with reduced RIL incidence. At six months, patients with RIL exhibited significantly lower MoCA scores and impaired physical and emotional functioning compared with patients without RIL.

Conclusion: Early-onset RIL affects nearly one-third of GBM patients treated with the STUPP protocol and is associated with early cognitive and functional decline. No specific clinical, genetic, or treatment-related risk factors, including losartan exposure, were identified. Early monitoring and larger prospective studies are warranted.

EPO-0879 | Application of the PNS-care score in real world clinical practice: Insights from a neuro-immuno-oncology perspective

M. García-Castillo¹; S. Jorquera-Ortega¹; A. Alfranca²; A. Barbosa³; F. Giló¹; S. Sánchez⁴; M. Conversa³; J. Rogado⁵; B. Hernández⁵; A. Gonzalez-Martinez¹

¹Facultad de Medicina, Universidad Autónoma de Madrid, Madrid, Spain; ²Neurology Service, Hospital Universitario de la Princesa, Madrid, Spain; ³Instituto de Investigación Sanitaria Princesa (IIS-Princesa), Madrid, Spain; ⁴Immunology Service, Hospital Universitario de la Princesa, Madrid, Spain; ⁵Neuroradiology Service, Hospital Universitario de la Princesa, Madrid, Spain; ⁶Laboratory, Hospital Universitario de la Princesa, Madrid, Spain; ⁷Oncology Service, Hospital Universitario de la Princesa, Madrid, Spain

Background and aims: To describe the diagnostic criteria compliance of patients with suspicion of paraneoplastic neurologic syndromes (PNSs) who have positive antibody testing.

Methods: We performed an observational retrospective study of a prospectively collected cohort of patients under PNSs suspicion with positive paraneoplastic antibodies between January-2024 and December-2025. Patients were classified using the PNS-Care Score.

Results: We included 14 patients, 8 (57%) were male, median of age of 66 (SD: 19) years. The PNSs-Care Score was definite in 3 (21%), probable in 1 (7%) and possible in 4 (29%) with 6 (43%) patients classified eventually as non-PNSs. In the definite PNS group, 1/3 (33%) patient presented with Morvan syndrome with anti-titin, anti-LGI1 and anti-CASPR2 positive antibodies, and was diagnosed with metastatic thymoma; 1/3 (33%) patient had anti-Hu and Anti-SOX1 positive antibodies presenting with Eaton-Lambert phenotype and small-cell lung cancer (SCLC); and 1/3 (33%) patient had also anti-Hu positive antibody and SCLC presenting with sensory neuronopathy. The patient with probable PNS showed a positive anti-SOX1 antibody, but did not present with a defined phenotype nor and a tumor was not found after diagnosis workup. In patients with possible PNSs 2 (50%) had anti-NMDAR encephalitis, 1 (25%) had epileptic crisis with anti-recoverin, anti-Ma2 and anti-CV2 antibodies, and 1 (25%) had anti-Yo positivity with atypical parkinsonism.

Conclusion: These findings offer an insight of the application of the PNS-Care Score in real world clinical practice, supporting the association between “high-risk antibodies” and “high or intermediate risk neurologic phenotypes” with cancer. Further multicenter studies focusing on PNS-Care Score applications are granted.

¹Section of Genomics and Transcriptomics, Fondazione Pisana per la Scienza, San Giuliano Terme, Italy; ²Neurosurgery Division, Azienda USL Toscana Nordovest, Hospital of Livorno, Italy; ³Department of Oncology, Azienda USL Toscana Nordovest, Hospital of Livorno, Italy; ⁴Unit of Pathology, Hospital of Livorno, Italy; ⁵ASL Toscana Nord Ovest, UO Anatomia Patologica Carrara, Italy; ⁶Unit of Neuroradiology, Hospital of Livorno, Italy; ⁷Nervous System Medical Oncology Department, IRCCS Istituto Delle Scienze Neurologiche di Bologna, Bologna; ⁸Neurology Unit, IRCCS Ospedale San Raffaele Scientific Institute, Milan, Italy

Background and aims: This study aimed to explore the correlation between the effectiveness of second-line chemotherapy in patients with recurrent glioblastoma (rGBM) who underwent second surgery and drug treatment tests on patient-derived explants.

Methods: Sixteen adult patients diagnosed with IDH wild-type glioblastoma underwent surgery for recurrent GBM, with 9 cases studied retrospectively and 7 prospectively. Patient-derived 3D glioblastoma organoids (GBM-EXPs) were established from resected tumors and treated with chemotherapy. NADH FLIM method was used to assess drug-sensitivity in vitro.

Results: Among patients progressing during first-line temozolomide (TMZ) therapy or within three months after discontinuation, most exhibited TMZ resistance by NADH-FLIM ($p=0.02$), with a longer PFS1 in TMZ-sensitive compared with TMZ-resistant rGBM-EXPs (15.9 vs 10.9 months; $p=0.07$), independent of MGMT promoter methylation. In the second-line setting, patients treated with regorafenib whose rGBM-EXPs were regorafenib-sensitive experienced a significantly longer PFS2 than those with resistant organoids (7.5 vs 3.6 months; $p=0.04$). In the prospective cohort, ex-vivo testing prior to second-line therapy was associated with a trend toward longer PFS2 (7.4 vs 4.6 months; $p=0.08$) and a significantly improved OS2 (not reached vs 6.3 months; $p=0.03$) compared with the retrospective cohort, with no difference in MGMT promoter methylation rates. Paired longitudinal analyses demonstrated acquisition of TMZ resistance in rGBM-EXPs compared with untreated GBM-EXPs.

Conclusion: This study shows that the sensitivity of rGBM-EXP to TMZ mirrors the timing of recurrence observed in vivo. NADH-FLIM-based drug response assessment in rGBM-EXP may play a role in predicting the efficacy of second-line therapies.

Background and aims: In the management of patients diagnosed with high-grade glioma (HGG), practices and rehabilitation programs display significant variability in real-world settings. The HGG Rehab survey aimed to glean insights from physicians specialized in neuro-oncology and affiliated with scientific societies in Italy: AINO, SINch and SIRN.

Methods: The questionnaire was released in June 2023, and responses were recorded until February 2024. One hundred eleven responses were collated.

Results: A median value of 40% of HGG patients from Neurosurgical and Neuro-oncologic/Oncologic Divisions were evaluated for rehabilitation, and a median value of 20% were deemed eligible for a rehabilitation. The rate of requests for physiatric evaluation was progressively higher as KPS increased, especially patients with KPS 60–70 (80%). Over 50% of responders reported viable outpatient rehabilitation programs during adjuvant radio-chemotherapy, with good tolerance (>55%). Seventy percent of practitioners recommended rehabilitation evaluation for newly diagnosed GBM patients and over 50% for those with recurrent GBM. Clinical benefits were observed in a median of 80% of patients, ranging from 30% to 100%. Recognized benefits of rehabilitation encompassed facilitating home discharges (82%), psychological benefits (65%), aiding the progress of adjuvant oncologic therapies (58%), and enhancing quality of life (40%). Key rehabilitation time points for newly diagnosed HGG patients included 5 days post-surgery, after histo-molecular diagnosis/treatment plan definition, and at recurrence.

Conclusion: The HGG Rehab Survey offers invaluable insights shared by three scientific societies into rehabilitation pathways for HGG patients in Italy. It highlights the usual criteria employed for the selection of patients and time points for outcome evaluation.

Background and aims: Glioblastoma (GBM) lethality stems from its aggressive infiltration of healthy brain tissue.

FIGURE 1 Automated segmentation and tracking of patient-derived glioblastoma (GBM) cells. Representative single frame from a 72-hour live-cell microscopy video showing patient-derived GBM cells. The cells were automatically segmented using the Cellpose software.

FIGURE 2 Delta Scaling (δ) Analysis of Glioblastoma Cell Lines via Diffusion Entropy Analysis This figure illustrates the distribution of the Delta scaling parameter values, derived from the Diffusion Entropy Analysis (DEA), for 28 patient-derived GB IDH1 Wild Type.

FIGURE 3 Survival stratification of GBM IDH-wildtype patients based on migration efficiency. (a) Kaplan-Meier survival curves for the initial three-tier stratification (low, medium, and high δ scaling).

Traditional metrics often fail to capture the complexity of this movement. This study aimed to characterize GBM cell motility using advanced modeling to identify new therapeutic vulnerabilities and stratification markers.

Methods: We developed Single-Cell Behavior Live Imaging (ScBLI), integrating live imaging with Diffusion Entropy Analysis (DEA) across 28 primary patient-derived cultures. By analyzing 3,842 trajectories, we classified cells into Low (L), Medium (M), and High (H) groups based on their δ scaling parameter.

Results: High δ scaling cells exhibited Lévy-like, persistent migration. Paradoxically, while these cells were slower and covered less total distance, they demonstrated the highest migratory efficiency and superior chemotactic performance. Clinical correlation revealed a clear linear progression: High δ Scaling: Shortest patient survival (poorer prognosis). Low δ Scaling: Longest patient survival. Transcriptomic analysis confirmed distinct gene expression signatures corresponding to these behavioral clusters, suggesting a biological basis for these movement strategies.

Conclusion: This study introduces migratory efficiency as a superior predictor of GBM malignancy over traditional metrics like speed or distance. We demonstrate that a highly efficient spatial exploration strategy—rather than the sheer magnitude of movement—is a critical driver of tumor invasiveness and poor clinical outcomes. These findings redefine GBM motility, establishing δ scaling as a novel biomarker for aggressive disease.

Disclosure: Nothing to disclose.

EPO-0883 | Clinical, molecular, and transcriptomic factors associated with seizures at onset in patients with glioblastoma

⁴Service de Neuro-oncologie, Institut de Neurologie, Hôpital Pitié-Salpêtrière, AP-HP, Paris, France; ⁵Paris Brain Institute (ICM), Sorbonne Université, Inserm, CNRS, UMR S 1127, Paris, France; ⁶Reperto di Diagnostica per immagini, Salus Hospital, GVM Care & Research, Reggio Emilia, Italy; ⁷Neurosurgery

Background and aims: Epileptogenesis in glioblastoma (GBM) primarily arises within the peritumoral cortex, yet the contribution of this region to tumor progression and seizure generation remains poorly understood. This study investigated the interactions between the tumor core and the peritumoral microenvironment by comparing gene expression profiles between GBM patients presenting with seizures at onset (GBM-EP+) and those with other symptoms (GBM-EP-). We also evaluated differences in clinical and molecular characteristics, as well as overall survival (OS) and progression-free survival (PFS).

Methods: We analyzed a retrospective cohort of 32 GBM patients using spatial transcriptomics. All patients had confirmed GBM, and complete clinical and molecular data. Molecular profiling, including IDH mutation and MGMT promoter methylation status, was performed by next-generation sequencing. Spatial transcriptomic analyses were conducted using the GeoMx DSP® platform.

Results: Seizures at presentation were not associated with OS or PFS, and no clinical or molecular variables were significantly linked to seizure occurrence. Spatial analyses revealed limited differences between tumor and peritumoral compartments. However, distinct transcriptional programs characterized the two groups. EP+ tumors exhibited broader gene deregulation with a mesenchymal-like invasive phenotype, whereas EP- GBMs showed a more proliferative profile marked by enhanced protein synthesis and mitochondrial activity, along with a relatively more inflamed immune microenvironment. Transcription factor analysis identified BRD4 as a key regulator of the mesenchymal program in EP- GBMs.

Conclusion: These results highlight the peritumoral microenvironment's role in shaping GBM phenotype and demonstrate the value of spatial transcriptomics in linking tumor biology with epilepsy.

Disclosure: Nothing to disclose.

EPO-0884 | A new diagnostic and therapeutic care pathway for early palliative care integration in patients with glioblastoma: A single centre experience

L. Panicari¹; B. Muoio²; G. Pesce³; V. Espeli²; A. Cassarino³; E. Brumana¹; M. Zanon²; T. Fusi-Schmidhauser¹

¹Palliative and Supportive Care Clinic, Ente Ospedaliero Cantonale, Bellinzona, Switzerland; ²Oncology Service, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland; ³Radiation Oncology Service, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background and aims: Glioblastoma is the most aggressive primary brain tumour in adults characterised by major clinical challenge due to multidimensional symptoms, rapid progression and poor prognosis. Early integration of palliative care (PC) from diagnosis can improve quality of life, symptom control and psychosocial well-being. We developed and implemented an integrated care pathway for early PC in patients with glioblastoma.

Methods: The diagnostic and therapeutic care pathway (PDTA) was designed between February 15th 2024 and December 13th 2024 in a tertiary oncological institute involving oncologists, radiotherapists, PC specialists, nurses, and quality department. Implementation began on January 1st 2025 as standard care. Demographic and clinical data were collected from patient charts and analysed descriptively.

Results: The PDTA allows systematic identification of PC needs in patients with glioblastoma hospitalised for diagnosis or surgery. A neuro-oncology nurse specialist assesses PC needs and arranges either an in-hospital PC consultation or an outpatient PC visit with oncologist/radiotherapist within four to seven weeks after diagnosis. Between January 1st to December 31st 2025, 24 patients underwent in-hospital or outpatient PC consultations. The PDTA significantly shortened the time to the first PC consultation—from 80 days in 2024 to 37 days in 2025. Main clinical issues addressed included symptom management, advance care planning, and respite care.

Conclusion: Integrating early PC as a standard of care for glioblastoma enables systematic needs assessment, enhances quality of life, and fosters communication on treatment goals and preferred care settings. These findings encourage broader adoption of coordinated and patient-centred models to optimize outcomes.

Disclosure: Nothing to disclose.

EPO-0885 | Machine learning to predict distant recurrence spread in Glioblastoma: A radiomic signature from standard T1-CE tumor core and peritumoral margins

L. Conte¹; E. Lo Turco²; R. Abbritti³; C. Accettura⁴; G. Raso¹; E. Iaboni⁵; U. De Giorgi⁴; G. De Nunzio⁶; D. Cascio¹; M. Caffo⁵

¹Department of Physics and Chemistry, University of Palermo, Palermo, Italy; ²Azienda Ospedaliero Universitaria “R. Dulbecco”, Catanzaro, Italy; ³Service de Neurochirurgie Hôpital “Lariboisière”, Paris, France; ⁴University Oncology Unit, University of Salento, Lecce, Italy; ⁵Unit of Neurosurgery, Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Messina, Italy; ⁶Department of Mathematics and Physics, University of Salento, Lecce, Italy

Background and aims: Predicting tumor spread in Glioblastoma (GB) is essential for prognosis and guiding treatment decisions. The clinical challenge lies in distinguishing whether recurrence will remain confined to the original tumor bed (local) or manifest as distant spread. While perfusion MRI is often used for this purpose, it requires complex protocols. This study evaluated whether Radiomic features derived solely from standard contrast-enhanced T1-weighted (T1-CE) images could effectively predict this dissemination pattern.

Methods: We analyzed 109 patients with confirmed recurrence. Tumor was manually segmented by two experienced radiologists. Peritumoral margins were generated via a 5mm isotropic dilation of the core mask. Radiomic features were extracted separately from both regions using PyRadiomics. The pipeline included Z-score normalization and Mutual Information feature selection. Eight classifiers were benchmarked: Multi-Layer Perceptron, Support Vector Machine, XGBoost, K-Nearest

FIGURE 1 Receiver operating characteristic (ROC) curve comparison. The plot displays the performance of the eight machine learning classifiers benchmarked for distinguishing local from distant Glioblastoma recurrence.

Neighbors, Naive Bayes, Logistic Regression, Random Forest, and Linear Discriminant Analysis. Class weighting was applied where applicable, and all models were validated via Leave-One-Out Cross-Validation (LOOCV).

Results: The MLP model achieved the highest performance (AUC 0.80, accuracy 82.6%, Figure 1). Feature selection analysis revealed a robust "Radiomic signature" of 8 features consistently selected across different classifiers. Notably, 3 of these predictors were derived from the geometric dilated peritumoral margins.

Conclusion: This analysis demonstrates that T1-CE Radiomics provides a robust method for predicting GB recurrence topography. The significant contribution of marginal features confirms that infiltration signals are detectable in structural images. While these preliminary findings warrant prospective validation, this approach transforms widely available standard baseline imaging into robust non-invasive prognostic biomarkers.

Disclosure: Nothing to disclose.

EPO-0886 | Neurological immune related adverse events of checkpoint inhibitors: A prospective study

M. Havlíček¹; D. Krýsl¹; H. Boček¹; M. Elišák¹; L. Casas Mendez²; A. Bulová³; T. Buchler³; P. Marusič¹

¹Department of Neurology, Second Faculty of Medicine, Charles University, Motol and Homolka University Hospital;

²Department of Pneumology, Second Faculty of Medicine, Charles University, Motol and Homolka University Hospital;

³Department of Oncology, Second Faculty of Medicine, Charles University, Motol and Homolka University Hospital

Background and aims: Neurological immune related adverse events (nirAEs) of checkpoint inhibitors (ICIs) are increasingly recognized in clinical practice. Retrospective studies may underreport nirAEs. The aim of this study was to prospectively determine the incidence of nirAEs, including grade 1 events.

Methods: Electronic PRO-CTCAE based questionnaire was administered to immunotherapy-naïve ICIs treatment candidates at baseline and at 3, 6 and 12 months to assess neurological and

psychiatric symptoms including: insomnia, fatigue, symptoms of depression, poor concentration, memory problems, dizziness, problems with vision, swallowing, urination, numbness/weakness/clumsiness in extremities, nausea, vomiting, headache, muscle pain, joint pain. Reported symptoms were grouped into putative clinical syndromes and analyzed in relation to other clinical characteristics (age, sex, type of tumor and treatment).

Results: Seventy-nine of 89 patients responded at baseline. Fifty-nine patients responded to at least one follow-up questionnaire (age median 66 [36–79], twenty-three [39.0%] females). The most common tumor was non-small cell lung carcinoma (22; 37.3%). Nineteen (32.2%) patients reported new or worsened symptoms indicative of polyneuropathy (10), myositis/myopathy (5) and/or encephalopathy (4). 7/10 patients with polyneuropathy symptoms had prior or ongoing chemotherapy. Thus, possible nirAEs occurred in 12/59 (20.3%) patients. Age, gender, tumor type, treatment (PD1/PDL1 ICIs alone or in combination with CTLA4 ICIs) and a history of autoimmune disease were not found to be statistically significant risk factors.

Conclusion: The incidence of adverse reactions, especially those of a lower grade, may be underestimated. Dedicated questionnaires can improve the detection of these events.

Disclosure: This work was supported by the Charles University project GA UK No 171324. PRO-CTCAE questionnaire (<https://healthcaredelivery.cancer.gov/pro-ctcae/>) was used in this study.

EPO-0887 | Neurological vulnerability to ICANS in CAR T-cell therapy: Impact of comorbidity and EEG-cognitive monitoring

P. Dumez; H. Marquez; P. Devic; C. Seurret; S. Souci; B. Joubert
Neurology Unit, University Hospital of Lyon Sud, Hospices Civils de Lyon, France

Background and aims: Immune effector cell-associated neurotoxicity syndrome (ICANS) frequently complicates chimeric antigen receptor (CAR) T-cell therapy, yet neurological vulnerability factors remain poorly defined. This study aimed to identify neurological predictors of ICANS and assess combined EEG-MoCA monitoring.

Methods: We conducted a retrospective monocentric study (Hospices Civils de Lyon), including adults treated with CAR T-cells for B-cell lymphoma between 2019 and 2024. Neurological comorbidity was defined as any pre-existing central nervous system disorder, including lymphoma involvement, cerebrovascular, neuroinflammatory, traumatic, neoplastic, or neurodegenerative disorders, or prior seizure history. EEG and MoCA were obtained at baseline and day 7. ICANS risk factors were assessed using logistic regression, and longitudinal MoCA changes using linear mixed-effects models.

Results: Among 356 patients, 152 (43%) developed ICANS, including 29 (18%) with severe forms. Neurological comorbidity was independently associated with ICANS (adjusted odds ratio [aOR] 2.07, 95% confidence interval [CI] 1.22–3.55; $p=0.007$), along with older age (per 10-year increase: aOR 1.42, 95% CI 1.19–1.70; $p<0.001$) and treatment with Yescarta versus other CAR T-cell products (aOR 2.44, 95% CI 1.53–3.94; $p<0.001$). EEG abnormalities during days 4–10 affected up to 68% of patients with ICANS. A MoCA decline of at least 2 points at day 7 was

TABLE 1 Baseline characteristics according to immune effector cell-associated neurotoxicity syndrome status.

Table 1. Baseline characteristics by ICANS status			
Variable	No-ICANS, N = 201	ICANS, N = 152	p-value
Age	63 [18–82]	67 [29–88]	<0.003

FIGURE 1 Neurological predictors of immune effector cell-associated neurotoxicity syndrome (ICANS). (A) Univariable and multivariable logistic regression analyses. (B) Forest plot of adjusted odds ratios with 95% confidence intervals.

FIGURE 2 Change in Montreal Cognitive Assessment score after CAR T-cell infusion according to ICANS status. Individual trajectories, smoothed group trends with 95% confidence intervals, and group means at days 0, 7, and 21 are shown.

more frequent in ICANS (31.2% vs 12.8%; $p < 0.001$), with greater longitudinal decline (beta -0.09 points per day; $p = 0.038$).

Conclusion: Pre-existing neurological comorbidities are independently associated with an increased risk of ICANS.

Combined EEG and MoCA monitoring provides a pragmatic framework to characterize neurological vulnerability and follow ICANS-related cognitive trajectories.

Disclosure: Nothing to disclose.

EPO-0888 | Peripheral nerve toxicity of immune checkpoint inhibitors and CAR-T therapy: A multicentric cohort study

V. Guerra-Fernandez¹; E. Fonseca¹; I. Martin¹; M. Alaña²; G. Lafuente³; L. del Pino³; G. Velilla⁴; D. Perez-Rancangel⁴; S. Garcia-Bellido Ruiz⁴; A. Llaurodo⁵; H. Ariño⁵; E. Muñoz⁶; A. Ramos-Fransi¹; J. Padrosa⁷; N. Martinez⁸; L. Naranjo⁹; R. Ruiz⁹; Y. Blanco¹; J. Cabrera-Maqueda¹; E. Martinez-Hernandez¹

¹Neuroimmunology and Multiple Sclerosis Unit, Neurology Department, Hospital Clinic Barcelona, Fundació de Recerca Clinic Barcelona IDIBAPS, Barcelona, Spain; ²Neurology Department, Hospital Clinico Universitario de Salamanca, Salamanca, Spain; ³Neurology Department, Hospital General Universitario Gregorio Marañón, Madrid, Spain; ⁴Neurology Department, Hospital Universitario 12 de Octubre, Madrid, Spain; ⁵Neurology Department and Centre d'Esclerosi Múltiple de Catalunya (Cemcat), Hospital Universitari de Vall d'Hebron, Barcelona, Spain; ⁶Neurology Department, Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain; ⁷Medical Oncology Department, Hospital Clinic Barcelona, Fundació de Recerca Clinic Barcelona IDIBAPS, Barcelona, Spain; ⁸Hematology Department, Hospital Clinic Barcelona, Fundació de Recerca Clinic Barcelona IDIBAPS, Barcelona, Spain; ⁹Immunology Department, Hospital Clinic Barcelona, Fundació de Recerca Clinic Barcelona IDIBAPS, Barcelona, Spain

Background and aims: Among neurological complications of cancer immunotherapy peripheral neuropathies are recognized immune-related adverse events (NP-irAE) of checkpoint inhibitors (ICI), whereas CART-related neuropathies (NP-CART) are rarely reported. We aim to describe clinical features, treatment, and outcomes of this complication.

Methods: Retrospective multicenter study of NP-irAE and NP-CART across 20 Spanish hospitals (2018–2025). Neuropathies were classified as acute (<4 weeks), subacute (4–8w) or chronic (>8w). We assessed severity with INCAT scale and outcomes at one month and last follow-up (good outcome: complete recovery or ≥ 2 -point mRS decrease).

Results: NP-irAE occurred in 13/144 (9%) neurological irAE; 3 male (23%), median age 72 years (IQR: 68–74). Median onset was 44 days (24–113) post-ICI initiation, median INCAT 0+3.5. Twelve (92%) had polyradiculopathy, and 1 (8%) sensory neuropathy. Three (23%) had CNS involvement with high-risk antibodies (2 anti-Hu, 1 anti-Ma2). Twelve (92%) received steroids and 8 (62%) IVIg. At 1 month, 11 (85%) improved; at last follow-up (median 33 months, 15–54), 7 (54%) had good outcomes. Among 600 anti-CD19 CAR-T recipients, 4 (0.6%) developed NP-CART; 3 male (75%), median age 54.5 years (45–57). One patient (25%) had prior severe ICANS. Median onset was 26 days (16–35) post-infusion. Three (75%) had polyradiculopathy with median INCAT 2+5; 1 (25%) cranial neuropathy. Two received steroids and 2 IVIg. All improved at 1 month; at last follow-up (median 40 months, 9–86), 2 (50%) had good outcomes.

Conclusion: NP-CART occurred earlier than NP-NiRAE. Although both are severe, high therapy responsiveness highlights the importance of prompt recognition and treatment.

EPO-0889 | Characteristics of the intestinal microbiome in Parkinson's disease patients

N. Mansurova¹; D. Rakhmatova²; S. Akhrova²

¹Tashkent State Medical University Tashkent, Uzbekistan;

²Bukhara State Medical Institute, Bukhara, Uzbekistan

Background and aims: Growing evidence implicates the gut-brain axis and gut microbiome dysbiosis in PD pathogenesis via immune mediators, the enteric nervous system and the vagus nerve, leading to microglial activation and chronic inflammation that may promote α -synuclein aggregation.

Methods: The cohort included 73 PD patients followed at a municipal outpatient clinic in Tashkent. Gastrointestinal autonomic dysfunction was quantified using the gastrointestinal domain of SCOPA-AUT, with a working severity grading (0–3 minimal; 4–7 mild; 8–12 moderate; ≥ 13 severe). Gut microbiota composition was analyzed using Osipov's gas chromatography–mass spectrometry (GC–MS) method, based on detection of microbial markers (specific fatty acids and related compounds) without culture.

Results: Signs of dysbiosis were identified in 90% of patients. Total bacterial load ranged from 16,848 to 38,784 units (mean $27,488 \pm 8,012$), exceeding reference values for healthy individuals; 44.4% showed hypercolonization ($>35,000$), potentially linked to slowed motility and constipation. The “microbiota core” (Firmicutes + Actinobacteria) varied between 28–48% (mean $39.2 \pm 6.9\%$), and was reduced in 20% of patients, indicating depletion of obligate anaerobes. Fungal flora (mainly *Candida*) exceeded the accepted threshold in 55.5%. The viral component averaged $7.0 \pm 2.3\%$ (reference $\sim 6\%$), with elevated levels in $\sim 20\%$ of patients, accompanied by higher endotoxin and a more pronounced anaerobic deficit; a positive correlation between viral load and *Clostridium* spp. was reported ($r \approx 0.58$).

Conclusion: Overall, the findings indicate a persistent dysbiotic profile in PD, with depletion of obligate flora and increased opportunistic and viral components, potentially contributing to chronic inflammation and disease progression.

Disclosure: Nothing to disclose.

EPO-0890 | Inflammatory mechanisms in Parkinson's disease and vascular Parkinsonism: IL-6, fecal calprotectin, and *Helicobacter pylori*

N. Mansurova¹; Y. Madjidova²; D. Khodjueva³; D. Rakhmatova³

¹Central Asian University, Tashkent, Uzbekistan; ²Tashkent

State Medical University, Tashkent, Uzbekistan; ³Bukhara State Medical Institute, Uzbekistan

Background and aims: This study aimed to evaluate local and systemic inflammatory markers (interleukin-6, fecal

calprotectin) and *Helicobacter pylori* infection in patients with Parkinson's disease (PD) and vascular parkinsonism, and to determine their clinical and laboratory associations.

Methods: A total of 52 patients were consecutively enrolled (32 with PD and 20 with vascular parkinsonism) and followed in an outpatient setting in Tashkent during 2020–2025. Clinical and demographic parameters were recorded; disease stage was assessed using the Hoehn and Yahr scale, and motor severity was evaluated with UPDRS. Fecal calprotectin was measured by ELISA, serum IL-6 by ELISA, and *H. pylori* infection by the urease breath test. Statistical analysis included parametric and non-parametric comparisons, chi-square/Fisher's exact tests, and Spearman correlations, with $p < 0.05$ considered significant.

Results: Elevated fecal calprotectin was detected in 34.4% of PD patients versus 9.3% in vascular parkinsonism ($p < 0.05$). Calprotectin levels correlated with Hoehn and Yahr stage ($r = 0.42$; $p < 0.05$) and UPDRS III ($r = 0.38$; $p < 0.05$), showing a tendency toward higher values at later disease stages. Increased IL-6 was more frequent in PD (85%; mean 10.28 ± 4.30 pg/mL) than in vascular parkinsonism (59.4%; 8.13 ± 3.13 pg/mL; $p < 0.05$). In addition, *H. pylori* prevalence was higher in PD (37.5% vs 8.3%; $p < 0.05$) and was associated with longer disease duration and greater motor impairment. Positive correlations were also observed between *H. pylori* parameters and both calprotectin and IL-6.

Conclusion: The findings support the contribution of intestinal and systemic inflammation to parkinsonism mechanisms and suggest that these markers may be useful for differential diagnosis, risk stratification, and more personalized clinical.

Disclosure: Nothing to disclose.

EPO-0891 | Rapidly progressive posterior cortical syndrome with alien limb: Diagnostic clues to sporadic Creutzfeldt–Jakob disease

C. Santoro; G. Guglielmini; N. Pilolli; G. Boero

Complex Structure of Neurology, SS Annunziata Hospital, Taranto, Italy

Background and aims: Corticobasal syndrome (CBS) is classically attributed to corticobasal degeneration (CBD), yet sporadic Creutzfeldt–Jakob disease (sCJD) can present with a CBS phenotype, often driven by posterior network dysfunction.

Methods: We reviewed the “CJD-CBS/alien limb” literature to extract specific discriminators—particularly patterns of cognitive involvement and structural involvement that can meaningfully shift pre-test probability early.

Results: Posterior alien limb phenomenon with non-dominant parietal dysfunction and visual-parietal signs (optic ataxia/neglect) supported a reproducible clinico-anatomical motif in CJD-CBS. While most CJD-CBS reports include striatal/basal ganglia abnormalities, a small subset shows complete structural and metabolic sparing of basal ganglia with dominant posterior cortical DWI changes and posterior hypometabolism on FDG-PET. This “striatum-sparing, posterior-cortical” phenotype is unusual for typical sCJD and can misdirect clinicians toward CBD unless specifically recognized. Contrary to the heuristic that early dementia is obligatory in CJD, several CJD-CBS cases show minimal cognitive impairment at onset, with later emergence of visuospatial deficits consistent with posterior network

primacy and helping explain early diagnostic anchoring on CBD. A parallel biomarker–imaging dissociation with markedly elevated total tau and normal p-tau plus RT-QuIC positivity supports prion disease even when amyloid markers are reduced, as low Aβ42 in CJD may not imply concomitant Alzheimer pathology.

Conclusion: The combination of posterior ALP + visual-parietal signs should trigger a topographic differential: assess posterior cortical DWI ribboning, actively interrogate basal ganglia involvement (or sparing) on MRI/FDG-PET, and integrate RT-QuIC with tau patterns—especially when cognition is initially preserved. Recognizing the “posterior, striatum-sparing CJD-CBS” subgroup may prevent systematic misclassification as CBD and accelerate appropriate prion-focused work-up.

Disclosure: Nothing to disclose.

EPO-0892 | Essential tremor five years follow-up study of MRgFUS in a real-world setting

C. Ferrer¹; A. Sanchez Fraga¹; R. Martuscello²; L. Knight²; I. Pyle²; K. Gant²; A. Grinspan²

¹Insightec Europe GmbH, Munich, Germany; ²Insightec, Inc, Miami, USA

Background and aims: This study evaluated the long-term outcomes of magnetic resonance-guided focused ultrasound (MRgFUS) thalamotomy in patients with medication-refractory essential tremor (ET). ET is a common neurological condition. Unilateral and staged-bilateral (≥9 months apart) MRgFUS thalamotomy are CE-approved. This global, open-label FDA Mandated extension study enrolled participants after completion of the pivotal trial as the first cohort in a real-world setting. It further investigates long-term follow-up outcomes after MRgFUS thalamotomy.

Methods: Treatment effectiveness was assessed by changes in tremor severity and motor function using the Clinical Rating Scale for Tremor (CRST) and quality of life with the Quality of Life in Essential Tremor (QUEST) questionnaire. Safety was monitored through documentation of adverse events (AEs).

FIGURE 1 Patient disposition.

FIGURE 2 CRST scores and QUEST.

TABLE 1 Number of subjects reporting adverse events.

Adverse event	Total (n = 61)	1 Month (n = 11)	2 Months (n = 11)	3 Months (n = 11)	4 Months (n = 11)	5 Months (n = 11)	6 Months (n = 11)	7 Months (n = 11)	8 Months (n = 11)	9 Months (n = 11)
Headache	20 (33%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Headaches/migraine	10 (16%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Fatigue	20 (33%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Dizziness	10 (16%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Joint discomfort	10 (16%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Stomach	10 (16%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Depression	10 (16%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Insomnia	10 (16%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)
Weight	10 (16%)	14	11	10 (16%)	10	10	8	8	8	8 (13%)

Results: Among 61 subjects (mean age 69.5 ± 14.0 years; 67.2% male), 26 (42.6%) completed 5-year follow-up (Figure 1). MRgFUS thalamotomy produced sustained improvements in tremor, motor function, and disability. From baseline to 1 and 5 years, percentage improvements were: CRST A+B 62.2% and 51.9%, tremor severity 75.6% and 67.4%, and CRST-C 65.4% and 35.4%, respectively. Quality-of-life scores improved 53.6% at 1 year and 43.7% at 5 years (Figure 2). Most treatment-related AEs were mild (85%) or moderate (12%), 3% were severe; over half resolved within six months (Table 1).

Conclusion: These findings complement the original pivotal data outcome supporting long-term safety and effectiveness of MRgFUS thalamotomy in 1st side medication-refractory ET patients. Further studies should assess 2nd-side treatment requirement and long-term outcomes. Meanwhile, MRgFUS thalamotomy offers a safe, durable, and meaningful option for improving quality of life in ET.

EPO-0893 | Homer 3 antibodies: Emerging biomarkers in cerebellar dysfunction

E. Karatzioula; V. Poulidou; S. Kalampokini; V. Kimiskidis; M. Arnaoutoglou

1st Department of Neurology, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background and aims: Homer-3 is a postsynaptic scaffolding protein expressed in Purkinje cells and plays a crucial role in calcium signaling mediated by metabotropic glutamate receptors. Cerebellitis associated with anti-Homer-3 antibodies is rare. Most reported patients present with vertigo and gait disturbance, while neurological examination almost invariably reveals ataxia and nystagmus. Cerebrospinal fluid (CSF) analysis typically shows pleocytosis and type 2 oligoclonal bands, whereas brain MRI findings are usually non-specific. Anti-Homer antibodies may be detected in serum or CSF. Various immunotherapeutic strategies have been used, including corticosteroids, intravenous immunoglobulin (IVIG), plasmapheresis, mycophenolate mofetil, and rituximab, with variable clinical responses

Methods: A 51-year-old woman presented with subacute cerebellar ataxia, choreiform movements, and inability to walk, since five months. Corticosteroid therapy worsened choreiform movements. Neurological examination revealed gaze-evoked nystagmus, dysmetria, choreiform movements in all four limbs, impaired deep sensation, and inability to stand unassisted. Deep tendon reflexes were absent. CSF analysis showed a normal cell count and type 1 oligoclonal bands. Brain MRI and EEG

were unremarkable. Extensive immunological, virological, and screening for malignancy, revealed no pathological findings. Serum testing was positive for anti-Homer-3 antibodies, while CSF was negative.

Results: Treatment with IVIG resulted in significant clinical improvement, allowing ambulation with bilateral support.

Conclusion: Anti-Homer-3 cerebellitis should be considered in the differential diagnosis of subacute-onset ataxia, as early identification and timely immunotherapy may improve outcome if initiated before irreversible neuronal damage occurs.

Disclosure: Nothing to disclose.

EPO-0894 | Phase angle as a robust indicator of clinical severity in patients with Huntington's disease

G. Foresti¹; A. Rizzardi¹; C. Agosti²; N. Agostini¹; N. Martinazzi¹; A. Pilotto¹; A. Padovani¹

¹Department of Clinical and Experimental Sciences, Neurology Unit, University of Brescia, Italy; ²Neurology Unit, Department of continuity of care and frailty, ASST Spedali Civili Brescia Hospital, Italy

Background and aims: Huntington's disease (HD) is a hereditary neurodegenerative disorder involving progressive motor, cognitive, and neuropsychiatric impairment, alongside systemic alterations in body composition. Bioelectrical impedance analysis (BIA)-derived parameters, specifically phase angle (PA), are potential markers of cellular integrity but remain underexplored in HD.

Methods: We enrolled 23 patients with genetically confirmed HD and 25 age- and sex-matched healthy controls (HC). Body composition and hydration were assessed via BIA. Within the HD group, we analysed clinical severity (UHDRS motor score ≤ 25 vs > 25) and genetic burden (CAG repeats < 42 vs ≥ 42). Multivariable regression models adjusted for age, sex, and height were used to control for anthropometric confounding. Partial correlations controlling for age were also performed.

Results: Compared to HC, HD patients showed significantly lower PA ($p = 0.008$) and body cell mass index (BCMI) ($p = 0.013$), with higher extracellular and lower intracellular water percentages ($p < 0.02$). Within the HD cohort, higher UHDRS scores were independently associated with lower PA ($p < 0.03$), while differences in muscle mass did not survive adjustment. Higher CAG repeats were associated with increased extracellular water volume ($p < 0.02$) but not with PA. In multivariable models, the UHDRS score was the primary predictor of PA.

Conclusion: HD is associated with reduced cellular integrity and altered fluid distribution. Phase angle appears to be a robust, severity-sensitive marker independent of body size and genetic load. BIA-derived PA may represent a clinically meaningful biomarker of disease severity in HD, warranting further longitudinal investigation.

Disclosure: Nothing to disclose.

“favorable outcome” (FO; mRS < 5). Biomarkers were compared with ANCOVA, correlations tested, and ROC analysis performed.

Results: Compared with controls, iNPH patients showed higher triglycerides, triglyceride/high-density lipoprotein (TG/HDL) and neutrophil/HDL ratios, and lower HDL. Within iNPH, patients with “high-grade” CSO-EPVS exhibited higher TG/HDL and neutrophil/HDL ratios than those with low-grade. PO patients had higher TG and TG/HDL and lower HDL than FO patients. A TG/HDL cut-off of 2.91 best predicted PO at 5 years.

Conclusion: iNPH patients exhibit a characteristic lipid profile within metabolic dysregulation and peripheral inflammation, tracked on a structural level by increased CSO-EPVS, a marker of glymphatic impairment. TG/HDL index appears to predict long-term clinical outcome, supporting its potential as prognostic marker in iNPH.

Disclosure: Nothing to disclose.

EPO-0897 | Deep stimulation in brain the Middle East: First UAE experience comparing subthalamic and pallidal targets for Parkinson's disease

S. Mittal; E. De Freitas; F. Roser; Y. Abdelmajid; M. Thomas; T. Maiti
Neurological Institute, Cleveland Clinic Abu Dhabi, United Arab Emirates

Background and aims: Deep brain stimulation (DBS) of the subthalamic nucleus (STN) and globus pallidus internus (GPi) is an established therapy for advanced Parkinson's disease (PD). However, comparative outcome data from the Middle East are limited, and it remains unclear whether target-specific differences reported in randomized trials translate to regional real-world practice. We report outcomes of STN and GPi DBS from a single tertiary center in the United Arab Emirates.

Methods: We retrospectively reviewed 50 consecutive patients with PD who underwent bilateral STN or GPi DBS between 2020 and 2025 (37 STN, 13 GPi). Demographics, clinical phenotype, levodopa equivalent daily dose (LEDD), Unified Parkinson's Disease Rating Scale part III (UPDRS-III) scores, and adverse events were collected. Outcomes were summarized by target, with exploratory comparisons acknowledging baseline heterogeneity and limited statistical power.

Results: GPi patients had earlier motor symptom onset and universal dyskinesias, while STN candidates demonstrated

more heterogeneous phenotypes. Both targets were associated with substantial LEDD reduction (STN $49.9\% \pm 32.4$; GPi $37.5\% \pm 22.0$). Variability and unequal sample sizes limited definitive target comparisons. Mean OFF-medication to DBS-ON UPDRS-III improvement exceeded 80% for both targets, likely influenced by high levodopa responsiveness, non-blinded assessments, and variable postoperative timing.

Conclusion: In this first comparative DBS analysis from the UAE, both STN and GPi DBS produced meaningful medication reduction and robust motor improvement. Methodological limitations preclude conclusions on target superiority, supporting individualized, phenotype-guided target selection and the need for larger prospective regional studies.

Disclosure: Nothing to disclose.

EPO-0898 | Spatial multi-omics identifies early synaptic pruning and context-specific dopaminergic vulnerability in Synucleinopathies

S. Rumpf¹; F. Strübing¹; K. Nalbach¹; C. Vargi²; S. Lichtenthaler¹; P. Parchi²; P. Gao¹; W. Chen¹; G. Berg¹; M. Brendel³; J. Gnörich³; A. Bernhardt¹; G. Höglinger⁴; J. Herms¹; T. Koeglsperger¹

¹German Center for Neurodegenerative Diseases (DZNE), Munich, Germany Diseases; 81377 Munich, Germany;

²IRCCS Istituto delle Scienze Neurologiche, Ospedale Bellaria, Laboratorio di Neuropatologia; 40139 Bologna, Italy;

³Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, Germany; ⁴Department of Neurology, LMU University Hospital, Ludwig-Maximilians-Universität (LMU) München, Munich, Germany

Background and aims: The molecular events that precede overt neurodegeneration in Parkinson's disease (PD) remain poorly defined. Incidental Lewy body disease (iLBD), a prodromal state characterized by brainstem-predominant Lewy pathology in the absence of clinical symptoms, provides a unique opportunity to investigate early pathogenic mechanisms underlying PD.

Methods: We applied a multi-omic spatial profiling approach to post-mortem midbrain tissue obtained from neurologically unaffected controls, iLBD cases, and patients with PD. This integrated strategy combined spatial transcriptomics, proteomics, and α -synuclein seed amplification assays (SAA), along with proximity ligation assay (PLA), to assess molecular alterations and misfolded α -synuclein across disease stages.

Results: We identified early and spatially distinct molecular changes in the substantia nigra pars compacta (SNpc) of iLBD cases, including a marked upregulation of the microglial synaptic pruning factor C1QC. These alterations occurred independently of overt Lewy pathology or detectable misfolded α -synuclein, as determined by SAA and PLA, and were preferentially enriched at GABAergic synapses, indicating early vulnerability of inhibitory circuits. Notably, similar changes were absent in Alzheimer's disease cases with comorbid SNpc Lewy pathology, suggesting that α -synuclein aggregation alone is insufficient to drive SNpc remodeling.

Conclusion: Our findings implicate microglia-mediated synaptic dysfunction as an early, preclinical feature of PD and suggest that targeting microglial-synaptic interactions may represent a

FIGURE 1 STN vs. GPi deep brain stimulation: First comparative outcomes from the UAE.

therapeutic strategy to halt disease progression prior to the onset of neurodegeneration.

EPO-0899 | **Gastrointestinal autonomic dysfunction defines an axial-functional vulnerability phenotype in drug-naïve Parkinson's disease**

Y. Hwang¹; M. Kim²; J. Park³; J. Seok⁴
¹Jeonbuk National Medical School and Hospital, Jeonju, Korea; ²Bobath Memorial Hospital, Seongnam, Republic of Korea; ³Director, Parkinson Neuropain Clinic, Neurologist and Movement Disorder Specialist, Cheonan, Republic of Korea; ⁴Department of Neurology, Ewha Womans University Seoul Hospital, Seoul, Republic of Korea

Background and aims: Autonomic dysfunction is common in Parkinson's disease (PD) from its prodromal stage, yet its heterogeneity and relationship with clinical features remain incompletely understood.
Methods: We analyzed a two-center cohort of 88 newly diagnosed, drug-naïve PD patients who were assessed using the SCOPA-AUT (The scales for autonomic dysfunction) questionnaire. Motor-related ADL and severity were evaluated using UPDRS parts II and III, with predefined subscores for bradykinesia, rigidity, tremor, and postural instability/gait difficulty (PIGD). Autonomic burdens, especially gastrointestinal (GI) dysautonomia severity, were examined using a median split to define mild and moderate to severe subgroups, and the comparisons between the groups were performed.

Sexual function-IV	0.5 ± 0.5	0.5 ± 0.5	0.988						

Results: SCOPA-AUT scores showed non-normal, right-skewed distributions, indicating substantial heterogeneity in autonomic burden. Among autonomic domains, GI symptoms showed the strongest correlation with activities of daily living (UPDRS II; $r=0.64, p<0.001$), exceeding other autonomic domains. GI dysautonomia correlated with overall motor severity ($r=0.38, p<0.001$), bradykinesia ($r=0.31, p=0.003$), and PIGD score ($r=0.28, p=0.008$), but not with tremor severity. Compared with GI-mild patients, the GI-moderate to severe subgroup demonstrated significantly worse UPDRS II and III scores, higher PIGD burden, lower MoCA-K scores, and a higher proportion of PIGD motor subtype, without increased motor asymmetry. In multivariable analysis, functional disability (UPDRS II) and cognitive performance independently predicted GI-moderate to severe status.
Conclusion: In drug-naïve PD, GI autonomic dysfunction identifies a distinct axial-functional vulnerability phenotype characterized by greater postural-gait impairment, functional disability, and cognitive vulnerability. Early GI dysautonomia may represent a key clinical marker of PIGD type with higher motor burden at diagnosis.

EPO-0900 | **Parkinson's disease patients present with more pronounced impairment of vertical eye movements**

Z. Popovic¹; T. Gilman Kuric¹; E. Strujic¹; S. Matosa¹; T. Mirosevic Zubonja¹; L. Kusic²; A. Sadikov³; D. Georgiev⁴; S. Tomic¹
¹Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia; Department of Neurology, University Hospital Center Osijek, Osijek, Croatia; ²Faculty of Medicine Osijek, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia; ³Faculty of Computer and Information Science, University of Ljubljana, Ljubljana, Slovenia; ⁴Faculty of Computer and Information Science, University of Ljubljana, Ljubljana, Slovenia; Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background and aims: Eye movement impairment is present in 75% of patients with Parkinson's disease (PD). Most pronounced impairment is in smooth pursuit which become hypometric with prolonged latency. We aimed to investigate differences in smooth pursuit eye movements in PD patients, depending on the movement axis.
Methods: This is a cross-sectional study with idiopathic PD patients. Velocity, phase, and number of fixations of horizontal

TABLE 1 Characteristics of PD patients.

FIGURE 1 Comparison of smooth pursuit eye movements with axis of movement.

FIGURE 2 Comparison of number of fixations during smooth pursuit eye movements with axis of movement.

and vertical smooth pursuit eye movements were evaluated using eye-tracker analysis with a battery of tests. The results for pursuit gain, speed, and range of motion are expressed as mean square error (MSE), ranging from 0 to 1, with lower values indicating smaller deviation from expected values.

Results: Fifty subjects (36 men and 14 women) with early-stage idiopathic PD were evaluated. Most patients (38%) were in Hoehn and Yahr stage II. Patients' characteristics can be seen in Table 1 PD patients showed significantly more impaired gain, velocity, and range of motion (Figure 1) of smooth pursuit eye movements, as well as an increased number of eye fixations (Figure 2) in the vertical axis compared to the horizontal axis. Differences were more pronounced during slow movement tasks.

Conclusion: Vertical smooth pursuit is more prominently impaired, with significantly lower gain and prolonged latencies. This axis-specific deficit is present even in mild cases and is especially evident during slower cycles, when horizontal movement is still preserved. A possible cause is more complex interactions between the frontal and parietal eye fields and the basal ganglia, mainly the substantia nigra pars reticulata.

Disclosure: Nothing to disclose.

Sleep-Wake Disorders 2

EPO-0901 | Sleepwalking and risk of Parkinson's disease: A pooled analysis of 183,848 adults from the UK and USA

A. Otaiku
UK Dementia Research Institute, Imperial College London, London, UK

Background and aims: Sleepwalking is a non-rapid eye movement (NREM) parasomnia that commonly occurs in Parkinson's disease (PD). Whether sleepwalking may precede the development of PD is unknown. This study investigated the association between sleepwalking and the risk of incident PD in the general population.

Methods: This prospective study used data from 183,848 community-dwelling adults without PD (ages 18–96, 58% female) pooled from the UK Biobank Study (UK) and Parkinson's Progression Markers Initiative Online Study (USA). Sleepwalking (ever vs never) was self-reported at baseline. Incident PD at follow-up was defined by doctor-diagnosis. Multivariable Firth logistic regression was used to estimate odds ratios (OR) for incident PD according to baseline sleepwalking status.

Results: Amongst 183,848 participants included at baseline, 10,316 (5.6%) had a history of sleepwalking. During a maximum follow-up of 3.6 years, 284 participants were diagnosed with PD. After adjusting for demographic characteristics, participants who sleepwalked had a 2-fold risk of developing PD during follow-up (adjusted OR: 1.99; 95% CI 1.27–3.12; $p=0.003$). The association between sleepwalking and incident PD was similar after adjusting for a wide range of possible confounders, including polygenic risk score for PD and idiopathic REM sleep behaviour disorder at baseline.

Conclusion: In this large prospective study spanning the UK and US, sleepwalking was independently associated with an increased risk of developing PD, suggesting it may represent a prodromal symptom of PD. These novel findings may help to identify individuals at risk of PD and could facilitate early prevention strategies.

Disclosure: Nothing to disclose.

EPO-0902 | Nightmares predict future cardiometabolic diseases: A pooled analysis of 113,073 participants across three continents

A. Otaiku

UK Dementia Research Institute, Imperial College London, London, UK

Background and aims: Nightmares are cross-sectionally associated with cardiometabolic diseases (CMD), which are major contributors to neurodegeneration and premature mortality. Whether nightmares increase the risk of developing CMD is unknown. This prospective study investigated whether nightmares predict incident CMD in the general population.

Methods: Data from 113,073 CMD-free participants (ages 31–96; 64% female) from seven population-based cohort studies across three continents (UK Biobank; Midlife in Japan; Midlife in the United States; Wisconsin Sleep Cohort; The Osteoporotic Fractures in Men Study, Study of Osteoporotic Fractures, and Study of Women's Health Across the Nation) were used in this longitudinal analysis. Nightmare frequency was self-reported at baseline. Incident CMD at follow-up was defined as doctor-diagnosed myocardial infarction, stroke, hypertension, or diabetes. Multivariable logistic regression was used to examine the association between nightmare frequency and incident CMD. Participants' genetic risk for CMD was measured at baseline using polygenic risk scores.

Results: During a maximum follow-up of 17 years, 2,786 participants developed a CMD. After adjustment for potential confounders, a higher frequency of nightmares was linearly associated with a greater risk of incident CMD (p for trend < 0.001). Compared with participants who had no nightmares at baseline, those with weekly nightmares had a 1.3-fold risk of developing a CMD (adjusted odds ratio = 1.28; $p = 0.002$). Notably, there was no interaction between nightmare frequency and genetic risk ($p = 0.32$).

Conclusion: Nightmare frequency was independently associated with the development of CMD, regardless of genetic risk. Future studies are needed to determine whether treating nightmares could help reduce CMD risk in the general population.

Disclosure: Nothing to disclose.

EPO-0903 | REM sleep without atonia across dementia with Lewy body stages: Correspondence with clinical RBD and dopaminergic correlates

C. Bonomi¹; A. Castelli²; C. Motta¹; F. Izzi²; A. Chiaravalloti³; L. Verdesca³; R. Ludovisi²; F. Placidi²; D. Centonze⁴; A. Martorana¹

³Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy; ⁴Neurology Unit, University of Rome Tor Vergata, Rome, Italy

Background and aims: Dementia with Lewy bodies (DLB) and its prodromal stage with mild cognitive impairment (MCI-LB), are frequently accompanied by REM sleep behavior disorder (RBD). REM sleep without atonia (RSWA), its neurophysiological correlate, is increasingly recognized as a biomarker of synucleinopathy; however, polysomnographic features across

FIGURE 1 Correspondence between clinical RBD and pathological RSWA. Bar plots show the distribution of concordant (dark green and light green) and discordant (dark red and light red) classifications in patients with MCI-LB and DLB.

FIGURE 2 Brain rendering showing clusters obtained in SPM regression analysis for the negative correlation between DaT uptake and RSWA index.

disease stages and their relationship with dopaminergic dysfunction remains incompletely elucidated.

Methods: Thirty-three patients (17 MCI-LB, 16 DLB) underwent overnight polysomnography (PSG) and dopamine transporter (DaT)-SPECT. PSG parameters were compared using ANCOVA adjusted for age, sex, levodopa and acetylcholinesterase-inhibitor doses. Concordance between clinical RBD and pathological RSWA was explored in patients with artifact-free RSWA quantification. Associations between RSWA and regional DaT availability were assessed using voxel-wise regressions.

Results: Groups were comparable for age, sex, and motor severity, while cognitive fluctuations were more prevalent in DLB. DLB also showed longer nighttime total sleep time and greater daytime sleepiness (Epworth Sleepiness Scale). Conversely, RSWA-index values were higher in MCI-LB than in DLB. Concordance between clinical RBD and pathological RSWA was only partial (Cohen's $k = 0.23$, see Fig. 1), indicating incomplete overlap between clinical and physiological definitions. Across the whole cohort, higher RSWA was associated with reduced DaT uptake in bilateral insulae, extending to the claustrum and right caudate (see Fig. 2).

Conclusion: Sleep macrostructural alterations are equally present at the prodromal stage of DLB. Partial correspondence between clinical RBD and RSWA supports the added value of quantitative analysis, and the association between RSWA and extrastriatal dopaminergic dysfunction highlights RSWA as a translational biomarker linking sleep physiology with underlying neurodegenerative mechanisms.

prevalence, characteristics, and cognitive impact of sleep disorders in a local ALS cohort.

Methods: Newly diagnosed ALS patients evaluated at our Neurology Unit in Parma (Italy) were prospectively enrolled. Participants underwent an overnight type III polysomnography and standardized questionnaires assessing disease severity, multidomain cognitive function, sleep quality, daytime sleepiness, and quality of life.

Results: Among 22 recruited ALS patients, 57.1% were affected by obstructive sleep apnea (OSA), with 23% deemed as moderate-to-severe forms. Numerous nocturnal respiratory parameters were strongly correlated ($p = 0.01$) with immediate and delayed memory impairment. Particularly, the hypoxic burden (HB) and the time spent with a peripheral blood oxygen saturation level below 90% were significantly predictive of memory compromise (Table 1). According to current guidelines, most patients with significant memory dysfunction were affected by mild OSA. Memory compromise is commonly described for patients with moderate-to-severe OSA. Our results suggest a higher prognostic relevance of the central hypoxic load than the apnoeic events count and support an increased sensitivity of ALS patients to the hypoxic damage.

Conclusion: Sleep breathing disorders may adversely affect not only survival but also cognitive performance in ALS, particularly memory. A comprehensive sleep evaluation emphasizing hypoxic overload rather than apnea frequency may improve clinical management and outcomes in this population.

Disclosure: Nothing to disclose.

Background and aims: With the aim to discover new biomarkers for narcolepsy type 1 (NT1) and the narcolepsy borderland (NBL), and in order to facilitate diagnosis and find more individualized treatment options, the prospective, longitudinal Swiss Primary Hypersomnolence and Narcolepsy Cohort Study (SPHYNCS) was started in 2020 and expanded internationally in 2023 (iSPHYNCS). New technologies, hypotheses- and data driven approaches have the potential to improve patient care and management.

Methods: The study has recently included new study sites in Norway and Austria and now counts 12 active study sites all over Europe. It plans to include 500 CDH patients and 60 healthy controls (HC) by the end of 2026. The multi-modal approach includes questionnaires, clinical assessments, video-polysomnography, the Multiple Sleep Latency Test (MSLT), vigilance tests, actigraphy, long-term activity monitoring with Fitbit, immunological studies, quantitative hypocretin measurements, proteomics, gut microbiomics, and genetics/epigenetics. AI-powered analyses, including unsupervised clustering, are used for data-driven patient phenotyping.

Results: 366 participants, including 13 children, have been recruited. The study population comprises 81 individuals with NT1, 233 individuals of the NBL, as well as 52 HC. So far, 6 publications have resulted from the study and have revealed notable differences among the study groups by analyzing questionnaires, neuropsychiatric profiles, Actigraphy and Fitbit, more are currently in review.

Conclusion: The study is heading towards its inclusion goal of 500 participants. In the next phase, the focus will be on the longitudinal data, “omics”- analyses and comprehensive machine learning analyses of (a) different raw data types and (b) multi-modal data integration.

Disclosure: The authors declare no conflict of interest. The study is supported by the Swiss National Science Foundation (SNF 320030_185362; SNF 32003B_215721).

Background and aims: Central disorders of hypersomnolence (CDH) are marked by excessive daytime sleepiness and/or increased sleep duration; narcolepsy type 1 is defined by hypocretin-1 deficiency. This study aimed to identify symptoms beyond cataplexy that signal hypocretin-1 deficiency and to examine how CDH symptom severity relates to hypocretin-1 levels.

Methods: CDH patients from the European Narcolepsy Network database were included: 257 had low hypocretin-1 (≤ 200 pg/mL; 163 ≤ 40 , 59 at 41–110, 35 at 111–200 pg/mL) and 45 had levels >200 pg/mL. Stochastic gradient boosting identified non-cataplexy predictors of hypocretin-1 deficiency, while logistic and quantile regression assessed associations between hypocretin-1 levels and 26 demographic, clinical, polysomnographic, MSLT variables, adjusted for age, sex, and BMI. Cataplexy features were analyzed only in hypocretin-1 ≤ 200 pg/mL cases.

Results: The machine-learning model predicted degrees of hypocretin-1 deficiency with moderate accuracy. Across all CDH patients, lower hypocretin-1 levels were associated with shorter REM and sleep latencies, more SOREMPs, higher Epworth scores, increased periodic limb movements, and more

FIGURE 2 Cataplexy frequency and certainty across hypocretin-1 levels. (A) frequency coding: 0=never, 0.2=1/day; (B) hypocretin groups: ≤40pg/mL; 41–110pg/mL; 111–200pg/mL; >200pg/mL.

disturbed nocturnal sleep. In patients with cataplexy and hypocretin-1 ≤200pg/mL, lower levels were linked to earlier onset of excessive daytime sleepiness, younger age at diagnosis, greater certainty of hypnagogic hallucinations and sleep paralysis, and more frequent and complete cataplexy. In contrast, sleep drunkenness was more common at higher hypocretin-1 levels and associated with longer daytime sleep duration.

Conclusion: Lower hypocretin-1 levels were linked to greater symptom severity across CDH and within hypocretin-deficient cataplexy patients (≤200pg/mL). Even within this range, level differences explained clinical variability, highlighting a larger role for hypocretin-1 in CDH heterogeneity than previously recognized.

Disclosure: Nothing to disclose.

EPO-0907 | Neurometabolic differentiation of central disorders of hypersomnolence: A harmonized spectroscopy study

N. de Jooze¹; J. Gool²; N. Cross³; E. van Heese¹; R. Fronczek²; G. Lammers⁴; C. Grova⁵; Y. van der Werf¹; T. Dang-Vu⁶
¹Amsterdam UMC, Anatomy and Neurosciences, Amsterdam, Netherlands; ²Department of Neurology, Leiden University Medical Centre, Leiden, Netherlands; ³The Brain and Mind Centre, School of Psychology, The University of Sydney, Sydney, Australia; ⁴Sleep-Wake Center, Stichting Epilepsie Instellingen Nederland (SEIN), Heemstede, The Netherlands; ⁵Physics, Concordia University, Montreal, Canada; ⁶CIUSSS du Centre-Sud-de-l'Île-de-Montréal, Institut Universitaire de Gériatrie de Montréal and CRIUGM, Montreal, Canada

Background and aims: Narcolepsy type 1 (NT1), narcolepsy type 2 (NT2), and idiopathic hypersomnia (IH) are central disorders of hypersomnolence (CDH); NT1 involves hypocretin deficiency, while NT2 and IH lack reliable biomarkers. We examined whether default mode network neurometabolites differ from controls, relate to symptoms and diagnostic differentiation. **Methods:** Sixty-two CDH patients (NT1 n=20, NT2 n=15, IH n=27) and 18 well-rested and sleep-restricted healthy controls underwent GABA-edited MEGA-PRESS 3T MRI of the medial prefrontal (mPFC) and posterior cingulate (PCC) cortices. Water-scaled, tissue-corrected GABA⁺, glutamate-glutamine, excitatory-inhibitory ratio, and secondary metabolites were analyzed using linear mixed models adjusted for age, sex, site, and IQ. Correlations assessed links with clinical measures, and ROC analyses evaluated diagnostic discrimination.

Results: No GABA⁺ or glutamate-glutamine differences survived FDR-correction between CDH and rested controls. Sleep-restricted controls showed higher PCC excitatory-inhibitory ratio and lower PCC myo-Inositol than CDH. Across CDH, higher mPFC total-N-acetylaspartate correlated with poorer sleep quality, and higher PCC total-Choline with longer MSLT sleep latency. Subtype-specific associations emerged: in NT2, lower mPFC glutamate-glutamine related to greater

FIGURE 1 Voxel placement and representative spectra. A. Group-level voxel placement overlap maps for the medial prefrontal cortex and posterior cingulate cortex. Representative LCModel reconstruction for the standard MEGA-PRESS editing scheme.

FIGURE 2 Group differences in mPFC metabolites (A) and preregistered clinical associations (B).

sleepiness; in IH, PCC glutamate-glutamine and excitatory-inhibitory ratio correlated with disease duration. ROC analyses showed good discrimination of NT1 vs NT2 (mPFC glutamate-glutamine, myo-Inositol) and NT2 vs IH (PCC total-Choline, total-N-acetylaspartate).

Conclusion: Despite no differences versus rested controls, subgroup analyses revealed distinct frontal (NT1/NT2) and posterior (IH) default mode network neurometabolic profiles. Frontal metabolites differentiated NT1-NT2 and tracked NT2 severity, while posterior markers distinguished IH-NT2 and related to disease duration, suggesting biologically grounded signals for improved CDH subtype differentiation beyond current criteria.

Disclosure: Nothing to disclose.

EPO-0908 | Phenoconversion in isolated REM sleep behavior disorder: Long-term data from the Innsbruck cohort

M. Aktan Süzgün¹; A. Ibrahim¹; M. Wildt¹; Q. Tang¹; V. Anselmi¹; E. Holzknecht¹; E. Brandauer¹; N. Campese¹; M. Defrancesco²; M. Delazer¹; R. De Marzi¹; A. Djamshidian-Tehrani¹; A. Fanciulli¹; R. Granata¹; B. Heim¹; F. Leys¹; P. Mahlknecht¹; K. Seppi¹; H. Stockner¹; L. Zamarian¹; S. Kiechl¹; B. Högl¹; A. Stefani¹

¹Department of Neurology, Medical University Innsbruck, Innsbruck, Austria; ²Department of Psychiatry, Psychotherapy, Psychosomatics and Medical Psychology, Medical University Innsbruck, Innsbruck, Austria

Background and aims: Polysomnographically-proven isolated REM sleep behaviour disorder (iRBD) is a prodromal alpha-synucleinopathy, with over 90% phenoconverting eventually to Parkinson's disease (PD), Lewy body dementia (LBD) or multiple system atrophy (MSA). This study aimed at analyzing phenoconversion characteristics along with clinical-demographic features in the Innsbruck iRBD cohort.

Methods: We included 166 iRBD patients followed-up longitudinally; those developing an overt alpha-synucleinopathy were classified as “phenoconverters,” those remaining iRBD as “non-converters”. Survival analyses assessed phenoconversion characteristics by demographic and clinical factors.

Results: Thirty-nine (23.4%) subjects phenoconverted over a median of 62.1 (IQR 12.5–249.6) months follow-up, mostly to PD (64.1%), followed by LBD (25.7%) and MSA (10.2%).

FIGURE 1 Kaplan-Meier-based cumulative and annual incremental phenoconversion plot.

FIGURE 2 Survival curves of the phenoconverters grouped by phenoconversion type, abbreviated as Parkinson's disease: PD, Lewy body dementia: LBD, and multiple system atrophy: MSA.

Phenoconverters were older at diagnosis (68.3 vs 64.0y, $p=0.017$), had longer follow-up (80.6 vs 51.1 months, $p=0.008$), higher mortality (51% vs 13%, $p<0.001$) and more cardiovascular (44% vs 25%, $p=0.028$) and cerebrovascular (28% vs 12%, $p=0.014$) comorbidities. Cumulative phenoconversion risk (Kaplan-Meier analysis) was 13.4% at 3-years, 17.6% at 5-years, 26.5% at 10-years, and 62.7% at 20-years (annual phenoconversion rate: 3.2%, Figure1) without sex differences. We found a trend toward faster phenoconversion in MSA compared to PD and LBD (log-rank $p=0.061$, Figure2). LBD phenoconverters presented more depressive symptoms (LBD 70%, PD 20%, MSA 0%, $p=0.010$).

Conclusion: Our findings are consistent with prior reports, although with relatively more PD and MSA and fewer LBD cases compared to other cohorts. Beyond age and disease duration, our data suggest that cardio/cerebrovascular comorbidities may influence phenoconversion. Prospective studies are needed to determine whether targeted vascular risk management influences phenoconversion probability or timing.

Disclosure: Nothing to disclose.

M. Aktan Süzgün¹; A. Ibrahim¹; M. Wildt¹; Q. Tang¹; V. Anselmi¹; E. Holzknecht¹; E. Brandauer¹; N. Campese¹; M. Defrancesco²; M. Delazer¹; R. De Marzi¹; A. Djamshidian-Tehrani¹; A. Fanciulli¹; R. Granata¹; B. Heim¹; F. Leys¹; P. Mahlknecht¹; K. Seppi¹; H. Stockner¹; L. Zamarian¹; S. Kiechl¹; B. Högl¹; A. Stefani¹

¹Department of Neurology, Medical University Innsbruck, Innsbruck, Austria; ²Department of Psychiatry, Psychotherapy, Psychosomatics and Medical Psychology, Medical University Innsbruck, Innsbruck, Austria

Background and aims: Olfactory dysfunction in isolated REM sleep behaviour disorder (iRBD) is a known risk factor of short-term phenoconversion to overt alpha-synucleinopathy. Yet data about longitudinal changes in olfactory function is scarce. This study aimed at investigating long-term olfactory function changes in iRBD.

Methods: This long-term observational study included iRBD with annual olfactory testing using the Sniffin' Stick 16-item identification task. Those developing overt-synucleinopathy were classified as "phenoconverters," those remaining iRBD as "non-converters". Longitudinal olfaction scores were used to model the predictive power of olfactory function on phenoconversion.

Results: 89 patients were included; 14 (15.7%) phenoconverted over 4.82 ± 3.87 years follow-up (age at baseline: 65.02 ± 10.19 y, M/F:80/9). The baseline olfactory score was 11.3 ± 3.1 in non-converters, 10.1 ± 3.5 in phenoconverters ($p=0.162$). The olfactory score at last follow-up was significantly higher in non-converters compared to phenoconverters (11.0 ± 3.6 vs

8.5 ± 2.8 , $p=0.019$). Longitudinal mixed-effects model (Figure1) showed lower olfactory scores in phenoconverters ($\beta=-1.664$, $p=0.047$). Higher olfactory score reductions were associated with longer follow-up time ($\beta=-0.107/\text{year}$, $p=0.017$) and older age at diagnosis ($\beta=-0.088/\text{year}$, $p=0.002$), with no sex effect ($p=0.802$). In Kaplan-Meier analysis (Figure 2), baseline olfactory scores ≤ 12 were associated with higher phenoconversion risk (HR=1.168 per 1-point decrease; $p<0.001$).

Conclusion: In our iRBD cohort, olfactory identification performance showed a gradual decline over time, underscoring its role as dynamic biomarker. Olfactory dysfunction was more severe at last follow-up in phenoconverters, confirming the previously-reported association with short-term phenoconversion risk. The strong association between lower baseline olfactory scores and increased phenoconversion risk supports the prognostic value of quantitative olfactory testing in prodromal alpha-synucleinopathies

Disclosure: Nothing to disclose.

EPO-0910 | Long-term assessment of social jetlag by Fitbit smartwatch in patients with central disorder of hypersomnolence

Z. Zhang¹; R. Morand²; L. Fregolente²; J. van der Meer²; E. Wenz²; J. Warncke²; K. Zub²; S. von Manitus³; S. Miano⁴; J. Acker⁵; M. Strub⁶; U. Kallweit⁷; S. Knudsen-Heier⁸; G. Lammers⁹; C. Bassetti²; M. Schmidt²; R. Khatami²

¹Center for Sleep Medicine, Sleep Research and Epileptology, Clinic Barmelweid AG, Barmelweid, Switzerland; ²Sleep-Wake Epilepsy Center, NeuroTec, Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; ³Department of Neurology, Health Ostschweiz (HOCH), Kantonsspital St. Gallen St. Gallen, Switzerland; ⁴Sleep and Epilepsy Center, Neurocenter of Southern Switzerland, Regional Hospital (EOC) of Lugano, Lugano, Switzerland; ⁵ZurzachCare, Clinic for Sleep Medicine, Bad Zurzach, Switzerland; ⁶Centre for Sleep Medicine Basel, Basel, Switzerland; ⁷Center for Narcolepsy and Hypersomnias, Professorship for Narcolepsy and Hypersomnolence Research, Department of Medicine, University Witten/Herdecke, Witten, Germany; ⁸Norwegian Centre of Expertise for Neurodevelopmental Disorders and Hypersomnias (NevSom), Department of Rare Disorders, Oslo University Hospital, Ullevål, Norway, Norway; ⁹Sleep Wake Centre SEIN, Stichting Epilepsie Instellingen Nederland, Heemstede, The Netherlands

Background and aims: Central disorders of hypersomnolence (CDH) are characterized by excessive daytime sleepiness and altered sleep-wake patterns. Social jetlag (SJL), reflecting misalignment between circadian rhythm and social schedules, has rarely been examined in CDH. Using smartwatch data, we characterized SJL in CDH and hypothesized greater SJL compared to healthy controls (HC).

Methods: Sleep-wake data from Fitbit smartwatches were analyzed in 37 HC, 50 patients with narcolepsy type-1 (NT1), and 116 narcolepsy borderline (NBL) patients enrolled in the Swiss Primary Hypersomnolence and Narcolepsy Cohort Study. Weekly SJL was defined as the difference between weekend and weekday mid-sleep times; monthly SJL was averaged across weeks. Linear-mixed-models assessed effects of diagnosis on

FIGURE 1 Kaplan-Meier analysis of phenoconversion-free survival in iRBD stratified by baseline Sniffin' Sticks scores. iRBD, isolated REM sleep behaviour disorder.

FIGURE 2 Linear mixed model aims to predict Sniffin' Sticks score over the follow-up period. DF, degrees of freedom; iRBD, isolated REM sleep behaviour disorder, SE, standard error.

monthly SJL, adjusting for age, BMI, gender, season, daylight saving time (DST), and nocturnal sleep duration (NSD).

Results: NBL patients showed significantly larger SJL than HC (19.0 min, $p=0.0015$), while NT1 showed a trend toward larger SJL (12.3 min, $p=0.074$). Differences between NBL and NT1 were not significant. Findings were replicated during summer-time DST, whereas in winter-time only NBL differed from HC. HC exhibited greater SJL in winter versus summer, a seasonal effect absent in CDH. SJL was unrelated to BMI or gender but negatively associated with NSD. CDH patients showed greater weekend variability in NSD than HC.

Conclusion: Wearables enable longitudinal assessment of SJL in CDH. Patients exhibit increased SJL, particularly in summer-time, with DST effects differing from HC. Persistent SJL in NBL may represent a disease marker, while reduced seasonal adaptability in CDH suggests limited compensation for circadian disruption or sleep debt.

Disclosure: Nothing to disclose.

EPO-0911 | Heterogeneous daily vigilance responses during supervised in-lab CBT-I in insomnia

Z. Zhang; R. Khatami

Center for Sleep Medicine, Sleep Research, and Epileptology, Clinic Barmelweid, Barmelweid, Switzerland

Background and aims: Cognitive behavioral therapy for insomnia (CBT-I) is the first-line treatment for chronic insomnia disorder (CID), with sleep restriction therapy (SRT) as a core component. Previous home-based CBT-I studies reported increased daytime sleepiness and impaired vigilance during SRT, findings that may be confounded by limited adherence and supervision. We therefore investigated changes in daytime sleepiness and vigilance during a tightly supervised, in-lab CBT-I program.

Methods: We retrospectively analyzed data from 56 CID patients who completed a standardized two-week in-house CBT-I program including SRT (5–6 h/night). Daily Stanford Sleepiness Scale (SSS), subjective sleep quality (SQ), and afternoon psychomotor vigilance tests (PVT) were collected over 10 working days. Linear mixed-effects models assessed changes in vigilance (inverse mean reaction time), SSS, and SQ, adjusting for age and sex. Subject-level bootstrap analyses were used to evaluate robustness of individual vigilance trajectories.

Results: SQ improved significantly over time ($p<0.001$), whereas vigilance and SSS showed no systematic change. Higher sleepiness was consistently associated with poorer vigilance ($p<0.001$). Individual responses were heterogeneous: 19 patients showed improving and 26 declining vigilance. Subgroups did not differ in demographics or fatigue severity, but higher depressive symptom severity (Beck Depression Inventory score ≥ 16) tended to be more frequent in patients with declining vigilance ($p=0.092$). SQ was positively associated with vigilance only in the improving subgroup ($p=0.032$).

Conclusion: Unlike prior home-based studies, supervised in-lab CBT-I did not produce consistent increases in daytime sleepiness or vigilance impairment during SRT. Improved sleep quality may mitigate adverse daytime effects despite restricted sleep opportunity.

EPO-0912 | Redefining the accuracy of clinical diagnosis of Parkinson's disease: A systematic review and meta-analysis

D. Urso¹; S. Giannoni-Luza²; M. Guidetti³; F. Neri⁴; L. D'Amico⁵; S. Landolfo⁶; A. Sánchez Boluarte⁷; C. Santoro⁸; G. Volpe²; A. Priori³; G. Logroscino¹

¹Center for Neurodegenerative Diseases and the Aging Brain, University of Bari 'Aldo Moro', 'Pia Fondazione Cardinale G. Panico', Tricase, Lecce, Italy; ²Department of Translational Biomedicine and Neuroscience (DiBrain), University of Bari 'Aldo Moro', Bari, Italy; ³Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, University of Milan, Italy; ⁴Humanitas University, Milan, Italy; ⁵Università degli Studi di Milano, Milan, Italy, Neurology Residency Program, San Giacomo – Monopoli, Italy; ⁶P.O. San Giacomo – Monopoli, Italy; ⁷Department of Global Health, University of Washington, Seattle, USA; ⁸Complex Structure of Neurology, SS Annunziata Hospital, Via Francesco Bruno, Taranto, Italy

Background and aims: Accurate diagnosis of Parkinson's disease (PD) remains challenging, particularly in early stages, with major implications for patient care, biomarker research, and clinical trials. Although modern diagnostic criteria such as the Movement Disorder Society (MDS) 2015 criteria were designed to improve diagnostic precision, their real-world performance relative to earlier frameworks is incompletely defined.

Methods: We conducted a systematic review and meta-analysis of studies evaluating the accuracy of clinical PD diagnosis against neuropathological confirmation. Studies using UK Parkinson's Disease Society Brain Bank (UKPDSBB), Gelb, and MDS-PD 2015 criteria were included. Bayesian bivariate random-effects models were used to estimate pooled sensitivity and specificity for early PD (first clinical assessment) and late PD (final diagnosis before death), and to explore between-study heterogeneity and temporal trends.

Results: Twelve studies including 9,659 participants were analysed. In early PD, pooled sensitivity and specificity were 57% and 76%, respectively, with substantial heterogeneity across studies. Conversely, late PD showed markedly higher accuracy, with pooled sensitivity of 87% and specificity of 89%. Among late-stage criteria, UKPDSBB provided the highest sensitivity (91%), whereas the MDS-PD 2015 criteria achieved the highest specificity and overall diagnostic precision. Meta-regression demonstrated progressive improvement in specificity over recent decades, with a modest decline in sensitivity, suggesting increasing diagnostic stringency.

Conclusion: Clinical diagnosis of PD is strongly stage-dependent and suboptimal in early disease. Although modern criteria, particularly the MDS-PD 2015, improved specificity and overall precision, misclassification in early PD remains common, underscoring the need for objective biomarkers to enhance diagnostic reliability in clinical practice and trials.

Disclosure: Nothing to disclose.

EPO-0913 | Evolving drivers of advanced therapy selection in essential tremor: European neurologists show a measurable shift toward patient-centered priorities

A. Sanchez Fraga¹; C. Tengelin¹; N. Kaempf¹; P. Crivelli¹; K. Gant²; C. Ferrer¹; A. Grinspan²
¹Insightec Europe GmbH, Munich, Germany; ²Insightec, Inc, Miami, USA

Background and aims: The introduction of new advanced therapies reshaped the landscape for patients with essential tremor (ET). This study aimed to assess whether these developments influence the factors considered by neurologists when selecting advanced therapies.

Methods: A cross-sectional survey was conducted among 270 general neurologists (GN) and movement disorder neurologists (MDN) across Europe. Prescribing drivers, perceptions of advanced therapies, and unmet educational needs were assessed. Outcomes were compared with the results of the same survey performed in 2023.

Results: Compared with 2023, improvement in quality of life became the leading driver of choice for advanced therapy selection (2023: $13.9 \pm 2.9\%$. 2025: $26.9 \pm 4\%$). Patients' willingness to undergo therapy ranked second in Italy (15%), Germany (13.3%) and UK (17.5%) (Figure 1). This factor had a greater influence on prescribing MRgFUS (22.9%) than DBS (4.1%) (Figure 2). Familiarity with MRgFUS increased across Europe (2023: $86.9 \pm 6.5\%$. 2025: $96.5 \pm 3.5\%$), becoming the most frequently cited advanced therapy for ET in Spain (23.6%) and Italy (16.7%). When asked about unmet educational needs, neurologists reported a marked increase, compared with 2023, in the need to

FIGURE 1 Neurologists' clinical priorities for advanced therapies in ET.

FIGURE 2 Patient profile besides severity for advanced therapies.

FIGURE 3 Recommendations for education.

improve patient information and education (2023: $14.2 \pm 5.1\%$. 2025: $25.2 \pm 9.1\%$) (Figure 3).

Conclusion: These findings demonstrate a shift in clinical decision-making within the Neurology community towards patient-centered priorities. Patient preferences and quality-of-life considerations are gaining importance alongside traditional efficacy and safety endpoints. Future efforts should enhance patient education, awareness and access to advanced therapies, ultimately enhancing their quality of life and treatment satisfaction.

Disclosure: All authors are Insightec employees.

EPO-0914 | Atypical late-onset PRKN-related Parkinson's disease due to compound heterozygosity: A case report

H. Rodrigues¹; C. Oliveira¹; B. Teixeira²; P. Almeida³; R. Rodrigues¹

¹Neurology Department, Local Health Unit Entre Douro Vouga, Santa Maria da Feira, Portugal; ²Neurology Department, Local Health Unit of the Aveiro Region, Aveiro, Portugal; ³Genetics Department, Local Health Unit Entre Douro Vouga, Santa Maria da Feira, Portugal

Background and aims: Approximately 5–10% of Parkinson's disease (PD) cases have a monogenic cause. PRKN is the commonest autosomal recessive gene. The typical phenotype involves early-onset PD, limb dystonia and slow progression.

Methods: Case report

Results: A 58-year-old man (patient 1) presented with a 7-year history of resting tremor, initially affecting the right lower limb and later the left upper limb, with gait impairment. Family history revealed a brother (patient 2) with similar symptoms beginning around 50s and a deceased father with PD. Both neurological examinations showed tremor-predominant parkinsonism with more evident resting tremor in the right lower limb and bradykinesia and rigidity in the contralateral left upper limb. Cognitive functions were preserved, and no pyramidal, cerebellar, or autonomic signs were observed. They were investigated with brain MRI and laboratory panel, unremarkable. Both showed a good response to levodopa. Genetic testing started in patient 1, with LRRK2 single test that was negative. A NGS panel identified two heterozygous pathogenic variants in the PRKN gene, which confirmed to be present in the brother (patient 2), and in the descendant (son of patient 2) it was only found a single pathogenic PRKN variant, supporting a compound heterozygous configuration in trans in the affected cases.

Conclusion: We report two cases of genetic PD due to compound heterozygous PRKN variants, with an unusual phenotype:

involvement of opposite limbs, absence of dystonia despite lower-limb onset, and a later age-at-onset. The distinctive clinical presentation, positive family history, slow progression, good response to levodopa and confirmation of trans configuration allow a genotype–phenotype correlation.

Disclosure: Nothing to disclose.

EPO-0915 | Caregiver burden in Parkinson's disease and implications for a CBT/ACT-based caregiver-intervention (Care-PD)

K. Bereswill; J. Reimer; A. Johannes; A. Kühn; P. Krause
Department of Neurology, Movement Disorder and Neuromodulation Unit, Charité-Universitätsmedizin Berlin, Berlin, Germany

Background and aims: Parkinson's disease (PD) progressively increases patients' needs for medical care and everyday support, most of which is provided by relatives without medical education. These informal caregivers frequently experience substantial physical and psychological strain summarized as caregiver burden (CB). The CARE-PD study aims to quantify CB in caregivers of individuals with PD and identify patient- and caregiver-related predictors to develop a targeted psychological caregiver intervention.

Methods: PD patients and their primary informal caregivers were recruited at the Charité movement disorders day clinic between December 2024 and May 2025. CB was measured using the Zarit Burden Interview (ZBI). Patient assessments included motor severity (MDS-UPDRS-III) and depressive symptoms (BDI-II). Caregiver assessments included BDI-II, mindfulness (MAAS), psychological inflexibility/experiential avoidance (AAQ-II), and sociodemographic data. Multiple linear regression models were used to identify predictors of ZBI scores.

Results: 57 PD patients (age=58.79 years, 19 female) and 57 caregivers (age=63.71 years, 38 female) completed the study. Caregivers reported mild to moderate burden (ZBI=21.30±8.64). Higher UPDRS-III predicted higher CB ($p=0.006$), whereas BDI-II did not ($p=0.838$). Higher caregiver depressive symptoms ($p=0.002$), lower psychological flexibility (AAQ-II; $p=0.046$), and female caregiver gender ($p=0.033$) were significant predictors of CB; mindfulness was not ($p=0.549$).

Conclusion: CB in PD is driven by both patient motor impairment and caregiver psychological vulnerability, particularly depressive symptoms and psychological inflexibility, with female caregivers at increased risk. These findings can support early identification of at-risk caregivers and guide the development of targeted cognitive behavioral therapy (CBT)/Acceptance and Commitment Therapy (ACT)-based interventions to mitigate CB and enhance care delivery.

Disclosure: Nothing to disclose.

EPO-0916 | Baseline dopaminergic treatment profiles of patients with advanced Parkinson's disease prior to Levodopa-Entacapone-Carbidopa intestinal gel infusion

J. Szasz¹; V. Constantin²; R. Szasz¹; K. Orban Kis¹; M. Ciorba¹; R. Neagoe¹; N. Craciun-Ciorba¹; J. Szederjesi¹; K. Kelemen¹; I. Mihaly³; S. Szatmari¹

¹GE Palade University of Medicine, Pharmacy, Science and Technology Targu Mures, Targu Mures, Romania; ²Emergency Clinical County Hospital Targu Mures, Targu Mures, Romania; ³County Hospital Miercurea Ciuc, Romania

Background and aims: Continuous intra-jejunal infusion of Levodopa-Entacapone-Carbidopa intestinal gel (LECIG) is an effective therapy for the treatment of advanced Parkinson's Disease (APD) associated with severe motor fluctuations with-or-without dyskinesias. The objective was to describe the characteristics of the last dopaminergic treatment in a large group of patients with APD in which current non-invasive therapy alone was no longer effective.

Methods: We conducted a retrospective review of all APD patients treated in our department before the initiation of LECIG treatment between December 2021 and November 2025. We analyzed the use of dopaminergic agents based on the most recent treatment recommendations.

Results: During the four years that were included in the study, we initiated LECIG treatment in 50 patients with APD; mean age 65.2 ± 8.65 (mean ± SD), disease duration 11.2 ± 4.6 years. The average treatment duration with Levodopa was 10.0 ± 4.01 years. Patients were on relatively high-dose levodopa regimens (mean: 857 ± 240 mg/day), administered at 5.34 ± 0.56 doses daily (5 to 7 times daily). Most patients also had treatment with dopamine agonists (82%; pramipexole $n=10$, 2.35 ± 0.87 mg; ropinirole $n=11$, 12.36 ± 5.5 mg; rotigotine patch $n=21$, 8.48 ± 1.89 mg) as well as selective monoamine oxidase B inhibitors (MAO-Bi, 60%, $n=30$), apomorphine pen (14%, $n=7$), Amantadine (28%, $n=14$) and Entacapone (70%, $n=35$).

Conclusion: The usage of dopaminergic treatments in patients with APD prior to LECIG treatment was more complex than those described in the literature. Such analyses help general neurologists identify the limits of conventional dopaminergic therapy and prompt timely referral to tertiary centers.

Disclosure: Nothing to disclose.

EPO-0917 | From scores to signals: A task-level atlas of movement disorder rating scales

K. Sampson¹; A. Sadnicka²

¹Department of Clinical and Movement Neuroscience, University College London, London, UK; ²Gatsby Computational Neuroscience Unit, University College London, London, UK

Background and aims: Clinical observation and rating scales are the currency of movement-disorder assessment, guiding diagnosis, tracking progression, and judging treatment response. Digital tools can quantify motor behaviour at scale in real-world settings, but to translate this into clinically meaningful endpoints we must first understand what existing scales actually “sample.” We therefore mapped the content of widely used movement-disorder

FIGURE 1 Inventory of movement disorder rating scales. (a) Candidate scales for motor phenotypes. (b) Proportion devoted to motor (dark), function (pale), or non-motor (white) assessment. (c) Source of motor-assessment items. (d) Licensing status of scales.

FIGURE 2 Overview of rating-scale items and regional assessments. (a) Classification of items by sampling mode. (b) Emphasis of body region(s) within region-based assessments. (c) Not examined items: patient-reported questions and qualitative judgements.

FIGURE 3 Overview of task-based assessments across movement disorder rating scales. Frequency plot displaying each task's occurrence across included rating scales, identifying core and scale-specific tasks. Grid plot indicates task inclusion by scale.

rating scales to identify common anchors and syndrome-defining phenomena.

Methods: Using a pragmatic, phenotype-centred strategy, we selected scales spanning ataxia, chorea, dystonia, functional movement disorders, myoclonus, parkinsonism, tardive syndrome, tic disorders, and tremor. We analysed content at two levels: (i) scale composition (motor vs functional/ADL vs non-motor) and (ii) item structure, classifying items by body region and task (Figure 1). Where available, structured video/examination protocols defined items; otherwise, items were extracted from text.

Results: Across scales we collated 270 discrete items (Figure 2). Direct motor examination dominated (median ~73%), and each phenotype carved out a distinct “examination space,” emphasising different regions and tasks. Item-frequency mapping revealed a shared backbone of cross-phenotype tasks (including gait, speech, and bilateral finger–nose testing), supporting a feasible harmonised core for digital capture (Figure 3). Other scale-specific items encode constructs clinicians use to distinguish syndromes, so a “core-only” approach could risk reducing sensitivity. Scales for disorders with prominent non-motor/behavioural/cognitive features allocated a smaller proportion to motor assessment.

Conclusion: Digital measurement will not replace rating scales; it should be built on them. By using scales to define clinically grounded targets we can develop harmonised, interpretable, and more sensitive next-generation outcomes.

Disclosure: Nothing to disclose.

EPO-0918 | Clinical and kinematic assessment of Parkinsonian features in young adults with 22q11.2 deletion syndrome

L. Angelini¹; A. Mazzeo²; E. Cerulli Irelli²; A. De Core²; D. Birreci²; A. Grandolfo²; M. Borioni²; S. Aloisio²; M. De Riggi²; F. Pulvirenti³; C. Di Bonaventura²; M. Bologna²
¹IRCCS Neuromed, Pozzilli (IS), Italy; ²Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy; ³Reference Centre for Primary Immune Deficiencies, Sapienza University Hospital Policlinico Umberto I, Rome, Italy

Background and aims: 22q11.2 deletion syndrome (22q11.2DS) is associated with an increased risk of early-onset parkinsonism, yet its motor phenotype in young adults remains poorly defined. We aimed to characterize parkinsonian features in young adults with 22q11.2DS using clinical and kinematic assessments, and to compare them with Parkinson's disease (PD) patients and healthy controls (HC).

Methods: Seventeen consecutive young adults with 22q11.2DS were enrolled and compared with 14 HC (age- and sex-matched) and 35 PD patients. Motor assessment included UPDRS part III. Distinct bradykinesia features were objectively quantified using optoelectronic motion analysis of finger tapping. Cognition was assessed using the Montreal Cognitive Assessment (MoCA). Four patients were receiving antipsychotic treatment.

Results: All 22q11.2DS patients exhibited clinically detectable bradykinesia. Eight patients (47%) fulfilled criteria for parkinsonism, presenting with rigidity ($n = 5$), resting tremor ($n = 2$), or both ($n = 1$). UPDRS-III total scores were comparable between 22q11.2DS and PD. Kinematic analysis showed that 22q11.2DS

FIGURE 1 Kinematic Features of Bradykinesia in 22q11.2DS, PD, and HC. Bar plots show coefficient of variation (CV), movement amplitude (AMP), and velocity (VEL) during finger tapping. Asterisks indicate significant between-group differences.

patients performed finger tapping more slowly than HC but similarly to PD. Compared with HC and PD groups, movements in 22q11.2DS patients were smaller in amplitude and less regular. MoCA scores were significantly lower in 22q11.2DS compared with PD. No correlations were found between UPDRS-III or cognitive performance and any of the kinematic measures.

Conclusion: Young adults with 22q11.2DS show a parkinsonian motor phenotype partially overlapping with PD but with distinct additional features (i.e, hypokinesia and dysrhythmia). Movement abnormalities are independent of cognitive impairment. These findings highlight kinematic analysis as a valuable tool for assessing motor function in young adults with 22q11.2DS.

Disclosure: Nothing to disclose.

EPO-0919 | Clinical subtypes of essential tremor: Neurological soft signs versus age at onset

L. Gattermeyer-Kell; D. Kern; M. Suetter; M. Zangl; P. Katschnig-Winter; M. Kögl; C. Enzinger; P. Schwingschuh
Department of Neurology, Medical University of Graz, Graz, Austria

Background and aims: Essential tremor (ET) subtypes may be defined by presence or absence of additional neurological signs (pure ET vs. ET-plus) or by age at tremor onset (early-onset ET, EOET vs. late-onset ET, LOET). Prospective studies with detailed clinical phenotyping comparing these concepts are scarce.

Methods: We prospectively enrolled 79 ET-patients (38.0% female) undergoing structured clinical assessment focused on predefined ET-plus signs, including resting tremor, impaired tandem gait, questionable dystonia, questionable bradykinesia, mild parkinsonian signs (hypomimia, reduced arm swing) and marked action tremor asymmetry. Patients were classified as pure ET or ET-plus and stratified by age at onset (40-year cut-off) into EOET and LOET. Tremor severity was assessed using TETRAS.

Results: Overall, 88.6% of patients were classified as ET-plus and 11.4% as pure ET. ET-plus-patients were older at baseline, but groups did not differ in disease duration, tremor severity or alcohol responsiveness (Table 1). 70% of ET-plus-patients had more than one soft sign (Figure 1). EOET and LOET accounted for 62.0% and 38.0% of cases, respectively. LOET were older and had shorter disease duration than EOET ($p < 0.001$). Alcohol responsiveness was reported by 80.0% of EOET vs. 33.3% of LOET

TABLE 1 Demographic and clinical parameters in essential tremor (ET)-plus vs. pure ET-patients. Statistical significance was assessed at the $\alpha=0.05$ level. Values with $p < 0.05$ are displayed in bold.

parameter	ET-plus	pure ET	p-value
Number of patients [n/N (%)]	70/79 (88.6)	9/79 (11.4)	
Median baseline age [years]	64.0	41.1	0.011
sex [% female]	35.7	55.6	0.240
Median age at onset [years]	28.7	19.3	0.099
Disease duration [years]	19.4	22.4	0.853
TETRAS [points]	17.5	11.5	0.085
Family history for ET [% positive]	85.7	66.7	0.247
Alcohol responsiveness [n/N (%)]	29/50 (58)	3/4 (75)	0.306

FIGURE 1 UpSet plot visualizing the frequency and distribution of additional neurological signs in patients with essential tremor plus.

TABLE 2 Demographic and clinical parameters in early-onset (EOET) vs. late-onset essential tremor (LOET)-patients. Statistical significance was assessed at the $\alpha=0.05$ level. Values with $p < 0.05$ are displayed in bold.

parameter	early-onset ET	late-onset ET	p-value
Number of patients [n/N (%)]	49/79 (62.0)	30/79 (38.0)	
Median baseline age [years]	45.9	74.0	<0.001
sex [% female]	35.7	46.6	0.773
Median age at onset [years]	18.0	57.1	<0.001
Disease duration [years]	25.6	25.3	<0.001
TETRAS [points]	16.0	23.8	<0.001
Family history for ET [% positive]	85.0	86.7	0.356
Alcohol responsiveness [n/N (%)]	24/30 (80)	8/24 (33.3)	<0.001
ET-plus [n/N (%)]	40/49 (81.6)	30/30 (100)	0.021

($p < 0.001$). Despite shorter disease duration, tremor severity was higher in LOET than EOET ($p < 0.001$; Table 2).

Conclusion: Additional neurological signs are common in ET, but ET-plus and pure ET do not differ in key aspects like alcohol responsiveness. In contrast, alcohol responsiveness is more frequent in EOET than LOET, while LOET appears characterized by faster tremor progression, suggesting different underlying pathophysiologies of these age-defined ET-subtypes.

Disclosure: Nothing to disclose.

EPO-0920 | Intrafamilial phenotypic heterogeneity in FBXO7-related PARK15 with compound heterozygosity: A case report of two siblings

M. Vomero; C. Cabato; R. De Micco; M. Cirillo; O. Ciaramaglia; F. Ambrosio; A. Tessitore
Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy

Background and aims: Biallelic pathogenic variants in the FBXO7 gene cause PARK15, a rare juvenile-onset parkinsonism characterized by motor and nonmotor features, with limited reports of intrafamilial phenotypic variability. This case report describes two Italian siblings with the same compound heterozygosity in the FBXO7 gene (p.Val233GlufsTer8 and p.Ile74Met), showing different clinical presentations despite identical genotypes. We also identified a potential novel pathogenetic FBXO7 variant.

Methods: Patient 1 (male, 21-years-old) had childhood-onset dysarthria and 2-year history of progressive slowness of movement. He was diagnosed with juvenile-onset parkinsonism and started dopaminergic medications with good levodopa response. Neurological examination showed mild left-predominant parkinsonism, and fragmentation of saccadic movements. Patient 2 (female, 27-years-old) presented at age 20 with verbal aggression and visual hallucinations, followed by a 2-year history of psychomotor slowing and gait impairment. Neurological examination showed mild-to-moderate left-predominant parkinsonism, fragmentation of saccadic movements and mild oculomotor apraxia. She also presented dysarthria and stimulus-induced myoclonus in the left hand. She shown poor levodopa tolerance due to behavioural side effects.

Results: Both patients exhibited MRI nigrosome-1 bilateral loss. Next-generation sequencing confirmed the presence of a compound FBXO7 heterozygosity with a pathogenic variant (p.Val233GlufsTer8) and a variant of unknown significance (p.Ile74Met). Mother and father carried the frameshift and missense variant respectively and were asymptomatic. A third sister was genetically wild-type and clinically healthy.

Conclusion: These cases highlight the possible intrafamilial heterogeneity in FBXO7-related PARK15 and support a potential pathogenic role for the p.Ile74Met variant (ACMG class 3), warranting functional studies for reclassification of variants in the FBXO7 gene.

Disclosure: Nothing to disclose.

EPO-0921 | Continuous subcutaneous foslevodopa/foscarbidopa improves nonmotor fluctuations in Parkinson's disease

O. Ciaramaglia¹; R. De Micco¹; C. Cabato¹; V. Sant'Elia¹; M. Siciliano¹; M. Sicialiano²; F. Ambrosio¹; A. Tessitore¹
¹*Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy;*
²*Neuropsychology Laboratory, Department of Psychology, University of Campania "Luigi Vanvitelli", Caserta, Italy*

Background and aims: Non-motor fluctuations (NMFs) in Parkinson's disease (PD) are disabling features often related to pulsatile dopaminergic stimulation from oral levodopa.

Continuous subcutaneous foslevodopa/foscarbidopa infusion (CSFLI) provides stable 24-hour levodopa delivery, but real-world data on NMFs remain limited.

Methods: We evaluated the effects on motor and nonmotor fluctuations after 3 months of treatment with CSFLI. Sixty-one PD patients initiated CSFLI at our Center. Longitudinal data were available for 40 subjects. Motor fluctuations were assessed using the Unified Parkinson's Disease Rating Scale part IV (UPDRS-IV), non-motor fluctuations with the Nonmotor Fluctuation Assessment questionnaire (NoMoFa) and non-motor symptom burden with the Non-Motor Symptom Scale (NMSS). Sleep quality, behavioural features, autonomic dysfunction and quality of life (QoL) were also assessed using validated scales. Total levodopa equivalent daily dose (LEDD) was calculated at each timepoint. Within-subject longitudinal differences on clinical variables were assessed using repeated-measures ANOVA.

Results: After 3 months of treatment with CSFLI, significant changes were observed in the total NoMoFa score, mainly driven by a reduction in OFF-related NMFs, particularly within the sleep/fatigue, depression/anxiety and miscellaneous domains. Significant improvement in NMSS scores, sleep quality and QoL were also found. As expected, wake time spent in the OFF state decreased, with a concomitant increase in good ON time due to reduced troublesome dyskinesias. No significant changes were observed in total LEDD after 3 months of treatment.

Conclusion: Our data reveal that, along with motor fluctuation stabilization, treatment with CSFLI markedly reduces NMFs severity, with broad non-motor and motor benefits in PD.

Background and aims: This study aimed to evaluate the Aggregation Network Diffusion (AND) model for predicting

individualized atrophy progression by simulating the spatiotemporal dynamics of misfolded α -synuclein spread and aggregation across functionally connected brain networks in PD.

Methods: Eighty-seven PD patients and 60 controls underwent 3D T1-weighted and resting-state functional MRI at baseline, with PD patients followed longitudinally over 7 years. A cohort of 34 PD patients from the Parkinson's Progression Markers Initiative with 4-year follow-up was included. The AND model simulated alpha-synuclein spread across the functional connectome through a system of ordinary differential equations modeling protein aggregation, and network diffusion based on parameters adaptable to individual patient dynamics. Patient-specific parameters were optimized using surrogate optimization to reproduce observed atrophy at first follow-up available. Model performance was assessed by Pearson's correlation between predicted and observed atrophy.

Results: The AND model successfully accurately predicted atrophy trajectories. Prefibrillar α -synuclein species combined with intermediate-weight protein aggregates most frequently yielded optimal atrophy predictions. Seed regions were predominantly localized to temporal and frontal lobes in PD patients. The model revealed two distinct atrophy progression patterns: one associated with low transmissibility, characterized by focal atrophy and gradual spread, and another linked to high transmissibility, marked by early, widespread bilateral involvement.

Conclusion: This study demonstrates the feasibility of using the AND model for personalized prediction of PD atrophy progression. By accounting for subject-specific patterns of protein spread and optimizing key model parameters, this approach provides new insights into the mechanisms driving neurodegeneration in PD.

EPO-0923 | CREXONT® (IPX203) significantly increases the duration of “Good on” intervals: Interim real-world results from the first 100 patients in ELEVATE-PD

S. Isaacson¹; L. Cloud²; D. Kreitzman³; S. Brillman⁴; G. Banisadr⁵; S. Fisher⁵; R. Hauser⁶

¹Parkinson's Disease and Movement Disorders Center of Boca Raton, Boca de Rotan, USA; ²Virginia Commonwealth University, Department of Neurology, USA; ³Movement Disorders Center of Long Island; ⁴Parkinson's Disease and Movement Disorders Center of Silicon Valley, USA; ⁵Amneal Pharmaceuticals; ⁶University of South Florida Parkinson's Disease and Movement Disorders Center, USA

Background and aims: CREXONT is a novel extended-release carbidopa-levodopa formulation containing a mucoadhesive polymer, designed to improve levodopa delivery and absorption. We evaluated the impact of CREXONT on the duration of “Good On” intervals and daily motor fluctuations in patients with PD after switching from other levodopa-based therapies.

Methods: ELEVATE-PD is an ongoing real-world, open-label phase 4 study where PD patients are converted from prior levodopa-based therapies (IR CD/LD, IR+COMT inhibitors, Rytary) to CREXONT. Following a 5-week dose-optimization period and a 1-week stable dosing, patients are followed for 12 months. The average duration of continuous “Good On” intervals and daily number of motor fluctuations were assessed using data from patient PD diaries. This interim analysis includes 111 patients who completed Day 42/Visit 4.

Results: At baseline, mean duration of continuous “Good On” intervals across all treatment groups was 2.92 ± 1.38 hrs and average number of daily motor fluctuations was 5.86 ± 1.99 . CREXONT treatment increased mean duration of continuous “Good On” intervals to 6.65 hrs (+3.94 hrs increase) for patients switching from IR CD/LD ($n=74$), to 3.46 hrs (+0.99 hrs increase) from IR+COMT inhibitor ($n=9$), to 6.58 hrs (+3.09 hrs increase) from Rytary ($n=22$). Moreover, switching to CREXONT resulted in a reduction in the average number of daily motor fluctuations; it decreased to 2.96 (-3.25 [52.85%] reduction) in subjects converting from IR CD/LD, 5.15 (-1.11 [17.73%] reduction) from IR+COMT inhibitor and 2.79 (-1.92 [40.42%] reduction) from Rytary.

Conclusion: The longer duration of continuous “Good On” intervals and reduction of motor fluctuations after switching to CREXONT provide greater time and predictability for patients with PD “Off” fluctuations to perform their daily activities.

Background and aims: The symbol digit modalities test (SDMT) score is crucial for assessing cognitive impairment in multiple sclerosis (MS), but is often influenced by a learning effect, regarded as unwanted variance. The goal of this study was to evaluate SDMT learning as a proxy of cognitive performance. **Methods:** Learning of people with MS and healthy controls (HCs) was evaluated using a two-part piecewise linear regression on daily smartphone SDMT (sSDMT) scores (see Figure 1). Cognitive impairment (CI) and preservation (CP) were defined using z-scores of baseline sSDMT relative to HC (CI: $z < -1.67$, CP: $z \geq -1.67$). sSDMT learning of HC/CP/CI was compared using ANCOVA and was correlated to baseline variables. Linear regression was performed to relate sSDMT learning to clinical outcomes and brain volumes.

Results: CP/CI: 66/19 MS and 20 HCs were analysed. A learning effect plateau was identified in HC/CI/CP: 80%/82%/100%, Figure 1 A higher baseline sSDMT was related to a higher plateau sSDMT ($\rho = 0.930$, $p < 0.001$) and a lower %-learned ($\rho = -0.266$, $p = 0.013$). The %-learned was higher for CI than CP (CP/CI = 15.52%/22.04%, adj. $p = 0.004$), but the Δ -learned and breakpoint were similar for HC/CI/CP, Figure 2 Relations of disability, cognition, and brain volumes with the plateau sSDMT were stronger when compared to the baseline sSDMT, Table 1.

Conclusion: Early-phase sSDMT learning was related to cognitive performance in MS. However, learning was not unique to disease status, and was not associated with disease severity. Moreover, plateau sSDMT showed stronger associations with disability and brain volumes than baseline sSDMT, underscoring the need to account for learning effects.

FIGURE 2 Network plot of relations between biomarkers related to worsening.

had lower cortical thicknesses at all timepoints and atrophy of nTBV and cortex, with an increase of nChPV and GFAP over follow-up. For inter-biomarker associations, see Figure 2. Baseline brain age (pooled OR=0.95, $p=0.020$) and high lesion volume (pooled OR=1.08, $p=0.049$) predicted disability progression (AUC=0.68), high cortical thickness decreased predicted the odds of cognitive decline (pooled OR=0.49, $p<0.001$, AUC=0.69) and combined worsening (pooled OR=0.57, $p=0.022$, AUC=0.65).

Conclusion: Our results indicate that 10-year disability progression and cognitive decline correlate with different biomarker patterns. Disability progression was associated inflammation (swelling of the choroid plexus), and the combination of low brain age with high lesional brain-burden, whilst cognitive decline was associated to cortical grey matter atrophy.

EPO-0926 | Impact of OCT acquisition parameters on GCIPL thickness measurements in multiple sclerosis: A protocol comparison

N. Krajnc¹; M. Bertich²; F. Föttinger¹; S. Macher¹; F. Schwarz¹; C. Stapf²; B. Pemp²; G. Bsteh¹

¹Department of Neurology, Medical University of Vienna, Austria; ²Department of Ophthalmology, Medical University of Vienna, Vienna, Austria

Background and aims: Retinal layer thickness measured by optical coherence tomography (OCT), particularly the ganglion cell and inner plexiform layer (GCIPL), is an established marker of neuroaxonal integrity in multiple sclerosis (MS). However, small longitudinal changes at the individual level often approach inter-scan variability, limiting clinical utility.

Methods: In this prospective study, participants with MS (pwMS) diagnosed according to the 2017 McDonald criteria and age- and sex-matched healthy controls (HC) underwent spectral-domain OCT at baseline and after two and four weeks. At each visit, five macular scan protocols were acquired: standard, high-ART, high-lines, high-resolution, and maximum. Reliability was assessed using intraclass correlation coefficients (ICC; two-way mixed-effects model, absolute agreement). Absolute test-retest reproducibility was quantified using mean absolute difference (MAD).

Results: Thirty-eight eyes from 9 pwMS (mean age 34.1 years [SD: 8.0], 44.4% female) and 10 HC (31.7 years [SD: 11.1], 50.0% female) were included. Mean baseline GCIPL thickness ranged from 70.8 to 71.5 μ m across protocols, demonstrating excellent inter-protocol agreement (ICC 0.99; 95% CI: 0.98–0.99; $p<0.001$). All protocols showed excellent test-retest reliability. High-ART and high-lines protocols demonstrated marginally lower absolute measurement variability (MAD 0.26–0.27; 95% CI: 0.21–0.32), while temporal agreement remained comparable across protocols. Mean acquisition time was shortest for the standard protocol (10.6s) and increased progressively for high-resolution, high-lines, high-ART, and maximum protocols.

Conclusion: All OCT acquisition protocols demonstrated excellent inter-protocol and test-retest reliability for GCIPL measurements. The high-lines protocol provides the most favorable

balance between measurement reliability and acquisition time, supporting its use for longitudinal GCIPL monitoring.

Disclosure: The authors declare no conflicts of interest related to this study.

EPO-0927 | Exploring genetically determined leukocyte telomere length in relation to age at onset in multiple sclerosis

G. Visentin¹; F. Clarelli²; M. Sorosina²; A. Giordano¹; E. Mascia²; M. Rocca¹; S. D'Alfonso³; M. Filippi¹; F. Esposito¹
¹Vita-Salute San Raffaele University, Milan, Italy; ²IRCCS San Raffaele Hospital, Milan, Italy; ³Department of Health Sciences, UPO University of Eastern Piedmont Novara, Italy. CAAD (Interdepartmental Research Center of Autoimmune and Allergic Diseases), University of Eastern Piedmont Novara, Italy

Background and aims: Telomere length is a marker of biological ageing and immune-cell senescence. In multiple sclerosis (MS), telomere shortening has been linked to disease severity, but its relationship with age at onset (AAO), a major source of phenotypic heterogeneity, remains incompletely understood. Genetically determined leukocyte telomere length (gLTL) provides an opportunity to investigate telomere biology independently of disease-related and environmental influences.

Methods: We analysed 2,824 relapsing–remitting MS patients with genome-wide genotype data imputed to the Haplotype Reference Consortium panel. Polygenic risk scores for gLTL (gLTL-PRS) were derived using summary statistics from a large genome-wide association study of UK Biobank participants. Eight PRS were constructed using a clumping-and-thresholding approach across increasing p-value thresholds. Associations between gLTL-PRS and AAO were assessed using linear regression models adjusted for relevant covariates.

Results: Across all PRS models, higher genetic predisposition to longer telomere length was associated with later AAO in MS. The strongest association was observed using the most inclusive PRS (p -value threshold <0.2 ; $\beta=0.57$, $SE=0.21$, $p=0.008$), consistent with a polygenic contribution of telomere-related variants to AAO variability.

Conclusion: These findings suggest that genetic variation underlying telomere biology may contribute to inter-individual differences in AAO in MS. The progressive strengthening of associations across increasingly inclusive PRS models supports the complex polygenic nature of this relationship and highlights telomere-related pathways as potentially relevant to MS phenotypic heterogeneity.

Disclosure: G. Visentin: nothing to disclose; F. Clarelli: nothing to disclose; M. Sorosina: nothing to disclose; A. Giordano: received consulting fees and travel grants from Novartis; E. EPO-0928 | Mitochondrial impact of fingolimod on peripheral immune cells in multiple sclerosis

I. Gómez-Delgado¹; A. González-Jiménez¹; P. López-Cotarelo¹; A. Moreno-Jerez¹; J. Vela-Artiza¹; E. Mena-Plaza¹; Y. Aladro²; B. Pilo²; C. Oreja-Guevara³; I. Gómez-Estévez³; A. R. López-Pastor¹; E. Urcelay¹

¹Laboratory of Genetics and Molecular Bases of Complex Diseases, Health Research Institute of Hospital Clínico San Carlos (IdISSC), Madrid, Spain; ²Department of Neurology, Hospital Universitario de Getafe, Getafe, Spain; ³Department of Neurology, Hospital Clínico San Carlos, Health Research Institute of Hospital Clínico San Carlos (IdISSC), Madrid, Spain

Background and aims: Fingolimod (FLM) limits lymphocyte egress from lymphoid organs. Mitochondrial dysfunction and metabolic reprogramming contribute to multiple sclerosis (MS) pathogenesis and disease progression. However, the impact of FLM treatment on mitochondrial activity and metabolism of peripheral immune cells (PBMCs) remains incompletely characterized. The aim of this study is to evaluate FLM effects on

FIGURE 1 Effects of fingolimod on mitochondrial respiration of PBMCs stratified by MS clinical form. Oxygen consumption rate profiles and parameters of PBMCs from healthy controls and MS patients treated with IFN or FLM.

E. Abed
Neurology Department, Al-Azhar University, Cairo, Egypt

Background and aims: Progressive multifocal leukoencephalopathy is a serious complication of natalizumab-treated multiple sclerosis, with anti-John Cunningham virus antibodies used for risk stratification. This study explores the role of the interferon- β -B cell activating factor axis in anti-John Cunningham virus antibody development.

Methods: This prospective study was conducted at Al-Azhar University Hospitals and Cairo Fatemic Hospital and included 186 patients with relapsing–remitting MS receiving natalizumab between October 2022 and November 2025. Serum anti-JCV antibody levels were assessed at baseline and after 12 and 24 months of treatment. Expression of type I and II IFN-inducible genes and BAFF was measured in peripheral blood using quantitative RT-PCR. BAFF gene polymorphisms (rs9514828, rs1041569, rs9514827) were analyzed using RFLP-PCR.

Results: No significant association was observed between type I or II IFN-inducible gene expression and serum anti-JCV antibody titers. In contrast, anti-JCV levels showed a significant correlation with BAFF gene expression. The BAFF TTT haplotype was significantly more prevalent among male anti-JCV–positive patients compared with anti-JCV–negative males at baseline, 12 months, and 24 months of natalizumab therapy. The BAFF TTT haplotype demonstrated 88% specificity, 70% sensitivity,

FIGURE 1 Anti-JCV seropositivity over time in male MS patients.

TABLE 1 Baseline characteristics.

Variable	Value
Total patients	186
Age (years), mean $\pm$ SD	34.6 $\pm$ 8.9
Male sex	82 (44.1%)
Female sex	104 (55.9%)
Anti-JCV positive	98 (52.7%)
Anti-JCV negative	88 (47.3%)
Natalizumab duration (months), median (IQR)	24 (12–35)

FIGURE 2 Effect of fingolimod on glycolysis of PBMCs stratified by MS clinical forms. Extracellular acidification rate profiles and parameters of PBMCs from healthy controls and MS patients treated with IFN or FLM.

mitochondrial function of PBMCs from MS patients, compared with interferon (INF)-treated patients and controls (HC).

Methods: Mitochondrial respiration and glycolytic activity were assessed by Seahorse XFP extracellular flux analyzer in MS patients treated with FLM ($n=24$) or IFN ($n=45$), and HC ($n=35$). Mitochondrial mass, membrane potential, reactive oxygen species (ROS) production, and glycolytic mediators were evaluated by flow cytometry. Mitochondrial electron transport chain (ETC) complexes were analyzed by Western Blot.

Results: In RRMS patients with FLM therapy, a pre-stimulated respiratory profile with significantly higher basal, maximal, and ATP-linked respiratory values were detected compared to IFN-treated patients and HC. Milder pre-stimulation, but also precluding further PHA-stimulation, was found in SPMS patients. In parallel, significant increases in unstimulated basal and maximal glycolytic capacities upon FLM-treatment led to a lower glycolytic reserve upon PHA-stimulation. FLM treatment produced lower fold-changes after PHA and significantly decreased mitochondrial depolarization with lower increase of complex II, leaving ROS and coupling at basal levels. After PHA-stimulation, decreased fold-changes of mitochondrial mass and lactate transporters (MCT1/4) were observed in FLM-treated compared to IFN-treated patients and HC, with no changes in PFKFB3.

Conclusion: Fingolimod modulates mitochondrial activity and PBMCs metabolism, which probably contribute to its therapeutic response in MS patients.

Disclosure: C.O.G. has received speaking and/or consultancy fees from Alexion, Biogen Idec, Bristol-Myers-Squibb, Janssen, Merck, Novartis, Roche, Sanofi-Genzyme, and Teva. Y.A. has received research grants, travel support, and lecturing and consulting fees from Bayer, Biogen, Roche, Merck, Novartis, Almirall, Sanofi-Genzyme, Janssen, and Bristol Myers Squibb. B.P. has received speaking, travel and/or training fees from Novartis, Almirall, Merck and Sanofi-Genzyme. The other authors nothing to disclose.

TABLE 2 BAFF TTT Haplotype performance.

Parameter	Value
BAFF TTT haplotype prevalence	Higher in anti-JCV (+) males
Specificity	88%
Sensitivity	70%
Positive predictive value	45%

and a 45% positive predictive value for identifying anti-JCV-positive male patients after 24 months of treatment.

Conclusion: These findings support a role for the BAFF pathway in regulating anti-JCV antibody production. The BAFF TTT haplotype may represent a novel genetic risk marker for anti-JCV seropositivity and, indirectly, for PML development in male MS patients treated with natalizumab.

Disclosure: Nothing to disclose.

Background and aims: There is no consensus on the definition of disability accrual (DA) in patients with multiple sclerosis (MS) with a baseline Expanded Disability Status Scale (EDSS) score of 5.5. Indeed, progression has been variably defined as either a 1.0- or 0.5-point increase. This study aims to compare the proportion of DA and its confirmation at the end of the follow-up using the two definitions.

Methods: In this multicentric, retrospective, cohort study based on prospectively acquired data from the Italian Multiple Sclerosis Register, inclusion criteria were: diagnosis of Clinically Isolated Syndrome or relapsing-remitting MS, first visit on or after January 1, 2000, ≥ 3 EDSS evaluations, ≥ 5 years of follow-up. In patients with roving baseline EDSS of 5.5, confirmed DA (CDA) was defined as a 24-week confirmed disability increase of either 0.5- or 1-point. Proportions of CDA and sustained DA (absence of subsequent EDSS improvement until follow-up end) were calculated and compared.

Results: The whole sample included 30203 relapsing MS patients followed-up for 11.3 $\pm$ 4.3 years. A total of 228 (0.8%) patients had roving baseline EDSS = 5.5. Among those, CDA with 0.5- or 1-point EDSS increase occurred in 200 (87.7%) and 59 (25.9%) patients, respectively ($p < 0.001$). 104 out of 141 (73.8%) CDA with 0.5-point EDSS increase and 51 out of 59 (86.4%) CDA with 1-point EDSS increase were sustained at the end of the follow-up ($p = 0.05$).

Conclusion: In patients with MS and baseline EDSS score of 5.5, the 0.5-point CDA definition identifies a greater proportion of long-term disability worsening than the 1.0-point definition and should be preferred in this subgroup of patients.

Disclosure: E. Portaccio has received compensation for travel, advisory boards and/or speaking activities from Biogen, Merck Serono, Sanofi, Teva, Roche, BMS Celgene, Janssen, and Novartis, and serves on the editorial board of Frontiers in Neurology and Brain Sciences. Vita-Salute San Raffaele University, Milan, Italy; ⁴Neurology Unit, Multiple Sclerosis Center, Neurorehabilitation Unit, Neurophysiology Service and Neuroimaging Research Unit, Division of Neuroscience IRCCS San Raffaele Scientific Institute, Milan, Italy. Vita-Salute San Raffaele University, Milan, Italy

Background and aims: Neuromyelitis optica spectrum disorders (NMOSD) is a rare, inflammatory, central nervous system disease historically treated with rituximab (RTX). Satralizumab (SATRA), an anti-IL6 receptor monoclonal antibody, has recently been approved for AQP4-IgG-positive patients switching from RTX for inefficacy or adverse events. We report our real-world experience.

Methods: We retrospectively collected demographic, clinical and MRI data from all patients starting SATRA at our center between February 2023 and July 2025.

Results: 11 NMOSD patients (10 females) were enrolled. At SATRA initiation, median age was 48.5 years (25.7–71.8), median disease duration was 16.3 years (range: 1.0–34.1), median EDSS was 3.5 (0–6.0). Prior therapy was tocilizumab (TOCI) in 5/11 patients and RTX in 6/11. Among TOCI-treated patients, 3/5 had previously received RTX and 2/5 autologous hematopoietic stem-cell transplantation. TOCI was started for disease activity and the switch to SATRA was to shift to an on-label anti-IL-6R drug. All RTX switched for safety and among them 5/6 had hypogammaglobulinemia with recurrent infections. One started monthly intravenous immunoglobulin supplementation in February 2025. Over a median SATRA follow-up of 2.2 years (0.6–3.0) all patients remained clinically stable (median EDSS 3.5, 0–6.0) and showed no radiological disease activity. For patients switching from TOCI, global follow-up in anti-IL-6R therapy was 10.3 years (4.1–12.9).

Conclusion: In our small cohort, SATRA has proven to be effective and well tolerated, including long-term anti-IL-6R treated patients. Those who switched to SATRA to change mechanism of action stopping B-cell depletion because of worsening

hypogammaglobulinemia all experienced a reduction of adverse events in both frequency and severity.

Disclosure: VM has nothing to disclose. IG received honoraria for speaking from Novartis, Roche and Merck. ADS has nothing to disclose. She receives research support from the MS Society of Canada, the Italian Ministry of Health and FISM. LM received compensations for speaking activities and/or for participating to advisory board from Merck, Celgene, Biogen, Sanofi, Novartis, Roche, Alexion, and Amgen. MF received compensation for consulting services and/or participation in Advisory Boards from Alexion, Almirall, Biogen, Merck, Novartis, Roche, Sanofi; speaking activities from Bayer, Biogen, Celgene, Chiesi Italia SpA, Eli Lilly, Genzyme, Janssen, Merck-Serono, Neopharmed Gentili, Novartis, Novo Nordisk, Roche, Sanofi, Takeda, and TEVA; scientific direction of educational events for Biogen, Merck, Roche, Celgene, Bristol-Myers Squibb, Lilly, Novartis, Sanofi-Genzyme; he receives research support from Biogen Idec, Merck-Serono, Novartis, Roche, the Italian Ministry.

EPO-0933 | Multiple sclerosis and outpatient physician care in the last years of life: A population-based study

W. Kim¹; C. Watt²; S. Fung²; S. Yoo¹; C. Webber²; D. Rotstein³; M. Howard⁴; P. Tanuseputro⁵; U. Ramanathan³

¹University of Ottawa, Ottawa, Canada; ²Brüyère Health Research Institute, Ottawa, Canada; ³University of Toronto, Toronto, Canada; ⁴McMaster University, Canada; ⁵University of Hong Kong, Hong Kong

Background and aims: Patients with MS require increasing healthcare support, particularly in the last year of life. Despite the benefits of palliative care in addressing symptom burden and improving quality of life, its integration into MS care remains inconsistent. This study aimed to characterize healthcare utilization and palliative care access among people with MS in the last years of life and to identify key factors associated with optimal care.

Methods: A retrospective cohort study was conducted using linked health administrative data. The cohort consisted of all adult decedents between 2016 and 2020, and we compared health care utilizations. Demographics, healthcare utilization, palliative care involvement, and medical interventions were analyzed. Predictors of palliative care receipt and hospital deaths were evaluated.

Results: MS decedents ($n=1975$) were younger and had fewer comorbidities than non-MS decedents ($n=500,904$). High percentage of MS decedents had outpatient neurology visits in the last five years of life but a steep decline closer to death. Palliative care use was similar but occurred earlier in MS. Multivariable regression showed that rural residence was associated with increased odds of hospital death and lower odds of receiving

palliative care, while receiving palliative care within the last five years of life reduced the odds of hospital death. Higher comorbidity and outpatient visits to urology were associated with a greater odd of receiving palliative care.

Conclusion: While palliative care receipt was comparable, rural disparities and high hospital deaths persist in MS. Earlier palliative integration, particularly through neuropalliative care, could improve quality of life and reduce hospitalizations.

Disclosure: Nothing to disclose.

Background and aims: Restless Legs Syndrome (RLS) is a difficult-to-treat chronic neurological condition. Cognitive Behavioral Therapy (CBT) can support coping and self-care in chronic diseases, yet no evidence-based digital CBT programs exist to complement medication for RLS. Therefore, this project aims to investigate, from the perspectives of patients, relatives, and healthcare professionals, gender- and age-related differences in experiences, symptom management, and treatment needs among patients with RLS, and to co-create a digital CBT-based intervention.

Methods: A four-step longitudinal multimethod design, including a randomized controlled trial (RCT) with long-term follow-up, will be used (Figure 1). Approximately 30 multiprofessional members, including people with RLS, researchers, and healthcare professionals (physicians, nurses, psychologists, and sociologists) specialized in RLS, sleep problems, and CBT, collaborate in the co-design of the digital CBT-based intervention.

Results: Step 1 (2022–2026) used various qualitative methods to explore and describe RLS-related care needs as experienced by patients, relatives, and healthcare professionals. Step

FIGURE 1 Project overview from step 1–4.

2 (2022–2026) validated five instruments for shared decision-making, mastery, wellness, e-health literacy, and self-care. Steps 1 and 2 have produced 11 publications to date (Table 1). In Step 3 (2026), the co-designed digital CBT-based intervention will be pilot-tested at one primary care center. In Step 4 (2026–2028), a

multicenter RCT conducted at eleven primary care centers will evaluate its long-term (12-month) effects.

Conclusion: The project's mapping of the experiences of patients, relatives, and healthcare professionals provides an evidence-based foundation for the co-created digital CBT-based intervention, which, if successful, can complement pharmacological treatment and improve quality of life for patients with RLS.

Disclosure: Nothing to disclose.

EPO-0935 | Pupillometric biomarkers of autonomic dysfunction in isolated REM sleep behaviour disorder

B. Křupková¹; T. Serranová¹; P. Dušek¹; K. Šonka¹; E. Růžicka¹; O. Slanař²; O. Bartošová²

¹Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic; ²Department of Pharmacology, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic

Background and aims: Pupillary abnormalities are common in neurodegenerative disorders. In isolated REM sleep behaviour disorder (iRBD), increased pupil size and reduced pupillary light reflex have been reported, suggesting parasympathetic dysfunction. This study aimed to assess pupillary abnormalities in prodromal synucleinopathy using a bedside portable pupillometer.

Methods: Sixty individuals with iRBD (mean age=66.9 years, SD=9.6; 5 females) and 48 controls (mean age=67.0 years, SD=9.7; 5 females) underwent pupillometry using a portable infrared pupillometer (Neuro-Light, IDMed, France) after 5 minutes of dark adaptation. Five measurements were obtained from each eye following stimulation with a 320-lux white light flash lasting 1 second. Median values of maximum and minimum pupil diameter, their difference and variation were calculated for each eye. Maximum constriction velocity and latency to onset of constriction were calculated as median values from ten measurements across both eyes. Between-group comparisons were performed using ANCOVA with age as a covariate.

Results: After adjustment for age, the iRBD cohort showed significantly prolonged pupillary constriction latency compared with controls (239.3 ms, SD=34.3 ms vs. 215.6 ms, SD=37.9; $p=0.002$). No significant group differences were found in other parameters. Age significantly influenced most pupil size-related measures.

Conclusion: Pupillometry identified prolonged pupillary constriction latency in iRBD, consistent with early parasympathetic dysfunction. However, latency alone is unlikely to represent a robust marker. Further studies exploring its relationship with other clinical or laboratory biomarkers are warranted.

Disclosure: Supported by NW24-04-00456 and NW25-04-0079.

EPO-0936 | Association of endoplasmic reticulum stress and BDNF levels with disease severity and sleep quality in patients with restless legs syndrome

C. Birimoglu Okuyan¹; H. Okuyan²; E. Çiçekli³; Ş. Ayçiçek Özen²; D. Kotan³

¹Department of Public Health Nursing, Sakarya University, Sakarya, Türkiye; ²Department of Physiotherapy and Rehabilitation, Sakarya University of Applied Sciences, Sakarya, Türkiye; ³Department of Neurology, Sakarya University, Sakarya, Türkiye

Background and aims: Restless legs syndrome (RLS) is a neurological condition associated with a significant socioeconomic burden and reduced quality of life. Endoplasmic reticulum (ER) stress can trigger adverse cellular processes, including inflammation and cell death, and has been implicated in various neurological disorders. Brain-derived neurotrophic factor (BDNF) plays a crucial role in neuroplasticity, neuronal development, neuroprotection, and neuronal survival. However, the precise involvement of ER stress and BDNF in the molecular pathogenesis of RLS remains unclear. Therefore, this study aimed to evaluate the expression of ER stress-related proteins and BDNF in patients with RLS, assess their diagnostic potential, and examine their relationships with disease severity, quality of life, sleep quality, depression, and laboratory parameters.

Methods: This cross-sectional study included 35 patients with RLS and 25 healthy controls. Serum concentrations of ER stress-related proteins (ATF6, GRP78, and SERP1) and BDNF were measured using ELISA. Disease severity, sleep quality, quality of life, and depressive symptoms were assessed using validated scales.

Results: Serum levels of ATF6, GRP78, SERP1, and BDNF were significantly higher in patients with RLS compared to healthy controls. Correlation analyses revealed positive associations between these biomarkers and disease severity, as well as poorer sleep quality. ROC analyses indicated that ATF6 levels above 302.05 pg/mL, GRP78 above 1.24 ng/mL, SERP1 above 155.14 pg/mL, and BDNF above 6.50 ng/mL could predict the presence of RLS.

FIGURE 1 Elevated ER stress proteins (ATF6, GRP78, SERP1) and BDNF in Restless Legs Syndrome and their associations with disease severity and sleep quality, highlighting their potential role in RLS pathogenesis and diagnostic value.

Conclusion: These findings provide novel evidence suggesting that ER stress and BDNF may play a significant role in the pathophysiology of RLS and may represent potential biomarkers for disease identification.

EPO-0937 | Interplay between diagnostic features and treatment biomarkers in narcolepsy type 1

B. Tracey¹; M. Olsen¹; K. Galinsky¹; R. Retnam¹; Y. Gong¹; P. Tierney¹; E. Mignot²; D. Volfson¹

¹Takeda Development Center Americas, Inc, Cambridge, USA;

²Stanford Center for Sleep Sciences and Medicine, Stanford University, Palo Alto, USA

Background and aims: Physiological features with diagnostic utility may also serve as disease-specific prognostic and treatment-response biomarkers. Here we study features emerging from recent work on multimodal diagnosis of narcolepsy type 1 (NT1), integrating sleep phenotyping, genetics, and artificial intelligence. We explore how these features change in individuals treated with oreporexton, an oral orexin receptor 2-selective agonist, in one phase 2 trial (NCT05687903) and two phase 3 trials (The First Light [FL]: NCT06470828; The Radiant Light [RL]: NCT06505031).

Methods: Participants with NT1 were randomized to receive oreporexton (dose varied by trial) or placebo. Nocturnal polysomnography (nPSG) was collected at baseline and at end of treatment. Maintenance of Wakefulness Tests (MWTs) were performed after each PSG night. In addition to manual scoring, nPSG and MWT data were analyzed to compute hypnodeltadensities from which overall sleep probability and NT1 diagnostic scores were calculated. Several NT1-relevant sleep features were also evaluated. Treatment effects were evaluated with baseline-adjusted models.

Results: Early-night rapid eye movement (REM) features known to be elevated in NT1 were reduced with oreporexton versus placebo, including first-quarter time in REM ($p < 0.001$ in all trials and treatment arms) and NT1-specific transitions (REM to/from Wake or N1). The nPSG-based NT1 diagnostic score was reduced in FL and RL 2 mg/2 mg arms versus placebo (both $p < 0.05$). In oreporexton-treated participants, MWT sleep probability was reduced versus placebo ($p < 0.05$, Phase 2), consistent with reduced daytime sleepiness.

Conclusion: Diagnostic NT1 features responded significantly to oreporexton treatment, reflecting reduced daytime sleepiness and fewer sleep abnormalities.

EPO-0938 | Sleep biomarkers of stroke-related delirium: The STORM study

E. Rollo¹; V. Brunetti²; F. Colò³; M. de Scisciolo³; R. Di Iorio²; M. Monforte²; A. Broccolini²; G. Frisullo²; P. Calabresi²; G. Della Marca²

¹Center for Neurodegenerative Diseases and the Aging Brain, University of Bari Aldo Moro at Pia Fondazione "Card. G. Panico", Tricase, Italy; ²Neurology Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; ³Department of Neurosciences, Università Cattolica del Sacro Cuore, Rome, Italy

Background and aims: Delirium is a frequent complication after acute stroke and is associated with worse outcomes. Sleep disturbances are common after stroke and may contribute to delirium, but evidence based on objective sleep measures is limited. The aim of this study is to investigate the association between sleep alterations and post-stroke delirium, and to assess their impact on 90-day functional outcome.

Methods: We retrospectively analyzed patients with acute ischemic stroke who underwent overnight bedside polysomnography during stroke unit hospitalization. Delirium was diagnosed using DSM-5 criteria. Functional outcome at 90 days was assessed using the modified Rankin Scale (mRS).

Results: The cohort included 128 patients (mean age 70.8 ± 12.6 years, 53.1% females); delirium occurred in 28.9% of patients. Patients with delirium were older and had more severe strokes. Delirium was associated with lower sleep efficiency (SE) ($p = 0.041$), higher wake after sleep onset ($p = 0.047$), and lower REM% ($p < 0.001$). In multivariate analysis, lower SE independently predicted delirium (aOR 0.964, $p = 0.010$), along with higher stroke severity. At 90 days, delirium was strongly associated with poor functional outcome (mRS > 2). Unfavorable outcome was also linked with reduced SE ($p = 0.032$), shorter total sleep time ($p = 0.015$), reduced REM% ($p < 0.001$), higher nocturnal heart rate ($p = 0.035$), and increased daytime sleep ($p = 0.002$). Delirium, diabetes, and daytime sleep (aOR = 0.984; $p = 0.037$) independently predicted poorer recovery.

Conclusion: Reduced sleep efficiency is an independent risk factor for post-stroke delirium, and sleep-wake disturbances are associated with worse long-term outcomes. Sleep assessment in acute stroke may help identify patients at risk for delirium and represents a potential target for interventions to improve stroke prognosis.

Disclosure: Nothing to disclose.

EPO-0939 | Sleep disorders in dementia with Lewy bodies: A prospective cohort study

E. Rollo¹; L. Tamburrino¹; D. Urso¹; A. Valguarnera¹; D. Vilella¹; G. Volpe¹; M. Sozzo¹; A. Giugno¹; A. Anastasia²; V. Gnani¹; G. Logroscino¹

¹Center for Neurodegenerative Diseases and the Aging Brain, University of Bari Aldo Moro at Pia Fondazione "Card. G. Panico", Tricase, Italy; ²Department of Nuclear Medicine, Pia Fondazione "Card. G. Panico", Tricase, Italy

Background and aims: Sleep disturbances are highly prevalent in Dementia with Lewy Bodies (DLB), yet their role in the clinical phenotype remains under-investigated. This study

evaluates sleep disorders prevalence in DLB patients and their correlations with cognitive, and neuropsychiatric symptoms.

Methods: Consecutive patients with probable DLB or DLB-Mild Cognitive Impairment (McKeith criteria 2017/2020) were enrolled in a tertiary neurodegenerative diseases clinic. All participants underwent a standardized diagnostic protocol, including neuropsychological assessment, and Dopamine Transporter (DAT) scan. Sleep was assessed in all patients both subjectively with questionnaires and objectively with overnight in-lab video-polysomnography (VPSG).

Results: Thirty DLB patients (mean age 73.1 years; 60% males) were included. REM Behavior Disorder was diagnosed in 85.7% and insomnia in 50% of patients. Periodic limb movements (PLM > 15/h) were observed in 71.4%. Prevalence of Obstructive Sleep Apnea and Excessive Daytime Sleepiness was respectively 25% and 32.1%. Overall poor sleep quality was reported by 78.5% of patients. Worse performances in executive functions correlated with lower REM% ($p=0.008$), and higher PLM index ($p=0.024$), while worse performances in visuospatial functions correlated with higher N1% ($p=0.009$). Lower mean saturation during sleep correlated with higher severity of visual hallucinations ($p=0.038$). Lower DAT uptake in the caudate correlated with lower Sleep Efficiency ($p=0.022$), lower N3% ($p=0.028$), and higher PLM index ($p=0.045$). Finally, Insomnia Severity Index ($p=0.021$) and Epworth Sleepiness Scale ($p=0.018$) inversely correlated with putamen uptake.

Conclusion: Sleep disorders are highly prevalent in DLB, being associated with worse cognitive functions and more severe neuropsychiatric symptoms. Reduced striatal uptake is associated with worse quality sleep, higher insomnia and daytime sleepiness.

Disclosure: Nothing to disclose.

EPO-0940 | Effect of oreporexton (TAK-861) on cognitive symptoms in patients with narcolepsy type 1: Pooled data from two phase 3 trials

F. Pizza¹; Y. Dauvilliers²; R. Del Rio Villegas³; G. Lammers⁴; G. Plazzi⁵; T. Scammell⁶; T. Banerjee⁷; A. Cai⁷; P. Maruff⁸; H. Romero⁷; E. Stukalin⁷; B. Harel⁷

¹Department of Biomedical and Neuromotor Sciences, University of Bologna and IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, ²Sleep-Wake Disorders Center, Department of Neurology, Gui-de-Chauliac Hospital, CHU, Institute of Neurosciences of Montpellier, INSERM, University of Montpellier and National Reference Network for Narcolepsy, Montpellier, France, ³Neurophysiology and Sleep Disorders Unit, Vithas Hospitals and Department of Clinical Medical Sciences, Universidad Ceu San Pablo, CEU Universities, Madrid, Spain, ⁴Sleep Wake Centre, Stichting Epilepsie Instellingen Nederland, Heemstede and Department of Neurology, Leiden University Medical Centre, Leiden, Netherlands, ⁵Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio-Emilia, Modena and IRCCS, Istituto delle Scienze Neurologiche, Bologna, Italy, ⁶Department of Neurology, Beth Israel Deaconess Medical Center and Boston Children's Hospital, Boston, USA, ⁷Takeda Development Center Americas, Inc, Cambridge, USA, ⁸Cogstate, Melbourne, Victoria, Australia

Background and aims: Cognitive symptoms are frequent and disruptive in narcolepsy type 1 (NT1). Using pooled data from

two randomized, double-blind, phase 3 studies (The First Light: NCT06470828; The Radiant Light: NCT06505031) we report the effect of oreporexton (TAK-861) on cognitive symptoms in participants with NT1.

Methods: Participants aged 16–70 years diagnosed with NT1 were randomized to twice daily oral oreporexton 1 mg (The First Light only), 2 mg, or placebo, ≥ 3 hours apart for 12 weeks. Cognitive impairment was assessed with neuropsychological tests of attention (Psychomotor Vigilance Test [PVT] from 2 intraday sessions [9 am, 3 pm]), memory (Continuous Paired Associate Learning, CPAL) and executive function (International-Digit Symbol Substitution Test-Symbols, IDSST-S; One-Back Test, ONB). Patient-reported cognitive difficulties were assessed with the Functional Impacts of Narcolepsy Instrument Cognitive Function domain (FINI-CF) and British Columbia Cognitive Complaints Inventory (BC-CCI). For both trials, PVT and FINI-CF were secondary endpoints while the remainder were exploratory.

Results: Overall, 273 participants were randomized to oreporexton 1 mg/1 mg ($n=61$), 2 mg/2 mg ($n=136$), or placebo ($n=76$). Compared with placebo, 12-week of treatment with oreporexton (1 mg/1 mg or 2 mg/2 mg) resulted in improvement from baseline for each objective (PVT, CPAL, IDSST-s, ONB) and subjective (FINI-CF; BC-CCI) cognitive assessment. Group mean differences from placebo in change from baseline scores for each cognitive assessment are shown in Table 1.

Conclusion: The benefit to cognition based on both objective neuropsychological tests and subjective ratings of cognition, following 12 weeks treatment, indicates that oreporexton reduces cognitive symptoms in NT1.

Disclosure: This research was funded by Takeda Development Center Americas, Inc, who also provided funding to Envision Catalyst, an Envision Medical Communications agency, a part of Envision Pharma Group, to provide writing assistance under the direction of the authors. Fabio Pizza participated in an advisory board for Takeda and received support for congress participation and funding from Bioprojet. Yves Dauvilliers received funds for seminars, board engagements, and travel to conferences from Avadel, Bioprojet, Idorsia, Jazz Pharmaceuticals, Centessa,

TABLE 1 Group mean (least square and 95% CI) difference between oreporexton and placebo for endpoints from the objective and subjective cognitive assessments at week 12 in adults with NT1.

Cognitive Endpoint*	Oreporexton 1 mg/1 mg	Oreporexton 2 mg/2 mg
Objective neuropsychological tests		
Psychomotor Vigilance Test: number of lapses	-18.29 (-13.27, -23.32)	-10.87 (-12.86, -7.34)
P value	<0.0001	<0.0001
Continuous Paired Associate Learning: number of errors	-20.03 (-27.81, -12.14)	-18.77 (-26.76, -12.76)
P value	<0.0001	<0.0001
International-Digit Symbol Substitution Test: number of correct responses	14.37 (10.31, 18.42)	13.41 (12.20, 14.61)
P value	<0.0001	<0.0001
One-Back Test: speed of performance	-0.58 (-6.12, -0.04)	-0.18 (-6.12, -0.07)
P value	<0.0001	<0.0001
Subjective ratings of cognitive difficulties		
Functional Impacts of Narcolepsy: Impaired Cognitive Function domain	-30.42 (-37.73, -23.11)	-34.12 (-38.77, -29.47)
P value	<0.0001	<0.0001
British Columbia Cognitive Complaints Inventory	-4.44 (-5.65, -3.23)	-5.88 (-6.01, -4.15)
P value	<0.0001	<0.0001

*For all tests except the IDSST negative signs for group mean differences indicated a benefit of oreporexton versus placebo. For IDSST a positive sign indicates benefit of oreporexton versus placebo. Change from baseline is placebo-adjusted. In this analysis all P values are unadjusted.

EPO-0941 | Improving automatic sleep stage scoring for narcolepsy through fine-tuning with data from central disorders of hypersomnolance

H. Thrainsson; Z. Zhang; K. Gevorgyan; J. Tepperberg; T. Lerchmüller; R. Khatami
Center of Sleep Medicine & Epileptology, Clinic Barmelweid, Barmelweid, Switzerland

Background and aims: Sleep stage classification is essential for narcolepsy diagnosis but remains time-intensive. Current deep learning models, trained primarily on healthy controls and patients with common sleep disorders have, show reduced performance on narcolepsy patients due to the condition's low prevalence and distinct sleep patterns. We investigated whether fine-tuning with data from central disorders of hypersomnolance (CDH) could improve automatic sleep stage classification in narcolepsy patients.

Methods: We employed a CNN-Transformer network predicting sleep stages from one EOG and three EEG channels from overnight polysomnography. The baseline model was trained on 58 healthy controls, 18 OSA patients and 78 insomnia patients. Fine-tuning used 15 insomnia patients, 7 OSA patients, 3 narcolepsy type 1 (NT1) patients, 4 narcolepsy type 2 (NT2) patients, 24 patients with other sleep disorders, and 23 narcolepsy borderland patients. Testing included 9 NT1, 6 NT2 and 8 narcolepsy borderland patients.

Results: The baseline model achieved Cohen's kappa of 0.72 and accuracy of 79%. Fine-tuning improved kappa to 0.75 ($p=0.002$) and accuracy to 81% ($p=0.002$). N1 detection improved with kappa increasing from 0.46 to 0.54 ($p<0.001$) and sensitivity from 45% to 56% ($p<0.001$). REM stage detection showed kappa improvement from 0.77 to 0.79 ($p<0.001$), and specificity from 93% to 97% ($p<0.001$).

Conclusion: Fine-tuning with rare sleep disorder data improved automatic sleep stage classification in narcolepsy patients. Enhanced N1 classification enables more precise sleep-onset and fragmentation assessment, while improved REM stage detection facilitates SOREMP identification. These results demonstrate that targeted fine-tuning can bridge performance gaps between common and rare sleep disorders in automated scoring.

Disclosure: Nothing to disclose.

EPO-0942 | Does age matter? Subjective and objective responses to hypoglossal nerve stimulation in older patients with obstructive sleep apnea

H. Moon¹; U. Cho²; C. Lee³; K. Im⁴

¹Department of Neurology, Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea; ²Department of Psychiatry, Inha University Hospital, Incheon, Republic of Korea; ³Department of Internal Medicine and Lung Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; ⁴Department of Clinical Psychiatry and Human Behavior, University of California, Irvine, USA

Background and aims: Obstructive sleep apnea (OSA) is common in elderly and is associated with higher CPAP failure rates due to comorbid sleep disorders and cognitive decline. Hypoglossal nerve stimulation (HNS) has emerged as an alternative treatment for OSA; however, data on age-related treatment response remain limited.

Methods: We retrospectively analyzed 82 patients who underwent HNS implantation for OSA, stratified into ≤ 65 years ($n=29$) and >65 years ($n=53$). Subjective benefit was assessed at 12 months using a three-point scale: very satisfied (2), somewhat satisfied (1), and dissatisfied (0). Treatment success was defined as a $\geq 50\%$ reduction in apnea-hypopnea index (AHI) from baseline polysomnography to 12-month home sleep test, with a final AHI ≤ 20 events/hour.

Results: Baseline polysomnographic parameters did not differ between age groups. During the HNS titration study, patients >65 years showed higher periodic limb movement index, longer sleep latency, and shorter total sleep time, while apnea-hypopnea index (AHI) was similar between groups. At 12-month home sleep testing, total AHI did not differ by age; however, the >65 -year group demonstrated lower supine AHI and oxygen desaturation index, along with significantly greater subjective satisfaction. Overall treatment success was achieved in 42 patients (51.2%), with similar success rates in the >65 -year group (56.6%) and the ≤ 65 -year group (41.4%).

Conclusion: Despite less favorable sleep-related findings during titration, older patients reported greater subjective satisfaction after HNS, with objective treatment success comparable to younger patients. Advanced age should not be considered a limiting factor for HNS therapy.

Disclosure: Nothing to disclose.

EPO-0943 | Telemedicine consultation as diagnostic triage for adult and children with suspected narcolepsy: The TENAR reliability and diagnostic accuracy study

Background and aims: Sleep centres specialised in the care of narcolepsy are few and scattered in terms of countries and regions in countries distribution. Telemedicine consultation (TMC) could be important in guiding the diagnostic workup in cases where symptoms suggesting narcolepsy are present in people far from sleep centres. This study aimed at assessing the

FIGURE Diagram of participant flow in the reliability and diagnostic accuracy studies.

inter-procedural reliability (compared to the in-office consultation) and the diagnostic accuracy of the TMC when excessive daytime sleepiness (EDS) due to narcolepsy is suspected.

Methods: Cross-sectional diagnostic study (2019–2023). Consecutive people of any age referred for EDS complaint to the Clinic for Narcolepsy in Bologna. The TMC was conducted via tablet for the patient, and via equipped personal computer in another room for the physician (interviewer). Interviewers expressed diagnostic orientation indicating narcolepsy as “probable”, “possible”, “excluded”. The final diagnosis was established by applying the ICSD-3 criteria. Inter-procedural reliability (Kappa statistics) and diagnostic accuracy measures were assessed.

Results: 221 participants were included in the reliability study, 198 in the diagnostic accuracy study. The agreement between the two consultation modalities on diagnostic orientation was “substantial” (Kappa 0.74, 95% CI 0.66–0.82). Agreement on the narcoleptic pentad symptoms was “substantial” (EDS, hypnagogic hallucinations, disrupted nocturnal sleep) or “almost perfect” (cataplexy, sleep paralysis). Telemedicine and in-office consultation had identical sensitivity (100%, 95% CI 94–100) and similar specificity (43%, 95% CI 35–52, vs 40%, 95% CI 32–49).

Conclusion: TMC is a reliable diagnostic triage procedure when EDS possibly due to narcolepsy is suspected, in particularly to exclude people who do not suffer from narcolepsy without the risk of false negatives.

Disclosure: Nothing to disclose.

M. Watt¹; S. Crawford¹; I. Ubillos²; B. Podmore²; A. Azpeitia²; J. Knop³; A. Kitchin²; D. Obermueller⁴; R. Norris⁴; R. Almeida Schreck⁵

¹Takeda Development Center Americas, Inc, Cambridge, USA; ²OXON Epidemiology, Madrid, Spain; ³Takeda Pharma Vertrieb GmbH & Co. KG, Berlin, Germany; ⁴InGef – Institute for Applied Health Research Berlin GmbH, Berlin, Germany; ⁵Sleep Medicine Center, Clinic and Polyclinic for Psychiatry and Psychotherapy, Regensburg, Germany

Background and aims: Narcolepsy (types 1 and 2) is a neurologic hypersomnolence disorder defined by a range of symptoms including excessive daytime sleepiness (EDS) and cataplexy (type 1 only). The study evaluated the incidence, prevalence and burden of narcolepsy in Germany.

Methods: Retrospective cohort study using anonymized health-care claims data involving 8.2 million people within the InGef database (2018–2023). Cohorts included pre-existing narcolepsy cases (PCN), incident narcolepsy cases (ICN) and controls (Figure 1).

Results: A total of 1,757 narcolepsy cases were identified; 1,163 PCN and 594 ICN. Mean (SD) age was 40.13 (19.52) for ICN and 48.11 (18.1) for PCN cohorts. 13% of ICN and 4% of PCN were children/adolescents (<18 years). Overall (2018–2023) prevalence per 100,000 people was 21.29 (95% CI: 20.30–22.31); annual incidence decreased from 1.93 to 1.18 per 100,000 people between 2018 and 2023 (Figure 2). Overall prevalence and annual incidence were higher in adults (≥18 years) vs. children/

adolescents (prevalence: 25.13 vs 7.10 per 100,000; annual incidence, 2018–2023: 1.27–2.08 vs 0.60–1.38 per 100,000, respectively), with comparable rates in males and females. Comorbidities were more frequent in ICN and PCN vs. controls, including non-narcolepsy sleep disorders (42.6% and 45.4% vs. 7.4%, respectively), psychiatric disorders (43.9% and 58.5% vs. 20.6%), and nervous system diseases (50.3% and 47.7% vs. 22.0%). The most frequently prescribed narcolepsy medications in ICN were modafinil (122 [24.95%] patients) and methylphenidate (43 [8.8%] patients).

Conclusion: This study provides robust estimates of incidence, prevalence and comorbidity burden associated with narcolepsy within the German population relative to controls.

Disclosure: Funding by Takeda Development Center Americas, Inc, who also provided funding to Envision Catalyst, an Envision Medical Communications agency, a part of Envision Pharma Group, to provide writing assistance under the direction of the authors.. InGef acted as subcontractor and received funding from WIG2 for execution of the analysis. Neurological Manifestation of Systemic Diseases

EPO-0946 | Paroxysmal events in leptomenigeal carcinomatosis: The role of video-EEG in differentiating seizures from intracranial hypertension

C. Baiata; R. Brusa; E. Verrengia; S. Leva; L. Politini; G. Toscano

Department of Neurology, ASST-Ovest Milanese, Legnano, Italy

Background and aims: The objective of this study is to describe a case of leptomenigeal carcinomatosis (LC) presenting with recurrent transient neurological events (TNEs). We aim to emphasize the critical importance of a comprehensive diagnostic work-up, including video-electroencephalography (video-EEG), to correctly differentiate these paroxysms from focal epilepsy.

Methods: We report the case of a 41-year-old woman with a remote history of breast cancer on negative follow-up, presenting with recurrent episodes of intense headache and neck pain, tinnitus, upper limbs paraesthesia, right ptosis, and left hemiparesis with variable loss of consciousness (3–5 minutes). The work-up included brain computed tomography angiography (CTA), magnetic resonance imaging (MRI), video-EEG monitoring, and a lumbar puncture (LP).

Results: Brain imaging showed no pathological findings, while standard EEG showed focal slow anomalies. Thus, an initial suspicion of focal epilepsy was raised, and anti-seizure medications

FIGURE 1 Study design.

FIGURE 2 Prevalence and incidence.

FIGURE 1

FIGURE 2

FIGURE 3

(ASMs) were started, which were ineffective. Video-EEG during an episode showed paroxysmal posterior bi-hemispheric monomorphic delta activity and subsequently generalized rhythmic delta activity (GRDA), without electrographic seizures. Subsequent LP revealed a high opening pressure of 32 cmH₂O and EpCAM-positive malignant cells. Body CT scan confirmed breast cancer recurrence. A diagnosis of LC with transient elevations in intracranial pressure (ICP) was made. Events resolved following CSF drainage and the introduction of acetazolamide.

Conclusion: Paroxysmal events in LC are not always epileptic; they may result from transient ICP increases known as “plateau waves”. These may cause brainstem dysfunction by reducing cerebral perfusion pressure. Video-EEG is essential to redefine the setting of recurrent, atypical TNEs, preventing inappropriate ASM use.

Disclosure: Nothing to disclose.

EPO-0947 | Presentation, treatment and outcome of a first stroke-like episode in a carrier of the compound heterozygous variants c.695G>A and c.2209G>C in POLG

J. Finsterer¹; D. Zieglgänsberger²

¹Neurology and Neurophysiology Center, Vienna, Austria;

²Kantonsspital St. Gallen, St. Gallen, Switzerland

Background and aims: A patient with two heterozygous POLG variants in different exons, which manifested phenotypically as polyneuropathy and later with a first stroke-like episode (SLE) and seizures, has not yet been reported.

Methods: Case report

Results: The patient is a 19-year-old female who has suffered from POLG-related neuropathy since the age of 14 and was admitted for her first SLE, which manifested clinically as hemianopia and two days later led to impaired consciousness, hemiparesis, seizures and status epilepticus. Cerebral MRI showed a corresponding stroke-like lesion (SLL) in the right occipital lobe. The seizures were treated with levetiracetam, lacosamide and perampanel, but the treatment of status epilepticus required anesthesia with thiopental, ketamine and midazolam. In addition, glucocorticoids, NO precursors and antioxidants were administered. Under this treatment, the SLL initially increased in size and intensity before regressing. After extubation, a recurrent focal motor status epilepticus occurred, which could be stopped with midazolam. Since then, she has remained seizure-free and recovered completely

Conclusion: This case shows that POLG mutations can initially manifest phenotypically with polyneuropathy and SLE that SLE occurs before the onset of seizures, that status epilepticus due to POLG variants may require thiopental anesthesia and that levetiracetam, lacosamide and perampanel may have a favorable long-term effect on seizure activity in carriers of POLG mutations

Disclosure: Nothing to disclose.

EPO-0948 | Beyond the classic triad: Sudden hearing loss and demyelinating polyneuropathy in wernicke encephalopathy

L. Caballero Sánchez; M. Vargas Cobos; A. De Luca; R. Alfonso González; M. Capra; C. Gómez López de San Román; I. Bermejo Casado; D. Cerdán Santacruz; A. Castrillo Sanz; A. Mendoza Rodríguez

General Hospital of Segovia, Segovia, Spain

Background and aims: Wernicke encephalopathy (WE) is an acute neurological disorder caused by thiamine deficiency, classically defined by the triad of encephalopathy, ocular signs, and gait ataxia. However, this triad is present in a minority of patients, and several atypical manifestations have been described. Among them, sudden sensorineural hearing loss and peripheral neuropathy are uncommon but increasingly recognized features.

Methods: We report a single case of WE presenting with atypical neurological manifestations. Clinical findings, laboratory results, neuroimaging, electrophysiological studies, and response to treatment were retrospectively reviewed.

Results: A 46-year-old man with chronic alcohol abuse and pre-existing hypoacusis presented with sudden hearing loss of

one-week duration, associated with disorientation and progressive gait disturbance. Brain MRI showed characteristic lesions consistent with WE. Laboratory evaluation revealed hypertransaminasemia and multiple vitamin deficiencies. Paraneoplastic and autoimmune studies were negative. Electromyography demonstrated a demyelinating sensorimotor polyneuropathy, a finding that has been previously reported in WE and is likely related to severe thiamine deficiency and nutritional deficits. High-dose intravenous thiamine was promptly initiated, leading to marked clinical improvement, particularly in cognitive function and gait, although mild to moderate ataxia persisted at discharge.

Conclusion: This case highlights sudden sensorineural hearing loss and demyelinating polyneuropathy as atypical but documented manifestations of Wernicke encephalopathy. Thiamine deficiency can affect both central and peripheral nervous systems, including auditory pathways and peripheral nerves. Awareness of these non-classical features is essential to avoid diagnostic delay and to initiate timely thiamine treatment, thereby reducing the risk of permanent neurological damage.

Disclosure: Nothing to disclose.

EPO-0949 | Large vessel vasculitis and Ischemic stroke: A 10-year experience in Seville, Spain

L. Manzano-Hernandez; A. Luque Ambrosiani; L. Fernández Espigares; J. Román Rueda; P. García Nuñez; A. Palomino García; F. Hernández Ramos

Department of Neurology, Virgen del Rocío University Hospital, Seville, Spain

Background and aims: Ischemic stroke (IS) and transient ischemic attack (TIA) are rare but severe manifestations of large vessel vasculitis, including giant cell arteritis and Takayasu arteritis, with limited evidence guiding management.

Methods: Single-center retrospective database review of patients with GCA or TAK presenting with IS/TIA between 2014 and 2024 at a tertiary stroke center in Seville, Spain.

Results: Fifteen patients with LVV-related ischemic stroke were identified: 9 GCA-related, 5 TAK-related, and one with overlapping GCA/TAK. Median age was 64 years (range 40–86), and 66% (9/15) were female. In 13 cases, IS was the presenting manifestation leading to LVV diagnosis. Vertebral artery stenosis was observed in 67% of GCA patients, while all TAK patients had internal carotid artery (ICA) stenosis; the overlapping case showed both. Acute treatments included fibrinolysis (6.7%), thrombectomy (13%), and angioplasty with stenting (20%). For secondary prevention, 80% received dual antiplatelet therapy and 87% full-dose prednisone, with adjunctive immunosuppressors in four cases; two required treatment switch due to refractory disease. Tocilizumab was initiated after the first IS in one patient with prior TAK. At 90 days, 14 patients had mRS ≤ 3 , four experienced recurrent IS/TIA, and one TAK relapse was observed.

Conclusion: Although ischemic stroke secondary to LVV is uncommon, in our cohort, 87% of cases of GCA and TAK had IS as the initial presentation, highlighting the importance of having a high index of suspicion, which can guide clinical decision-making.

Disclosure: Nothing to disclose.

EPO-0950 | Neurological complications of infective endocarditis: Retrospective study

M. Perdicoulis; N. Ribeiro; J. Pona-Ferreira; S. Lima; M. Mendes

Neurology Department, Unidade Local de Saúde de Trás-os-montes e Alto Douro, Vila Real, Portugal

Background and aims: Infective endocarditis (IE) is an infectious disease of the endocardial surface, mostly involving heart valves and cardiac devices. It presents with a wide spectrum of clinical manifestations and may affect multiple organ systems. Neurological complications are the most frequent extra-cardiac manifestations and are associated with significant morbidity and mortality.

Methods: We conducted a retrospective study reviewing electronic medical records of 158 patients diagnosed with IE at our hospital between 2017 and 2025.

Results: IE predominantly affected men (70.3%), the mean age of patients being 68.8 ± 14.6 years. The aortic valve was most frequently involved (46.2%), followed by the mitral valve (30.4%). Prosthetic valve involvement was observed in 30.4% of cases. *Staphylococcus aureus* was the most frequently identified pathogen (24%). Overall mortality rate was 28.5%. Neurological complications occurred in 24.1% of patients, most commonly ischemic stroke (57.9%), followed by encephalopathy (34.2%). Neurological symptoms were the initial manifestation in 50% of patients with neurological affection. A statistically significant association was found between the presence of neurological complications and mortality. Older age was associated with a higher frequency of neurological complications, whereas no association was observed with sex or the affected valve.

Conclusion: Neurological complications in the context of IE are fairly frequent, and often constitute the initial manifestation, with ischemic stroke being the most common manifestation. Their occurrence is significantly associated with mortality. Advanced age appears to be a predictive factor for neurological involvement. These findings emphasise the importance of early recognition and multidisciplinary management, particularly in older patients.

Disclosure: Nothing to disclose.

EPO-0951 | Cognitive function and sleep disturbances in rheumatoid arthritis: Clinical and inflammatory correlates

M. Yakubova; N. Abdurakhmanova; M. Abzalova; C. Rustamova

Department of Neurology and Medical Psychology, Tashkent State Medical University, Uzbekistan

Background and aims: This study aimed to evaluate cognitive function and sleep quality in RA and their associations with disease activity and inflammation.

Methods: This cross-sectional study included 68 RA patients (ACR/EULAR 2010). Cognitive function was assessed with MMSE and MoCA, sleep with the Munich Chronotype Questionnaire (MCTQ) and Epworth Sleepiness Scale (ESS). Disease activity and inflammation were measured using DAS28 and CRP. Patients were divided into two equal groups: with

cognitive impairment ($n=34$, 50%) and without ($n=34$, 50%). Sleep quality, cognitive scores, and inflammatory markers were compared between groups.

Results: Cognitive impairment was present in 50% of patients. Among these, 76% reported excessive daytime sleepiness (ESS > 10), 68% fatigue, 62% attention deficits, 59% memory complaints, and 53% poor sleep duration/quality (MCTQ midpoint > 03:00). Patients without cognitive impairment reported lower rates: 29% excessive sleepiness, 35% fatigue, 24% attention deficits, and 21% memory complaints. DAS28 and CRP were higher in the cognitively impaired group (DAS28 5.4 ± 0.6 vs 3.8 ± 0.5 ; CRP 23.1 ± 8.9 mg/L vs 9.2 ± 4.7 mg/L; $p < 0.001$). A significant positive correlation was observed between sleep disturbances (ESS, MCTQ) and cognitive impairment severity (MoCA $r = -0.48$, MMSE $r = -0.43$; $p < 0.01$) and with inflammatory activity.

Conclusion: Sleep disturbances are common in RA and closely associated with cognitive impairment and inflammation. Routine assessment may allow earlier identification of at-risk patients and support multidisciplinary management.

Disclosure: Nothing to disclose.

EPO-0952 | Universal neurological involvement in triple-A syndrome: Evidence from the largest genetically confirmed cohort

Background and aims: Triple-A (AAAS, Allgrove) syndrome is a rare autosomal recessive disorder caused by biallelic mutations in the AAAS gene, which encodes ALADIN, a nuclear pore complex protein. It is classically defined by achalasia, alacrima, and adrenal insufficiency. While traditionally viewed as an endocrine disorder, increasing evidence suggests broader systemic involvement. Neurological symptoms such as neuropathy and dysautonomia have been described but remain poorly characterized and are often underrecognized. This study aimed to systematically define the neurological phenotype and underlying genetic landscape in the largest genetically confirmed AAAS cohort to date.

Methods: We analyzed 47 individuals with genetically ($n=43$) or clinically ($n=4$) confirmed AAAS from 13 international centers. All underwent standardized neurological assessment. Nerve conduction studies ($n=18$), electromyography ($n=10$), muscle MRI ($n=3$), and skeletal muscle proteomics ($n=2$) were performed. Genetic analysis identified variant types and frequencies; genotype-phenotype correlations were explored.

Results: Neurological manifestations were universal. Motor weakness (84%), hyperreflexia (80%), autonomic dysfunction (91%), and gait instability (92%) were predominant. Electrophysiology showed length-dependent axonal neuropathy; EMG confirmed chronic neurogenic changes. MRI revealed

FIGURE 1 Graphical Abstract. Multisystem neurological involvement and genetic spectrum in Triple-A syndrome.

symmetric denervation. Proteomics identified consistent dysregulation of cytoskeletal, metabolic, and extracellular matrix pathways. Genetic testing revealed nine previously unreported AAAS variants. The most frequent variant, c.787T>C (p.Ser-263Pro), was found in 18 individuals, 17 of Serbo-Croatian origin. Truncating variants were associated with earlier and more severe phenotypes.

Conclusion: Neurological involvement in Triple-A syndrome is early, universal, and clinically defining. Our data support reclassifying the disease as a neurogenetic multisystem disorder, warranting systematic neurological assessment and integrated care.

Disclosure: Nothing to disclose.

EPO-0953 | Inflammation-mediated cognitive impairment following bone fracture

P. Fu

The Fourth Medical Center of the PLA General Hospital, Beijing, China

Background and aims: Bone fracture is increasingly recognized as a risk factor for cognitive dysfunction beyond local tissue injury. However, the temporal characteristics of fracture-induced cognitive impairment and its underlying mechanisms remain unclear. This study investigated the effects of tibial fracture on hippocampus-dependent cognitive function in mice and explored the role of inflammation.

Methods: Male C57BL/6J mice were randomly assigned to fracture (Fx), sham (S), or control (C) groups. Behavioral and molecular assessments were conducted immediately and on postoperative days 7, 14, and 28. Locomotor activity was evaluated using the open field test, while contextual fear conditioning assessed hippocampus-dependent memory. Serum levels of IL-1 β , IL-6, and TNF- α were measured by ELISA. Hippocampal expression of BDNF and PSD95 was analyzed by Western blot, and microglial activation was assessed by Iba1 immunohistochemistry.

Results: Fx mice exhibited significant contextual memory impairment from day 7, peaking at day 14 and partially recovering by day 28, without motor deficits. These cognitive changes were accompanied by sustained peripheral inflammation, excessive hippocampal microglial activation, and downregulation of synaptic plasticity-related proteins.

Conclusion: Bone fracture induces persistent systemic and central inflammation, leading to hippocampus-dependent cognitive impairment. Inflammation may represent a key mechanistic link within the bone-brain axis and a potential therapeutic target.

Disclosure: Nothing to disclose.

EPO-0954 | Double trouble: Fungal brain abscess unmasking a lung malignancy

S. Shree¹; A. Agarwal¹; D. Garg¹; S. Gaikwad²; A. Garg²

¹Department of Neurology, AIIMS, New Delhi, India;

²Department of Neuroimaging and Interventional Neuroradiology

Background and aims: Ring-enhancing brain lesions are commonly attributed to tuberculomas in tuberculosis-endemic regions, often leading to empirical treatment. The objective of this report is to highlight diagnostic challenges and adverse consequences of misattributing ring-enhancing lesions to tuberculosis when alternative etiologies coexist.

Methods: We describe the clinical presentation, neuroimaging findings, systemic evaluation, microbiological studies, and histopathological confirmation in a patient initially treated for presumed central nervous system tuberculosis and later reassessed at a tertiary care center.

Results: A 48-year-old woman presented with progressive headache followed by focal neurological deficits. She was empirically treated with antitubercular therapy and corticosteroids

FIGURE 1 CT Chest showing left lower lobe lung mass.

FIGURE 2 MRI Brain - T2 FLAIR sagittal section showing ring enhancing lesion with intracavitary projections in frontal lobe and brainstem.

FIGURE 3 PET scan depicting multiple site metastasis.

prior to referral. Magnetic resonance imaging of the brain demonstrated multiple heterogeneous ring-enhancing lesions with diffusion restriction along the wall and intracavitary projections, suggestive of fungal abscess or metastasis. Systemic imaging revealed a left lower lobe lung mass with widespread metastatic disease. Endobronchial ultrasound-guided biopsy confirmed lung adenocarcinoma with epidermal growth factor receptor exon 19 deletion and concomitant *Aspergillus* colonization. Cerebrospinal fluid analysis and infectious workup were negative. Antitubercular therapy and corticosteroids were discontinued, and antifungal therapy with liposomal amphotericin B followed by voriconazole was initiated. Neurological deficits stabilized at three-month follow-up under palliative care.

Conclusion: This case emphasizes the need for cautious evaluation of ring-enhancing brain lesions in tuberculosis-endemic settings. Early tissue diagnosis, multidisciplinary assessment, and careful radiological interpretation are essential to avoid diagnostic delay and treatment-related harm.

Disclosure: Nothing to disclose.

EPO-0955 | Shunting, venous stenting, ONSF, and bariatric surgery for refractory IIH: A systematic review and meta-analysis

T. Elboraay¹; Y. Nabil¹; O. Rageh²; K. AbuElkair³; A. Aboali⁴; A. Alkheder⁵; M. Karam Allah Elkholy⁶; A. Samy Elboraay⁷; M. Alaa Hussein¹; M. Maged¹; M. Taha⁸

¹Faculty of Medicine Zagazig University; ²Faculty of Medicine Tanta University; ³Pediatric Surgery Department, Zagazig University; ⁴Radiology Department Damanhour Teaching Hospital, General Organization for Teaching Hospitals and Institutes; ⁵Faculty of Medicine Damascus University and Syrian Private University; ⁶Faculty of Pharmacy, Zagazig University; ⁷Faculty of Medicine East Port Said National University; ⁸Department of Neurosurgery Faculty of Medicine Zagazig University

Background and aims: Idiopathic intracranial hypertension (IIH) is characterized by elevated intracranial pressure (>25 mm H₂O) without an identifiable cause, mainly affecting obese

women of reproductive age. Patients present with headaches, papilledema, tinnitus, and visual disturbances, with potential vision loss. First-line treatment includes medical therapy and lifestyle modification, but optimal surgical management for medically refractory cases remains debated

Methods: A systematic review and meta-analysis were conducted. PubMed, Web of Science, Cochrane Library, and Scopus were searched until March 2024. Studies evaluating surgical interventions for IIH, including cerebrospinal fluid (CSF) diversion, dural venous sinus stenting (VSS), optic nerve sheath fenestration (ONSF), and bariatric surgery, were included. Data on clinical outcomes, visual parameters, complications, and re-intervention rates were pooled.

Results: A total of 119 studies were included: 2,561 CSF-diversion procedures, 888 VSS placements, 1,189 ONSF procedures, and 249 bariatric surgeries. Improvement rates for headaches were 38%, 47%, 36%, and 14%; papilledema 39%, 25%, 10%, and 14%; tinnitus 27%, 27%, and 14%; and visual field defects 32%, 43%, 33%, and 72% for CSF diversion, VSS, ONSF, and bariatric surgery, respectively. Visual acuity improved most with bariatric surgery (33%, 57%, 31%, and 71%). Bariatric surgery had the lowest rates of subsequent procedures (0%) and lowest minor and major complications (1% each)

Conclusion: Dural venous sinus stenting and bariatric surgery showed favorable clinical and visual outcomes with lower complication and reintervention rates than traditional surgical approaches. These interventions may represent among the most effective options for medically refractory IIH.

Disclosure: Nothing to disclose.

EPO-0956 | Brain health awareness among solid organ transplant candidates and recipients: A single centre survey

V. Lo Re¹; E. Lo Gerfo¹; M. Rizzo²; V. Agnese²; I. Colonna³; A. Toscano⁴; M. Pinzani²

¹Neurology Service, Istituto Mediterraneo per i Trapianti e Terapie ad Alta Specializzazione (ISMETT) - Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS); ²Department of Research, Istituto Mediterraneo per i Trapianti e Terapie ad Alta Specializzazione (ISMETT) - Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Palermo, Italy; ³Complex Operative Unit of Neurology, "F. Ferrari" Hospital, Casarano, Italy; ⁴ERN-NMD Centre for Neuromuscular Disorders of Messina, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy

Background and aims: Solid organ transplant candidates and recipients are a highly vulnerable population for brain disorders variably alongside their transplant history. This population would greatly benefit from brain health programs. In order to set up brain health multidimensional plans targeting patients affected with peripheral organ disease, including solid organ transplant candidates and recipients, we explored their view on brain health

Methods: This study employed a descriptive qualitative methodology to review the answers received through a pencil and paper survey conducted in a single surgical centre. Gender, age, and clinical status differences in brain health awareness were included in our analysis.

FIGURE 1 Peripheal organs influencing brain health on the view of the survey's participants.

FIGURE 1 Barriers to make changes in lifestyle.

Results: A little over half of our respondents, above all women, reported always or often thinking about their brain health. Just over half of our patients exercise regularly and perform cognitively stimulating activities, with this figure being even lower for older patients and men. There is low health literacy on neurology and brain diseases. We have found full recognition that peripheal organ functioning, above all heart, may have an impact on brain health. Lack of time, lack of information on what to do, and lack of motivation emerged as main barriers to enforcing lifestyle changes. Most of our respondents were willing to undergo a cognitive screening test and receive educational information on brain health.

Conclusion: Our survey provided insights on brain health topic previously unexplored among patients affected by non-neurological disorders. The gathered results will be used to implement multidomain interventional brain health plans for transplant candidates and recipients.

Disclosure: This work was supported by a grant of the Italian Ministry of Health, Fondi 5x1000, year 2020 and Ricerca corrente-Linea 2.

Background and aims: Cognitive impairment (CI) is common in chronic kidney disease (CKD) above all in end-stage phases as for kidney transplant (KTx) candidates. The pattern and etiology of CKD-related CI are not well understood, mainly related to mechanisms involving pathogenetic pathways typical of Alzheimer Disease (AD). The aim of this study was to assess the association between cognitive dysfunction and AD-related blood-based biomarkers (BBBs) profile in KTx candidates.

Methods: 119 end-stage CKD patients underwent a cognitive assessment through the Montreal Cognitive Assessment (MoCA) test, Trail Making Test (TMT) A and B and the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). Enrolled participants also underwent Aβ40, Aβ42 and p-tau-217 assessment

Results: demographic and clinical features of our cohort are reported in Table 1 According to equivalent scores of MoCA, 18.5% of our CKD patients resulted cognitively impaired. RBANS detected a greater number of cognitively impaired patients (63.9% with a mild and 12.6% with severe impairment) when a stratification based on severity was performed. Table 2 shows the number and the type of RBANS pathological domains. Plasma Aβ40,

TABLE 2 Frequencies of number and type of RBANS pathological domains.

N of impaired domains	Total number of patients	Immediate Memory	Visuospatial/Executive abilities	Language	Attention	Delayed memory
0	11 (9.2 %)	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
1	20 (16.8 %)	0 (0%)	0 (0%)	8 (40%)	2 (10%)	4 (20%)
2	22 (18.5 %)	16 (72.7 %)	3 (13.6 %)	11 (50 %)	9 (40.9 %)	5 (22.7 %)
3	24 (19.8 %)	13 (58.5 %)	5 (21.5 %)	21 (88.8 %)	24 (100 %)	7 (29.2 %)
4	11 (9.2 %)	29 (100 %)	9 (29 %)	27 (87.1 %)	29 (100 %)	30 (100 %)
5	9 (7.6 %)	9 (100 %)	9 (100 %)	9 (100 %)	9 (100 %)	9 (100 %)

TABLE 3 Biomarkers distribution by cognitive impairment according to RBANS and MoCA.

Biomarkers	RBANS - Cognitive impairment			MoCA - Cognitive impairment		
	No	Yes	P-value	No	Yes	P-value
Aβ42 (pg/ml, median [IQR])	402 (348 - 452)	461 (191 - 209)	0.2229	405 (358 - 446)	462 (241 - 496)	0.4922
Aβ42 (pg/ml, median [IQR])	150 (88 - 129)	133 (116 - 125)	0.1489	111 (88 - 126)	111 (88 - 125)	0.7146
Aβ42/ACβ42 (ratio, median [IQR])	0.1113 (0.0817 - 0.1312)	0.1102 (0.0808 - 0.1307)	0.9887	0.1113 (0.0817 - 0.1312)	0.1102 (0.0808 - 0.1307)	0.9194
p-tau-217 (pg/ml, median [IQR])	0.19 (0.16 - 0.49)	0.09 (0.24 - 0.94)	0.2007	0.18 (0.08 - 0.91)	0.18 (0.11 - 0.48)	0.8810

Aβ42 and p-tau-217 did not showed a significant association with CI as defined by either MoCA or RBANS. However, higher values for these biomarkers were found in cognitively impaired patients (Table 3).

Conclusion: In this exploratory cross-sectional study AD-related BBBs did not reliably discriminate cognitively impaired from unimpaired patients in a cohort of end-stage CKD patients, highlighting the strong influence of alternative pathways beyond amyloid pathology.

Ageing and Dementia 5

EPO-0958 | Cataract surgery, cognitive trajectories, and blood–brain barrier integrity in ageing: A multimodal longitudinal study

A. Garcia Gallardo¹; A. McGlinchey²; K. Robb²; M. Campbell²; S. Hutchinson¹
¹Neurology Department, St James's Hospital, Dublin, Ireland;
²Genetics Department, Trinity College Dublin, Ireland

Background and aims: Sensory impairment is a modifiable contributor to cognitive decline and dementia risk. Cataracts cause progressive visual deprivation and increased perceptual effort, potentially accelerating neurocognitive and neurovascular ageing. Cataract surgery provides a human model of sensory restoration without direct brain intervention. This study examined whether cataract-related visual impairment and its correction are associated with changes in cognition, blood–brain barrier (BBB) integrity, brain structure, and brain-age trajectories in older adults.

Methods: 18 older adults undergoing bilateral cataract surgery were assessed at baseline, 3-months, and 9-months post-surgery. Each visit included assessments of visual function, cognition, neuroimaging, and blood sampling. Cognition was evaluated using the Repeatable Battery for Assessment of Neuropsychological Status-Update, with mood and anxiety monitored for affective confounding. Neuroimaging included dynamic contrast-enhanced MRI to quantify whole-brain BBB permeability and structural imaging for volumetric, cortical thickness, and brain-age analyses. Serum samples were collected for proteomic profiling.

Results: Cataract surgery induced significant visual improvement. Cognitive performance improved across domains, with greatest gains in immediate and delayed memory, independent of affective changes. BBB permeability decreased significantly by 9-months, while structural brain measures remained stable. Brain-age modelling demonstrated slowed ageing trajectories relative to chronological age. Proteomic analysis revealed modest changes in proteins related to cellular and metabolic regulation, without inflammatory activation or altered serum-BBB markers.

Conclusion: Visual restoration after cataract surgery was associated with improved cognition, reduced BBB permeability, and decelerated brain ageing, without structural brain change. These findings support sensory integrity as contributor to cognitive and neurovascular resilience and suggest cataract surgery may modify brain ageing trajectories.

Disclosure: Nothing to disclose.

EPO-0959 | Anti-amyloid drugs for patients with idiopathic normal pressure hydrocephalus and positive Alzheimer's disease biomarkers?

B. Pizzarotti¹; G. Bommarito²; P. Salvioni Chiabotti²; O. Rouaud²; M. Messerer³; G. Allali²
¹Neurology Service, Department of Clinical Neurosciences, University Hospital of Lausanne and University of Lausanne, Lausanne, Switzerland; ²Leenaards Memory Center, Department of Clinical Neurosciences, University Hospital of Lausanne and University of Lausanne, Lausanne, Switzerland; ³Neurosurgery Service, Department of Clinical Neurosciences, University Hospital of Lausanne and University of Lausanne, Lausanne, Switzerland

Background and aims: Anti-amyloid therapy (AAT) has recently been approved for Alzheimer's disease (AD). Idiopathic normal pressure hydrocephalus (iNPH) frequently co-occurs with AD, yet the presence of degenerative comorbidities is considered an exclusion criterion for anti-amyloid therapy. Given the potential reversibility of iNPH and its frequent association with AD, a targeted evaluation of these patients is warranted. This study aimed to assess the prevalence and characteristics of iNPH patients with AD-positive biomarkers potentially eligible for (AAT).

Methods: We retrospectively identified iNPH patients according to international diagnostic criteria. Demographic, clinical, cerebrospinal fluid (CSF), and MRI data were collected. AD positivity was defined as A+T+, and eligibility for AAT was evaluated based on established exclusion criteria.

Results: Eighty-one iNPH patients (mean age 78.9 ± 5.1 years) referred from the Neurosurgery Service to the Leenaards

Memory Center (Lausanne University Hospital, Switzerland) between May 2019 and December 2023 were included. Eleven patients (13.6%) showed AD-positive biomarkers, and seven (8.6%) met eligibility criteria for AAT. Among ineligible patients, exclusion was due to >4 cerebral microbleeds on MRI (18%), Clinical Dementia Rating (CDR) >1 (9%), or active anticoagulant treatment (9%). No significant differences in clinical or radiological features were observed between eligible and ineligible patients.

Disclosure: Funding declaration: This study was supported by a joint grant of the Lausanne University Hospital Foundation and the Private Foundation of the Geneva University Hospital (Project #ROMENS 22). GB received fundings from Novartis and the UNIL Faculty of Biology and Medicine. GA received fundings from the Faculty of Biology and Medicine of the University of Lausanne, the Swiss National Science Foundation (#214855), the Solis Foundation, the Empiris Foundation and the Marina Cuennet-Mauvernay Foundation.

Background and aims: Subjective cognitive decline (SCD) may represent a preclinical stage of Alzheimer's disease (AD), but its trajectory is highly heterogeneous. We compared cognitive profiles, AD blood biomarkers, and brain connectivity in SCD, amnesic mild cognitive impairment (aMCI) and healthy controls (HC).

Methods: Cognitive performance was assessed using the Italian Uniform Data Set Neuropsychological Battery, and metacognition (cognitive insight) with computerized tasks estimating metacognitive efficiency. Plasma p-tau217, GFAP, and NfL were measured using the Fujirebio Lumipulse platform ($n = 79$), and resting-state functional 3T MRI data were analyzed with independent component analysis ($n = 51$). Group comparisons and correlation analyses were performed.

Results: We enrolled 106 participants (36 HC, 39 SCD, 31 aMCI; age 55–85 years). Compared with HC, SCD showed lower global cognition ($p=0.008$) and metamemory efficiency ($p=0.002$). GFAP was increased in SCD ($p=0.01$) and aMCI ($p=0.001$)

FIGURE 1 Study flowchart. Abbreviations: I-UDSNB, Uniform Data Set Neuropsychological Test Battery, Italian adaptation; ATI (N), amyloid, tau, neuroinflammation, neurodegeneration; rs-fMRI, resting-state functional MRI.

VAN connectivity, z-score, mean (SD)	4.0 (± 1.2)	4.15 (± 1.3)	3.9 (± 1.2)	0.38	

FIGURE 2 Plasma GFAP and p-Tau217 levels (A) and Default Mode Network connectivity (B) across diagnostic groups.

versus HC and remained significant after adjustment for age and education ($p=0.0039$). P-tau217 was higher in aMCI than HC ($p=0.01$), with a trend versus SCD ($p=0.078$), while NfL did not differ between groups. Default mode network connectivity was reduced in aMCI ($p=0.021$) and showed a trend toward reduction in SCD ($p=0.065$) compared with HC. Across the sample, global cognition correlated negatively with p-tau217 ($r=-0.34$, $p=0.007$), GFAP ($r=-0.23$, $p=0.05$), and NfL ($r=-0.25$, $p=0.04$). Nominal associations were observed between meta-cognitive efficiency and default mode and dorsal attention network connectivity ($\rho=0.35$; $p\approx 0.02$).

Conclusion: SCD showed subtle cognitive deficits, increased glial reactivity and connectivity changes, supporting its place along the AD continuum and the value of integrating multimodal biomarkers for early disease characterization.

Disclosure: Nothing to disclose.

EPO-0961 | Cerebrospinal fluid CCL25 as a biomarker for Alzheimer's disease: Associations with pathology, neurodegeneration, and cognitive decline

Y. Chen; S. Li
Hebei Medical University, Hebei, China

Background and aims: Neuroinflammation plays a crucial role in Alzheimer's disease (AD) pathogenesis. We investigated the relationship between cerebrospinal fluid (CSF) C-C chemokine ligand 25 (CCL25), an inflammatory regulator, and AD pathology and progression.

Methods: We analyzed CSF CCL25, AD biomarkers (CSF β -amyloid [$A\beta$]42, phosphorylated tau [pTau]181, amyloid positron emission tomography [PET]), postmortem neuropathology, magnetic resonance imaging-based neurodegeneration, and cognitive function from 703 participants in the Alzheimer's Disease Neuroimaging Initiative cohort.

Results: We found that elevated CSF CCL25 levels were associated with cognitive impairment, abnormal $A\beta$ and tau pathology, greater brain atrophy, and worse cognitive performance (all $p<0.05$). CSF CCL25 exhibited nonlinear relationships with $A\beta$ and tau pathology, reaching a plateau as AD pathology increased. CSF CCL25 showed acceptable diagnostic accuracy in distinguishing amyloid-positive/negative ($A_{\pm}$) and tau-positive/negative ($T_{\pm}$) participants (area under the curve [AUC]=0.71–0.77) and autopsy-confirmed AD cases (AUC=0.77), with optimal performance in differentiating $A_{+}T_{+}$ from $A_{-}T_{-}$ participants (AUC=0.82–0.85 with age and sex adjustment). Longitudinally, higher baseline CSF CCL25 predicted accelerated amyloid accumulation, hippocampal atrophy, and cognitive decline. Mediation analyses revealed that CCL25 partially mediated associations between $A\beta$ pathology and tau pathology (mediating effect: 54.5%), neurodegeneration (18.2%), and cognitive decline (7.4%). Among 37 CSF CCL and CXCL chemokines examined, 28 were associated with at least one AD-related outcome, with CCL25 demonstrating the strongest associations

Conclusion: These findings suggest that CSF CCL25 is involved in early AD pathological progression and may serve as an inflammatory biomarker for diagnosis and monitoring disease progression in AD.

Disclosure: Nothing to disclose.

FIGURE 1 Association between CSF CCL25 and AD core pathology.

¹Netis Informatics Ltd, Hungary; ²ALSAD Medical, Hungary; ³S-Medicon, Hungary; ⁴Kliniken am Goldenen Steig, Hospital Freyung, Germany; ⁵Department of Psychiatry, New York University Langone Health, New York, USA

Background and aims: Global aging drives increased dementia prevalence. While early detection is crucial for better prognosis and quality of life, diagnosis is often delayed because early symptoms are subtle. Since no widely available AI algorithm reliably identifies early dementia signs from digital behavioral patterns, our objective was to develop and validate such an AI-based tool for timely diagnosis and treatment.

Methods: We utilized the PreDEM system, an AI-based platform, for this investigation. Data was collected from 4,334 participants between September 2021 and March 2025, during which 171,577 cognitive tests were completed, resulting in 6,049,916 data points. A unified, normalized evaluation system was established for objective comparison across tests. The AI algorithm analyzed participants' digital behavioral patterns to identify early signs of dementia.

Results: Participants were categorized into "potentially treated" and "potentially healthy" groups. Analysis, including density function comparison and cluster analysis, showed clear differences between the groups. Within the affected group, a lower-performing subgroup was identified and subsequent neurological/neuropsychological examinations confirmed cognitive impairment. In the higher-performing affected subgroup, cognitive dysfunction was often linked to organic causes. Treating these underlying organic causes, combined with regular use of the PreDEM platform, led to significant cognitive improvement in these participants.

Conclusion: The study's platform is a promising new tool for the early detection and prevention of dementia. During pilot studies, the AI-based system reliably identified dementia patients, significantly surpassing the accuracy of traditional diagnostic methods. This method is therefore suitable for detecting the first, often unnoticed signs of dementia through AI-processed risk analysis.

EPO-0963 | When hearing loss is the first clue: An atypical onset of Creutzfeldt-Jakob disease with an isolated thalamic lesion

M. Elguezal; M. Gilot; M. Herrezuelo; P. Sánchez; N. Amazian; N. Juárez; N. Huertas

Department of Neurology, University Hospital Severo Ochoa, Madrid, Spain

Background and aims: Creutzfeldt-Jakob disease (CJD) is a rapidly progressive prion encephalopathy typically characterized by progressive dementia, myoclonus and ataxia. However, early presentations may be misleading, as atypical symptoms such as hearing loss and non-suggestive neuroimaging can pose a diagnostic challenge.

FIGURE 2 Accuracy of CSF CCL25 in predicting AD pathology.

FIGURE 3 Correlation between chemokines and AD biomarkers.

FIGURE 1 Axial T2-FLAIR MRI showing an isolated hyperintense lesion in the right thalamus.

FIGURE 2 Axial diffusion-weighted MRI showing cortical ribboning in the frontoparietal regions.

Methods: We report the case of a 54-year-old woman with dyslipidaemia, ulcerative proctitis and chronic thrombocytopenia. In August 2025, she developed acute unilateral hearing loss, progressing to bilateral involvement within days, unresponsive to topical corticosteroids. In September 2025, she was assessed by otorhinolaryngology (ENT); audiometry showed normal hearing thresholds with impaired speech discrimination and

topical and oral corticosteroids were prescribed without improvement. In October 2025, following language impairment, she presented to the emergency department for neurological evaluation. Neurological examination revealed scanning dysarthria, mixed aphasia with paraphasias, slow reading with apraxia, nystagmus, myoclonus and a wide-based ataxic gait.

Results: Initial brain magnetic resonance imaging (MRI) in September 2025 showed an isolated unilateral hyperintense lesion in the right thalamus (T2/FLAIR) without diffusion restriction. Subsequent MRI in October 2025 demonstrated the evolution of classic “cortical ribboning” in frontoparietal regions and ipsilateral caudate nucleus involvement on diffusion-weighted imaging (DWI). Cerebrospinal fluid analysis revealed positive 14-3-3 protein with otherwise normal biochemistry. Electroencephalography showed diffuse encephalopathy with characteristic periodic sharp wave complexes.

Conclusion: This case highlights that CJD can masquerade as a primary ENT pathology. Hearing loss and atypical isolated thalamic lesions do not preclude a prion disease diagnosis. Recognizing these rare phenotypes is crucial for timely diagnosis in the absence of early “classic” imaging markers.

Disclosure: Nothing to disclose.

EPO-0964 | Acute and longitudinal effects of transcranial pulse stimulation on vascular, neuronal, and cognitive function in Alzheimer's models

M. Karakatsani¹; D. Nozdriukhin¹; I. Gezginer¹; C. Maschio¹; S. Tiemann¹; H. Yoshihara¹; D. Kindler¹; M. Reiss¹; R. Storz²; M. Belau²; R. Ni³; X. Deán-Ben¹; D. Razansky¹

¹Institute for Biomedical Engineering and Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland; ²Institute for Biomedical Engineering, Department of Information Technology and Electrical Engineering, ETH Zurich, Zurich, Switzerland; ³Storz Medical AG, Switzerland; ³Institute for Regenerative Medicine, University of Zurich, Zurich, Switzerland

Background and aims: Transcranial Pulse Stimulation (TPS) is a non-invasive neuromodulation technique with growing therapeutic relevance for neurodegenerative disease. This work investigated both the acute physiological effects of TPS on cerebrovascular, neuronal, and network-level function, as well as the longitudinal impact of repeated TPS on Alzheimer's disease (AD) pathology and cognition.

Methods: Acute experiments were conducted in CD1, GCaMP-expressing, 5xFAD, and 3xTg-AD mice using multimodal imaging: real-time optoacoustic tomography, contrast-enhanced MRI, wide-field calcium imaging, c-Fos immunohistochemistry, and resting-state fMRI. Longitudinal study followed a clinical-analogous TPS protocol (six sessions over two weeks) to 3xTg-AD mice with sham controls. BBB integrity, amyloid and tau pathology (targeted AOI987 imaging, immunohistochemistry), cognition (Novel Object Recognition, Fear Conditioning), and proteomic signatures were assessed.

Results: Acute TPS induced robust, energy-dependent increases in cortical blood volume (~28–50%), with AD mice showing reduced vascular responsiveness consistent with vascular amyloidosis. BBB integrity remained intact across all modalities. TPS evoked strong neuronal activation, including immediate

calcium influxes and ~2-fold increases in c-Fos expression, and transiently reorganized functional connectivity within hypothalamic–hippocampal–limbic circuits. Longitudinal TPS caused no BBB disruption and produced modest reductions in amyloid burden and attenuated tau accumulation. Behaviorally, TPS improved short-term object recognition and enhanced forgetting of remote fear memory in 3xTg-AD females. Proteomics revealed upregulation of pathways related to calcium handling, energy metabolism, ion transport, and neurotransmission.

Conclusion: TPS safely modulates vascular, neuronal, and network dynamics while mitigating aspects of AD pathology and improving cognitive and molecular outcomes. These findings support TPS as a mechanistically grounded therapeutic strategy for neurodegenerative disease.

Disclosure: Nothing to disclose.

EPO-0965 | **Whole-brain DTI-ALPS: A novel voxel-based biomarker for white matter dysfunction in Alzheimer's and Parkinson's disease**

N. Schröter¹; M. Reiser²; H. Wiendl³; L. Schappe¹; S. Groppa¹; J. Hosp³; H. Urbach⁴; A. Rau⁴

¹Department of Neurology, Saarland University and Saarland University Medical Center, Homburg, Germany; ²Medical Physics, Department of Radiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Germany; ³Department of Neurology and Neurophysiology, Medical Center-University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany; ⁴Department of Neuroradiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany

Background and aims: The glymphatic system's role in neurodegenerative waste clearance is established, but non-invasive assessment remains challenging. This study compares the standard DTI-ALPS method with a novel whole-brain voxel-based DTI-ALPS approach to quantify perivascular flow in Alzheimer's (AD), Parkinson's disease (PD) and Dementia with Lewy Bodies (DLB).

Methods: Retrospective analysis included 25 PD patients with dementia (PDD), 58 with mild cognitive impairment (PD-MCI), 50 cognitively intact PD (PD-NC), 77 AD and 13 DLB patients, and 30 healthy controls (HC) (Table 1). Cognitive impairment was assessed by Mattis Dementia Rating Scale (DRS-2). DTI-ALPS was calculated using Frangi-filter-based perivascular space (PVS) segmentation on high-resolution T2-weighted MRI. A PVS orientation template enabled voxel-wise diffusivity assessment along/perpendicular to PVS. Mean whole-brain

TABLE 1 Demographics.

	HC (N=30)	PD-NC (N=50)	PD-MCI (N=58)	PDD (N=25)	DLB (N=13)	AD (N=77)

FIGURE 1 DTI-ALPS and voxel-based DTI-ALPS indices across HC, PD-NC, PD-MCI, PDD, DLB, and AD, highlighting group differences and statistical significance.

DTI-ALPS was extracted from white matter (tissue probability > 0.5). Group comparisons and clinical associations were analyzed.

Results: Conventional DTI-ALPS revealed no significant group differences. Voxel-based-DTI-ALPS was significantly lower in PD-NC ($p=0.040$, Cohen's $d=0.635$), DLB ($p<0.001$, Cohen's $d=1.599$) and AD ($p<0.001$, Cohen's $d=0.971$) compared with HC. Furthermore, DTI-ALPS was lower in DLB than PD-MCI ($p=0.026$, Cohen's $d=1.027$), Figure 1. A significant association was observed with initiation ($p=0.003$), but not with DRS-2 total- or subscores ($p>0.05$).

Conclusion: This novel whole-brain voxel-based approach, using a PVS template, demonstrates significant white matter dysfunction in AD, DLB, and cognitively intact PD, with the most pronounced impairment in DLB. The association with initiation deficits highlights its potential as a sensitive biomarker for early white matter dysfunction.

Background and aims: Spinal metastases progress from asymptomatic disease to debilitating pain, instability, and neurological deficits. Although timely recognition is essential, referral delays are common because patients often first present to non-spine clinicians and red flags rarely expedite referral. Existing

FIGURE 1 Front page of the SMS pocket map with the referral algorithm for patients with spinal metastases.

American Spinal Injury Association (ASIA) Impairment Scale

A The impairment is complete. There is no motor or sensory function below the level of injury.

B The impairment is incomplete. Sensory function, but not motor function, is preserved below the neurologic level (the key is preserved above the level of injury) and some sensation is preserved in the sacral segments S4 and S5.

C The impairment is incomplete. Motor function is preserved below the neurologic level and more than half of the key muscles below the neurologic level have a strength grade of 3 or more.

D The impairment is incomplete. Motor function is preserved below the neurologic level and at least half of the key muscles below the neurologic level have a strength grade of 3 or more.

E The patient's function is normal. All motor and sensory functions are undisturbed.

Bilsky grading (Best assessed with an MRI)

Grade 0: disc-only disease

Grade 1: spinal extension without cord compression (Bilalov)

Grade 2: spinal cord compression with cerebrospinal fluid (CSF) stubble around the cord

Grade 3: spinal cord compression with no CSF stubble around the cord

Spinal neoplastic instability score (SNS)

Element of SMS	SCORE	Element of SMS	SCORE
Location		Neurological to spinal alignment	
Junctional (cervical-C2, C2-C3, T11-T12)	3	Subluxation/translation present	4

Remarks

- Neurological function/instability are different, discuss with your specialist who has experience in this field
- If unsure about SNS or Bilsky, please consult your local radiologist
- See QR code for minimum referral information, anatomy, and support with pain types, ASIA, SNS, and Bilsky

FIGURE 2 Back page of the SMS pocket map with explanation of items on the front and a QR link to further educational material.

guidelines target spine surgeons and radiation oncologists, leaving a gap for staging and referral tools for non-spine clinicians. We aimed to develop the Spinal Metastasis Staging (SMS) referral tool.

Methods: We defined the SMS system as four stages following natural progression of most spinal metastases: SMS I, asymptomatic; SMS II, inflammatory pain; SMS III, mechanical pain and/or instability; and SMS IV, neurological deficits and/or high-grade spinal cord compression. To aid clinical use, we translated the SMS stages into a referral algorithm, organized by urgency, presented in the form of a color-coded pocket map. The four stages and pocket map were revised by regional and international multidisciplinary expert panels, including spine and non-spine clinicians, and subsequently evaluated in an international online survey.

Results: Expert panels endorsed the four SMS stages. Among non-spine clinician survey respondents (32/120), 94% found the pocket map easy to understand, 91% judged the format suitable, and 91% expected improved referrals. Overall, 88% indicated at least occasional use, including 61% who would use the pocket map frequently or always.

Conclusion: The SMS referral tool was well received by spine specialists and non-spine clinicians, supporting that it is both expert-driven and user-friendly. A digital version with educational materials is provided for local implementation. Future work will focus on clinical validation to confirm the impact.

Disclosure: Nothing to disclose.

EPO-0967 | **Late transient post-radiotherapy enhancements in patients with high grade brain tumors – between pseudoprogression and radionecrosis: A case series**

C. Pérez Prol; J. Gállego Pérez de Larraya; A. Atorrasagasti Villar; S. Urtasun Galmes; J. Ulloa Bravo; R. Villino Rodriguez; C. Espinoza Vincas
Department of Neurology, Clínica Universidad de Navarra, Pamplona, Spain

Background and aims: High-grade malignant brain tumors have a poor prognosis despite treatment. Pseudoprogression and radionecrosis are contrast-enhancing phenomena that usually appear before 3 months (post-radiotherapy) in a transient manner or between 3–12 months permanently, respectively. Distinguishing pseudoprogression and radionecrosis from true progression is of extreme importance, with variable treatment and prognostic implications. The aim of this work is to describe treatment related changes on MRI defined as late transient post-radiotherapy enhancements (LTPE) which do not fit the definition of pseudoprogression or radionecrosis and can be misdiagnosed as tumor progression.

Methods: Retrospective description of a case series of 7 patients with malignant high-grade brain tumors who showed late transient post-radiotherapy contrast-enhancing lesions that did not fit the definitions of pseudoprogression or radionecrosis and could be misdiagnosed as progressive disease. Demographic, tumor, treatment and LTPE characteristics (time of appearance and resolution, location), date of tumor progression, and MRI and methionine PET features were collected.

Location of LTPE	Peritumoral	Peritumoral	Peritumoral	Peritumoral	Peritumoral	Peritumoral	Peritumoral

Table 1. Data collected from 7 patients. Age, cardiovascular risk factors, tumor diagnosis, MGMT and MMR status, complete or partial resection, date of start and end of RT, dose of concomitant and adjuvant CT, date of appearance and disappearance of LTPE, and tumor progression, location and previous fields of targeted RT field.

FIGURE 1 Representative MRI/PET images of the seven reported cases before, during, and after LTPE (Late transient post-radical enhancements).

Results: Seven patients aged 47–65 years were included: 4 had glioblastoma, 2 grade 4 IDH-mutated astrocytomas and 1 medulloblastoma. All patients underwent surgery followed by radio-chemotherapy. LTPE were located within the radiotherapy field, appeared between 11–30 months post-radiotherapy, and spontaneously resolved within 4–30 months after onset. Six LTPE showed frontotemporal distribution and four periventricular/ependymary.

Conclusion: The small size, late post-radiotherapy onset, and reversibility of these contrast-enhancing lesions highlight the overlap between LTPE, pseudoprogression and radionecrosis. Further studies are needed to better characterize this phenomenon and establish clear criteria to avoid misdiagnoses of tumor progression.

Disclosure: Nothing to disclose.

¹The DCCC Brain Tumor Center and Department of Cancer Treatment, Rigshospitalet, Copenhagen, Denmark; ²Department of Cancer Treatment, Rigshospitalet, Copenhagen, Denmark; ³Biotech Research & Innovation Centre (BRIC), The Finsen Laboratory, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; ⁴Neurobiology Research Unit, Copenhagen University Hospital and Epilepsy Clinic, Department of Neurology, Rigshospitalet, Copenhagen, Denmark

Background and aims: More than half of glioblastoma patients experience epileptic seizures. Epilepsy–glioma interactions are linked to poor prognosis, yet predictors of epilepsy remain unclear. We examined associations with prognosis, as well as predictors of epilepsy and seizure control.

Methods: From a prospective database, 595 glioblastoma IDH-wildtype patients treated with standard therapy from 2016–2024 at Rigshospitalet were included and divided into training (2016–2021) and validation (2022–2024) datasets. Epilepsy diagnosis and medication use were extracted from medical records. As a surrogate marker of seizure control, we used dose burden of anti-seizure medication calculated as prescribed daily dose relative to WHO defined daily dose. Candidate genetic factors comprised pathogenic and likely pathogenic variants from genomic profiling. We used Cox regression and generalized linear models for survival and prediction analysis.

Results: Pre- and postdiagnostic epilepsy (HR: 1.41 [95% CI 1.06–1.87], $p=0.018$ and HR: 3.08 [2.34–4.05], $p<0.0001$, respectively) and higher dose burden at time of tumour diagnosis (HR: 1.06 [1.03–1.10], $p<0.0001$) were associated with poor overall survival. Multifocal disease and absence of RB1 alterations were associated with postdiagnostic epilepsy. Multifocal disease predicted higher dose burden in both pre- and postdiagnostic epilepsy ($p=0.009$ and $p=0.016$). In pre-diagnostic epilepsy, resection predicted lower dose burden than biopsy.

Conclusion: Epilepsy and lack of seizure control negatively impact prognosis in glioblastoma. They can be predicted using clinical and genomic factors. This can support clinical risk stratification and early epilepsy management if validated.

Background and aims: In glioblastoma (GBM), fatigue is a widely understudied and may particularly impact patients. Several hypotheses may explain the development of fatigue, including direct effect of the tumor and its treatments. Moreover, concomitant depressive state and dysregulation of the autonomic nervous system may be observed. We postulate that a combined measure of physical and autonomic activities, acquired through a wearable device will provide biomarkers of the clinical and physical evolution.

Methods: We used a wearable device (Embrace+ smartwatch, Empatica) and an electronic diary to monitor patient seizures as well as daily the fatigue using a Visual Analog Scale (VAS). Every 2 months, at time of planned MRI, patients complete questionnaires about medications and validated fatigue and quality of life questionnaires.

Results: As of January 2026, 15/20 patients were enrolled. Daily values of the VAS have been weakly linked standardized fatigue questionnaires. However, findings suggests that patients tend to be less active during days in which they end up feeling more fatigued. Furthermore, machine learning models show promising results regarding prediction of fatigue and disease progression, based on parameters acquired by the wearable device. More results regarding interactions between fatigue and mood, impact of therapies and life expectancy are under investigation.

Conclusion: Our preliminary data suggest that fatigue measured by standardized questionnaires might be anticipated based on the completion of a simple VAS question completed daily by the patient and correlated to continuous activity measures obtained by a wearable device.

P. Gómez Ramírez; M. El Harmochi Daoud; A. Sánchez Gómez; A. Herrera Ortega; V. Ros Escolar; M. Carrillo Carrillo; M. Usero Ruiz; M. Corrales Arroyo; J. Flores Barragán; A. Hernández González
Department of Neurology, Ciudad Real General University Hospital, Ciudad Real, Spain

Background and aims: Oculomotor disorders in oncology patients are usually caused by brainstem, orbital, metastases or meningeal infiltration, and may be the presentation of an occult tumor. Another etiology is paraneoplastic syndromes, such as myasthenia gravis or Eaton-Lambert syndrome (LES), showing variable clinical patterns. We report a case of progressive ophthalmoparesis evolving into One and a Half Syndrome (OAHS) as the initial manifestation of a lung carcinoma.

Methods: A 56-year-old woman, ex-smoker, presented with left ptosis and diplopia with limited bilateral abduction, unresponsive to pyridostigmine and corticosteroids. Diplopia progressively worsened over three weeks without fatigability. Examination only revealed a horizontal OAHS with left ptosis.

Results: TSH, antithyroid antibodies, anti-AChR, anti-MuSK, anti-P/Q-type VGCCs, ANA, onconeural antibodies were negative. Brain MRI and angio-TC: normal. Jitter and repetitive stimulation: normal. CSF: normal. Body CT: pulmonary mass in the right middle lobe. Biopsy: lung adenocarcinoma. High-dose

methylprednisolone followed by tapering and intravenous immunoglobulins produced partial improvement. One month after surgery the patient was asymptomatic. Adjuvant chemotherapy was added.

Conclusion: The absence of structural lesions and resolution after surgery suggest a paraneoplastic mechanism. LES with isolated ophthalmoplegia is rare and may even precede cancer diagnosis, more commonly small-cell lung carcinoma, but exceptionally other subtypes (including adenocarcinoma). Anti-P/Q-type VGCCs can be negative in 15% of LES associated with lung carcinoma, but the absence of neurophysiological abnormalities in our case suggests that progressive ophthalmoparesis may represent an independent paraneoplastic syndrome, already suggested in other cases with exophthalmos and non-infiltrative ophthalmoparesis. This presentation should prompt awareness and thorough search for occult tumors.

Disclosure: Nothing to disclose.

EPO-0971 | Delayed acute motor axonal neuropathy following BCMA-directed CAR-T therapy in relapsed/refractory multiple myeloma

T. Jordà-Baleri¹; A. Llauredó⁴; A. Rivas Delgado²; G. Iacoboni²; C. Carpio²; B. Rodríguez-Acevedo³; Á. Cobo-Calvo³; N. Raguer⁵; P. Barba²; X. Montalban³; H. Ariño³

¹Neurology Department, Vall d'Hebron University Hospital, Barcelona, Spain; ²Department of Haematology, Vall d'Hebron University Hospital, Barcelona, Spain; ³Centre d'Esclerosi Múltiple de Catalunya (Cemcat), Hospital Universitari de Vall d'Hebron, Barcelona, Spain; ⁴Clinic of Neuromuscular Disorders and Rare Diseases, Vall d'Hebron University Hospital, Barcelona, Spain; ⁵Department of Clinical Neurophysiology, Vall d'Hebron University Hospital, Spain

Background and aims: Chimeric antigen receptor T-cell (CAR-T) therapies targeting B-cell maturation antigen (BCMA) have transformed the treatment of relapsed/refractory multiple myeloma (MM). However, compared with CD19-directed constructs, BCMA-directed CAR-T therapies are associated with a distinct and still incompletely characterized spectrum of neurological complications.

Methods: A patient treated with BCMA-directed CAR-T therapy developed delayed neurological symptoms. Clinical, neurophysiological, neuroimaging, and cerebrospinal fluid (CSF) studies were performed.

Results: A 65-year-old woman with relapsed/refractory IgA kappa MM and high tumor burden received fourth-line BCMA-directed CAR-T therapy (ciltacabtagene autoleucel). On day +25, she developed grade 2 cytokine release syndrome without immune effector cell-associated neurotoxicity syndrome (ICANS). One month after infusion, disease assessment showed a partial response, and she developed a sixth nerve palsy with normal CSF findings, which resolved after corticosteroid treatment. Two months post-infusion, she presented with subacute progressive symmetric tetraparesis causing severe disability, without sensory loss or dysautonomia. Neurological examination revealed global areflexia and marked weakness, followed by encephalopathy. CSF analysis showed marked lymphocytic pleocytosis (685 cells/ μ L; 96% CAR-T cells) and thiamine deficiency, without other abnormalities. Electromyography demonstrated features

consistent with acute motor axonal neuropathy. Brain and spinal MRI excluded central nervous system involvement. Treatment included intravenous immunoglobulins, corticosteroids, thiamine supplementation, and anakinra. Encephalopathy resolved rapidly, but motor recovery was limited. The patient died four months after CAR-T infusion due to respiratory infection.

Conclusion: BCMA-directed CAR-T therapy may cause severe delayed peripheral neurotoxicity, highlighting the need for prolonged multidisciplinary neurological monitoring beyond the acute post-infusion period.

Disclosure: Nothing to disclose.

FIGURE 1 EMG findings: Marked reduction in compound motor action potential amplitudes in the bilateral median and ulnar nerves, and the right common peroneal nerve. Below, preserved sensitive responses.

FIGURE 2 EMG findings: normal F-waves in the right median nerve, absent F-waves in the ulnar nerve, and delayed F-waves in the right posterior tibial nerve.

EPO-0972 | Optimized parameters in image-guided focused ultrasound enable safe and reproducible blood–brain barrier opening in preclinical glioma models

T. Kuhn¹; T. Knobloch¹; M. Platten²; L. Bunse²

¹CCU Neuroimmunology and Brain Tumor Immunology, Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany; ²Department of Neurology, MCTN, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany

Background and aims: Focused ultrasound (FUS) in combination with systemically administered nanobubbles is an emerging, non-invasive strategy to transiently disrupt the blood–brain barrier (BBB) and enhance drug delivery to the central nervous system. Despite its promise, defining acoustic parameters that ensure both efficacy and safety remains challenging, particularly in pathological settings such as brain tumors.

Methods: We systematically optimized key FUS parameters—including acoustic pressure, burst length, pulse repetition frequency, and number of bursts—to achieve consistent and safe BBB opening in healthy mice. The optimized protocol was then evaluated in several GL261 based glioma mouse models. BBB disruption was assessed using contrast-enhanced MRI, Acoustic Feedback Mapping, and Evans Blue dye extravasation, with histological validation. Safety was evaluated using FLAIR and T2*-weighted MRI to detect hemorrhage or tissue damage.

Results: An optimized set of FUS parameters (1 MPa, 10 ms bursts, 0.5 Hz, 60 bursts) reliably opened the BBB in healthy mice without parenchymal injury, confirmed by T1- and T2*-weighted MRI (Figure 1). The same protocol effectively opened the BBB in tumor and peritumoral regions in GL261 based-glioma models (Fig. 2). Higher pressures or increased burst number or frequency caused hemorrhage, establishing a safety threshold. Acoustic Feedback Mapping showed subharmonic and ultraharmonic emissions correlated with contrast

FIGURE 1 Successful BBBO achieved using an optimized MRI-guided FUS protocol, as evidenced by post-FUS T1 contrast-enhanced imaging and subharmonic/ultraharmonic frequency analysis.

FIGURE 2 Successful BBBO in GL261 tumor-bearing mice demonstrated by T1 contrast-enhanced MRI after FUS, with no evidence of hemorrhage on T2* post-FUS Imaging.

enhancement, and histology confirmed Evans Blue extravasation supporting successful BBB disruption.

Conclusion: We establish a reproducible and safe FUS protocol for BBB opening and demonstrate its successful application in preclinical glioma models. These findings provide an important foundation for the clinical translation of image-guided, FUS-mediated drug delivery strategies in neuro-oncology.

Disclosure: Nothing to disclose.

EPO-0973 | Cognitive decline as a prognostic marker of disease activity in patients with glioblastoma

E. Konrath; B. Calabek-Wohinz; S. Oberndorfer

Department of Neurology, University Hospital St. Pölten – NOE LGA, Karl Landsteiner University, St. Pölten, Austria

Background and aims: In patients with glioblastoma, cognitive impairment is influenced by treatment- and patient-related factors, but is strongly driven by tumor-related pathological processes. There is evidence that cognitive decline has predictive value for disease progression. However, existing studies are limited by small sample sizes, heterogeneous tumor entities, insufficient control of important covariates, and the lack of a direct comparison between neuropsychological outcomes and the Karnofsky Performance Status Scale (KPS).

Methods: The present study investigated the predictive value of a neuropsychological test battery comprising eight subtests (NeuroCogFX) in comparison with the KPS for predicting tumor progression according to the RANO criteria. A Cox regression model with time-dependent covariates was applied, including the control variables age, education, sex, MGMT

promoter methylation status, extent of resection, tumor hemisphere, and the use of steroids, anticonvulsants and psychotropic medication. The sample consisted of 99 patients with a total of 309 assessment time points.

Results: Cognitive decline, defined as deterioration in three tests relative to baseline, was associated with a fivefold increased risk of radiologically confirmed tumor progression (HR= 5.00; $p < 0.001$). In contrast, decline in KPS was not a significant predictor. Among the covariates, MGMT promoter methylation (HR=0.42; $p = 0.005$) and a higher number of years of education (HR=0.87; $p = 0.019$) emerged as protective factors.

Conclusion: These results highlight the value of continuous neuropsychological monitoring as a sensitive approach for detecting disease progression. It provides clinically meaningful information, particularly in cases of equivocal radiological findings or for treatment-related decision-making.

EPO-0974 | Predicting intracranial aneurysm rupture risk from DSA images: Automated segmentation, multimodal prediction, and validation

H. Jin; R. Zhang; G. Liang
Department of Neurosurgery, General Hospital of Northern Theater Command, Shenyang, China

Background and aims: Subarachnoid hemorrhage (SAH) is a highly fatal acute cerebrovascular event, most commonly caused by the rupture of an intracranial aneurysm (IA). Current methods for predicting IA rupture are limited in accuracy and consistency. These methods often rely heavily on clinician experience and carry a non-negligible risk of oversight, falling short of the requirements for precise clinical management.

Methods: To address these limitations, we conducted a retrospective study using digital subtraction angiography (DSA) images from 890 patients with IAs. Initially, the aneurysm regions of interest (ROIs) were annotated. We then developed a U-KAMA segmentation algorithm to achieve fully automated IA segmentation. From these segmented regions, 1834 radiomic features were extracted. Following a feature selection process, 57 key imaging features were retained and subsequently integrated with clinical characteristics to build a multimodal model for predicting IA rupture.

Results: The model demonstrated robust performance. For automated IA segmentation, it achieved a mean Dice similarity coefficient of 0.815. The process was 92.62% faster than manual segmentation, reducing the average time per case from 8.36 minutes to 0.617 minutes. For rupture prediction, the multimodal model achieved an area under the curve (AUC) of 0.893, significantly outperforming models based on single data modalities.

Conclusion: This study demonstrates high performance in both fully automated IA segmentation and rupture prediction. Our work provides a reliable, artificial intelligence-driven solution to advance the automated and precise assessment of IA rupture risk, showing significant potential for clinical translation and application.

Disclosure: Nothing to disclose.

EPO-0975 | Platelet function-defined clopidogrel inactivity as an independent contributor to recurrent ischemic stroke: A confounder-adjusted analysis

R. Ramesh; B. Bagath Srinivasan; H. Arumugam; L. Narasimhan R; N. Gampa; S. Shanmugam; P. Hazeena; I. Tiruviru
Department of Neurology, Sri Ramachandra Institute of Higher Education and Research, Chennai, India

Background and aims: Recurrent ischemic stroke despite antiplatelet therapy remains a significant clinical challenge. Reduced or absent clopidogrel activity, reflected by reduced inhibition of platelet aggregation, may represent an under-recognised and potentially modifiable contributor to recurrence. We aimed to evaluate clopidogrel antiplatelet activity as an independent factor in recurrent ischemic stroke, accounting for major confounders

Methods: Patients admitted with recurrent ischemic stroke between 2019 and 2025 were retrospectively analysed. Of 254 screened patients, 105 were included based on aggregometry test (assessed using adenosine diphosphate-induced platelet aggregation) being done, compliance to medication and availability of records. Platelet activity was categorized and clopidogrel inactivity was evaluated as an independent contributor to recurrence after excluding confounders, including atrial fibrillation, poorly controlled diabetes (HbA1c >8), uncontrolled LDL, large vessel occlusion, and coagulopathies.

Results: Among 105 patients, 40 were on clopidogrel alone and 43 on dual antiplatelet therapy. In the clopidogrel-only group,

FIGURE 1 Study design and patient allocation across anti-thrombotic therapy groups.

FIGURE 2 Distribution of platelet inactivity and competing mechanisms of recurrent ischemic stroke across antiplatelet strategies.

suboptimal activity was observed in 31/40 patients (77.5 %) with poor activity in 16/40 patients (40%). After exclusion of all confounders, clopidogrel inactivity alone plausibly contributed to recurrence in 17 patients/105 (16.1%, 8.5 % [Poor activity]). Comparatively this cohort had only 17 patients on aspirin alone of which 4 patients developed recurrence (3.8%) after exclusion of all confounders.

Conclusion: Suboptimal clopidogrel antiplatelet activity is especially common in south Asians and Indians may independently contribute to recurrence in almost one-fifth of the even after accounting for major confounders. Platelet function-guided tailoring of antiplatelets may represent an important strategy for secondary stroke prevention.

Disclosure: Nothing to disclose.

EPO-0976 | Prior stroke or transient ischaemic attack history and intensive care unit outcomes: A propensity-matched cohort study

S. Biswas¹; S. Vasireddy²; Y. Srivastava¹; S. Arora³; J. Rajamani⁴; N. Mally⁵
¹Department of Internal Medicine, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine; ²Department of Neurology, NMC Specialty Hospital, Abu Dhabi, United Arab Emirates; ³Department of Internal Medicine, University of Debrecen, Hungary; ⁴Department of Internal Medicine Medical College, Caucasus University, Tbilisi, Georgia; ⁵Department of Internal Medicine, Humanitas University, Milan, Italy

Background and aims: Prior cerebrovascular disease may increase vulnerability during critical illness through reduced cerebral reserve and impaired autoregulation. Whether prior stroke or transient ischaemic attack (TIA) independently predicts intensive care unit (ICU) mortality remains unclear. We evaluated whether prior stroke/TIA history affects ICU mortality and

FIGURE 1

FIGURE 2

FIGURE 3

recurrent cerebrovascular events independent of cardiovascular comorbidity burden.

Methods: Retrospective propensity-matched cohort study using the Medical Information Mart for Intensive Care IV (MIMIC-IV) database (2008–2022). Adults with ICU stay ≥24 hours were included; those admitted for acute stroke or TIA were excluded. Prior stroke/TIA was identified using International Classification of Diseases codes. One-to-one propensity score matching balanced cardiovascular risk factors and comorbidities. Primary outcome was in-hospital mortality; secondary outcomes included recurrent stroke, seizures, and delirium.

Results: Among 69,903 eligible ICU stays, 6,604 (9.4%) had prior stroke/TIA history. After matching (4,703 pairs), groups were well-balanced (all standardized mean differences <0.1). In-hospital mortality was similar between prior stroke/TIA patients (11.4%) and controls (11.5%; matched odds ratio 0.99, $p=0.95$). Kaplan-Meier analysis showed no survival difference (log-rank $p=0.54$). However, prior stroke/TIA patients experienced higher rates of recurrent ischemic stroke (4.3% vs 2.6%), seizures (16.2% vs 8.0%), and delirium (8.8% vs 6.3%). On multivariable analysis, prior stroke/TIA independently predicted recurrent stroke (odds ratio 1.36, 95% confidence interval 1.09–1.71, $p=0.007$).

Conclusion: After controlling for cardiovascular comorbidities, prior stroke/TIA history does not independently increase ICU mortality. However, these patients experience significantly higher rates of recurrent cerebrovascular events and

neurological complications, warranting enhanced neurovascular monitoring during critical illness.

Disclosure: Nothing to disclose.

EPO-0977 | **Mortality in stroke survivors during a global health crisis: The Geneva population-based study**

S. Pandit; E. Dirren; E. Carrera
Stroke Research Lab, Division of Neurology, Department of Clinical Neuroscience, Geneva University Hospital, Geneva, Switzerland

Background and aims: We examined 5-year mortality among stroke survivors and whether the impact of the COVID-19 pandemic on mortality was higher in stroke patients compared to the general population.

Methods: We evaluated 5-year mortality in all patients who suffered from a first-ever stroke in the canton of Geneva (504'257 inhabitants) in 2018-2019. Mortality was ascertained through official records. Predictors of mortality were identified using Cox proportional hazards models, and mortality among stroke survivors (alive ≥90days post-stroke) was compared with that of the general population using standardized mortality ratios (SMRs).

Results: In 2018 and 2019, there were 1123 first-ever stroke patients (1,000 ischemic strokes [IS] and 123 intracerebral hemorrhages [ICH]). Five-year mortality was 40.3% in IS and 56.1% in ICH. In IS, mortality was associated with age (HR=1.06), premorbid disability (mRS, HR=1.28), stroke severity (NIHSS, HR=1.09), and coronary heart disease (HR=1.54; all $p < 0.001$). In ICH, mortality was associated with age (HR=1.07) and stroke severity (NIHSS, HR=1.10; both $p < 0.001$). During follow-up, mortality was consistently higher among stroke survivors than in the general population. However, no excess mortality was observed during the pandemic period (2020–2021) compared with the post-pandemic years 2022–2024 (SMR 1.88 [1.56–2.25] vs 1.94 [1.62–2.30], $p = 0.82$).

Conclusion: While stroke survivors have sustained excess mortality compared with the general population, no increase was observed during the pandemic years (2020–2021) compared with the post-pandemic years (2022–2024).

Disclosure: Nothing to disclose.

FIGURE 1 Kaplan Meier curves.

FIGURE 1 MRI scans from 9 cases analyzed in this study.

FIGURE 2 Topography of brain lesions in the cohort of patients with CADASIL.

Background and aims: CADASIL is a dominant autosomal disease caused by mutations at the NOTCH 3 gene. This study aims to evaluate demographic aspects and clinical symptoms of patients with CADASIL in a region with a high prevalence of this disease in Rio de Janeiro/Brazil, analyze morphometrically white matter in cerebral MRI, and study variants of NOTCH3 gene.

Methods: Clinical evaluation and follow-up of patients at a Specialized Center in CADASIL in the north of the State of Rio de Janeiro/Brazil (2018–2025). Research on mutations in NOTCH3 gene. Brain morphological evaluation by 1.5-Tesla MRI.

Results: 33 patients from 27 different families. 19 (58%) men and 14 (42%) women; 70% white and 30% Afro-descendant. Mean age at first symptom: 42.3 (± 10.6); 19 (58%) presented migraine, 7 (21%) cognitive impairment. 32 patients heterozygous for the pathogenic allele variant c.457C>T from the ten probably unrelated kindreds. One patient is heterozygous for the pathogenic allele c.328C>T. All patients with pathogenic allele had

FIGURE 3 Pedigree of six families with NOTCH3 gene mutations or variants. Square symbols, men; circular symbols, women; filled symbols, CADASIL affected.

MRI lesions; MRI analyses: 61% presented bilateral white matter lesions, 48% bilateral temporal pole lesions, 55% parietal lobe, 27% basal ganglia, and 24% cerebellar lesions.

Conclusion: CADASIL is a rare and neglected disease. In this study, conducted in a region of Rio de Janeiro with a high prevalence of the disease, there was a predominance of men and white individuals, and migraine was the main neurological symptom. Regarding the changes in MRI, the parietal and temporal lobes were the most affected regions; bilateral temporal lesion (a hallmark of the disease) was observed in 48% of cases.

Disclosure: Nothing to disclose.

EPO-0979 | Simulating and augmenting clinical workflows in emergency stroke triage: A multi-center comparative study of three artificial intelligence paradigms

X. MD¹; S. Yang²; Y. Shi²; M. Li²; J. Wu¹

¹Beijing Tsinghua Changgung Hospital, Beijing, China;

²Tsinghua University, Beijing, China

Background and aims: Early diagnosis and rapid identification of ischemic stroke and LVOs are demanding and challenging. This study aimed to simulate three typical emergency work

paradigms using a large model in order to explore the robustness of different levels of information integration in real-world multi-center settings.

Methods: We developed three paradigms: Paradigm 1 (Clinical-Only): Relies solely on medical records (simulating preliminary expressions after a clinical consultation and examination). Paradigm 2 (Report-Guided): Medical records plus radiology reports (obtained from brain non-contrast CT, simulating decisions based on the reports). Paradigm 3 (Holistic Review): Medical records, radiology reports, and original CT images (simulating high-level physicians making comprehensive decisions by combining reports and personally reviewing the images).

Results: Paradigm 1 performs excellently in the central hospital but fails in external centers due to heterogeneity in medical record documentation (F1 score 93.6 vs. 57.4), revealing the limitations of relying solely on empirical inquiries. Paradigm 2 improves the stability of general diagnosis but is limited in identifying large vessel occlusion (LVO) due to missed descriptions of subtle signs in reports (Information Loss). Paradigm 3, by introducing direct interpretations of the original images, the model achieves the best performance in LVO tasks across all centers (F1 score 68.8), significantly outperforming Paradigm 2.

Conclusion: Although radiology reports provide important references, in high-risk emergency tasks, AI (and doctors) must be able to read the original images directly (Paradigm 3) in order to overcome the heterogeneity of medical records and the limitations of report information, achieving a satisfactory diagnosis and treatment.

Disclosure: Nothing to disclose.

EPO-0980 | Long term outcomes of symptomatic intracranial atherosclerotic stenosis: A 3 year follow up study

TABLE 2 Multivariate analysis of factors affecting mortality rates in patients with ICAS.

Variable	OR (95% CI)	P-value
Achieved maximal medical therapy	8.41 (1.08 – 65.36)	0.042
Age	0.98 (0.92 – 1.01)	0.086
Diabetes	2.61 (0.87 – 7.85)	0.087
Chronic kidney disease	5.25 (1.14 – 24.6)	0.027

analysis regarding the effectiveness of this in reducing rates of mortality, recurrent strokes and cardiovascular events.

Methods: This multicentre prospective cohort study included patients who were treated for symptomatic ICAS between 2020 and 2022. Patients were stratified into two groups; those who achieved maximal medical therapy and those who did not. The rates of adverse outcomes such as recurrent strokes, mortality and myocardial infarction were compared between the two groups via univariate and multivariate binary logistic regression.

Results: Among 399 patients, 33.2% achieved maximal medical therapy. Mortality occurred in 4.9% of patients, recurrent stroke in 17.0% and myocardial infarction in 2.3%. On multivariate analysis, achieving maximal medical therapy was associated with lower rates of mortality (OR 8.41; CI 1.08–65.36, $p=0.042$) and a longer duration of survival (Chi-square=9.871; $df=1$; $p=0.002$). Achieving maximal medical therapy was not associated with a significant reduction in rates of recurrent strokes and myocardial infarction.

Conclusion: ICAS is a serious condition which carries high rates of complications. Aggressive medical therapy to achieve optimum control of cardiovascular risk factors remains crucial to improving outcomes.

Disclosure: Nothing to disclose.

EPO-0981 | Is the mini-cognitive evaluation superior to MMSE and MOCA to identify mild post stroke cognitive impairment?

Y. Lesnard; O. Godefroy; S. Wannepain; A. Routier-Thorel; S. Canaple; C. Lamy; C. Leclercq; A. Courselle; M. Roussel
Departments of Neurology and Laboratory of Functional Neurosciences Jules Verne University of Picardie, Amiens, France

Background and aims: The diagnosis of post-stroke cognitive impairment (PSCI) is imperative for its effective management. However, the sensitivity and specificity of screening tests are inadequate for the diagnosis of mild PSCI. The objective of this study was to assess the discriminatory capacity of a newly developed screening test, the Mini-cognitive evaluation (MCE), in patients with at most mild PSCI (defined by an MMSE score ≥ 20). The primary objective was to ascertain the most accurate screening test (MMSE, MoCA, MCE) for discriminating stroke from controls. The secondary objectives were (1) to determine the most accurate test for identifying patients with PSCI, and (2) to examine the associations between MCE and the location of cerebral atrophy using VBM analysis.

Methods: We included 122 patients referred in the acute stroke unit (ASU) of Amiens University Hospital (62 at the ASU and 60 at post-stroke visit) and 436 controls (comprehensive assessment performed in 89 patients, 44 with PSCI).

Results: The MCE demonstrated superiority ($p=0.0001$) to the MMSE and MoCA in (1) discriminating between patients and controls (ROC AUC of 0.791 [0.731, 0.851]) and (2) discriminating patients with PSCI (ROC AUC=0.896 [0.838-0.954]) ($p=0.001$). MCE score was associated with overall brain atrophy ($p=0.01$) and using VBM analysis with atrophy of numerous hemispheric structures, predominantly on the left side ($p\leq 0.001$, uncorrected).

Conclusion: This study demonstrated that MCE is a promising diagnostic tool for identifying PSCI. The potential benefit of its use as a first line test in the management of stroke patients has now to be determined.

EPO-0982 | Prominent vessel sign on susceptibility-weighted imaging is associated with CTP perfusion-core mismatch in anterior circulation ischemic stroke

Z. Wang; X. Hu; Q. Li
Department of Neurology, The Second Affiliated Hospital of Anhui Medical University, Hefei, China

Background and aims: Perfusion imaging can identify salvageable ischemic brain tissue but requires use of contrast agents and professional post-processing software. This study aims to evaluate the role of prominent vessel sign (PVS) on acute susceptibility-weighted imaging (SWI).

TABLE 1 Baseline characteristics between patients with and without prominent vessel sign.

	All (N=303)	Without PVS (N=203)	With PVS (N=100)	p value
Clinical characteristics				
Age	66 (57 – 75)	66 (57 – 75)	67.5 (57 – 82)	0.753
Male sex	101 (66.3)	114 (66.7)	67 (65.7)	0.864
Stroke onset type				
Witnessed	134 (77.2)	138 (78.6)	76 (76.5)	0.422
Unwitnessed	69 (22.8)	43 (21.4)	26 (25.5)	
Pre-morbid mRS	0 (0 – 0)	0 (0 – 0)	0 (0 – 0)	0.933
Baseline NIHSS	4 (2 – 7)	3 (2 – 5)	5 (3 – 11)	<0.001
Medical history				
Hypertension	231 (76.2)	159 (79.1)	72 (70.8)	0.190
Diabetes	78 (25.7)	63 (31.3)	15 (14.7)	0.002
Hypercholesterolemia	126 (41.6)	88 (43.8)	38 (37.3)	0.276
Atrial fibrillation	31 (10.2)	15 (7.5)	16 (15.7)	0.028
Previous stroke	65 (21.5)	49 (24.4)	16 (15.7)	0.082
Imaging characteristics				
Onset or last known well to baseline MRI, hours	7.2 (2.9 – 13.7)	7.4 (3.1 – 13.6)	6.6 (2.8 – 14.5)	0.688
Time from baseline MRI to CTR, days	50 (38 – 75)	51 (39 – 69)	58 (36 – 76)	0.794
CTP core infarct volume	0 (0 – 0)	0 (0 – 0)	0 (0 – 4)	<0.001
CTP penumbra volume	3 (0 – 52)	0 (0 – 7)	73 (28 – 130)	<0.001
Mismatch volume	3 (0 – 48)	0 (0 – 7)	70 (28 – 130)	<0.001
Presence of LVO	82 (27.1)	23 (11.4)	59 (57.8)	<0.001
Presence of CTP mismatch	124 (40.9)	41 (20.4)	83 (81.4)	<0.001

CTP core infarct volume was defined as the area with rCBF<30%. CTP penumbra volume was defined as the area with Tmax>6s. Presence of CTP mismatch was identified according to the imaging criteria of the EXTEND trial: core infarct volume < 70ml, mismatch volume > 10ml, and mismatch ratio > 3.2.

TABLE 2 Univariable and multivariable logistic regression analyses of factors associated with presence of CTP perfusion-core mismatch.

	Univariable		Multivariable	
	OR (95% CI)	p value	OR (95% CI)	p value
Age	1.01 (0.99 – 1.03)	0.124	-	
Female sex	1.30 (0.80 – 2.10)	0.269	-	
Time from onset or last known well to baseline MRI	1.01 (0.97 – 1.04)	0.783	-	
Hypertension	0.77 (0.45 – 1.31)	0.333	-	
Diabetes	0.51 (0.10 – 0.99)	0.018	0.84 (0.41 – 1.68)	0.615
Hypercholesterolemia	0.87 (0.54 – 1.30)	0.543	-	
Atrial fibrillation	1.04 (0.35 – 6.30)	0.006	2.11 (0.77 – 5.75)	0.144
Baseline NIHSS	1.11 (1.06 – 1.17)	<0.001	1.01 (0.95 – 1.07)	0.846
Previous stroke	0.95 (0.54 – 1.67)	0.864	-	
Presence of large vessel occlusion	9.54 (5.23 – 17.40)	<0.001	3.94 (1.89 – 8.21)	<0.001
Prominent vessel sign	17.05 (9.31 – 31.22)	<0.001	10.25 (5.32 – 19.74)	<0.001

Methods: We included consecutive patients with anterior circulation acute ischemic stroke (AIS) admitted within 24 hours from onset or last known well from a prospective observational cohort between June 2023 and April 2025 in China. Emergency MRI was performed as the initial imaging modality for stroke diagnosis. PVS was defined as a focal increase in the number or diameter of hypointense vessels compared with the contralateral hemisphere. Perfusion-core mismatch on CT perfusion was obtained according to the Extending the Time for Thrombolysis

FIGURE 1 Representative image of prominent vessel sign on SWI with MCA occlusion and perfusion-core mismatch.

in Emergency Neurological Deficits (EXTEND) trial immediately after baseline MRI scan.

Results: Among 303 patients (median age 66 [IQR 57–75] years, 33.7% females), 102 (33.7%) had PVS on SWI at admission. The sensitivity of the PVS for identifying CTP mismatch was 66.9%, specificity 89.4%, positive predictive value 81.4%, and negative predictive value 79.6%. The presence of PVS on SWI remained associated with CTP mismatch (OR 10.25, 95% CI 5.32–19.74, $p < 0.001$) after adjusting for diabetes, atrial fibrillation, baseline stroke severity, and presence of large vessel occlusion.

Conclusion: PVS on SWI is frequently observed and associated with CTP mismatch among patients with anterior circulation AIS within 24 hours from onset. The MRI marker may serve as a readily available tool for rapid identification of patients who may benefit from acute therapeutic intervention.

Disclosure: Nothing to disclose.

MS and Related Disorders 7

EPO-0983 | Elevated serum BAFF in patients with neuromyelitis optica spectrum disorder after rituximab treatment

M. Deng; A. Lin

The First Affiliated Hospital of Fujian Medical University, Fuzhou, China

Background and aims: Despite achieving complete peripheral B cell deletion after over six months of rituximab therapy, a clinically significant minority of neuromyelitis optica spectrum disorder (NMOSD) patients experience breakthrough relapses, yet the underlying mechanism remains unclear.

Methods: From January 2024 to April 2025, this study enrolled 55 NMOSD patients and 15 healthy controls (all negative for autoimmune antibodies) at The First Affiliated Hospital of Fujian Medical University. Among the patients, 32 were in the remission phase under RTX treatment, and 23 were in the acute phase of the disease (16 were not receiving RTX treatment, and 7 were experiencing relapse despite RTX treatment). Serum BAFF protein concentrations were measured using ELISA. The non-parametric Kruskal-Wallis H test was used to assess overall differences among groups, followed by Dunn's test with Bonferroni correction for pairwise comparisons.

Results: Results showed that RTX-treated patients in remission had significantly higher serum BAFF levels compared to healthy controls ($p < 0.0001$). In contrast, there was no significant difference in BAFF levels between the overall acute phase group and controls. Notably, one RTX-treated patient in the stable group exhibited an exceptionally high BAFF level (1771.26 pg/mL) and experienced a clinical relapse one month later.

Conclusion: NMOSD patients treated with rituximab exhibit persistently high expression of BAFF. Extremely high BAFF levels may predict relapse in RTX-treated patients, serving as a potential early biomarker for relapse.

Disclosure: Nothing to disclose.

EPO-0984 | Menopause in multiple sclerosis: Treatments and quality of life

C. Oreja-Guevara¹; J. Casablanca Mezquita¹; L. García-Vasco¹; J. Moarquech Rodriguez¹; A. Paz Tamayo¹; P. Coronado Martin²; I. Gómez Estévez¹

¹Neurology, Hospital Clínico San Carlos, Madrid, Spain;

²Gynecology, Hospital Clinico San Carlos, Madrid, Spain

Background and aims: Menopausal symptoms may overlap with multiple sclerosis (MS) manifestations and contribute to reduced quality of life (QoL). To characterize the use of menopausal hormone therapy (MHT) and symptomatic pharmacological treatments during menopause and to assess the effect of menopause on quality of life (QoL) in women with MS

Methods: Cross-sectional, observational study including postmenopausal women with MS. QoL was measured with the Short Cervantes Scale (SF-16). Demographic and clinical data, as well as current MHT and symptomatic drug use, were recorded. Suitability for MHT was evaluated using a standardized algorithm derived from Spanish Society of Gynecology recommendations.

Results: Ninety-eight women were enrolled (mean age 52 years), with a mean interval of 4 years since the final menstrual period. Anxiety was present in 65%, fatigue in 76%, and urinary symptoms in 51%. Only 7.1% were on MHT, despite a large proportion fulfilling eligibility criteria (56.5% for combined oral MHT and 83% for combined transdermal MHT). Compared with the premenopausal phase, menopause was associated with increased prescriptions of symptomatic medications: antidepressants +33%, anxiolytics +42%, hypnotics +33%, and drugs for urinary symptoms +48%. Higher symptomatic drug use correlated with poorer baseline QoL. The worst scores were found in the menopause/health and psychological domains. The mean global Cervantes score was 37.6 (SD 19.0), and 50% of participants showed impaired QoL (29.6% mild impairment, 20.4% QoL could be improved).

Conclusion: Menopause increases the QoL burden in women with MS and worsens shared “invisible” symptoms. Optimizing menopause care, including appropriate MHT, may reduce polypharmacy and improve well-being

Disclosure: Celia Oreja-Guevara has received speaker and consultation fees from Alexion, Amgen, Biogen Idec, BMS, Juvise, Merck, Novartis, Roche, Sanofi-Genzyme, Sandoz, Viartis and Neuraxpharm. The rest of authors nothing to disclose.

¹Department of Neuroscience, Aziz Sancar Institute of Experimental Medicine, Istanbul University, Istanbul, Türkiye;

²Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye

Background and aims: Neurofilament light chain (NfL) is an important serological biomarker with prognostic relevance in multiple sclerosis (MS). This study aimed to investigate the presence of humoral immunity against NfL in patients with MS.

Methods: Patients fulfilling the 2017 MS diagnostic criteria with a minimum follow-up of three years were included. Baseline cerebrospinal fluid (CSF) NfL levels, serum NfL levels at the last visit, anti-NfL antibodies, and the levels of interleukin-10, IL-27, IL-35, C-X-C motif chemokine ligand 13 (CXCL13) and transforming growth factor-beta were measured. Associations between antibody and cytokine levels and disability accumulation were analyzed.

Results: The study included 47 patients with relapsing remitting MS, nine with primary progressive MS (PPMS), and 20 healthy controls. The median age of MS patients was 33 (IQR: 26–48), and the median disease duration was 5.4years (IQR: 4.4–8.7). No association was found between CSF anti-NfL antibody levels and the time to reach an Expanded Disability Status Scale (EDSS) score of 3 ($p=0.95$) or the time to the second relapse ($p=0.6$). Serum CXCL13 levels were lower in PPMS patients compared with healthy controls ($p=0.03$). No correlation was observed between NfL levels and anti-NfL antibodies in serum/CSF. Serum NfL was better at distinguishing MS subgroups than CSF NfL. CSF IL-27 levels were lower in samples obtained during relapse compared with remission ($p=0.02$).

Conclusion: Anti-NfL antibody presence was not associated with prognostic outcomes in MS. Serum NfL levels were more sensitive than CSF NfL levels in differentiating MS subgroups.

Disclosure: The present work was supported by the Research Fund of Istanbul University and the “Geleceğimsin” Project Support Program of the Turkish Multiple Sclerosis Society. Project No: 41971.

EPO-0986 | Clinical and MRI correlates of overactive bladder symptoms in relapsing–remitting multiple sclerosis: A preliminary study

F. Sarıdaş; F. Hojjati; S. Albak; E. Koç

Department of Neurology, Faculty of Medicine, Bursa Uludağ University, Bursa, Türkiye

Background and aims: Overactive bladder (OAB) is a common but underrecognized condition in relapsing–remitting multiple sclerosis (RRMS). Its associations with clinical characteristics, disability, magnetic resonance imaging (MRI) findings, and symptom-specific contributors remain unclear. This study evaluated factors associated with OAB symptoms and the contribution of individual OAB Questionnaire–V8 items.

Methods: Between February 2023 and February 2024, 197 patients assessed with the OAB-V8 and with MRI performed

FIGURE 1: Correlation analyses between overactive bladder status and age, disease duration, annualized relapse rate, and EDSS.

FIGURE 2 Proportional distribution of lesion localization according to overactive bladder status and contribution of individual OAB-V8 questionnaire items to the total score

TABLE 1 Comparison of demographic, clinical, and radiological characteristics according to OAB-V8 score.

		OAB Score <8	OAB Score ≥8	P value
Sex	Female, n=112	46(37.7%)	76(62.3%)	0.028
	Male, n=58	7(18.4%)	51(81.6%)	
Age		45.33±10.01, 45 (19–85)	37.7 (11.38, 37 (18–67)	0.003
Disease duration		7.55±5.66, 8 (0–25)	5.91±5.42, 4 (0–25)	0.058
ARR		0.67±0.35, 0.33 (0.08–1.87)	0.53±0.37, 0.34 (0.07–2)	0.323
EDSS		1.63±1.06, 1 (0–5.5)	1.21±0.85, 1 (0–4)	0.011
Periventricular	Present	51(32.9%)	194(67.1%)	0.741
	Absent	3(40%)	3(60%)	
Cortical/subcortical	Present	50(34.7%)	94(65.3%)	0.615
	Absent	3(18.8%)	13(12.1%)	
Temporal	Present	22(35.5%)	46(41.9%)	0.199
	Absent	31(31.6%)	67(68.4%)	
Spinal Cord	Present	58(34.5%)	73(65.5%)	0.622
	Absent	5(41.7%)	5(38.3%)	
Infratentorial	Present	17(31.5%)	57(68.5%)	0.753
	Absent	26(34%)	70(66%)	
Cerebellum	Present	4(33.3%)	18(66.7%)	1
	Absent	44(33.3%)	88(66.7%)	
Cervical	Present	18(35.2%)	70(64.8%)	0.378
	Absent	15(30.6%)	34(69.4%)	
Thoracic	Present	9(29%)	18(75%)	0.131
	Absent	14(37.8%)	25(62.2%)	

within the preceding year were screened; after exclusions, 160 patients with RRMS were included. Patients were grouped by OAB-V8 score (<8 vs. ≥8). Clinical and radiological characteristics were analyzed, and correlations between OAB-V8 scores and clinical parameters were assessed.

Results: Patients with OAB-V8 scores ≥8 were older and had higher Expanded Disability Status Scale (EDSS) scores than those with scores <8. OAB-V8 scores correlated moderately with age ($\rho=0.327$, $p<0.001$) and weakly with EDSS ($\rho=0.177$, $p=0.025$). No significant associations were found with disease duration, annualized relapse rate, or MRI lesion localization. Sub-question analysis showed that sudden urgency (Q3; $r=0.786$), bothersome urgency (Q2; $r=0.773$), and daytime frequency (Q1; $r=0.753$) were the strongest contributors to the total OAB-V8 score.

Conclusion: Although lesion localization—particularly spinal cord involvement—has been linked to urinary dysfunction in some studies, evidence remains inconsistent, with disability and overall disease burden emerging as stronger determinants of OAB symptoms. Urgency-related symptoms primarily drive OAB severity, highlighting the importance of focused symptom assessment.

Disclosure: Nothing to disclose.

EPO-0987 | MS-FLOWER, an ongoing U.S. multicenter pilot study to identify challenges to MSCopilot®'s integration into multiple sclerosis standard clinical care

L. Freeman¹; G. Pardo²; J. Feng³; T. Brodu⁴; L. Carment⁴; C. Gorin⁴; L. Klaylé⁴; S. Zinaï⁴; J. Graves⁵; R. Naismith⁶
¹Department of Neurology, Dell Medical School, The University of Texas at Austin, Austin, USA; ²Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, USA; ³Multiple Sclerosis Center of Excellence, Oklahoma Medical Research Foundation, Oklahoma City, USA; ⁴The Desi Roth Harrison Center for Multiple Sclerosis, Ochsner Medical Center, New Orleans, USA; ⁵Ad Scientiam, Paris, France; ⁶Department of Neurosciences, University of California, San Diego, USA; ⁶Department of Neurology, Washington University School of Medicine, St. Louis, USA

Background and aims: MSCopilot®, a clinically validated software-as-medical-device (SaMD), and its digital biomarkers measure Multiple Sclerosis (MS) impact on walking, vision, cognition, and dexterity enabling remote symptoms' self-assessment. While prior studies demonstrated that MSCopilot® scores correlate with the Extended Disability Scale Score (EDSS) and the 4-item MS functional composite, integrating the tool into routine care remains challenging. MS-FLOWER (NCT06922942) is a U.S. pilot study evaluating the feasibility, usability, and integration of MSCopilot® in routine care.

Methods: This 6-month prospective study follows people with MS and their healthcare providers (HCPs). Patients remotely complete MSCopilot® monthly digital tests and questionnaires: Patient Health Questionnaire (PHQ-8) and Modified Fatigue Impact Scale-5 (MFIS-5). HCPs review results through a web dashboard. Questionnaires evaluating training, onboarding process, ease of use of MSCopilot® at-home and clinical workflows integration are administered to both patients and HCPs (Figure).

Results: Eight MS specialists recruited 62 patients (75.8% female, mean age 45.3±11.2 years, median EDSS 2.0). The population included 92.0% relapsing-remitting MS, 3.2% active secondary progressive MS (SPMS), 1.6% non-active SPMS and 3.2% primary progressive MS. Following onboarding, all HCPs felt confident introducing MSCopilot® to patients with 75% doing so in 5 minutes or less. All patients surveyed after inclusion ($n=28$) reported MSCopilot® was easy to use.

Conclusion: Clinical integration of MSCopilot® could enhance disease monitoring, optimize clinical workflows, and improve patient engagement. This study paves the way for broader adoption of digital biomarkers in routine care, supporting personalized, data-driven disease management.

EPO-0988 | **Reduced hippocampus–amygdala transition area (HATA) volume in progressive multiple sclerosis: A cross-sectional MRI study**

F. Allahverdi¹; B. Celenk¹; A. Unal¹; B. Sunal²
¹Department of Neurology, Tekirdağ Namık Kemal University Hospital, Tekirdağ, Türkiye; ²Department of Radiology, Tekirdağ Namık Kemal University Hospital, Tekirdağ, Türkiye

Background and aims: MRI biomarkers of progression remain limited in multiple sclerosis. Progressive multiple sclerosis (PMS) is characterized by neurodegeneration and disability accumulation. Mesotemporal substructures, including the hippocampus–amygdala transition area (HATA), may undergo phenotype-related atrophy. We examined whether bilateral HATA volume differs between PMS and relapsing–remitting MS (RRMS).

Methods: Cross-sectional cohort of 106 MS patients (RRMS $n=68$; PMS $n=38$) underwent T1-weighted MRI. HATA and amygdala nuclei volumes were derived with FreeSurfer. The primary endpoint was bilateral HATA volume (mm³). Phenotype effects were estimated using multivariable OLS with HC3-robust standard errors, adjusting for age, sex, disease duration, and intracranial volume (ICV; per 100,000 mm³). Secondary ROI tests used Benjamini–Hochberg FDR.

Results: Bilateral HATA volume was lower in PMS than RRMS (mean [SD] 88.49 [17.85] vs 106.74 [18.49] mm³). In the adjusted model, PMS was associated with reduced bilateral HATA (beta = −10.11 mm³; 95% CI −17.62 to −2.60; $p=0.008$). The phenotype effect was significant for left HATA (beta = −6.59; $p=0.003$) but not right (beta = −3.52; $p=0.145$). No secondary ROI survived FDR correction. An HATA-by-phenotype interaction suggested a stronger HATA–MSFC association in PMS ($p=0.035$).

FIGURE 1 Normalized bilateral HATA volume is lower in PMS than RRMS (normalization: (HATA/ICV) × 10⁶).

FIGURE 2 ROI-wise PMS effect (β, 95% CI) from HC3-robust OLS models adjusted for age, sex, disease duration and ICV

TABLE 1 Primary model (bilateral HATA): PMS associated with lower HATA volume after adjustment (β = −10.11 mm³; 95% CI −17.62 to −2.60; $p=0.008$)

Primary model: Bilateral HATA volume (mm ³)			
Predictor	β (mm ³)	95% CI	p
PMS (vs RRMS)	−10.11	[−17.62, −2.60]	0.008
Age (per year)	−0.02	[−0.38, 0.34]	0.995
Male sex	−3.44	[−9.74, 2.87]	0.283
Disease duration (per year)	−0.12	[−0.64, 0.41]	0.651
ICV (per 100,000 mm ³)	−0.79	[−0.42, −1.15]	<0.001

Conclusion: Bilateral HATA volume is reduced in PMS after adjustment for intracranial volume and clinical covariates, consistent with HATA as a candidate mesotemporal marker of progressive phenotype. Longitudinal, lesion-aware validation is warranted.

Disclosure: Nothing to disclose.

Background and aims: Visual onset (VO) is common in multiple sclerosis (MS) and is associated with a better prognosis. Cerebrospinal fluid (CSF) biomarkers of intrathecal immunoglobulin synthesis are increasingly investigated for early prognostic stratification; however, the prognostic role of lambda-free-light-chain (L-FLC, Lambda) index remains unclear. This pivotal study investigated whether VO is associated with a distinct CSF biomarker profile, focusing on Lambda index.

Methods: This monocentric retrospective observational study included 217 MS-patients (2017 McDonald criteria) at diagnostic lumbar puncture, classified as VO ($n=50$) or non-VO (brainstem, cerebellar, sensory, motor, sphincteric, or spinal). Age at onset (AAO), disease duration (DD), and MRI features (lesion count, spinal cord involvement, and gadolinium-enhancing lesions) were collected. CSF/serum IgG, kappa and LFLC were collected to calculate IgG, Kappa, and Lambda indexes. Group comparisons (Student's, Mann-Whitney U and Chi-square test) and multivariable linear regression analyses were performed; sensitivity analyses used log-transformed Lambda values.

Results: VO-patients were younger than non-VO (mean $\pm$ SD: 36.0 ± 11.3 vs 42.0 ± 12.2 years), with no differences in MRI burden. Lambda index was significantly lower in VO (median [IQR]: 4.9 [10.4]) than non-VO (8.3 [17.0]; $p=0.019$). This difference remained after adjustment for AAO and DD, which were not independently associated with Lambda index, and persisted in sensitivity analyses. No differences were observed for other biomarkers.

Conclusion: In this pivotal study, VO is associated with a lower Lambda index despite similar radiological burden, suggesting a distinct intrathecal humoral responses across onset phenotypes. The Lambda-index may refine early prognostic stratification in MS and warrants validation in larger cohorts.

EPO-0990 | Quantitative gait analysis for the detection and longitudinal monitoring of progressive multiple sclerosis: Relevance of the semiogram

C. Voisard; D. Ricard

Université Paris Saclay, Université Paris Cité, Ecole Normale Supérieure Paris Saclay, Centre National de la Recherche Scientifique, Service de Santé des Armées, INSERM, Centre Borelli, Gif-sur-Yvette, France

Background and aims: In progressive multiple sclerosis (pMS), gait deterioration is a key marker of disability. To detect progression, conventional clinical scales such as the EDSS remains limited in sensitivity and granularity. Inertial sensors are relevant tools for quantifying gait quality in clinical settings. It may enable the development of digital movement biomarkers for detection and follow-up of progression, and to provide information for functional rehabilitation and therapeutic adaptation.

Methods: Twenty-two patients with pMS (11 women, mean age 58 years, mean EDSS 5.5 [3.5–6]) and 19 control subjects (12 women, mean age 51 years) performed 10-meter walking tests with u-turn every 6 months over 1 to 2 years, equipped with 3 inertial sensors. Parameters computed from accelerometry and gyrometry time-series were aggregated according to semiological criteria, compared to healthy population, and compiled into a visual radar named “semiogram” (see Figure). Correlations between these scores and established functional scales such as the EDSS were analyzed.

Results: The reproducibility of the parameters was excellent. All studied parameters, except stability, were able to discriminate patients from healthy subjects. A significant correlation was demonstrated between gait parameters and clinical scores, particularly the EDSS and motor subscores. It also support a better sensibility to progression compared with the EDSS.

Conclusion: Sensor-based gait analysis through a multidimensional score is an objective and sensitive biomarker of motor disability in pMS detection and follow-up. Sensors time-series provide clinically relevant information for personalized monitoring and rehabilitation, which will be crucial in coming years to evaluate new treatments for progressive forms of multiple sclerosis.

Disclosure: Nothing to disclose.

¹Department of Neurology, Habib Bourguiba University Hospital, Sfax, Tunisia; ²Department of Pulmonology, Hedi Chaker University Hospital, Sfax, Tunisia

Background and aims: Multiple sclerosis (MS) is an inflammatory demyelinating disease of the central nervous system, in which sleep disorders are frequent but often underrecognized, contributing to disability and reduced quality of life.

Methods: We conducted a cross-sectional, descriptive, and analytical study including patients with MS at Habib Bourguiba University Hospital between January 2023 and September 2024. Sleep disorders were assessed using the Insomnia Severity Index (ISI), the Epworth Sleepiness Scale (ESS), the Pittsburgh Sleep Quality Index (PSQI), and the STOP-BANG questionnaire. Restless legs syndrome and parasomnias were investigated through clinical interviews. Clinical, radiological, and therapeutic data were extracted from medical records.

Results: Eighty patients with MS were included; 63.8% had at least one sleep disorder. Poor sleep quality (PSQI > 5) was found in 57.5%, moderate to severe insomnia in 27.5%, parasomnias in 25%, excessive daytime sleepiness in 28%, and restless legs syndrome in 21.3%. Sleep disorders were significantly associated with unemployment ($p=0.037$), longer diagnostic delay ($p=0.045$), higher EDSS score ($p=0.048$), and symptoms such as spasticity, neuropathic pain, and decreased libido ($p=0.026$, $p=0.018$, and $p=0.043$, respectively). Radiologically, lesion localization in the corona radiata was associated with the presence of sleep disorders ($p=0.006$). Therapeutically, baclofen ($p=0.004$) and hypnotics ($p=0.045$) were associated with these disorders.

Conclusion: Sleep disorders are commonly observed in patients with MS and are influenced by clinical, psychological, and radiological factors. Systematic screening and multidisciplinary management are essential to improve quality of life.

EPO-0992 | Clinical phenotype at onset predicts early functional outcomes in pediatric acquired demyelinating syndromes

E. Maida¹; M. Risi¹; D. Iannaccone²; M. Gazzillo¹; A. Varone¹
¹Pediatric Neurology, Santobono-Pausilipon Childrens Hospital, Naples, Italy; ²Department of Pediatric, Università degli Studi di Salerno, Salerno, Italy

Background and aims: We assessed whether onset phenotype predicts functional severity at presentation and outcome at discharge in pediatric acquired demyelinating syndromes (ADS).

Methods: We retrospectively analyzed pediatric ADS ($n=65$), including myelin oligodendrocyte glycoprotein antibody-associated disease, classified at onset as encephalitic (acute disseminated encephalomyelitis/cortical/cerebral deficits), optic neuritis, brainstem/cerebellar, or myelitis. Functional severity was measured with the Pediatric Cerebral Performance Category (PCPC). PCPC at onset was compared using Kruskal–Wallis

TABLE 1 Demographic and clinical characteristics of the overall cohort and by onset phenotype in pediatric acquired demyelinating syndromes (ADS). Data are reported as n (%) or median (interquartile range).

Variable	Total (n=65)	Optic neuritis (n=16)	Encephalitic (n=23)	Brainstem/Cerebellar (n=15)	Myelitis (n=11)
Demographics (n (%))					
Age at onset (years; median (IQR))	7 (4-11)	6 (4-10)	6 (4-11)	6 (3-10)	6 (4-11)
Female:male ratio (n (%))	33 (50.8):32 (49.2)	16 (100):0 (0)	12 (52.2):11 (47.8)	8 (53.3):7 (46.7)	5 (45.5):6 (54.5)
Median time to diagnosis (months; median (IQR))	12 (3-20)	10 (3-18)	12 (3-20)	12 (3-20)	12 (3-20)

Total (n=65)					

IQR, Interquartile Range; n, absolute; PCPC, Pediatric Cerebral Performance Category.

FIGURE 1 PCPC severity at onset by clinical phenotype in pediatric acquired demyelinating syndromes (ADS). Boxplots show median and interquartile range. Pairwise differences are based on Dunn's post-hoc test with Bonferroni correction.

with Dunn post-hoc tests. Ordinal logistic regression assessed associations between phenotype and PCPC at onset and discharge, adjusting for age, sex, and preceding infection. Length of stay was analyzed using linear regression.

Results: PCPC at onset differed across phenotypes ($p<0.001$); Dunn post-hoc showed higher PCPC in encephalitic vs optic neuritis and myelitis vs optic neuritis (both $p<0.001$). In adjusted ordinal models, encephalitic phenotype (OR 48.7, 95% CI 9.33–341; $p<0.001$) and myelitis (OR 58.0, CI 9.49–474; $p<0.001$) were associated with worse PCPC at onset; older age (OR 1.17, CI 1.02–1.37; $p=0.034$) and preceding infection (OR 3.10, CI 1.03–9.89; $p=0.048$) were also associated with higher PCPC. At discharge, encephalitic phenotype remained associated with worse PCPC (OR 9.01, CI 2.34–39.3; $p=0.002$); myelitis showed a trend (OR 3.96, CI 0.92–18.4; $p=0.069$); age remained associated (OR 1.17 per year, CI 1.02–1.34; $p=0.027$). Encephalitic phenotype was associated with longer hospital stay (CI 1.67–19.7; $p=0.021$).

Conclusion: In our cohort, onset phenotype strongly predicts functional severity and early outcome. Encephalitic

presentations carry the highest acute burden, persistently worse discharge status, and longer hospitalization, supporting phenotype-informed risk stratification at admission.

Disclosure: Nothing to disclose.

EPO-0993 | **Optical coherence tomography (OCT)-based retinal nerve fibre layer thickness associations with radiological data in lithuanian patients with MS**

I. Vienažindytė¹; V. Danielius¹; R. Balnytė¹; A. Žygaitė²; B. Glebauskienė³

¹Department of Neurology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; ²Medical Faculty, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; ³Department of Ophthalmology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and aims: Longitudinal monitoring of multiple sclerosis (MS) relies mainly on repeated magnetic resonance imaging (MRI), which can be limited by cost, availability, and the need for contrast agents. The 2024 McDonald criteria now include the optic nerve as a fifth location for dissemination in space, enabling assessment with optical coherence tomography (OCT), a non-invasive and accessible alternative for tracking disease progression.

Methods: We conducted a retrospective medical documentation review of patients diagnosed with MS according to the 2010/2017 McDonald criteria, treated at the Department of Neurology of Kauno Klinikos, Lithuanian University of Health Sciences (LUHS) Hospital.

Results: A total of 84 MS patients were included, 85 % have relapsing-remitting disease course. Spearman's bivariate correlation analyses and odds ratio estimations using ordinal logistic regression were performed (Table 1). A marginally significant association was observed between changes in pRNFL thickness over time and the appearance of new periventricular lesions. An ordinal logistic regression analysis was performed to determine whether a single measurement of pRNFL thickness correlated with MRI lesion load, adjusted for age and gender. pRNFL thickness was a significant prognostic factor for MRI lesion load, with each 1 µm reduction in pRNFL thickness associated with a 5 % higher probability of being classified into a higher lesion category (Table 2).

TABLE 1 Correlation between MRI changes and peripapillary retinal nerve fiber layer (pRNFL) thickness changes over time in OCT measurements.

Lesion region	Spearman's ρ coefficient	Spearman correlation p-value	Odds ratio	95% confidence interval	p-value (OR)
Subcortical	-0.075	0.499	0.830	0.633-1.090	0.180
Periventricular	0.216	0.049	1.381	0.837-2.277	0.205
Infratentorial	0.056	0.613	1.051	0.936-1.181	0.395
Spinal cord	-0.018	0.869	0.992	0.923-1.065	0.818
Signs of activity	0.078	0.481	1.029	0.971-1.092	0.818

Spearman's ρ coefficients and p-values were obtained from bivariate correlation analysis. Odds ratios (OR), 95% confidence intervals (CI), and corresponding p-values were derived from ordinal logistic regression (PLUM method).

TABLE 2 Correlation between MRI changes (number of lesions) and pRNFL variation in a single OCT measurement.

Variables	B	SE	p-value	OR (Exp(B))	95% CI (OR)
Single OCT pRNFL	-0.052	0.023	0.023	0.95	[0.91, 0.99]
Gender	0.968	0.510	0.050	2.69	[1.00, 7.30]
Age	0.013	0.025	0.596	1.01	[0.96, 1.06]

Ordinal logistic regression predicting baseline MRI lesion load (dependent variable: MRI_total_1; higher values indicate a greater number of lesions). Dependence of MRI lesion changes on the predictor variables. SE – standard error; OR – odds ratio, CI – confidence interval.

Conclusion: No significant associations were found between single-timepoint pRNFL thickness and individual MRI lesion locations, while a weak borderline correlation with paraventricular lesion dynamics was considered a statistical artefact. Reduced pRNFL thickness was an independent predictor of higher overall MRI lesion burden.

Disclosure: Nothing to disclose.

EPO-0994 | **sNfL and sGFAP as prognostic biomarkers in pediatric multiple sclerosis**

M. Simone¹; F. Pennetta²; R. Palumbi²; M. Achille²; M. Ruggeri²; A. Frigeri²; L. Giuseppe³; D. Andrea²; M. Lucia¹; G. Monte⁴; L. Papetti⁴; M. Ferilli⁴; F. Piemonte⁵; M. Valeriani⁴

¹Department of Precision and Regenerative Medicine, Ionic Area, Child Neuropsychiatric Unit, University of Bari, Bari, Italy; ²Department of Translational Biomedicine and Neuroscience, Child Neuropsychiatric Unit, University of Bari, Bari, Italy; ³Center for Outcomes Research and Clinical Epidemiology (CORESEARCH), Pescara, Italy; ⁴Developmental Neurology Unit, Ospedale Pediatrico Bambino Gesù, Rome, Italy; ⁵Unit of Muscular and Neurodegenerative Diseases, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy

Background and aims: Pediatric multiple sclerosis (PedMS) is characterized by high inflammatory activity and neuroaxonal and glial damage. Serum biomarkers able to detect subclinical disease activity are relevant in this population. This study assessed the prognostic value of serum neurofilament light chain (sNfL) and glial fibrillary acidic protein (sGFAP) in predicting clinical, radiological, and cognitive outcomes in PedMS.

Methods: This study included PedMS followed at two Italian referral centers. All patients underwent cognitive assessment using the Symbol Digit Modalities Test (SDMT), physical disability evaluation using EDSS, as well as brain MRI scans and sNfL and sGFAP measurement by SIMOA and the Ella systems, at baseline and every 6 months for 24 months. Correlation analysis was performed using Spearman nonparametric test.

Results: Fifty-three PedMS [71.7% females; median age at onset: 14 (IQR 13.0–16.0) years; median EDSS: 2.0 (IQR 1.0–3.0); median SDMT scores: 49.0 (IQR 40.0–55.0)] were included. Baseline median levels of sNfL were 19.9 (IQR 7.5–37.0) pg/mL and those of sGFAP were 103.3 (IQR 86.6–131.3) pg/mL. Higher baseline sNfL levels were significantly ($p < 0.05$) associated with younger age at onset and, although not statistically significant

(range $p=0.05$ – 0.1), with increased physical and cognitive impairment and a treatment switch during follow-up. Elevated baseline sGFAP levels were significantly ($p<0.05$) associated with EDSS score at 24 months and higher number of clinical relapses ($p<0.05$) during the follow-up.

Conclusion: The integration of sNfL and sGFAP levels with clinical, radiological and cognitive assessments can improve early risk stratification and support personalised therapeutic strategies in PedMS.

Disclosure: Nothing to disclose.

EPO-0995 | Functional neurological symptoms in multiple sclerosis: A scoping review

Z. Soysal¹; S. Gluscevic²; S. Samadzadeh³; A. Dunalska⁴; K. Saramak⁵; A. Kulakowska⁶; M. Edwards⁷; S. Aybek⁸; N. Szejko⁹

¹Department of Neurology, Faculty of Medicine, Kocaeli University, Kocaeli, Türkiye; ²Department of Neurology, Clinical Centre of Montenegro, Podgorica, Montenegro; ³Experimental and Clinical Research Center, Charité-Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany; ⁴Department of Psychiatry, Faculty of Health Sciences, Medical University of Warsaw, Warsaw, Poland; ⁵Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria; ⁶Department of Neurology, Medical University of Białystok, Poland; ⁷Department of Basic & Clinical Neuroscience, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UK. Department of Neuropsychiatry, South London and Maudsley NHS Foundation Trust, London, UK; ⁸Department of Neurosciences, Faculty of Science and Medicine, University of Fribourg, Fribourg, Switzerland; ⁹Department of Bioethics, Medical University of Warsaw, Warsaw, Poland. Department of Experimental and Clinical Pharmacology, Center for Preclinical Research and Technology CEPT, Medical University of Warsaw, Warsaw, Poland

Background and aims: Functional neurological symptoms (FNS), including functional motor and sensory disturbances or non-epileptic seizures, may co-occur with multiple sclerosis (MS) and complicate both diagnosis and management. This scoping review aimed to synthesize available literature on the prevalence, clinical features, diagnostic approaches, and management strategies for FNS and functional overlay in individuals with MS.

Methods: Following the PRISMA-ScR guidelines, we searched PubMed, Embase, and PsycINFO from inception to July 2025. Studies were eligible if they reported FNS in people with MS. Two reviewers independently screened records, extracted data, and charted results. Data were summarized narratively across domains of prevalence, symptom types, diagnostic pathways, and management interventions.

Results: The search retrieved 1,042 records, of which 47 met inclusion criteria (15 observational studies, 20 case series, 12 single case reports). Reported prevalence of FNS varied widely, ranging from 3% to 21% across clinical samples. Functional motor symptoms (paresis, gait disturbance) and functional sensory loss were the most frequently described; psychogenic non-epileptic seizures and functional tremor were less common but

often led to diagnostic delay. Neuroimaging and neurophysiological testing were frequently used to distinguish functional from demyelinating symptoms, though misdiagnosis was reported in up to 15% of cases. Interventions most often involved multidisciplinary rehabilitation, psychological therapies, and patient education. Evidence for treatment effectiveness was limited, with most data from uncontrolled studies.

Conclusion: FNS are under-recognized but clinically relevant in MS. They may contribute to increased disability, healthcare utilization, and patient distress if not appropriately identified. This review highlights the need for high-quality prospective studies to evaluate targeted interventions.

Disclosure: Nothing to disclose.

EPO-0996 | Reassessing PML risk in multiple sclerosis: The impact of anti-JCV antibody Assay selection

J. Polovina; D. Landi; G. Mataluni; C. Nicoletti; F. Napoli; C. Dionisi; V. Di Gianvito; A. Miscioscia; M. Campobasso; G. Marfia

Department of Systems Medicine, MS Center, Tor Vergata University, Rome, Italy

Background and aims: Natalizumab (NTZ) treatment increases the risk of progressive multifocal leukoencephalopathy (PML) due to JC virus (JCV) reactivation in people with Multiple Sclerosis (pwMS). PML risk has been assessed for several years via the Stratify Test (ST), a reference anti-JCV antibody assay. A new assay, Immunowell JCV Test (IT), has recently entered clinical use with the introduction of biosimilar NTZ. The aim of our study is to reassess PML risk using the IT in comparison with the established assay ST.

Methods: We enrolled 169 NTZ-treated pwMS at Tor Vergata MS Center. Paired serum samples were collected and tested with both tests on the same day. Mean and median JCV index values were compared. Patients were categorized into four risk categories based on test-specific cut-offs, and frequency distributions were analyzed.

Results: Mean and median JCV index values were higher for IT (0.85 and 0.32) than for ST (0.63 and 0.00). Risk class distributions differed significantly between the two tests (McNemar test, $p<0.001$), especially at risk extremes. A discordant risk class was observed in 113 patients (66.9%). Sign and Wilcoxon tests confirmed a significant statistical difference, with IT assigning higher risk categories than ST in 107 cases, compared with only 6 cases in which ST assigned a higher class ($p<0.001$).

Conclusion: The new IT assay tends to reclassify patients into higher PML risk categories, which may influence clinical decisions. Further validation is needed to assess IT's specificity and correlation with JCV replication, to support accurate risk stratification and avoid unnecessary therapy changes.

Background and aims: Autologous haematopoietic stem cell transplantation (aHSCT) has historically been considered a rescue therapy for multiple sclerosis (MS) due to safety concerns. Improved transplant strategies and better patient selection are expanding its use, particularly in treatment-naïve patients.
Methods: In this retrospective single-centre observational study, all patients with MS treated with aHSCT per clinical practice (Muraro et al, Nature Reviews Neurology 2025) since 2022, were included.
Results: Fourteen patients (7F), all with ‘aggressive MS’, were included (Table 1): 13 with relapsing-remitting and one with active-progressive MS. Median age was 26.8 years (range 20.2–33.8), median EDSS 3.3 (range 1.0–6.0), and median disease duration 1.5 years (range 0.2–12.5). Patients were treatment-naïve (6/14) or early switchers (7/14). Only one patient, with paediatric onset, displayed longer disease duration and several previous treatments. Follow-up was more than 24 months in one patient, 12 months in six patients, six months in two, three months in

CYC+ATG† – no. (%)	1 (9.1)
Duration of follow-up – median (range), y	1.5 (1.3–2.2)

Abbreviations: tot. = total; aHSCT = autologous Hematopoietic Stem Cell Transplantation; CYC = cyclophosphamide; G-CSF = Granulocyte Colony Stimulating Factor; BEAM = busulfan, etoposide, cytarabine, melphalan; ATG = anti-thymocyte globulin.
*Chemo-free regimen was chosen due to previous CYC liver injury. In the same patient a conditioning regimen with mini-BEAM + ATG was chosen.
†CYC + ATG conditioning regimen was chosen in the patient with paediatric onset MS.

two, while three were still completing the procedure (2 post-apheresis, 1 post-mobilization). Mobilization and conditioning regimens are listed in Table2. No clinical relapses or MRI activity were observed after transplant. EDSS improved in 9/11 evaluable patients, one patient remained stable, whereas the progressive one worsened without inflammatory activity. Febrile neutropenia occurred in 9/11 patients and mild anti-thymocyte globulin reactions in 4/11. No late toxicities were reported.
Conclusion: Our findings support a paradigm shift toward earlier use of aHSCT in selected MS patients. Young age, short disease duration and low disability characterized our cohort. Larger studies with longer follow-up are needed to confirm efficacy and long-term safety.

EPO-0998 | Clinical course, safety, and pregnancy outcomes in multiple sclerosis patients treated with cladribine: Single center real-world experience

M. Koseoglu; M. Demir; U. Ozoglu; G. Yaman; K. Oguz
Neurology Clinic, University of Health Sciences, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Türkiye

Background and aims: To evaluate clinical, hematological, and pregnancy outcomes of relapsing-remitting multiple sclerosis (RRMS) patients treated with cladribine in a real-world setting.

Methods: We retrospectively analyzed 145 patients (screened from 190 admissions) with active follow-up and regular data. Demographics, EDSS scores, relapse rates, laboratory results (Years 1–2), MRI findings, adverse events, and pregnancy outcomes were evaluated.

Results: The mean age was 42.4 years (range 23–67), and 67% were female ($n=97$). Mean disease duration was 13.6 years. Relapses occurred in 26 patients (18%) during treatment, observing a higher frequency in females. Clinical and radiological stabilization was achieved in the majority. Regarding safety, Grade 3 lymphopenia ($<500/\text{mm}^3$) occurred in approximately 6–7% of patients, while Grade 4 ($<200/\text{mm}^3$) severe lymphopenia was rare (1%). Common adverse events included fatigue, herpes zoster, and alopecia. A total of 14 pregnancies were recorded (1 paternal). Outcomes included healthy live births and some pregnancy losses (ectopic/chemical/stillbirth); no developmental issues were reported in infants.

Conclusion: Cladribine demonstrated high efficacy and a manageable safety profile in this expanded real-world cohort ($n=145$). The incidence of severe lymphopenia was consistent with current literature. While healthy live births were achieved, pregnancy planning and monitoring remain crucial due to potential risks.

Disclosure: Nothing to disclose.

EPO-0999 | Exploratory CSF metabolomic profiling across oligoclonal band types 1–5 using ^1H -NMR spectroscopy

P. Sengul¹; A. Baykal²; M. Serteser³

¹Department of Neuroscience, Graduate School of Health Sciences, Acibadem Mehmet Ali Aydınlar University, Istanbul, Türkiye;

²Department of Medical Biochemistry, School of Medicine, Acibadem Mehmet Ali Aydınlar University, Istanbul, Türkiye;

³Acibadem Labmed Clinical Laboratories, Istanbul, Türkiye

Background and aims: Oligoclonal band (OCB) patterns in cerebrospinal fluid (CSF) represent distinct intrathecal immunological states and are routinely classified into five types (OCB Types 1–5). While OCB classification provides important diagnostic and immunological information, the associated biochemical heterogeneity within the CSF has not been systematically explored. To investigate whether CSF metabolomic profiles differ across OCB Types 1–5 using proton nuclear magnetic resonance (^1H -NMR) spectroscopy, focusing on spectral-level variability rather than definitive metabolite identification.

Methods: To investigate whether CSF metabolomic profiles differ across OCB Types 1–5 using proton nuclear magnetic resonance (^1H -NMR) spectroscopy, focusing on spectral-level variability rather than definitive metabolite identification.

Results: Distinct differences in CSF spectral profiles were observed across OCB-defined groups, with partial separation between specific OCB types. Several ppm regions demonstrated statistically significant or trend-level differences across OCB classifications. Exploratory pairwise evaluations suggested that comparisons involving OCB Types 4 and 5 tended to display more pronounced spectral variability, with selected ppm regions contributing disproportionately to group-wise patterns.

Conclusion: This exploratory analysis indicates that CSF metabolomic profiles vary across OCB Types 1–5, reflecting biochemical heterogeneity associated with distinct intrathecal immunological states. Although evaluated at the spectral level without definitive metabolite identification, these findings support the potential of CSF-based ^1H -NMR metabolomics as

FIGURE 1 Exploratory PCA score plot based on CSF ^1H -NMR spectral data, with samples colored according to OCB Types 1–5. PCA was performed at the ppm level without targeted metabolite annotation.

FIGURE 2 Distribution of CSF signal intensity at a representative ppm region across OCB Types 1–5.

a complementary approach to conventional OCB assessment. Further studies integrating targeted metabolite annotation and longitudinal clinical data are warranted.

Disclosure: Nothing to disclose.

EPO-1000 | From pregnancy to disability in multiple sclerosis: Can machine learning predict the course?

S. Alizada¹; M. Emec²; E. Kaya¹; Y. Simsek³; M. Ozcanhan⁴; S. Ozakbas³

¹Department of Neurology, Dokuz Eylul University, Izmir, Türkiye; ²Department of Computer Science, Istanbul University, Istanbul, Türkiye; ³Neurology Clinic, Izmir University of Economics, Izmir, Türkiye; ⁴Faculty of Engineering, Dokuz Eylul University, Türkiye

Background and aims: Pregnancy reduces relapse activity in relapsing–remitting multiple sclerosis (RRMS), yet postpartum disability evolution is heterogeneous. We aimed to predict postpartum disability trajectories using pregnancy-related clinical and obstetric variables with machine-learning models.

Methods: We retrospectively analyzed 662 women with RRMS contributing 909 pregnancies. Predictors included pre-/postpregnancy

FIGURE 1 Relative feature importance in predicting postpartum disability change top predictors of postpartum disability change (Δ EDSS) in women with multiple sclerosis. Feature importance values were averaged across Random Forest and XGBoost models.

TABLE 1 Performance of classification models for Δ EDSS categories.

Model	Train Acc	Test Acc	Train Precision	Test Precision	Train Recall	Test Recall	Train F1	Test F1
Random Forest	0.9794	0.8681	0.9804	0.8485	0.9794	0.8881	0.9794	0.8581
XGBoost	0.9986	0.8516	0.9986	0.8305	0.9986	0.8516	0.9986	0.8388

TABLE 2 Top 15 predictors of Δ EDSS across models.

Rank	Feature	P value
1	Postpartum Relapse	0.4911
2	Disease Duration at Pregnancy (years)	0.1050
3	Age	0.0770
4	Age at Pregnancy	0.0695
5	Pre-pregnancy EDSS	0.0560
6	Target EDSS	0.0559
7	Pregnancy Number	0.0317
8	Total Pregnancies	0.0253
9	Term Delivery	0.0203
10	RRMS Course	0.0170
11	Elective Termination	0.0163
12	SPMS Course	0.0138
13	Miscarriage	0.0110
14	Breastfeeding	0.0102
15	Birth After Diagnosis	0.0000

EDSS, disease duration, maternal age, postpartum relapse, pregnancy number, delivery type, and breastfeeding. After multiple imputation and standard preprocessing, regression (Δ EDSS) and 3-class classification (improved/stable/worsened) models were trained with an 80/20 split and 5-fold cross-validation (Random Forest, XGBoost, elastic net, and support vector methods).

Results: Classification generalized better than regression (test accuracy 85–88%, F1 0.84–0.87 vs test R^2 0.31–0.39; MAE 0.41–0.48 EDSS points). Postpartum relapse was the strongest predictor, followed by disease duration, age at pregnancy, and pre-pregnancy EDSS; obstetric variables showed smaller but relevant contributions. Performance was highest in women with multiple pregnancies (classification accuracy > 92%).

Conclusion: Machine learning can stratify postpartum disability risk in RRMS using routinely collected reproductive and clinical data, with categorical risk prediction outperforming continuous Δ EDSS prediction. Postpartum relapse remains the dominant driver of disability change, highlighting the postpartum period as a key therapeutic window; external validation is warranted.

EPO-1001 | Functional connectivity of sensorimotor network as function of EDSS: Preliminary resting state fMRI study in patients with secondary progressive MS

S. Gazdzinski¹; N. Hryniewicz²; E. Piątkowska-Janko²; K. Lipiński³; B. Błażejewska-Hyżorek⁴; A. Karlińska¹; P. Bogorodski³; P. Grieb⁵; M. Pawlak⁶; R. Rola¹; I. Kurkowska-Jastrzębska⁴

¹Military Institute of Aviation Medicine, Warsaw, Poland;

²Nalęcz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Warsaw, Poland; ³Warsaw University of Technology, Warsaw, Poland; ⁴Institute of Psychiatry and Neurology, Warsaw, Poland; ⁵Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland; ⁶Poznan University of Medical Sciences, Poznań, Poland

Background and aims: Demyelinating lesions in multiple sclerosis (MS) cause injury to neuronal paths and therefore lead to poorer communication between distant brain regions. This communication may be measured with functional magnetic resonance at rest (r-fMRI) and visualized as synchronization of neuronal activity between these regions. Sensorimotor network links regions responsible for processing sensory input and executing motor output; these regions are interconnected and their activity is synchronized even at rest. This preliminary analysis evaluated if higher EDSS scores are associated with sensorimotor network connectivity with other brain regions.

Methods: Seventeen patients with a diagnosis of secondary progressive MS (EDSS: 6.47 ± 1.42 (range: 3.5–8.5), age: 54.1 ± 1.4 , 7 males) without enhancing lesions on MRI were included. High resolution T1-w images and functional magnetic resonance data at rest were obtained at 3T and processed with CONN software.

Results: Higher scores on EDSS were related with poorer connectivity of sensorimotor regions with multiple regions in occipital cortex and cuneal cortex that is associated with visual processing, visual attention, spatial processing and object

recognition (blue color on FIGURE 1). However, higher EDSS scores demonstrated increased connectivity in the right crus of the cerebellum (contains motor tracts traveling from the cerebral cortex; red color on FIGURE 1).

Conclusion: Higher EDSS scores are associated with poorer connectivity with regions involved in visual processing. However, the increased connectivity with crus of the cerebellum suggests some compensatory mechanisms.

Disclosure: Nothing to disclose. This study was supported by Medical Research Agency of Poland, grant 2021/ABM/02/00002 – 00.

EPO-1002 | Brain volumetric MRI abnormalities associated with dysphagia in multiple sclerosis

D. Ranucci¹; A. Esposito¹; L. Corsaro¹; L. Mollo¹; C. Siniscalchi¹; F. Falco¹; G. Corsini¹; M. Aiello²; R. Iandolo²; V. Nicoletta¹; A. Castiello¹; S. Cocozza³; F. Briganti³; M. Moccia⁴; R. Iodice¹; V. Brescia Morra¹; R. Lanzillo¹; M. Petracca⁵; A. Carotenuto¹

¹Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples Federico II, Naples, Italy; ²IRCCS SYNLAB SDN, Naples, Italy; ³Department of Advanced Biomedical Sciences, University of Naples "Federico II", Naples, Italy; ⁴Department of Molecular Medicine and Medical Biotechnology, Federico II University of Naples, Naples, Italy; ⁵Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy

Background and aims: Multiple sclerosis (MS) patients may present dysphagia. The neuroanatomical alterations underpinning dysphagia in MS are debated.

Methods: In this cross-sectional study enrolling both MS patients and healthy controls (HCs), subjects underwent clinical assessment through Expanded Disability Status Scale (EDSS), Brief International Cognitive Assessment for MS (BICAMS), Swallowing Disturbance Questionnaire (SDQ), Beck Anxiety Inventory (BAI). Subjects performed brain MRI (T1/T2 sequences) at three sites. We assessed T2 lesions volume [lesion segmentation tool, SPM12, brain and gray matter volume (SIENAX), brainstem volume (Freesurfer), cerebellar volume (SUIT toolbox)]. We performed a multivariable linear regression using gray matter, T2 lesions, brainstem and cerebellar volume, BAI scores as factor of interest, SDQ as dependent variable and age, gender and sites as covariates.

Results: We enrolled 41 patients [30 females; age: 38.4 ± 10.4 years, 37 relapsing-remitting; disease duration: 8.5 (0–26) years; EDSS: 2.5 (1–5.5)] and 20 HCs (8 females; mean age 38.7 ± 13.4 years). Compared with HCs, MS patients had higher T2 lesion volumes (coeff. 6.97; $p=0.02$), lower normalized brain volume (coeff. -87.56 ; $p<0.01$) and reduced volumes of gray matter (coeff. -43.8 ; $p=0.001$), midbrain (coeff. -0.49 ; $p=0.003$), pons (coeff. -1.47 ; $p=0.002$) and medulla (coeff. -0.60 ; $p=0.003$) volume. Higher SDQ scores correlated with reduced volumes of pons (coeff. -0.93 ; $p=0.001$) and anterior cerebellar lobules (coeff. -1.12 ; $p=0.006$).

FIGURE 1 Regions in blue depict decreased functional connectivity with sensorimotor network in patients with higher EDSS scores, whereas the red regions in cerebral crus demonstrate better connectivity in patients with higher EDSS scores.

Conclusion: Dysphagia in MS may be caused by neurodegenerative processes affecting the infratentorial regions of the brain, leading to dysfunction of the cranial nerves that emerge from the pons and reduced motor coordination of the swallowing system related to anterior cerebellar damage.

Disclosure: Nothing to disclose.

EPO-1003 | Knowledge gaps in reproductive health among women with MS (KNOWwMS): An international survey

E. Baldin¹; C. De Santis¹; R. Bove²; D. Jacobs³; J. McDonell⁴; N. Rijke⁵; D. Saylor⁶; S. Viswanathan⁷; F. Nonino¹; KNOWwMS Working Group⁸

¹Epidemiology and Statistics Unit, IRCCS, Istituto delle Scienze Neurologiche di Bologna, Italy; ²UCSF Weill Institute for Neurosciences, University of California San Francisco, USA; ³Department of Neurology, University of Pennsylvania, Perelman School of Medicine, USA; ⁴MS Canada, Toronto, ON, Canada; ⁵Multiple Sclerosis International Federation, London, UK; ⁶Chapell Hill School of Medicine, University of North Carolina, USA; ⁷University Teaching Hospital, Lusaka, Zambia; ⁸Tunku Abdul Rahman Neuroscience institute, Kuala Lumpur Hospital, Department of Neurology, Malaysia; ⁸The KNOWwMS Working Group

Background and aims: Multiple sclerosis (MS) has typical onset in women during their reproductive years. Since reliable and consistent information about reproductive health is of pivotal importance for women with MS (WwMS), the KNOWwMS project was established to develop a core information set. As a first step, a global survey was conducted to assess access to information, knowledge gaps and misinformation concerning reproductive health in WwMS, focusing on limited resources settings.

Methods: The survey included 18 closed questions informed by a scoping review and refined by a multi-stakeholder Scientific Advisory Group, and one open-ended question. Target respondents of the online survey were WwMS aged ≥18 years. The survey was available from June to December 2025, in 9 languages.

Results: The questionnaire was completed by 480 WwMS (mean age 37.1 years, SD 9, 92% <50 years) from 31 countries (Figure 1: 23.5% from low- and middle- income countries), mostly from urban settings (91.9%). Gaps identified included: reproductive health issues never even discussed by their neurologist (42.6%), and absence of counselling about pregnancy while

FIGURE 1 Geographic distribution of survey responses.

TABLE 1 Survey responses- Items 1 to 3.

1. When did you first or were often exposed to a health issue?	N (%)	
At diagnosis	186 (38.1)	
Before leaving MS treatment	184 (37.5)	
When planning pregnancy	94 (19.3)	
While pregnant	11 (2.3)	
Never	204 (42.6)	

2. Did you ever receive counselling about the following reproductive health topics?	No (%)	Yes (%)
Contraception while you have MS	186 (38.1)	94 (19.3)
Recording pregnant and having MS	340 (70.8)	140 (29.2)
Taking medications for MS and becoming pregnant	333 (69.3)	147 (30.7)
How MS and its medications may affect pregnancy	330 (68.3)	150 (31.7)
Reproductive and having MS	430 (89.5)	50 (10.5)
Reproductive while taking medications for MS	427 (88.7)	63 (13.3)

3. What is your main source of information on reproductive health issues (contraception, pregnancy, breastfeeding)?	Not selected (%)	Selected (%)
Neurologist	226 (47.1)	254 (52.9)
General practitioner	430 (89.6)	50 (10.4)
Other specialist	397 (82.7)	63 (13.3)

Survey item	No (%)	Yes (%)	Not sure (%)	Not applicable (%)
4. Do you have access to contraception?	186 (38.1)	194 (40.4)	50 (10.4)	50 (10.4)
5. Do you have any concerns about contraception affecting reproduction of your MS?	186 (38.1)	94 (19.3)	136 (28.3)	50 (10.4)
6. Do you think MS will affect your ability to become pregnant and have children?	299 (62.1)	140 (29.2)	40 (8.3)	50 (10.4)
7. Do you think that if you have a diagnosed MS, you might become more pregnant?	406 (84.6)	144 (29.8)	40 (8.3)	110 (22.9)
8. Do you think pregnancy will worsen your MS symptoms?	131 (27.3)	140 (29.2)	180 (37.5)	50 (10.4)
9. Have you decided against having children due to concerns about MS?	300 (62.5)	140 (29.2)	50 (10.4)	50 (10.4)
10. Do you think that having MS while being pregnant affects the safety of the baby?	300 (62.5)	140 (29.2)	136 (28.3)	50 (10.4)
11. Do you think MS medications are safe for children?	186 (38.1)	140 (29.2)	140 (29.2)	50 (10.4)
12. Have you ever received counselling about pregnancy while taking medication for MS?	307 (63.8)	140 (29.2)	50 (10.4)	50 (10.4)
13. Do you think that if you get pregnant you will have to stop taking MS medications?	71 (14.6)	270 (56.3)	140 (29.2)	50 (10.4)
14. Have you ever heard of "pregnancy support"?	131 (27.3)	194 (40.4)	50 (10.4)	50 (10.4)
15. Do you have any concern that breastfeeding could worsen your MS symptoms?	147 (30.6)	140 (29.2)	136 (28.3)	50 (10.4)
16. Do you think that if you have MS you will have to stop taking MS medications?	186 (38.1)	140 (29.2)	50 (10.4)	50 (10.4)
17. Do you think that if you have MS you will have to stop taking MS medications?	131 (27.3)	140 (29.2)	50 (10.4)	50 (10.4)
18. Do you think that if you have MS you will have to stop taking MS medications?	131 (27.3)	140 (29.2)	50 (10.4)	50 (10.4)

NA, not applicable for the item.

taking medications for MS (44.1%). Most women believed, or were not sure, that MS would affect their ability to become pregnant and have children (57.9%); responses to MS being passed on

to children showed limited knowledge of familial risk (69% no, or unsure); 34.5% decided against having children due to MS-related concerns (Tables 1 and 2).

Conclusion: This global survey identified significant knowledge gaps among WwMS on key aspects of fertility, childbearing, and treatment safety. These findings will inform the core information set for WwMS.

Disclosure: Elisa Baldin, Claudia De Santis, Francesco Nonino, Deanna Saylor have nothing to disclose. ¹Multiple Sclerosis Clinical and Research Unit, Department of Systems Medicine, Tor Vergata University, Rome, Italy;

²Department of Life Sciences, Health and Health Professions, Link Campus University, Rome, Italy; ³Multiple Sclerosis Center, Azienda Sanitaria Locale di Cagliari Department of Medical Science and Public Health, University of Cagliari, Cagliari, Italy; ⁴Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Università Cattolica del Sacro Cuore, Centro di Ricerca Sclerosi Multipla "Anna Paola Batocchi, Rome, Italy; ⁵Multiple Sclerosis Center, II Neurological Clinic, University of Campania "Luigi Vanvitelli", Napoli, Italy; ⁶Department of Medical Sciences and Public Health, Multiple Sclerosis Center, Binaghi Hospital, ASL Cagliari, University of Cagliari, Italy

Background and aims: Despite being an established autoimmunity driver, the potential impact of cancer on MS activity remains largely unexplored. This study aims to compare the risk of MS reactivation in the 12 months before and after cancer diagnosis with that observed in a matched cohort of MS patients without cancer.

Methods: We conducted a retrospective cohort study including MS patients with cancer from four Italian MS centers, matched 1:1 by sex and age to pwMS without cancer. Index date corresponded to cancer diagnosis date in cases and was aligned by MS disease duration in controls. MS activity was assessed longitudinally collecting relapses and new T2/Gd+ lesions during the

24 months peri-index date. To account for repeated MRI scans within individuals, generalized estimating equation (GEE) negative binomial models were fitted, adjusting for DMT class at enrollment and MRI region, and including an interaction term between cancer status and time.

Results: We included 148 patients with cancer and 148 controls. During the peri-index period at least one clinical relapse occurred in 20.7% (30) of cancer patients, while no relapses were observed among controls ($p < 0.001$). At least one new T2 and/or Gd+ lesion was detected in 29.7% (78/263) of MRI scans from cases, compared with 6.7% (17/254) from control ($\chi^2 = 41.2, p < 0.001$). Adjusted GEE models showed greater increase in T2 and/or Gd+ lesion accrual over time among cases ($p = 0.019$).

Conclusion: Cancer development appears to trigger disease reactivation, possibly reflecting interactions between immunosurveillance and autoimmunity, warranting tailored MS management strategies and oncological vigilance in unexpected MS reactivations.

EPO-1005 | Dynamics of choroid plexus volume in multiple sclerosis patients treated with hematopoietic stem cell transplantation

G. Costantini¹; A. Mariottini¹; L. Noferini²; F. Susini²; E. Simonetti³; S. Paolucci²; A. Repice³; A. Gozzini⁴; E. Carlesi⁵; A. Ginestroni⁵; F. Di Pasquale⁵; G. Belli²; E. Fainardi⁵; C. Nozzoli⁴; L. Massacesi¹
¹Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy; ²Health Physics Unit, Careggi University Hospital, Florence, Italy; ³Emergency Neurology Unit, Careggi University Hospital, Florence, Italy; ⁴Cell Therapy and Transfusion Medicine Unit, Careggi University Hospital, Florence, Italy; ⁵Neuroradiology Unit, Careggi University Hospital, Florence, Italy

Background and aims: Choroid plexus volume (ChPv) is a potential magnetic resonance imaging (MRI) biomarker of immune cell trafficking into the central nervous system (CNS). Increased ChPv is associated with focal and chronic inflammation in multiple sclerosis (MS). While some therapies reduce ChPv in patients with recent inflammation, data regarding autologous hematopoietic stem cell transplantation (AH SCT) are lacking. We therefore investigated longitudinal ChPv changes in MS patients after AH SCT.

Methods: Consecutive relapsing MS patients undergoing AH SCT (BEAM-ATG conditioning) underwent standardized 3T MRI at baseline, 6–12 months post-AH SCT, and then yearly. ChPv and total brain volume (TBV) were segmented using FreeSurfer, T2-lesion volume (T2LV) manually by an expert operator.

Results: Twelve patients (92% female; 42% relapsing-remitting MS) were included. At baseline, 92% lacked recent focal inflammatory activity. During a median 26-month follow-up, two patients relapsed (months 8 and 15) with new spinal cord lesions only. Post-AH SCT, a median 7% ChPv reduction occurred at 6 months; the patients who relapsed both showed ChPv increase preceding disease activity. TBV decreased by 3% at 6 months, stabilizing at 12 months. No new brain lesions were detected after AH SCT, except for one case showing a mild increase in T2LV at month 6 without changes in ChPv.

Conclusion: ChPv decreased post-AH SCT regardless of recent focal inflammation, suggesting an effect on CNS cell trafficking independent from this latter and supporting AH SCT effect on both peripheral and compartmentalized inflammation. ChPv increases preceded spinal cord-only relapses, supporting the role of the choroid plexus as an entry point for pathogenic lymphocytes regardless of lesion location.

Disclosure: Nothing to disclose.

EPO-1006 | Multimodal assessment of optic nerve involvement in multiple sclerosis

V. Mauceri¹; E. Basili¹; M. Passamonti¹; M. Rozzi¹; D. Di Mare¹; A. Zolin¹; F. Rinaldi²; M. Zoccarato²; P. Perini²; M. Puthenparampil¹
¹University of Padua, Padua, Italy; ²Multiple Sclerosis Centre, Clinica Neurologica, Azienda Ospedale-Università Padova, Padova, Italy

Background and aims: The 2024 McDonald criteria for multiple sclerosis (MS) have formally recognized the optic nerve as a fifth anatomical site for demonstrating dissemination in space. This study aimed to assess the diagnostic accuracy of visual evoked potentials (VEPs), magnetic resonance imaging (MRI), and optical coherence tomography (OCT) in detecting optic neuritis (ON), and to identify the most effective test combinations.

Methods: We performed a cross-sectional analysis including 33 patients with relapsing–remitting MS (pwRRMS) and unilateral ON (ON+), 33 age- and sex-matched patients with other inflammatory neurological diseases (ONIND), and 107 pwRRMS without a clinical history of ON. All participants underwent VEP, MRI, and OCT. OCT peripapillary and macular scans followed OSCAR-IB QC4 and APOSTEL 2.0 standards. Diagnostic performance was evaluated using receiver operating characteristic (ROC) curve analysis.

Results: Compared with ONIND, VEPs showed the highest diagnostic accuracy in ON+ patients (AUC 0.9072, 93.94% sensitivity and 87.5% specificity). OCT demonstrated high specificity (92.19%) but lower sensitivity (69.7%; AUC 0.8094), while MRI reached 100% specificity with 63.64% sensitivity. The most accurate strategy was MRI or VEP plus OCT (AUC 0.931; sensitivity 84.85%; specificity 96.88%). The “one-out-of-three” and “two-out-of-three” rules also performed well (AUC 0.914 and 0.8935). Among pwRRMS without clinical ON, 9.8% fulfilled the MRI or

FIGURE 1 Multimodal characterization of optic neuritis. DIR MRI demonstrates acute right optic nerve involvement (A, red arrow). OCT reveals peripapillary retinal nerve fiber layer thinning consistent with left optic neuritis sequelae (B), while VEPs show delayed.

Diagnostic test	AUC	P-value	Sensitivity (%)	Specificity (%)	Optimal trade-offs	Maximal Index
VEP	0.9072	<0.0001	93.94	87.5	7.316	83.44
OCT	0.8094	<0.0001	69.7	92.19	8.021	81.89
MRI	0.8182	<0.0001	63.64	100	7.316	83.44
VEP + OCT	0.9317	<0.0001	84.85	96.88	7.316	83.44
VEP + MRI	0.9298	<0.0001	84.85	100	7.316	83.44
MRI + OCT	0.9204	<0.0001	63.64	100	7.316	83.44
1 out of 2	0.9142	<0.0001	100	91.91	8.021	83.44
1 out of 3	0.8935	<0.0001	81.82	96.88	8.021	76.7
2/3	0.9178	<0.0001	84.85	100	7.316	83.44
MRI or VEP + OCT	0.931	<0.0001	84.85	96.88	7.316	83.44

FIGURE 2 ROC-based comparison of diagnostic strategies for optic neuritis. ROC curves compare single-modality and combined diagnostic approaches. Optimal trade-offs between sensitivity and specificity are highlighted, with red indicating highest sensitivity.

FIGURE 3 Subclinical optic nerve involvement in RRMS patients without optic neuritis. Bar graph depicting the number and percentage of eyes testing positive on individual and combined diagnostic tests in 107 RRMS patients (214 eyes) with no prior optic neuritis.

(VEP + OCT) criterion, 8.4% were positive on at least two tests, and 37.8% on at least one.

Conclusion: A multimodal assessment improves detection of optic nerve involvement and may identify subclinical damage, with different criteria applicable according to clinical context.

EPO-1007 | Assessment of dietary habits in patients with multiple sclerosis in Opole and Silesian Province, Poland

V. Carbogno-Barnabe¹; M. Skrzypek²; P. Bednarczyk³; I. Zabicka³; B. Labuz-Roszak⁴

¹Department of Nutrition Related Prevention, Faculty of Public Health in Bytom, Medical University of Silesia in Katowice, Poland; ²Department of Biostatistics, Department of Epidemiology, Faculty of Public Health in Bytom, Medical University of Silesia in Katowice, Poland; ³Department of Neurology, St. Jadwiga Provincial Specialist Hospital, Opole, Poland; ⁴Department of Neurology, St. Jadwiga Provincial Specialist Hospital, Institute of Medical Sciences, University of Opole, Opole, Poland

Background and aims: The aim of the study was to assess dietary habits in patients with multiple sclerosis (MS) in relation to psychosocial factors and quality of life.

Methods: The study included 91 patients with MS (68 women and 23 men) with a mean age of 49.8±11.0 years. Dietary patterns were assessed using the Pro-Healthy Diet Index-10 (pHDI-10) and the Non-Healthy Diet Index-14 (nHDI-14), derived from the Dietary Habits and Nutrition Beliefs Questionnaire (KomPAN). Additionally, a nutritional interview was conducted, and the Hospital Anxiety and Depression Scale (HADS), Visual Analogue Scale (VAS), and the EQ-5D-5L quality of life questionnaire were administered.

Results: The intensity of both health-promoting (pHDI-10) and health-adverse (nHDI-14) dietary characteristics was low in examined MS patients. In 60.4% of participants, the daily energy intake was lower than the total metabolic rate. The majority of respondents had a below-average intake of dietary fiber (72.5%), vitamin D (93.4%), and iron (70.3%). Higher intakes of protein and saturated fatty acids were associated with higher nHDI-14 scores, whereas higher intakes of dietary fiber, calcium, magnesium, and vitamin B12 were associated with higher pHDI-10 scores. Men demonstrated significantly higher nHDI-14 levels than women. Neither disease duration nor disability level had a significant effect on dietary habits. Dietary habits were associated with pain intensity and quality of life, but not with depressive or anxiety symptoms.

Conclusion: Nutritional education should be an integral component of the comprehensive management of MS patients, as it may contribute to improving dietary habits and quality of life.

Disclosure: Nothing to disclose.

EPO-1008 | Abstract withdrawn

EPO-1009 | Characterization of natural killer cell aging and terminal differentiation in multiple sclerosis

J. Nolte¹; H. Vietzen²; T. Zrzavy¹; F. Föttinger¹; N. Krajnc¹; S. Zaic¹; E. Puchhammer-Stöckl²; T. Berger¹; P. Rommer¹; G. Bsteh¹

¹Department of Neurology, Medical University of Vienna, Vienna, Austria; ²Center for Virology, Medical University of Vienna, Vienna, Austria

Background and aims: Insights into immune aging and related functional impairment are essential for advancing understanding of multiple sclerosis (MS) course and pathophysiology and may inform individualized treatment decisions. CD57 expression on CD56dim natural killer (NK) cells and its proportion within the total NK cell population is a well-established indicator of mature NK cells. Here, we compared immunosenescence in patients with MS (pwMS) versus healthy controls (HCs) and evaluated influential covariates.

Methods: From an ongoing study, peripheral blood mononuclear cells from 69 pwMS and 10,437 HCs in Austria, Switzerland, and Germany were analyzed using flow cytometry, gated on CD3, CD56, CD57, NKG2D, DNAM-1, NKG2A, and TIGIT. Age-adjusted z-scores for CD57+CD56dim NK-cell proportions were estimated using a generalized additive model based on the HCs.

Results: Among 69 pwMS, 65.2% were female with a mean age of 40.5 years (SD 10.2), mean disease duration of 10.5 years (SD 9.47), and median EDSS of 2 (IQR 0–3). Age-adjusted z-scores for

CD57 on CD56dim NK cells were comparable between pwMS and HCs. No differences were observed by sex or disease course. Notably, the proportion of the immunoregulatory CD56bright cells was significantly reduced in pwMS.

Conclusion: CD57+CD56dim NK cells are a robust marker for NK-cell aging and may serve as a reliable surrogate of immunosenescence. Age-adjusted z-scores for the proportions of CD57+CD56dim NK cells can be estimated in pwMS to assess accelerated immune-cell aging. In future studies, this may be useful to assess the impact of immunosenescence on disease activity and progression.

Neurorehabilitation and Neurotraumatology

EPO-1010 | When copeptin and vasopressin diverge: Neuroendocrine dissociation and diffuse axonal injury in traumatic brain injury

A. Sacarescu¹; I. Plesca²; M. Turliuc³

¹Department of Medical Specialties III, “Grigore T. Popa” University of Medicine and Pharmacy, Iasi, Romania; ²Faculty of Mathematics, “Alexandru Ioan Cuza” University, Iasi, Romania; ³Department of Surgery II, “Grigore T. Popa” University of Medicine and Pharmacy, Iasi, Romania

Background and aims: Traumatic brain injury (TBI) can disrupt hypothalamic–pituitary regulation, leading to neuroendocrine alterations that may reflect injury severity. Copeptin and arginine vasopressin originate from the same precursor and are expected to show parallel regulation under physiological conditions. This study evaluated the relationship between copeptin and vasopressin levels in TBI and their association with injury severity and diffuse axonal injury (DAI).

Methods: Eighty-six adult patients admitted with TBI to a tertiary neurotrauma center were included. Clinical severity was assessed using the Glasgow Coma Scale (GCS). Serum copeptin and vasopressin levels were measured, and neuroimaging data from computed tomography and magnetic resonance imaging were reviewed to identify traumatic lesions, including DAI.

Results: Copeptin and vasopressin levels demonstrated a significant inverse correlation (Spearman $\rho = -0.45$, $p < 0.01$), indicating dissociated regulation following TBI. DAI was identified in 9.3% of patients and was associated with significantly higher copeptin levels compared with those without DAI ($p = 0.045$). Higher copeptin concentrations were observed in patients with lower GCS scores. In contrast, vasopressin levels showed a positive correlation with GCS ($\rho = 0.366$, $p = 0.003$) and were significantly lower in patients with unfavorable outcomes, including mortality ($p = 0.006$) and the need for neurosurgical intervention ($p = 0.048$).

Conclusion: TBI is associated with altered copeptin and vasopressin regulation, resulting in a dissociated neuroendocrine profile. Within this context, elevated copeptin levels and their association with DAI suggest that copeptin may reflect axonal damage severity, supporting its further evaluation as a biomarker in neurotrauma research.

Disclosure: Nothing to disclose.

EPO-1011 | Dynamic EEG markers of confusional state and cognitive outcome after moderate-to-severe traumatic brain injury

A. Comanducci; C. Derchi; T. Atzori; C. Valota; B. Mosconi; P. Arcuri; J. Navarro
IRCCS Fondazione Don Carlo Gnocchi, Milan, Italy

Background and aims: Cognitive impairment is a frequent and disabling consequence of moderate-to-severe traumatic brain injury. Post-traumatic amnesia (PTA) duration is a well-established prognostic marker of global disability, but its specificity for long-term cognitive outcome is limited. After emergence from PTA, recently conceptualized as part of the post-traumatic confusional state (PTCS), overt confusional symptoms typically resolve, while residual cognitive deficits persist. EEG may provide complementary prognostic information across this transition.

Methods: Forty-two patients with moderate-to-severe TBI admitted to inpatient rehabilitation underwent resting-state EEG at admission and discharge. EEG abnormalities were graded using the semi-quantitative Grand Total EEG score (GTE), with exploratory analyses of slow wave activity and background activity subdomains. Cognitive outcome at six months was assessed using the Montreal Cognitive Assessment (MoCA), while disability was evaluated using the Disability Rating Scale (DRS).

Results: At admission, GTE was associated with PTA/PTCS severity. At discharge, SWA showed substantial normalization, consistent with resolution of PTCS, whereas Background Activity abnormalities persisted in a subset of patients, suggesting ongoing cortical disorganization. In multivariate logistic regression models predicting MoCA impairment at 6 months, discharge GTE score was an independent predictor (OR = 2.61, 95% CI 1.47–4.66, $p = 0.002$). In contrast, PTA/PTCS duration was strongly associated with DRS ($p < 0.001$).

Conclusion: EEG provides prognostic information complementary to PTA/PTCS duration after severe TBI. While PTA/PTCS duration remains a robust predictor of global disability, EEG—particularly background organization at T1—better captures vulnerability to persistent cognitive impairment. EEG thus emerges as a dynamic prognostic tool in the subacute phase of TBI.

Disclosure: Nothing to disclose.

EPO-1012 | Effects of localized muscle fatigue on dynamic balance in healthy young adults: A randomized crossover study

A. Patrício¹; B. Carvalho¹; R. Brandão²; D. Tomás²

¹Department of Physiotherapy, Escola Superior de Saúde Atlântica, Barcarena, Portugal; ²Department of Physiotherapy, Escola Superior de Saúde do Alcoitão, Alcabideche, Portugal

Background and aims: Muscle fatigue is traditionally associated with impaired postural control; however, accumulating evidence suggests that exercise performed to the point of fatigue may also elicit short-term adaptive responses within the neuromuscular system. The effects of exercise-induced localized muscle fatigue, particularly when applied to different body segments, remain insufficiently understood. This study aimed to

investigate the effects of exercise protocols designed to induce localized muscle fatigue of the upper and lower limbs on dynamic balance in healthy young adults.

Methods: A randomized, controlled crossover study was conducted in 32 healthy young adults. Dynamic balance was assessed using the Y Balance Test before and immediately after exercise protocols targeting either the upper or lower limbs and designed to induce localized muscle fatigue. Sessions were separated by at least 48 hours to minimize carry-over effects. Heart rate and perceived exertion were monitored to ensure that the physiological response was predominantly muscular rather than cardiorespiratory.

Results: Following the exercise protocols, significant increases in reach distance were observed in the Y Balance Test across most directions, indicating short-term changes in dynamic balance performance. No significant differences were found between upper- and lower-limb exercise protocols. No significant associations were observed between self-reported physical activity levels and balance changes.

Conclusion: Exercise protocols designed to induce localized muscle fatigue were associated with short-term improvements in dynamic balance, regardless of the body segment involved. Although conducted in healthy individuals, these findings may inform the design of training and rehabilitation strategies incorporating controlled exposure to exercise-induced fatigue.

Disclosure: Nothing to disclose.

EPO-1013 | SPInal CSF leaks in chronic subdural hematoma (SPICE): Interim results of a prospective observational trial

N. Lützen¹; K. Wolf²; F. Volz²; A. El Rahal²; C. Zander¹; M. Overstijns²; L. Krismer²; H. Urbach¹; J. Beck²

¹Department of Neuroradiology, CSF Center, Medical Center, University of Freiburg, Freiburg, Germany, ²Department of Neurosurgery, CSF Center, Medical Center, University of Freiburg, Freiburg, Germany

Background and aims: Chronic subdural hematoma (cSDH) is the most common intracranial hemorrhage, characterized by slowly expanding subdural fluid collections that ultimately cause brain compression and neurological impairment. The underlying pathophysiology remains incompletely understood. An increasingly recognized and directly treatable cause are spontaneous spinal cerebrospinal fluid (CSF) leaks. This study aimed to estimate the prevalence of spinal CSF leaks in patients presenting with cSDH.

Methods: This interim analysis derives from a prospective, monocentric observational study of patients admitted with cSDH to the Department of Neurosurgery, University Medical Center Freiburg (07/2024–12/2025; NCT06323434). Standard cSDH treatment was followed by MRI of the brain and spine according to standard-workup in spontaneous intracranial hypotension. Patients with intermediate leak risk (Bern Score ≥ 3) or orthostatic headache underwent dynamic myelography. The primary outcome was the proportion of confirmed CSF leaks.

Results: Of 159 eligible patients, 132 consented; 22 withdrew. Six patients are awaiting myelography, and 20 were lost to follow-up before myelography. Among the 84 patients who underwent myelography, a spinal CSF leak was identified in 16.7%

FIGURE 1 Pipeline and interim results of the SPICE study: prevalence of underlying spontaneous spinal CSF leaks in patients with chronic subdural hematoma.

($n = 14$, 95% CI 10–26%), with a majority of CSF–venous fistulas ($n = 12$, 14.3%, 95% CI 8–23%). A more restrictive analysis yields a CSF leak prevalence of 13.5% (95% CI 8.2–21.3%) among the 104 primarily included patients.

Conclusion: Spinal CSF leaks represent a relevant and directly curable cause in a substantial proportion of patients with cSDH. These findings challenge prevailing assumptions regarding the relationship between spinal CSF leaks and cSDH and have important implications for future diagnostic pathways.

Disclosure: none

EPO-1014 | Daytime dysfunction in military personnel following blast injury

K. Sarazhyna; A. Son

Odesa National Medical University, Odesa, Ukraine

Background and aims: Blast injuries (BI) are a leading cause of trauma among Ukrainian military personnel (MP), often resulting in mild traumatic brain injury (mTBI) and sleep disturbances, particularly daytime dysfunction (DD). Both mTBI and anxiety may contribute to DD, but their relative impact remains unclear.

Methods: 136 male MPs with BI (median 36.0; range 22–56) were enrolled. Participants were divided into two groups: BI with mTBI ($n = 62$; 45.6%) and without mTBI ($n = 74$; 54.4%). Only acute mTBI cases (≤ 21 days) were included. Anxiety was assessed using the Hospital Anxiety and Depression Scale. DD was measured using component 7 of the Pittsburgh Sleep Quality Index and dichotomized: 0 = no disturbance (score < 2), 1 = DD (score ≥ 2). Binomial logistic regression models evaluated associations between DD, mTBI and anxiety.

Results: The model demonstrated good fit (AIC=151; McFadden $R^2 = 0.201$). Anxiety severity was significantly associated with DD ($\beta = 0.209$, SE=0.047, OR=1.23, 95% CI 1.13–1.35, $p < 0.001$). mTBI was also linked to higher DD risk ($\beta = 1.066$, SE=0.407, OR=2.90, 95% CI 1.31–6.45, $p = 0.009$). In Model 2, the anxiety $\times$ mTBI interaction did not improve fit. Anxiety remained a significant predictor of DD (OR=1.23, $p = 0.002$), whereas mTBI status (OR=2.64, $p = 0.327$) was not statistically significant.

Conclusion: Final analyses indicated that anxiety was the only statistically significant predictor of DD irrespective of mTBI status.

Disclosure: Nothing to disclose.

M. Ansari¹; S. Chavan²

¹Ayjnishd (D), Mumbai, India; ²DMIHER, Wardha, India

Background and aims: Voice onset time (VOT) is an auditory-based acoustic feature used to distinguish stop consonants in various languages. Children with sensorineural hearing impairment (HI) often struggle with discriminating between voiced and voiceless speech sounds. The role of this auditory ability in cochlear implant recipients has not been well understood. This study aimed to compare VOT contrast perception among Cochlear Implant (CI), Hearing Aid (HA) recipients, and Normal Hearing (NH) children.

Methods: A total of 60 subjects aged 6 to 12 years, divided into NH, HA, and CI groups, were selected. Test stimuli included 180 tokens of consonant-vowel-consonant combinations of non-sense Hindi stop phonemes with varying initial positions. These stimuli were presented in an ABX paradigm to assess identification scores.

Results: Statistical analysis revealed significant differences in VOT scores among all groups. There was no overlap in identification scores between NH & CI and HA & CI groups. CI children performed better than HA recipients but poorer than NH children. Significant differences were observed in scores between NH and both HA and CI groups, as well as between HA and CI groups. These findings align with previous research.

Conclusion: Children with CI and HA demonstrated different VOT discrimination abilities compared to NH children, likely due to limitations of CI and HA devices in processing speech signal characteristics. Older CI children with speech and language training and longer device use performed better than the HA group, suggesting that CI may enhance access to speech information and improve perception.

Disclosure: Nothing to disclose.

EPO-1016 | Neuroeducation and mindfulness-based meditation as novel group-based neurorehabilitation approach to improve cognition in multiple sclerosis

N. Gyger¹; T. Monschein²; T. Geiger¹; F. Leutmezer²; G. Pusswald²; I. Penner¹

¹Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Switzerland; ²Department of Neurology, Medical University of Vienna, Vienna, Austria

Background and aims: To evaluate the efficacy of a novel group-based neurorehabilitation approach, combining neuroeducation with mindfulness-based meditation, in reducing self-perceived but also objective cognitive deficits in people with relapsing-remitting multiple sclerosis (pwRRMS).

Methods: In this ongoing study, pwRRMS aged 18–50 years with EDSS <4 and disease duration ≤10 years are enrolled. Participants attend a group-based program (5–8 per group) consisting of seven MS-specific neuroeducation sessions (90 minutes, weekly) led by a trained neuropsychologist, each followed by 10–15 minutes of mindfulness-based meditation supported by home practice via an in-house app. Objective neuropsychological and patient-reported outcomes are assessed before

and after the 7-week intervention, with the Perceived Deficits Questionnaire (PDQ-20) as the primary outcome measure.

Results: Currently, 57 participants have been included. The PDQ-20 showed a significant reduction in perceived cognitive deficits ($d=0.39$). Change scores showed a significant increase in information processing speed (IPS) with moderate effect size (SDMT, $d=0.63$). More pronounced cognitive impairment at baseline tended to be associated with larger IPS gains. Moreover, significant improvements were observed in fatigue (FSMC, $d=0.47$), anxiety (HADS-A, $d=0.54$), and depression (HADS-D, $d=0.61$), together with increased coping self-efficacy (CSES, $d=0.61$), general self-efficacy expectation (SWE, $d=0.66$), and reduced perceived stress (PSS, $d=0.53$). Further, neuropsychological testing showed improved working memory.

Conclusion: These interim findings indicate that the combination of neuroeducation and mindfulness-based meditation significantly enhances well-being and additionally shows promising effects on cognitive functioning in pwRRMS.

EPO-1017 | Effect of rTMS on neuropsychological outcomes in mild to moderate traumatic brain injury: A prospective cohort study

S. Singh

Department of Neurosurgery, AIIMS, Raebareli, India

Background and aims: Traumatic brain injury (TBI) is a major global public health problem and a leading cause of long-term cognitive, behavioural, and psychological disability, particularly among the productive age group. Disruption of fronto-cortical networks and underlying white matter tracts has been strongly implicated in post-TBI neuropsychological deficits. Recent advances and international evidence have highlighted repetitive transcranial magnetic stimulation (rTMS) as a promising non-invasive neuromodulatory intervention in TBI rehabilitation.

Methods: Adult patients with mild to moderate TBI (GCS > 10) underwent MRI brain with Diffusion Tensor Imaging (DTI) and were classified based on white matter tract deviation and cerebral edema. Neuropsychological assessment using the Montreal Cognitive Assessment (MOCA) and Hamilton Depression Rating Scale (HDRS) was performed at baseline and follow-up. Patients with persistent deficits received high-frequency rTMS (10 Hz) over the right/left dorsolateral prefrontal cortex at 110% of individual resting motor threshold, delivered in 10 sessions over 5 days.

Results: Sixty patients (40 males, 20 females; mean age 36.24 years) were analyzed. Mean resting motor threshold reduced from 75.35% at baseline to 70.61% at follow-up, with a corresponding reduction in stimulus intensity (110% RMT) from 82.81% to 77.84%, indicating enhanced cortical excitability. Cognitive outcomes improved significantly, with mean MOCA scores increasing from 19.22 at baseline to 23.82 post-intervention. Mean HDRS scores decreased from 5.56 to 4.70, reflecting improvement in depressive symptoms.

Conclusion: rTMS resulted in sustained improvement in cortical excitability, cognitive performance, and psychological well-being in mild to moderate TBI patients, particularly those with white matter tract involvement.

Disclosure: The Study was funded by UP Counsel for Science and Technology (UP CST). Nothing else to disclose

EPO-1018 | Predicting long-term outcome in prolonged disorders of consciousness: Post-acute prognostic factors from the nationwide DOCTOR study

D. Driessen¹; C. Utens²; G. Ribbers¹; W. van Erp²; M. Heijnenbroek - Kal¹

¹Rehabilitation Medicine, Erasmus MC, Rotterdam, the Netherlands; ²Primary Care, Radboudumc, Nijmegen, the Netherlands

Background and aims: Prolonged disorders of consciousness (PDOC) following acquired brain injury are characterised by major prognostic uncertainty, complicating clinical decision-making and ethical deliberation. While acute-phase predictors have been studied extensively, less is known about prognostic factors available at admission to specialised neurorehabilitation. This study aimed to identify demographic and clinical predictors for recovery of consciousness, level of functioning, and independence in PDOC.

Methods: Prospective cohort study including PDOC patients ≥ 16 years admitted to the nationwide Dutch PDOC chain of care (2019–2023). Potential predictors at rehabilitation admission: demographic and clinical characteristics, time post-injury (TPI), level of consciousness, aetiology, Coma Recovery Scale-Revised (CRS-R). Outcomes: recovery of consciousness, level of functioning, and functional independence measured with the Functional Independence Measure (FIM) up to 104 weeks. Multivariable Generalized Estimating Equations were used, applying Bonferroni correction.

Results: Of 129 enrolled patients (mean age 38 years; 52% male), 62% regained consciousness. A non-smoking history was the only independent predictor for regaining consciousness (OR 2.46, 95% CI 1.33–4.52). Shorter TPI ($B = -0.26$, $p < 0.001$) and higher CRS-R at admission ($B = 3.15$, $p < 0.001$) independently predicted higher functional outcome. Higher CRS-R also predicted functional independence at 2 years (OR 1.38, 95% CI 1.13–1.67).

Conclusion: Prediction of long-term recovery in PDOC at the start of specialised rehabilitation remains challenging. Simple clinical variables, particularly smoking history and CRS-R score, provide limited but relevant prognostic information. These findings underline the need for integrated longitudinal prognostic models combining clinical, neurophysiological, and imaging data to better support personalised and ethically informed care pathways.

Disclosure: Nothing to disclose.

Headache 6

EPO-1019 | Post-traumatic headache: Evaluating repetitive transcranial magnetic stimulation (rTMS) as a novel treatment strategy

C. Nygaard¹; S. Futarmal Kothari¹; H. Winter Schytz²; T. Skandsen³; L. Odgaard¹; C. Bøcker Pedersen¹; M. Møller Thastum¹; H. Holm Stabel¹; L. Hellemose¹; S. Kristine Stage Pedersen¹; A. Munch Lauridsen¹; A. Bilgaard Nicolaisen¹; J. Feldbæk Nielsen¹

¹Hammel Neurorehabilitation Centre and University Research Clinic, Department of Clinical Medicine, Aarhus University, Hammel, Denmark; ²Danish Headache Center, Department of Neurology, Rigshospitalet Glostrup, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark; ³Department of Neuromedicine and Movement Science, Norwegian University of Science and Technology (NTNU), Trondheim, Norway and Clinic of Rehabilitation, St. Olavs Hospital, Trondheim University Hospital, Trondheim, Norway

Background and aims: Post-traumatic headache (PTH) is a disabling sequela of mild traumatic brain injury (mTBI), and currently there is no established effective treatment for PTH. Recently, repetitive transcranial magnetic stimulation (rTMS) has emerged as a promising treatment modality. Aim: To evaluate the effect of rTMS in adults with PTH 4–6 months after mTBI.

Methods: A randomised, sham-controlled clinical trial in adults with PTH was conducted from August 2023 to August 2024. Participants received 5 sessions of active rTMS ($n = 30$) or sham rTMS ($n = 31$) over a 2-week period, 4–6 months after mTBI. The primary outcome was defined as the mean change in the number of headache days of moderate to severe intensity per month before versus after intervention. Primary outcome data were collected via a prospective, daily headache diary. Follow-up was conducted at 1-month after end of treatment (EOT).

FIGURE 1 Headache subdivided by intervention and time in study.

Results: At 1-month EOT, preliminary results show no significant difference in the mean change of monthly headache days of moderate to severe intensity between the two groups. The mean reduction was 6.6 days in the active group versus 6.2 days in the sham group.

Conclusion: rTMS did not significantly reduce the number of monthly headache days of moderate to severe intensity compared with sham-rTMS in adults with PTH 4–6 months post-mTBI. Consequently, this study does not provide evidence to support rTMS as an effective treatment of PTH. Further research is needed to determine whether rTMS can improve long-term outcomes in patients with PTH.

Disclosure: The authors declare no conflicts of interest related to the manuscript. The study was funded by The Health Research Fund of Central Denmark Region. The funder was not involved in the study design; collection, analysis, or interpretation of data; and in the writing of the article.

EPO-1020 | Distinguishing migraine with aura from acute ischemic events in emergency settings: A cross-sectional study

M. Çakan Ercan¹; M. Topçuoğlu¹; R. Göçmen²; E. Arsava¹; I. Ünal-Çevik³
¹Hacettepe University, Faculty of Medicine, Departments of Neurology, Ankara, Türkiye; ²Hacettepe University, Faculty of Medicine, Department of Radiology, Ankara, Türkiye; ³Hacettepe University, Faculty of Medicine, Department of Neurology, Headache and Pain Unit, Ankara, Türkiye

Background and aims: Differentiating migraine with aura (MA) from transient ischemic attack (TIA) is challenging because both conditions can present with negative neurological symptoms. Here, we aimed to evaluate two venous imaging markers: “the venous asymmetry index” and “index vein sign” on susceptibility-weighted images (SWI) in MA and TIA groups, and to derive a simple, clinically applicable score to distinguish MA from TIA.

TABLE 1 Venous imaging findings on acute SWI in patients with TIA and migraine with aura.

Variable	TIA (n=209)	MA (n=21)	p-value
Venous Asymmetry Index			
2 (marked)	2 (0.9%)	9 (42.9%)	<0.001
1 (mild)	42 (20.1%)	18 (85.7%)	
0 (none)	225 (107.6%)	2 (9.5%)	
Venous Asymmetry location			
Central	42 (20.1%)	19 (90.5%)	0.001
Subcortical	2 (1.0%)	0 (0%)	
Venous Asymmetry pattern			
Focal	23 (11.0%)	7 (33.3%)	0.20
Diffuse	21 (10.1%)	12 (56.2%)	
Venous Asymmetry Distribution			
Frontal	8 (3.8%)	9 (42.9%)	0.02
Parietal	44 (20.9%)	17 (80.5%)	
Temporal	11 (5.3%)	16 (76.2%)	<0.001
Occipital	11 (5.3%)	11 (52.4%)	
Index Vein Signs			
Laterality – Right / Left	12 (5.7%) / 16 (7.7%)	9 (42.9%) / 9 (42.9%)	<0.001

Values are n (%) unless otherwise specified. For each row, the p-value refers to the central comparison between groups. For each row, the p-value refers to the central comparison between groups. For each row, the p-value refers to the central comparison between groups. For each row, the p-value refers to the central comparison between groups.

TABLE 2 Multivariate logistic regression analysis results and symptom-concordant venous imaging (SVI) scores.

Predictor	SE	aOR (Exp(B))	Lower cut-off of 95% CI for aOR	B (log-odds)	Score points	p
Age below 60	1.11	10.70	1.21	2.4	2	0.01
Venous Asymmetry Index						
Mild (1) vs None	0.84	10.47	2.01	2.3	2	0.005
Marked (2) vs None	1.98	785.3	16.97	6.7	7	0.001
Index vein sign	0.73	5.8	1.4	1.8	2	0.02
Speech impairment	0.96	9.38	1.71	2.23	2	0.01
Hypoesthesia	1.134	23.59	2.61	3.361	3	0.002

Model variables shown in figure. Regression model including age, gender, speech impairment, and index vein sign. B (log-odds) and aOR (Exp(B)) are presented with 95% confidence intervals (CI). Standard scores (SE), and corresponding log-odds coefficients (B). Points are based on comparison of each variable to the reference category in the model. The SVI score is the sum of the points for each variable. All p-values are two-tailed.

Methods: In this cross-sectional study, patients presented with acute stroke-like symptoms (speech disturbance, facial asymmetry, hemianopia, hemiparesis, or hypoesthesia) between January 2023 and December 2024, were prospectively evaluated. Primary analyses tested symptom-concordant venous asymmetry index and index vein sign, evaluating their relationship to the final diagnosis. The Symptom-concordant Venous Imaging (SVI) score was constructed.

Results: A total of 290 diffusion weighted image (DWI)-negative patients were eligible (TIA n=269; MA n=21). The symptom-concordant venous asymmetry index was present in 90.5% and the index vein sign in 85.7% of migraine with aura however these findings were observed in only 16.4% and 10.4% of the TIA group, respectively (Table-1). On follow-up MRIs, venous imaging signs frequently resolved in migraineurs. Multivariable analysis models revealed that symptom-concordant venous imaging findings were associated with MA (Table-2). The SVI score demonstrated a discriminatory performance with an AUC of 0.969 (95% CI: 0.949–0.990). At a cut-off value of ≥8 points, sensitivity was 71.4% and specificity was 95.9%.

Conclusion: In patients presented with acute stroke-like symptoms, marked venous asymmetry and index vein sign concordant with symptoms and SVI score of >8 were strongly associated with MA.

Disclosure: Nothing to disclose.

EPO-1021 | Effective migraine prevention improves cognitive complaints

M. Costa Taveira¹; F. Dourado Sotero¹; M. Dias da Costa¹; A. Costa²; B. Martins²; R. Rato²; J. Nobre³; M. Roque¹; I. Pavão Martins¹
¹Neurology Service, Department of Neurosciences and Mental Health, ULS Santa Maria, Lisboa, Portugal; ²Neurology Service, ULS São João, Porto, Portugal; ³Centro de Estudos Egas Moniz, Faculty of Medicine, University of Lisbon, Lisboa, Portugal

Background and aims: Cognitive complaints, such as memory and concentration difficulties, are increasingly recognized as part of the clinical spectrum of migraine. We aimed to evaluate whether subjective cognitive complaints improve with effective preventive treatment for migraine acting outside the central nervous system.

Methods: We conducted a prospective observational study including adults with migraine diagnosed according to the ICHD-3 criteria, initiating preventive treatment with either anti-CGRP monoclonal antibodies (mAbs) or OnabotulinumtoxinA (BT). Responders were defined as those who achieved $\geq 50\%$ reduction in monthly migraine days for episodic migraine and $\geq 30\%$ reduction for chronic migraine from baseline to 3–6 months follow-up. Cognitive complaints, assessed using the Subjective Memory Complaints scale (SMC) and depressive symptoms (Hospital Anxiety and Depression Scale (HADS-D)), were compared between the two evaluations according to responder status.

Results: Participants ($N=100$, mean age 42.27 years, 98% women, 71% with chronic migraine), received either mAbs ($N=66$) or BT (34), and 57 responded to treatment. Responders showed a significant improvement in subjective memory complaints ($B=-1.46$, $p=0.037$), regardless of the type of preventive treatment ($p=0.857$). The improvement was also significant in patients without depressive symptoms ($p=0.027$) but related to improvement of HADS scores in participants with higher scores.

Conclusion: Cognitive complaints are a frequent and burdensome manifestation of migraine, reflecting its broader ictal and interictal impact beyond pain. This study shows that effective preventive treatment is associated with significant improvement in these cognitive symptoms, reinforcing their role as part of the migraine spectrum.

Disclosure: Nothing to disclose.

EPO-1022 | Assessment of cortical excitability in migraine patients using the paired-pulse transcranial magnetic stimulation technique

M. Kutusheva¹; E. Sokolov¹; N. Grigoryan¹; A. Pyatkov¹; N. Vashchenko²; A. Sergeev¹

¹I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University), Moscow, Russian Federation; ²University Headache Clinic, Russian Federation

Background and aims: Thalamocortical dysrhythmia, observed in migraine, is often linked to cortical hyperexcitability. This pattern also appears in fibromyalgia, etc. This study examines neurophysiological markers in migraine via short-interval intracortical inhibition assessed with the threshold tracking technique (TT-SICI).

Methods: Participants included 15 patients with chronic migraine (CM; mean age 37.8 years; 86.6% female), 9 with episodic migraine (EM; mean age 34.5 years; 77.3% female), and 16 healthy controls (C; mean age 28.3 years; 68.8% female). Bilateral paired-pulse TMS targeted the primary motor cortex. Motorevoked potentials were recorded from hand muscles to evaluate threshold dynamics at interstimulus intervals (ISIs) of 2–7 ms using TT-SICI. Validated tools included PHQ-9, PDS (Personality Disorder Severity), clinical interviews for headache/psychiatric status, and the Edinburgh Handedness Inventory (EHI).

Results: A significant TT-SICI reduction occurred in CM versus C only in the left hemisphere at ISIs of 3.5 and 4 ms ($p<0.05$). No differences appeared at other ISIs, during right-hemisphere stimulation, or in EM versus controls. All subjects were right-handed (EHI). In CM, positive correlations emerged between

FIGURE 1 Individual inhibition curves (CM vs C).

TT-SICI and headache intensity at ISIs 3, 3.5, and 7 ms ($r=0.415$, 0.596 , 0.438); with PHQ-9 at 3.5 ms ($r=0.430$); and with PDS at 5 ms ($r=0.420$).

Conclusion: Reduced TT-SICI at 3.5–4 ms in the left hemisphere CM patients indicates intracortical hyperexcitability and GABAergic inhibition deficit. Positive correlations with depression (PHQ-9), personality disorder severity (PDS), and headache intensity suggest shared mechanisms linking emotional disturbances and chronic headache. These results reinforce central sensitization in CM and highlight TT-SICI as a potential biomarker for personalized assessment and treatment monitoring.

Disclosure: Nothing to disclose.

EPO-1023 | Inflammatory markers and white matter lesions on brain MRI in patients with migraine

S. Jorquera-Ortega¹; A. Barbosa²; S. Sánchez³; M. Conversa²; P. Vera⁴; Á. Planchuelo-Gómez⁵; Á. Sierra⁶; Y. González Osorio⁶; J. Matesanz⁶; Á. Guerrero-Peral⁶; H. de la Fuente⁴; A. Gonzalez-Martinez¹

¹Facultad de Medicina, Universidad Autónoma de Madrid, Madrid, Spain; ²Hospital Universitario de la Princesa, Madrid, Spain; ³Instituto de Investigación Sanitaria Princesa (IIS-Princesa), Madrid, Spain; ⁴Neuroradiology Service, Hospital Universitario de la Princesa, Madrid, Spain; ⁵Laboratory Service, Hospital Universitario de la Princesa, Madrid, Spain; ⁶Immunology Service, Hospital Universitario de la Princesa, Madrid, Spain; ⁷Laboratorio de Procesado de Imagen, UVA, Valladolid, Spain; ⁸Headache Unit, Neurology Service, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

Background and aims: Brain magnetic resonance imaging (MRI) frequently reveals white matter lesions (WML) in patients with migraine. Low grade systemic inflammation has been proposed as a contributing factor in migraine pathophysiology and may be associated with structural brain changes on MRI.

Methods: We performed a retrospective observational study including patients diagnosed with migraine with available brain MRI and blood analysis. Patients were classified as migraine with aura (MA) or migraine without aura (MWO), episodic migraine (EM) or chronic migraine (CM). Brain MRI

were reviewed to evaluate the presence of white matter lesions. Laboratory parameters obtained from routine blood analysis included platelet count, neutrophils, lymphocytes, monocytes, C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). Inflammatory ratios were calculated, including platelet-to-lymphocyte ratio (PLR), neutrophil-to-lymphocyte ratio (NLR), and lymphocyte-to-monocyte ratio (LMR). Descriptive and comparative analysis were performed.

Results: A total of 62 patients were included, 23/62 (37%) presented WML on brain MRI. WML were significantly more frequently present in patients with MA than in those with MWO [19/23 (83%) vs 15/39 (38%), $p < 0.001$]. Patients with WML showed significantly higher CRP levels compared to those without WML [0.28 (0.21–0.48) vs 0.10 (0.09–0.18), $p < 0.001$]. No significant differences were observed in other inflammatory parameters.

Conclusion: Our results show that WML are more prevalent in patients with MA and are associated with higher systemic inflammation, as reflected by elevated CRP levels. These findings may suggest the presence of inflammatory activity in patients with WML, highlighting the potential role of immune biomarkers in the underlying pathophysiology of WML which warrants further research.

EPO-1024 | Headache outcomes on the first day of fasting with once-daily Rimegepant: A post-hoc exploratory analysis

T. Alsaadi¹; G. Ifergane²; R. Suliman¹; I. Al Qaisi¹; J. Yang³; T. Fullerton⁴; D. Chou⁵; E. Whalen⁴; N. Vainstein⁶; D. Davidovici⁷; M. Tirosh⁷; A. Chan⁸; I. Rehman⁹; A. Hussain¹⁰
¹American Center for Psychiatry and Neurology, Abu Dhabi, UAE; ²Soroka Medical Center, Beer-Sheva, Israel; ³Pfizer Inc, New York, USA; ⁴Pfizer Inc, Groton, USA; ⁵Pfizer Inc, Cambridge, USA; ⁶Pfizer, Buenos Aires, Argentina; ⁷Pfizer Pharmaceuticals Israel Ltd, Herzliya, Israel; ⁸Pfizer Healthcare Ireland, Dublin, Ireland; ⁹Rutgers University, New Brunswick, USA; ¹⁰Touro College of Pharmacy, New York, USA

Background and aims: Rimegepant was evaluated previously for short-term prevention of fasting-triggered headache during Ramadan, with outcomes assessed over weekly intervals. This post-hoc analysis examined daily outcomes over the initial week of fasting, focusing on day 1, to evaluate rimegepant's potential for prevention of headache triggered by single-day fasting for religious or medical reasons.

Methods: Participants were randomized to open-label once-daily rimegepant 75 mg from weeks 1–4 (Immediate Start; $n = 52$) or 2–4 (Staggered Start; $n = 53$) of the fast. The proportion of participants with headaches by pain intensity (none, mild, moderate, severe), the proportion with moderate-to-severe headaches, and the duration of moderate-to-severe headaches was compared between groups using nominal p -values.

Results: Headache intensity on day 1 was lower in the Immediate Start arm than the Staggered Start arm ($p = 0.015$), with more participants reporting no headache (50.6% vs 27.8%) and fewer participants reporting moderate (21.0% vs 33.3%) or severe (8.0% vs 18.9%) headache. Fewer participants experienced moderate-to-severe

headache on day 1 in the Immediate Start arm than the Staggered Start arm (difference [95% CI]: -28.8% [-49.1% , -8.5%]; $p = 0.009$). Moderate-to-severe headache duration on day 1 was shorter in the Immediate Start arm than the Staggered Start arm (difference [95% CI]: -1.9 [-4.3 , 0.5] hours), although the difference was not significant ($p = 0.117$). Similar trends were observed across the initial week of fasting (not shown).

Conclusion: Rimegepant improved headache-related outcomes on day 1 in individuals with fasting-triggered headache. These exploratory findings support further evaluation of rimegepant's potential for prevention of headache triggered by single-day fasting.

Disclosure: This study was conducted as a collaboration between the American Center for Psychiatry and Neurology (ACPN; Abu Dhabi, UAE) and Pfizer. The ACPN funded the study and is the study sponsor. Ifra Rehman is a post-doctoral fellow at Pfizer. Azhar Hussain is a student at Touro College of Pharmacy.

Clinical Neurophysiology 1

EPO-1025 | Neurovascular reactivity during mental stress in narcolepsy with cataplexy: A microneurographic study

A. Furia; R. Liguori; V. Donadio
Dipartimento di Scienze Biomediche e Neuromotorie, Università di Bologna, Italy

Background and aims: Mental stress induces an arousal reaction and a subsequent response on various physiological parameters such as blood pressure (BP). Previous studies with microneurography, a technique allowing for in vivo nerve registration of muscle sympathetic nerve activity (MSNA), have shown that individuals with inhibited MSNA after arousal (“responders”) showed a lesser BP response when compared to “non-responders”. In narcolepsy with cataplexy (NC), microneurography has shown a deranged sympathetic activation during REM sleep: the aim of the study is to assess whether a similar occurrence is found in wake patients.

Methods: 15 male patients with NC (aged 37 ± 11 years) and 15 male healthy controls (aged 36 ± 11 years) were subjected to microneurography of the peroneal nerve and concomitant recording of respiratory movements, blood pressure and electrodermal activity. Responders and non-responders were defined by significant MSNA inhibition after electrical skin stimulation. All individuals were then recorded at rest, after mental arithmetic stress and after cold stimulation. BP variation was then analyzed between NC patients and healthy controls, as well as responders vs non-responders between groups.

Results: 3 NC patients and 3 healthy controls could be classified as responders, thus showing no difference. As expected, stress induced a BP increase which was less elevated in responders, both in the NC and in the healthy control group.

Conclusion: In this study, wake NC patients showed no difference in sympathetic response to stress, which differed in responders vs non-responders resulting in a different impact on blood pressure.

Disclosure: Nothing to disclose.

EPO-1026 | Direct current stimulation shapes metabolic phenotype of human i3 cortical neurons

S. Invernizzi¹; M. Ghirimoldi²; V. Borrini²; E. Barberis³; E. Albi⁴; M. Piccoli⁵; A. De Grado⁶; T. Bocci⁶; A. Priori⁶; M. Manfredi²; A. Ratti¹; P. Signorelli⁶

University Vita-Salute San Raffaele, Via Olgettina, Milan, Italy; ⁶Aldo Ravelli Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, Università degli Studi di Milano, Milan, Italy

Background and aims: Transcranial direct current stimulation (DCS) is a promising disease-modifying strategy in neurodegenerative disorders, offering a non-invasive alternative to deep brain stimulation (DBS) and a complementary approach to pharmacological therapies. However, clinical outcomes remain heterogeneous, with responders and non-responders, highlighting the need for mechanistic insight. At cellular level, we previously showed that DCS in neuroblastoma cells induces lipid metabolic remodeling, reduces inflammation, enhances mitochondrial oxidative metabolism and energy availability, and promotes extracellular vesicle release. We here aim at investigating the biological effects of DCS on human i³-neurons using a multi-omic approach.

Methods: Human i³-neurons, generated from healthy donor iPSCs via doxycycline-induced expression of an NGN2-containing cassette, were stimulated with DCS (0.5 μ A; $\approx$ 18 nA/cm²; 10 min), once or three times. Phenotypic modulation was assessed by mass spectrometry-based lipidomic and proteomic analyses and RNA sequencing.

Results: DCS induced a metabolic-nuclear response in i³-neurons, affecting lipid mobilization and persistent modulation of the gene expression machinery, with proteomic enrichment of RNA processing, transcriptional control, chromatin remodeling, and genome stability pathways. A single stimulation elicited a transient response at 24 h, characterized by membrane lipid remodeling and stress-metabolic proteins, that largely resolved by 72 h. In contrast, repeated stimulations stabilized a state marked by membrane reorganization, involving modulation of ether-linked lipids and fatty acid unsaturation, mitochondrial-lipid metabolic coupling, and transcriptional regulation impacting cellular signaling activity.

Conclusion: Our integrated multi-omics data show DCS induces biological changes on neuronal metabolism, signaling, and plasticity, supporting its clinical potential as a mechanism-based neuromodulation strategy.

EPO-1027 | Towards a neurophysiological biomarker of neurotoxicity in Charcot-Marie-tooth disease

A. De Grado¹; V. Iacobelli¹; C. Pisciotta²; C. Krarup⁴; H. Tankisi⁵; A. Priori³; P. Lanteri¹; M. Moldovan⁴; D. Pareyson²

¹Neurophysiology Unit, Fondazione IRCCS Istituto Neurologico "Carlo Besta", Milan, Italy - Università degli Studi di Milano, Milano, Italy; ²Unit of Rare Neurological Diseases, Fondazione IRCCS Istituto Neurologico "Carlo Besta", Milan, Italy; ³Aldo Ravelli Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, University of Milan, Milan, Italy; ⁴Clinical Neurophysiology, Department of Clinical Neurophysiology, Rigshospitalet, Copenhagen, Denmark; ⁵Department of Clinical Neurophysiology, Aarhus University Hospital, Aarhus, Denmark

Background and aims: Demyelinating Charcot-Marie-Tooth (CMT) is characterized by progressive demyelination with secondary axonal degeneration. Although axonal loss is the primary cause of neurological disability, marked phenotypic variability exists and the underlying neurotoxic mechanisms remain poorly understood. We explored the relationship between CMT severity and motor axonal properties preceding degeneration.

Methods: Patients with CMT1A (N=11), CMT1B (N=5), and CMTX1 (N=4) underwent conventional nerve conduction studies supplemented with median motor axon excitability testing at the wrist using threshold-tracking (TRONDNF protocol). Axonal excitability parameters were correlated with the Charcot-Marie-Tooth Examination Score version 2 (CMTESv2) using Spearman correlation and linear regression.

Results: Across groups, several axonal excitability parameters correlated with CMTESv2, with subgroup-specific regression patterns. For instance, refractoriness at 2ms of the recovery cycle was positively associated with CMTESv2 in CMT1A and negatively in CMT1B, with regression slopes differing significantly ($t = -2.906$, $p = 0.013$). Temperature did not differ across subgroups ($p = 0.46$).

Conclusion: Refractoriness at 2ms primarily reflects nodal voltage-gated sodium channel (VGSC) function, which is independent of passive membrane properties. Translational studies in CMT1B show that dysmyelination is associated with VGSC dysregulation, increasing motor axon vulnerability to activity-dependent degeneration. Notably, refractoriness changes occurred in opposite directions in CMT1A and CMT1B, enabling differentiation between these conditions, yet both indicate altered nodal VGSC function, supporting VGSC dysregulation as a shared pathophysiological mechanism across CMT subtypes. Recovery cycle refractoriness therefore reflects neuropathy

severity in demyelinating and intermediate CMT and may serve as a neurophysiological biomarker of neurotoxicity, with implications for prognostication and assessment of therapeutic efficacy in future disease-modifying trials.

Disclosure: Nothing to disclose.

EPO-1028 | Diagnostic ultrasound-induced changes of motor cortical excitability in humans

E. Sartirana¹; S. Annaloro²; M. Guidetti³; A. De Grado³; S. Marceglia³; M. Bologna⁴; A. Priori³; T. Bocci³

¹Clinical Neurology Unit, "Azienda Socio-Sanitaria Territoriale Santi Paolo E Carlo", Department of Health Sciences, University of Milan, Milan, Italy; ²Faculty of Medicine, Department of Health Sciences, University of Milan, Milan, Italy; ³"Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, Department of Health Sciences, University of Milan, Milan, Italy; ⁴Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy

Background and aims: This proof-of-concept study investigates whether certified diagnostic ultrasound effectively modulates cortical excitability. By targeting primary motor cortex, we demonstrate that conventional clinical protocols induce neuroplastic changes, potentially bypassing the experimental hardware hurdles and making transcranial ultrasound (TUS) immediately accessible for hospital applications.

Methods: Sixteen healthy volunteers (31.9 ± 11.0 years) participated in a sham-controlled crossover study. Using a certified DWL Multi-Dop X4 clinical system, 30 minutes sonication was delivered through the right transtemporal window via a 2.0 MHz linear probe, targeting the Abductor Pollicis Brevis (APB) hotspot at a depth of 45–58 mm. Cortical excitability was mapped via paired-pulse Transcranial Magnetic Stimulation (TMS), measuring Short-Interval Intracortical Inhibition (SICI), Intracortical Facilitation (ICF), and Long-Interval Intracortical Inhibition (LICI). Resting Motor Threshold (RMT) and Breath-Holding Index (BHI) monitored mechanical or vascular artifacts. Non-parametric tests and Bayesian inference (Bayes Factor, BF) quantified the evidence.

Results: Post-insonation, SICI was significantly reduced in the stimulated hemisphere (T0: 65.0%, T1: 67.5%; $p=0.016$, $BF_{10}=7.65$), indicating increased local excitatory drive. Conversely, the control hemisphere showed a robust LICI increase (T0: 54.0%, T1: 86.0%; $p=0.010$, $BF=7.88$). Inter-hemispheric comparisons confirmed that the reduction in inhibition was specific to the stimulated side ($p=0.046$, $BF=3.90$). No significant changes occurred in ICF, RMT, or BHI.

Conclusion: Diagnostic ultrasound elicits focal neuroplastic changes, likely via Gamma-Aminobutyric Acid-B (GABA-B) pathways. This represents the first evidence that standard clinical Doppler system can selectively modulate the motor cortex, traditionally requiring high-costly experimental hardware, establishing standard sonography as a viable neuromodulation tool ready for immediate clinical translation.

Disclosure: The authors declare that this research was conducted in the absence of any commercial or financial relationships that could be constructed as a potential conflict of interest.

EPO-1029 | Electrocortical changes due to vibro-tactile stimulation in patients with cervical dystonia

G. Ruocco¹; G. Leodori¹; M. Costanzo¹; F. Martino¹; D. Maccarrone¹; B. Sellani¹; G. Ferrazzano¹; D. Belvisi¹; G. Fabbrini¹; J. Konczak²; A. Berardelli¹; A. Conte¹

¹Department of Human Neurosciences, Sapienza University of Rome, Italy; ²School of Kinesiology, Human Sensorimotor Control Laboratory, University of Minnesota, Minneapolis, USA

Background and aims: Cervical dystonia (CD) involves involuntary, sustained, or intermittent neck muscle movements. Although its pathophysiological remain unclear, increasing evidence points to altered sensory processing, particularly in the tactile and proprioceptive domains. Vibro-tactile stimulation (VTS) has been proposed as a non-invasive neuromodulatory intervention. This study investigated the clinical effects of VTS in CD and the associated cortical and cortico-muscular correlates.

Methods: 10 CD patients underwent 64-channel EEG and surface EMG recordings from bilateral sternocleidomastoid and trapezius muscles. Head kinematics were measured using a wireless inclinometer, with the head angle index (HAI) as outcome. During a preliminary session, 1-minute VTS was applied to each of four muscles; the one producing maximal HAI improvement was selected. Patients then completed a randomized cross-over protocol with three 5-minute conditions: rest with inactive VTS, active VTS, and sham VTS (5 seconds per minute). EEG and EMG were analyzed for spectral power (theta, alpha, beta), cortico-muscular coherence (CMC), and intermuscular coherence (IMC).

Results: Active VTS progressively reduced HAI relative to baseline, significantly more than sham. During active-VTS EEG over the contralateral sensorimotor cortex showed increased alpha power and a trend toward reduced theta. Theta CMC decreased and alpha CMC increased during VTS. IMC between homologous muscles showed a non-significant trend toward increased theta coherence.

Conclusion: VTS applied to cervical muscles improves dystonic posture in CD, associated with modulation of cortical alpha/theta rhythms and cortico-muscular and intermuscular coupling. These findings support VTS as a promising non-invasive neuromodulatory strategy targeting sensory dysfunction in cervical dystonia.

Disclosure: The authors declare no conflict of interest

EPO-1030 | Pupillary light reflex index in insomnia disorder: An index of daytime autonomic arousal

E. Fasiello¹; E. Cini²; F. Bolengo²; S. Catena²; L. Dell'Acqua²; G. D'Este¹; C. Leitner²; F. Casoni²; P. Proserpio²; V. Castronovo²; L. De Gennaro³; A. Galbiati²; L. Ferini-Strambi²

³Department of Psychology, Sapienza University of Rome, Rome, Italy

Background and aims: The present study investigates whether dynamic Pupillary Light Reflex (PLR) metrics can serve as day-time physiological markers of arousal dysregulation in Insomnia Disorder (ID).

Methods: To evaluate diurnal autonomic nervous system activity, this study used the PLR as a noninvasive index of arousal. A Psychomotor Vigilance Test (PVT) was performed as a behavioral measure of objective daytime sleepiness, hypothesizing that, compared to Healthy Controls ($n=24$; mean (M)=49.87; standard deviation (SD)=11.75; 15F), ID patients ($n=29$; $M=49.03$; $SD=11.07$; 21F) would show objective signs of altered daytime arousal.

Results: The non-parametric t-test showed no significant group differences in PVT performance. Considering PLR metrics, ID patients showed a faster pupil re-dilation after constriction, alongside a slower return of the pupil to 50% of its original diameter. Spearman's correlations were performed to evaluate the association between the PLR indices and clinical features. Results demonstrate positive associations between pupil re-dilation after constriction and time for the pupil to return to 50% of its original diameter, more severe ID symptoms, higher pre-sleep arousal, and more dysfunctional beliefs about sleep.

Conclusion: The results confirm increased daytime arousal state in individuals with insomnia, supporting the use of pupil-ometry to assess physiological alterations in this condition.

EPO-1031 | Propofol anesthesia induces a brain state of intermediate consciousness: Insights from EEG-based time-evolving functional brain networks

N. Dissouky¹; T. Bröhl¹; A. Delis²; M. Thudium²; C. Helmstaedter¹

¹Universität Bonn, Universitätsklinikum Bonn, Epileptologie, Bonn, Germany; ²Universität Bonn, Universitätsklinikum Bonn, Klinik für Anästhesiologie und Operative Intensivmedizin, Bonn, Germany

Background and aims: Consciousness depends on the brain's ability to balance excitability and stability [1, 2]. While non-human primate studies suggest propofol disrupts cortical dynamics [3], its impact on dynamic network stability in humans remains unclear. We investigated how propofol alters cortical network stability and dynamics relative to sleep and wakefulness using EEG-derived time-evolving functional brain networks (TEFBNs), capturing dynamic changes in brain organization associated with consciousness [4].

Methods: We recorded EEG time-series (10–20 system) from adults across three groups: healthy controls during wakefulness ($n=51$), nighttime sleep ($n=14$), and propofol anesthesia ($n=10$). EEG in the anesthesia group was acquired prior electroconvulsive therapy (ECT) in depressed patients. Baseline network organization did not differ from controls, indicating no clinical influence. TEFBNs were constructed, and network-based measures of stability and dynamics were analyzed.

Results: Under propofol anesthesia, subjects occupied an intermediate brain state that was neither fully awake nor asleep. Although slow-wave activity resembled NREM sleep, TEFBNs revealed a distinct network organization. Bilateral cortical regions showed equal temporal importance, indicating increased

local synchronization and reduced functional differentiation. Network metrics further demonstrated subtle destabilization of cortical dynamics not observed during natural sleep or wakefulness, suggesting that propofol induces a state of symmetric local coherence despite disrupted global integration.

Conclusion: These findings extend primate work showing that propofol impairs consciousness by destabilizing cortical networks. To our knowledge, this is the first human evidence that propofol produces an intermediate state that is awake-like yet exhibits sleep-like slow waves, reflecting a mechanism distinct from natural sleep, not merely a deeper stage of it.

EPO-1032 | Pathophysiology of fatigue in chronic inflammatory demyelinating polyradiculoneuropathy: The importance of proximal demyelination

N. Başcı¹; M. Tutuncu¹; N. Uzun Adatepe²; A. Gündüz²

¹Department of Neurology, Cerrahpaşa Faculty of Medicine, Istanbul University-Cerrahpaşa, Istanbul, Türkiye; ²Department of Clinical Neurophysiology, Cerrahpaşa Faculty of Medicine, Istanbul University-Cerrahpaşa, Istanbul, Türkiye

Background and aims: Fatigue is a complex symptom that has multiple mechanisms from central nervous system to immunological processes. We hypothesize that fatigue's more pronounced in patients with proximal conduction blocks and proximal demyelinating and the involvement of cranial nerves.

Methods: CIDP patients were evaluated for fatigue and underwent electrophysiological investigations. Bilateral routine NCS, proximal assessments of median (wrist-elbow-axilla) and ulnar nerve (wrist-elbow-above-elbow-axilla), motor recordings on nasalis and trapezius muscles (stimulating from facial and spinal-accessory nerve), blink-reflex testing were performed. Conduction-blocks, conduction-slowing, F/A-waves in proximal-distal segments were evaluated. Fatigue was assessed with Krupp-Fatigue-Severity-Scale (FSS) (<2.8:no fatigue, >6.1:chronic, 2.8-6.1:mild).

Results: Ten CIDP patients were evaluated (mean age 49.8 ± 8.3). The mean FSS score was 4.32 ± 1.3 . The mean INCAT score was 2.2 ± 1.8 . Chronic fatigue was present in 20%, 10% had no fatigue. The mean number of conduction blocks was 3.9 ± 1.8 (min-max 1–6). In patients with chronic fatigue, conduction blocks in the median and ulnar nerves were more frequently located in proximal segments compared with the non-fatigued/mildly fatigued groups. There were no significant differences in nasalis-trapezius recordings. Blink reflex latencies tended to be longer in fatigued patients.

Conclusion: These findings suggest that fatigue in CIDP may be associated with the topographic distribution of conduction blocks. Although no marked differences were detected in cranial nerve studies, the tendency toward prolonged blink reflex latencies in fatigued patients is notable in terms of central-peripheral interactions. These results highlight the need to consider the distribution of conduction blocks to better understand the pathophysiology of fatigue in CIDP.

⁴Department of Diagnostic and Interventional Neuroradiology, University Hospital Centre Zagreb, Zagreb, Croatia

Background and aims: Novel 2024 McDonald criteria included the kappa free light chain (KFLC) index as an additional cerebrospinal fluid (CSF) biomarker representing intrathecal inflammation as well as evoked potentials (EPs) demonstrating functional central nervous system pathway dysfunction. Aim of this study was to evaluate association of these biomarkers reflecting inflammation and neurodegeneration in early relapsing–remitting multiple sclerosis (RRMS).

Methods: Analysis included 52 consecutive treatment-naïve people with newly diagnosed RRMS (34 females; mean age 37.7 ± 11.1 years; median Expanded Disability Status Scale [EDSS] 2.0). All patients underwent standardized diagnostic work-up including brain and cervical spinal cord MRI, CSF analysis with KFLC index calculation and multimodal EP testing (visual EP [VEP], brainstem auditory EP [BAER], and median and tibial somatosensory EP [mSSEP, tSSEP]). Pathological findings of EP were summarized calculating an EP score.

Results: Higher KFLC index correlated with shorter VEP P100 latency and higher VEP amplitude on left-eye stimulation, shorter BAER wave V latencies bilaterally, and with higher tSSEP amplitudes. Consistent with these findings, KFLC index values were significantly higher in participants with lower EP pathological burden (EP score classification; $p=0.01$), and similarly across VEP- and tSSEP-based pathological groupings ($p=0.015$ and $p=0.008$, respectively). No significant associations were observed between KFLC index and clinical or neuroradiological parameters in our cohort.

Conclusion: In newly diagnosed RRMS, higher intrathecal inflammatory activity was paradoxically associated with less neurophysiological pathway dysfunction. These findings suggest that KFLC index and EP scores represent different aspects of early MS neuropathology emphasising their complementary utilisation in fulfilment of new MS diagnostic criteria.

EPO-1034 | The effect of demyelination patterns on clinical course and prognosis in CIDP

S. Ozdemir; E. Ozbezen Kiziltan; S. Alpaydin Baslo; A. Soysal
Department of Neurology, Bakirkoy Prof. Dr. Mazhar Osman Research and Training Hospital for Psychiatry, Neurology, and Neurosurgery, Istanbul, Türkiye

Background and aims: Chronic inflammatory demyelinating polyneuropathy (CIDP) is a heterogeneous immune-mediated neuropathy characterized by multifocal demyelination affecting different nerve segments. Our study aimed to investigate the association between demyelination distribution patterns, clinical features, and prognosis in CIDP.

Methods: We retrospectively evaluated initial and follow-up electrophysiological studies of 42 patients with CIDP (2000–2024) according to the 2021 EFNS/PNS criteria. Patients were classified as distal (distal latencies $>150\%$ of the upper limit of normal), intermediate (conduction velocity $<70\%$ of the lower limit of normal and/or conduction block or abnormal temporal dispersion), or diffuse (combined distal and intermediate abnormalities). Patients were categorized according to electrophysiological patterns, and longitudinal changes were analyzed in relation to clinical prognosis.

Results: Forty-two patients were analyzed longitudinally. At baseline, electrophysiological patterns were classified as intermediate in 61.9%, diffuse in 28.5%, and distal in 9.6% of patients; 12.5% showed normalization at follow-up. Distal pattern was

FIGURE 1 Electrophysiological analysis: comparison between initial and final EMG results.

FIGURE 2 Based on electrophysiological patterns after initial assessment, comparison of INCAT and mRS scores before and after treatment.

FIGURE 3 Treatment records during initial treatment and follow-up period.

associated with shorter symptom duration, higher INCAT and mRS scores, more frequent triggering events, and a higher rate of subacute onset (all $p \leq 0.036$). Treatment was initiated 24.1 months earlier, partial remission lasted 51 months longer, and total disease duration was 11.6 years shorter in distal compared with intermediate pattern (all $p \leq 0.03$). Monophasic course was more frequent with temporal dispersion ($p = 0.023$), whereas axonal degeneration predicted lower remission rates ($p = 0.011$).

Conclusion: Demyelination patterns significantly influence the clinical course and prognosis of CIDP, highlighting the prognostic value of electrophysiological pattern analysis.

EPO-1035 | Transient loss and recovery of dorsal rootlet excitability during selective dorsal rhizotomy

G. Zabrodzets¹; M. Talabaev²; Y. Rushkevich¹

¹Department of Neurology, Republican Scientific and Practical Center of Neurology and Neurosurgery, Minsk, Belarus;

²Pediatric Neurosurgery Department, Republican Scientific and Practical Center of Neurology and Neurosurgery, Minsk, Belarus

Background and aims: Selective dorsal rhizotomy (SDR) is an established treatment for lower-limb spasticity in children with cerebral palsy (CP). Intraoperative neurophysiological monitoring (IONM) guides the procedure, yet its protocols are debated. This study aimed to assess the dynamics of dorsal root (DR) excitability during SDR.

Methods: A retrospective analysis of IONM data from 15 children with CP (mean age 7.1 ± 4.3 years, GMFCS III-V) was conducted. Surgery involved single-level laminectomy (L1/L2) under total intravenous anesthesia. The IONM protocol determined the threshold stimulation intensity (TSI) using 3-Hz pulses, followed by 50-Hz train stimulation for each whole DR and its subsequently subdivided rootlets.

Results: Analysis of 150 DRs (L2-S1) and 684 rootlets revealed significant inter-root differences. The median TSI (in mA) for whole DRs was lowest at S1 (0.48, IQR 0.28–0.61) and highest at L4 (0.98, IQR 0.60–1.21). Subdivision into rootlets increased median TSI markedly, peaking at L4 (2.03, IQR 1.05–2.72). A key finding was transient loss of EMG response in 8 patients despite stimulation up to 5 mA, which was reversed by irrigation

with warm saline during 5 min, leading to a significant decrease in recalculated TSI. Statistical analysis confirmed significant inter-root differences at each procedural stage (Kruskal-Wallis, $p < 0.05$) and a significant overall reduction in thresholds over time (Friedman test, $p = 0.007$), with the most pronounced decrease at L4 (from 2.03 to 1.22, $p = 0.004$).

Conclusion: The observed reduction in rootlet excitability may be attributed to specific surgical aspects of SDR. Thus, proper IONM interpretation is crucial to determine individual rootlet function at each segmental level.

EPO-1036 | Ischemia resistance in pathophysiology of early diabetic motor and sensory polyneuropathy

M. Mroczek¹; S. Omidbakhsh¹; A. Gramm Kristensen²;

P. Karlsson³; P. Grafe⁴; H. Tankisi⁵

¹Department of Clinical Neurophysiology, Aarhus University

Hospital, Aarhus, Denmark; ²Department of Clinical Neurophysiology, Aarhus University Hospital, Aarhus, Denmark;

Danish Pain Research Center, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; ³Core Center for

Molecular Morphology, Section for Stereology and Microscopy, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark;

Danish Pain Research Center, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; ⁴Institute of

Physiology, Ludwig-Maximilians University Munich, Germany; ⁵Department of Clinical Neurophysiology, Aarhus University

Hospital, Aarhus, Denmark; Department of Clinical Medicine, Aarhus University, Aarhus, Denmark

Background and aims: Nerve excitability testing has shown resistance to ischemia in motor nerves after 10–30 minutes of compression as an early and specific finding in diabetic neuropathy. Sensory nerves have not previously been investigated. We hypothesize that resistance to ischemia is seen in motor and sensory nerves before clinical and electrophysiological signs of neuropathy.

Methods: We tested diabetic patients (10 sensory, 13 motor measurements, age 30–60 yrs) and compared them with healthy controls (12 sensory, 9 motor measurements). The following protocol was applied at two separate sessions, one for the motor and one for the sensory nerves: short TRONDNF including strength/duration time constant (SDTC), multitasking: 5 min pre-ischemia, 5 min ischemia (induced with a pressure cuff), 10 min post-ischemia. We have tracked 4 parameters: threshold decrease (in multitask protocol), recovery cycle (RC) at 6 ms, TE_{d100}, and TE_h overshoot of threshold electrotonus.

Results: People with diabetes showed statistically highly significant less loss of axonal super-excitability in both sensory and motor axons (SupEx isc motor –10.7 % vs. 1.3%, SupEx isc sensory –3.5 % vs. 13.9 %; $p < 0.001$). Preliminary results showed also that they differed from normal controls in ischemia-induced changes in strength/duration time constant and in the time course of ischemia-induced changes in threshold current.

Conclusion: Resistance to compression-induced nerve ischemia in diabetic patients can be detected by the threshold current in the recovery cycle. The time course of ischemia-induced changes in threshold current and an abnormal strength/duration

time constant indicate that tissue acidification may contribute to nerve excitability parameters.

EPO-1037 | **Functional relationship between large and small fibers in diabetic neuropathy**

M. Baba¹; R. Haga¹; I. Kinoshita¹; M. Miura¹; K. Hiyama¹; Y. Murakami¹; T. Ueno¹; J. Matsui²; C. Suzuki³
¹Department of Neurology, Aomori Prefectural Central Hospital, Aomori City, Japan; ²Diabetes Centre, Aomori Prefectural Central Hospital, Aomori City, Japan; ³Department of Neurology, Hirosaki University School of Medicine, Hirosaki, Japan

Background and aims: Diabetic neuropathy (DN) has two different phenotypes, painful DN (PDN) and painless DN (PLDN). Small fiber (SF) damage has been suggested in pain production, however, role of large fibers (LF) remains unclear; We electrophysiologically investigated LF and SF functions in PDN and PLDN.

Methods: In 140 diabetics, we scaled SF and LF functions by electrodermal skin conductance (ESC) of SUDOSCAN and by nerve conduction study (NCS). NCS scale is defined as follows; NCS-0: No NCS anomalies, NCS-1: Prolonged F-wave latency with normal SNAP & CMAP amplitudes, NCS-2: Fall in SNAP less than 5 microvolts with normal CMAP, NCS-3: Fall in CMAP amplitude to between 2mV and 5 mV, NCS-4: Decrease in CMAP amplitudes less than 2mV.

Results: Fall in ESC and increase in the NCS-scale showed positive correlation with coefficient 0.55. Among the cases with ESC lower than 60 micro-siemens, 20% of the cases with NCS-0 and NCS-1 had pain, while 48% of the NCS-2, -3, and -4 groups ($p < 0.05$) complained of pain. Among the NCS-0 and -1 cases with lower ESC, PDN showed sural SNAP of $6.9 \pm 1.2 \mu V$, which was lower than $10.6 \pm 4.1 \mu V$ of PLDN ($p < 0.01$).

Conclusion: In diabetes, electrophysiological functions of LF and SF generally decline in parallel. Even if the ESC decreases, pain is unlikely to occur if LF function is maintained normally. LF activate collateral inhibitory neurons in the dorsal horn of the spinal cord. Reduced impulse input from the LF might facilitate pain impulse transmission from the damaged SF.

FIGURE 1 BP recordings and colorimetric maps for: (a) simple clonic hand movement, (b) foot movement, (c) complex clonic hand movement, (d) tonic hand movement and (e) blink movement.

study generalizability, multiple factors affecting BP morphology, and methodological heterogeneity, which collectively hinder definitive conclusions on BP onset timing and spatial distribution across body regions.

Methods: We cross-sectionally examined the BP during voluntary hand, foot, and eye movements in healthy participants. Simple and complex hand movements, foot dorsiflexion, and eyelid contraction were recorded, including brisk (< 0.5 s) and sustained (~ 1 s) actions. EMG onset at 50% maximal voluntary contraction served as the trigger, and BP was recorded via 64-channel DC EEG. A 7-second epoch window was applied, artifact-free trials averaged, and BP morphology, distribution, and lateralization were qualitatively assessed using scalp maps and waveforms.

Results: Fifteen healthy participants (mean age 28.0 ± 4.5 years; 9 females) underwent BP recordings. A contralateral centro-frontoparietal BP was observed during simple and complex clonic and tonic hand movements, whereas foot movements

elicited a bilaterally distributed central BP with ipsilateral diffusion, and blink movements showed a bilateral frontal distribution (Figure 1; Table 1). Within-subject analyses revealed an earlier onset of the early phase for complex hand and foot movements, and both earlier early phase onset and delayed late phase onset for tonic hand movements. No amplitude differences were observed (Table 2)

Conclusion: Several factors may influence differences in BP elicited by various movements. Studying normative models across healthy subjects is crucial to characterize BP topography, optimize electrode placement and analysis protocols, and provide a non-invasive window into movement characteristics and potential pathological alterations.

Disclosure: Nothing to disclose.

EPO-1039 | **Simulation of freezing of Gait in a virtual reality environment: An electrophysiological approach in Parkinson's disease**

R. Unkun Altun¹; A. Geriş²; A. Gündüz¹
¹Department of Neurology, Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Istanbul, Türkiye; ²Department of Computer and Instructional Technologies Education, Faculty of Education, Manisa, Türkiye

Background and aims: This study investigated electrophysiological changes in motor and brainstem pathways under virtual reality (VR) conditions mimicking freezing of gait (FoG)-triggering situations to better understand the pathophysiology of FoG in idiopathic Parkinson's disease (iPD).

Methods: In this prospective study (May 2024–August 2025), patients aged 40–80years with iPD with FoG (iPD-FoG), PD without FoG (iPD-nFoG), and age- and sex-matched healthy individuals were included. iPD diagnosis was based on Movement Disorder Society 2015 criteria, and FoG was assessed using established criteria. Clinical evaluation included the Unified Parkinson's Disease Rating Scale, Timed Up and Go test, auditory startle reflex, resting motor threshold, motor evoked potentials, and H-reflex assessment. All evaluations were performed in the off-medication state. Neurophysiological measurements were obtained at rest and during a VR condition designed to replicate the clinical setting of the Timed Up and Go test.

TABLE 1 Demographic and clinical findings of the study groups: iPD-FoG, iPD-nFoG, and healthy individuals.

Parameter	iPD-FoG n = 8	iPD-nFoG n = 18	Healthy individuals n = 10	P ^a

Abb. iPD = idiopathic Parkinson's disease, FoG = freezing of gait, LEDS = Levodopa equivalent daily dose, UPDRS = Unified Parkinson's Disease Rating Scale, Part I = Screening of total UPDRS score, Part II = Motor-related UPDRS subscore, TUG = Timed Up and Go test.
*p < 0.05, **p < 0.01, group differences between iPD-FoG and iPD-nFoG as per Kruskal-Wallis test.

FIGURE 1 Graphics of mean H/M ratios between rest and virtual reality conditions across the groups.

FIGURE 2 MEP amplitude change (% of rest) in iPD-FoG, iPD-nFoG, and healthy individuals.

Results: Eight iPD-FoG patients, ten iPD-nFoG patients, and ten healthy individuals were included. Mean ages were comparable across groups. Resting motor threshold was lower in both iPD groups than in healthy individuals. During VR exposure, mean H/M ratios were higher in healthy individuals and iPD-FoG patients than in iPD-nFoG patients. Percentage increases in motor evoked potential amplitudes were greater in iPD-FoG patients and healthy individuals than in iPD-nFoG patients. Auditory startle reflex amplitudes decreased under VR conditions in all groups.

Conclusion: VR exposure induces corticospinal facilitation while suppressing brainstem pathways. Spinal excitability is facilitated in iPD-nFoG patients, suppressed in iPD-FoG patients, and remains unchanged in healthy individuals.

Disclosure: Nothing to disclose.

T. Szczepanski¹; K. Nilsen¹; Ø. Dunker¹; A. Reiner²; T. Sand³; M. Tannemaat⁴; A. Yazidi⁵; K. Bach⁶; J. Zwart⁷; J. Jabre⁸; P. Omland³

¹Section for Clinical Neurophysiology, Department of Neurology, Oslo University Hospital, Oslo, Norway; ²Oslo Centre for Biostatistics and Epidemiology, Oslo University Hospital, Oslo, Norway; ³Department of Neurology and Clinical Neurophysiology, St. Olavs Hospital, Trondheim, Norway; ⁴Leiden University Medical Center, Netherlands; ⁵Oslo Metropolitan University, Oslo, Norway; ⁶Department of Computer Science, Norwegian University of Science and Technology, Trondheim, Norway; ⁷Faculty of Medicine, University of Oslo, Oslo, Norway; ⁸Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, USA

Background and aims: High-quality reference limits for nerve conduction studies (NCS) are essential for accurate diagnosis of neuromuscular disorders. Traditionally, reference limits are derived from examinations of healthy individuals. This is expensive and time-consuming, and it is challenging to include children and elderly. Alternative methods – extrapolated norms (E-norms), extrapolated reference values (E-Ref), and multivariate extrapolated reference values (MeRef) – estimate reference limits from historical hospital data. However, the performance of the current versions of these methods varies across different NCS measurements. We aimed to improve these methods by modifying them using changepoint detection.

Methods: The changepoint algorithm detects significant changes in a data sequence by evaluating different ways of segmenting the data based on segment mean and variance. The modified methods were used to calculate reference limits for common NCS measurements using a historical database of 24,816 patients. The results were compared with reference limits derived from 680 healthy subjects, and evaluated using the F1 score.

Results: The changepoint-modified methods achieved greater F1 scores on average than the original methods for lower-extremity NCS measurements (0.74 vs 0.64), but lower scores for upper-extremity measurements (0.56 vs 0.66). In most cases, good performance required at least 500 measurements and datasets containing fewer than 20% abnormal values.

Conclusion: Changepoint detection improves the performance of E-norms, E-Ref, and MeRef methods for lower-extremity nerves. These improvements are promising and may allow for more accurate diagnostics of neuromuscular disorders, in particular for children, elderly and people living in areas where obtaining local reference values from healthy subjects is unrealistic.

Disclosure: None of the authors has any conflict of interest to disclose. This work received financial support from the South-Eastern Norway Regional Health Authority and the Norwegian Medical Association.

¹Section for Clinical Neurophysiology, Department of Neurology, Oslo University Hospital, Oslo, Norway; ²Department of Neurology and Clinical Neurophysiology, St. Olavs Hospital, Trondheim, Norway; ³Oslo Metropolitan University, Oslo, Norway; ⁴Department of Computer Science, Norwegian University of Science and Technology, Trondheim, Norway; ⁵Faculty of Medicine, University of Oslo, Oslo, Norway

Background and aims: Reference limits are essential for correctly interpreting nerve conduction studies (NCS). Traditionally, these limits are established using large groups of healthy individuals which is expensive, logistically demanding, and raises ethical concerns. Alternatively, reference limits can be estimated indirectly using historical hospital data containing a mixture of normal and abnormal measurements. Most current alternative methods assess each NCS measurement separately when trying to distinguish normal from abnormal results. In this study, we introduce a novel method – MultiNorm – that instead identifies healthy nerves.

Methods: We combined different types of historical NCS measurements from individual nerves into multidimensional maps and identified regions most likely to represent healthy nerves. Measurements from the presumed healthy nerves were then used to establish reference limits for commonly used NCS and compared with traditional reference limits (from $N=680$ healthy individuals) and four recently published indirect methods (E-norms, E-Ref, MeRef, MMC) using F1 score.

Results: MultiNorm achieved a total average F1 score of 0.81, 0.13 higher than the second-best performing method, extrapolated norms. Reliable performance required datasets containing at least 500 measurements. Unlike the other methods, the performance of MultiNorm remained stable until the proportion of abnormal measurements exceeded 50%, 30% higher than the tolerance of the other approaches.

Conclusion: The MultiNorm approach performs favorably compared with existing indirect methods and shows improved robustness in datasets containing more than 20% abnormal values. It allows accurate estimation of NCS reference limits using historical hospital data and represents a practical and reliable complement to traditional, directly derived reference limits.

Disclosure: None of the authors has any conflict of interest to disclose. This work received financial support from the South-Eastern Norway Regional Health Authority and the Norwegian Medical Association.

EPO-1042 | **Change in functional impact of dyskinesias and motor fluctuations with foslevodopa/foscarbidopa in Parkinson's disease**

E. Freire-Álvarez¹; P. Odin²; R. Hauser³; J. Aldred⁴; L. Bergmann⁵; R. Gupta⁵; A. Saad⁵; A. Antonini⁶
¹General Universitario de Elche, Alicante, Spain; ²University of Lund, Lund, Sweden; ³University of South Florida, Tampa, USA; ⁴Selkirk Neurology and Inland Northwest Research, Spokane, USA; ⁵AbbVie Inc, North Chicago, USA; ⁶University of Padua, Padua, Italy

Background and aims: Foslevodopa/foscarbidopa (LDp/CDp), a continuous subcutaneous infusion of levodopa (LD) and carbidopa (CD) prodrugs, reduces dyskinesias and Off times in adults with advanced Parkinson's disease (aPD). Here, we investigated the functional impact of this reduction.

Methods: This post hoc analysis included two phase 3 aPD clinical trials: a 12-week, double-blind, double-dummy, randomized controlled trial (RCT) of LDp/CDp vs oral LD/CD (NCT04380142) and a 52-week open-label safety trial (OLST) of LDp/CDp (NCT03781167). Change from baseline was analyzed for items 4.2 (functional impact of dyskinesias) and 4.4 (functional impact of motor fluctuations) on the Movement Disorder Society-Unified Parkinson's Disease Rating Scale.

Results: In the RCT, the functional impact of dyskinesias significantly worsened from baseline to week 12 with oral LD/CD (mean=0.2, standard deviation [SD]=0.7, $p=0.045$), whereas it significantly improved with LDp/CDp (mean=-0.5, SD=1.0, $p=0.003$, between-group difference $p=0.001$). In the OLST, this functional improvement for dyskinesias with LDp/CDp was -0.6 at week 52 (SD=1.1, $p\leq 0.001$). The functional impact of motor fluctuations in the RCT did not change significantly with oral LD/CD ($p=0.344$), while it significantly improved

TABLE 1 RCT.

RCT			
Change from baseline	Oral LD/CD	LDp/CDp	Between-group difference, P value
Change from baseline in functional impact of dyskinesias, mean (SD), within-group P value			
Week 12, n = 108 ^a	0.2 (0.7), P = .045 [*]	-0.5 (1.0), P = .003 [*]	.001 [*]
Final visit, ^b n = 141 ^a	0.2 (0.6), P = .025 [*]	-0.4 (1.0), P = .003 [*]	.003 [*]
Change from baseline in functional impact of motor fluctuations, mean (SD), within-group P value			
Week 12, n = 108 ^a	-0.1 (1.2), P = .344	-1.0 (1.3), P < .001 [*]	.003 [*]
Final visit, ^b n = 141 ^a	-0.2 (1.2), P = .223	-0.6 (1.5), P = .001 [*]	.253

CD, carbidopa; CDp, foscarbidopa; LD, levodopa; LDp, foslevodopa.
RCT, randomized controlled trial; SD, standard deviation.
^aThis is the total sample size: the sum of participants in the oral LD/CD group and LDp/CDp group.
^bFinal visit is the last nonmissing postbaseline data available for the participant.
^{*}Indicates statistical significance, $P < .05$.

TABLE 2 OLST.

OLST		
Change from baseline	LDp/CDp	Within-group difference from baseline, P value
Change from baseline in functional impact of dyskinesias, mean (SD)		
Week 52, n = 133	-0.6 (1.1)	< .001 [*]
Final visit, ^a n = 244	-0.6 (1.1)	< .001 [*]
Change from baseline in functional impact of motor fluctuations, mean (SD)		
Week 52, n = 133	-1.2 (1.4)	< .001 [*]
Final visit, ^a n = 244	-0.9 (1.5)	< .001 [*]

CD, carbidopa; CDp, foscarbidopa; LD, levodopa; LDp, foslevodopa.
OLST, open-label safety trial; SD, standard deviation.
^aFinal visit is the last nonmissing postbaseline data available for the participant.
^{*}Indicates statistical significance, $P < .05$.

with LDp/CDp (mean = -1.0, SD = 1.3, $p \leq 0.001$, between-group difference $p = 0.003$). In the OLST, motor fluctuation impairment remained improved at 52 weeks (mean = -1.2, SD = 1.4, $p \leq 0.001$).

Conclusion: Functional impairment from dyskinesias and motor fluctuations significantly improved after LDp/CDp treatment in patients with aPD.

EPO-1043 | Cumulative symptoms improvement with foslevodopa/foscarbidopa vs oral medication in advanced Parkinson's disease

A. Antonini¹; A. Videnovic²; R. Hauser³; E. Freire-Álvarez⁴; B. Bergmans⁵; L. Bergmann⁶; A. Saad⁶; M. Li⁶; K. Onuk⁶; J. Parra⁶; J. Aldred⁷

¹Department of Neuroscience, University of Padova, Padova, Italy; ²Neurological Clinical Research Institute, Massachusetts General Hospital, Boston, USA; ³University of South Florida, Tampa, USA; ⁴General Universitario de Elche, Alicante, Spain; ⁵Department of Neurology, AZ St-Jan Brugge, Bruges, Belgium and Department of Neurology, Ghent University Hospital, Ghent, Belgium; ⁶AbbVie Inc, North Chicago, USA; ⁷Selkirk Neurology and Inland Northwest Research, Spokane, USA

Background and aims: This post hoc analysis evaluated cumulative symptom improvements with foslevodopa/foscarbidopa

FIGURE 1: Least squares mean differences between treatment groups of cumulated outcomes in the randomized controlled trial.

(LDp/CDp) vs oral medication in advanced Parkinson's disease (aPD).

Methods: Analyses included data from a 12-week, phase 3, double-blind, randomized controlled trial (RCT, NCT04380142) of LDp/CDp vs oral levodopa/carbidopa (LD/CD), and a 52-week open-label trial (OLT, NCT03781167) plus 96-week open-label extension (OLE, NCT04379050) of LDp/CDp vs oral standard of care (SoC) from a 24-month observational study (PROSPECT). Outcomes imputed between visits included change from baseline to week 12 in extrapolated cumulative hours in OFF, ON time with dyskinesia, "good" and "best" ON times from PD diaries (data normalized to 16-h awake time), and number of motor fluctuations. Additional outcomes were assessed using area under the curve. Extrapolated cumulative outcomes were defined as the sum between visits and were reported as least squares mean differences between treatment groups using repeated-measure analyses.

Results: In the RCT, over 85 days, participants receiving LDp/CDp experienced 5.9 fewer accumulative OFF days ($p=0.0219$) and 7.4 more normalized "best ON" days ($p=0.0438$) vs oral LD/CD. LDp/CDp also led to 163 fewer cumulative number of motor fluctuations ($p\leq 0.001$) vs oral LD/CD (Figure 1). When comparing MDS-UPDRS Part II scores, there were 3.5 times more cumulative improvements in motor activities of daily living (ADL) with LDp/CDp vs oral LD/CD ($p=0.3109$). Similar results were obtained from the OLT/OLE vs SoC analysis.

Conclusion: These findings highlight that a sustained and consistent response to LDp/CDp provides meaningful benefits in people with aPD, resulting in improvements in motor symptoms and ADL compared to optimized oral medication.

EPO-1044 | EEG microstates as predictors for cognitive decline in prodromal DLB

D. Ondracek¹; D. Ondracek²; K. Mitterova¹; L. Brabenec¹; M. Lamos¹; I. Rektorova¹; I. Rektorova²

¹Brain and Mind Research Program, CEITEC, Masaryk University, Brno, Czech Republic; ²First Department of Neurology, Faculty of Medicine, Masaryk University and St. Anne’s University Hospital, Brno, Czech Republic

Background and aims: EEG Microstates (MS) provide temporal and spatial characteristics of whole brain networks. We previously showed that changes in MS temporal parameters (occurrence, time coverage and mean duration) differ between healthy controls and subjects with mild cognitive impairment with Lewy bodies (MCI-LB), such that MCI-LB subjects display hyperexcitability, particularly in MS A (arousal network) and B (visual network). Here we studied whether baseline parameters of MS A and B predict cognitive decline in a prospective longitudinal study.

Methods: Altogether 85 participants on the prodromal spectrum of dementia with Lewy bodies (DLB) who were followed for up to 4 years were analysed: 38 cognitively normal subjects with core clinical features of DLB (CN-CCF), and 26 subjects with mild cognitive impairment with Lewy bodies (MCI-LB). The baseline MS topographies and their temporal parameters were calculated from 5-minute, 204-channel EEG recordings. Linear mixed models were used to predict cognitive decline both longitudinally and cross-sectionally while accounting for age, sex, and the interval between the visits.

Results: Our results show that higher occurrence of MS A tended to predict deterioration of executive functions with time ($p=0.053$). Higher occurrence of MS B predicted visual memory decline at baseline ($p=0.025$).

Conclusion: We demonstrated that increased excitability of the MS representing the arousal network tends to predict changes (decline) in executive functions within up to 4 years of follow-up.

Higher excitability of the MS representing the visual network predicted visual memory impairment at baseline.

Disclosure: Nothing to disclose.

EPO-1045 | Beyond advanced therapies: Sublingual apomorphine as rescue treatment for refractory freezing of gait in LCIG-treated Parkinson’s disease

D. Cerdán Santacruz; M. Vargas Cobos; A. De Luca; R. Alfonso González; M. Capra; C. Gómez López de San Román; I. Bermejo Casado; L. Caballero Sánchez; J. Berrio; G. Suárez Fernández; A. Castrillo Sanz; A. Mendoza Rodríguez
General Hospital Complex of Segovia, Segovia, Spain

Background and aims: Freezing of gait (FoG) is a disabling motor symptom in advanced Parkinson’s disease (PD) and may persist despite device-aided therapies such as levodopa-carbidopa intestinal gel (LCIG). In some patients, FoG episodes remain refractory to additional LCIG bolus doses, representing an unmet therapeutic need. Sublingual apomorphine provides rapid dopaminergic stimulation through a non-invasive route; however, evidence of its use in patients already receiving advanced therapies is scarce.

Methods: We report two male patients with advanced PD receiving stable LCIG therapy who presented recurrent FoG episodes not responding to additional LCIG boluses. The first patient was a 70-year-old man with 18 years of disease duration, treated with LCIG as first device-aided therapy, who received sublingual apomorphine 10mg as rescue treatment. The second patient was a 59-year-old man with 14 years of disease duration, previously treated with continuous subcutaneous apomorphine infusion and currently on LCIG due to suboptimal motor control. Sublingual apomorphine was introduced for persistent FoG. Clinical response, functional impact, and tolerability were assessed based on clinical evaluation and patient-reported outcomes.

Results: Both patients experienced a clear clinical improvement in FoG episodes after sublingual apomorphine administration, allowing recovery from motor blocks refractory to LCIG boluses. Treatment was well tolerated, with no reported adverse effects.

Conclusion: Sublingual apomorphine may represent a useful and well-tolerated rescue option for refractory FoG in complex PD patients treated with LCIG. These cases suggest that rescue strategies using different dopaminergic mechanisms should also be considered in advanced disease stages.

Disclosure: Nothing to disclose.

EPO-1046 | Seizures or Spells? What should the “S” stand for in FBDS associated with LGI1 encephalitis?

F. Brena²; F. Duca²; A. Bettinelli²; E. Sartirana²; V. Chiesa¹; C. Rosci¹; J. Bottini¹; G. Oggioni¹; A. Priori¹; E. Scelzo¹
¹Dipartimento di Neuroscienze, ASST Santi Paolo e Carlo, Ospedale San Paolo, Milan, Italy; ²Dipartimento di Scienze Della Salute, Università Degli Studi di Milano, Milan, Italy

Background and aims: Anti-leucine-rich glioma-inactivated 1 (LGI1) encephalitis is a rare antibody-mediated neurological disease affecting the central nervous system. Its main feature

is facio-brachial dystonic seizures (FBDS), defined as brief, paroxysmal, stereotyped movements affecting facial, cervical and proximal upper limb muscles. The pathophysiological origin of these movements is still unclear.

Methods: We performed a narrative review of the available literature on LGI1 encephalitis, focusing on the clinical and instrumental characterization of FBDS. In parallel, we describe the clinical course, diagnostic work-up, and therapeutic management of a 77-year-old man with LGI1 encephalitis, analyzing clinical and instrumental findings to assess which features supported an epileptic versus dystonic nature.

Results: In our patient, frequent FBDS-like episodes occurred despite persistently normal prolonged video-EEG recordings. The clinical course was atypical, with a prolonged isolated dystonic phase and no limbic seizures. These findings are in contrast to a purely epileptic genesis and suggest a prominent dystonic phenotype. In line with literature reports describing heterogeneous LGI1 presentations, our case is consistent with the existence of different phenotypes, with variable contributions of both epileptic and dystonic mechanisms.

Conclusion: Available evidence suggests that FBDS lie along a continuous spectrum, with one extreme representing a purely epileptic phenotype and the other a purely dystonic phenotype. This model may explain the heterogeneity observed in both clinical and instrumental findings, reflecting distinct patterns of cortical and subcortical network involvement. This perspective highlights why the meaning of the “S” in FBDS warrants reconsideration.

Disclosure: Nothing to disclose.

EPO-1047 | Frozen in Laughter: A curious case of paroxysmal facial pain

L. Basumatary¹; M. Bhoktiary²; D. Payeng¹

¹Neurology, Apollo Excelcare Hospitals, Guwahati, India;

²Pediatrics, Diphu Medical College Hospitals, Diphu, India

Background and aims: Hemimasticatory spasm (HMS) is a rare movement disorder with paroxysmal, unilateral contractions of jaw-closing muscles. Because it can mimic mandibular dystonia, temporomandibular joint disorders, trigeminal neuralgia, or hemifacial spasm, HMS is often under-recognized. Most reported cases are associated with facial hemiatrophy; idiopathic HMS without hemiatrophy is uncommon and diagnostically challenging.

Methods: We report the clinical, neurophysiological, imaging, and treatment features of HMS without facial hemiatrophy. A single-patient case report was conducted at a movement disorders clinic. Triggers and phenomenology were documented. Interictal and ictal needle EMG and trigeminal electrophysiology (blink reflex, masseter reflex, masseteric silent period) were performed, and brain/face MRI reviewed for structural lesions and masticatory asymmetry.

Results: A 34-year-old school teacher had 2 years of painful right masseter–temporalis spasms triggered by laughter/eating, sometimes causing brief jaw locking and teeth chattering, with occasional nocturnal episodes. Medications (clonazepam, haloperidol, cyclobenzaprine) were ineffective. Examination showed right masseter/temporalis hypertrophy with episodic contractions; cranial nerves and jaw jerk were normal and no sensory tricks were present. Autoimmune/inflammatory tests

FIGURE 1 EMG (Masseter): Normal at rest (no spontaneous activity; normal MUPs). During spasms, brief clonic bursts (10–200 ms) with variable inter-burst intervals (20–200 ms), sometimes merging into continuous activity; peak firing up to ~200 Hz.

FIGURE 2 Paroxysmal, painful involuntary spasms of the right masseter and temporalis muscles.

were normal. Interictal EMG was normal; ictal EMG showed clonic bursts (10–200 ms) with variable intervals and firing up to 200 Hz. Blink reflex was normal; during attacks, masseter reflex latency was delayed with reduced amplitude and an attenuated masseteric silent period. MRI showed right masseter enlargement only. Botulinum toxin produced marked improvement.

Conclusion: HMS should be considered in trigger-sensitive unilateral jaw-closing spasms with pain and hypertrophy even without facial hemiatrophy; attack-related impairment of inhibitory silent periods supports diagnosis and botulinum toxin is an effective first-line therapy.

Disclosure: Nothing to disclose.

EPO-1048 | Deep brain stimulation in KMT2B-related dystonia: Electrophysiological and clinical parameters during a 12 month-follow-up period in two children

L. Feldmann¹; A. de Almeida Marcelino¹; J. Kaplan¹; P. Krause¹; G. Brandt¹; G. Schneider²; A. Kuehn¹

¹Movement Disorders and Neuromodulation Section, Clinics of Neurology with Experimental Neurology, Charité University Medicine Berlin, Berlin, Germany; ²Clinics of Neurosurgery, Charité University Medicine Berlin, Berlin, Germany

Background and aims: Pathogenic variants in the KMT2B gene lead to childhood-onset, generalized dystonia (DYT-KMT2B).

Deep brain stimulation (DBS) to the internal globus pallidus (GPi) is an effective therapy. With sensing-enabled neurostimulators, electrophysiological biomarkers can be recorded chronically. Previously, pallidal theta activity correlated with symptom severity, and entrained gamma may indicate effective DBS. However, longitudinal dynamics of electrophysiological biomarkers in KMT2B-related dystonia are unknown.

Methods: Clinical and electrophysiological data were recorded regularly in the first 12-months follow-ups after GPi-DBS (COMEDD-trial, NCT07244549) in two children with DYT-KMT2B (age at surgery 5 and 9 years) with the Percept neurostimulator. Dystonia was quantified using the Burke-Fahn-Marsden-Dystonia-Rating-Scale motor score (BFMDRS-M). Pallidal electrophysiology during rest and movement was recorded ON/OFF DBS and analyzed using short-fourier-transformation and spectral parametrization. Peak activity in theta band and beta or gamma band was recorded out-of-hospital and analyzed for chronic biomarker changes and circadian periodicity.

Results: Both girls were DBS responders ($54 \pm 3\%$ improvement in BMFDRS-M at 12 months-follow-up). In both patients, entrained gamma occurred at clinically used amplitudes, and there was theta suppression over time. In one of the two patients, chronic recordings revealed increased peak biomarker activity especially around times of symptom deterioration. Circadian periodicity analysis suggests distinct patterns for theta, gamma and beta band activity.

Conclusion: DBS is an effective therapy in KMT2B-related pediatric dystonia. Theta suppression and occurrence of entrained gamma seem to be associated with clinical improvement and may be used to guide electrophysiology-based programming in future. Further, chronic biomarkers could be used to understand out-of-hospital symptom fluctuations.

Disclosure: This work is supported by the Dystonia Medical Research Foundation (award number DMRF-PRF-2024-1), by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – Project ID 424778381 - TRR 295 Grant and the Berlin Institute for Health (BIH) Clinician Scientist Program. A.A.K. reports a relationship with Boston Scientific Corporation that includes speaking and lecture fees, and travel reimbursement. All remaining authors have nothing to disclose.

EPO-1049 | Diagnostic sensitivity of a shortened accelerometry-only functional tremor battery

M. Cibula; N. Prezelj; R. Berlot; M. Kojović
Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background and aims: Electrophysiologically supported identification of positive signs is important in confirming the diagnosis of functional tremor. In this respect, the functional tremor

battery proposed by Schwingenschuh et al. is a valuable diagnostic tool but requires surface electromyography, specialised equipment and expertise, limiting its routine clinical use. As most battery tests rely on accelerometric data, we aimed to evaluate the diagnostic sensitivity of a shortened, accelerometry-only version of the functional tremor battery.

Methods: Thirty patients with clinically diagnosed functional tremor were included. All patients underwent the full functional tremor battery (maximum score 10 points). A proposed cutoff score of ≥ 3 points was used as a standard to ensure a homogeneous cohort. Among patients meeting this cutoff, we examined whether the cutoff would still be met after excluding surface electromyography-based tests (coactivation sign and tremor coherence). Subsequently, the weight loading test was also excluded to evaluate its redundancy in the overall diagnostic sensitivity of the shortened test battery.

Results: Twenty-four of 30 patients (80%) scored ≥ 3 points on the full battery and were included in further analyses. After exclusion of surface electromyography-based tests, all 24 patients (100%) continued to score ≥ 3 points. Following additional exclusion of the weight loading test, 23 of 24 patients (95.8%) still met the cutoff.

Conclusion: A shortened accelerometry-based functional tremor battery demonstrates diagnostic sensitivity comparable to the full battery that includes surface electromyography. This simplified approach reduces technical demands, examination time, and required expertise, potentially enabling wider clinical implementation.

Disclosure: Nothing to disclose.

EPO-1050 | Opicapone for management of sleep disturbances in Parkinson's disease: Post-hoc analysis of the OASIS trial in patients with and without probable RBD

J. Ferreira¹; M. Gago²; R. Costa³; M. Fonseca⁴; H. Brigas³; J. Holenz³; C. Trenkwalder⁵

¹Laboratory of Clinical Pharmacology and Therapeutics, Faculty of Medicine, University of Lisbon, Lisbon, Portugal; ²Department of Neurology, ULS Alto Ave, Hospital da Senhora da Oliveira, Guimarães, Portugal; ³BIAL – Portela & Ca S.A, Coronado, Portugal; ⁴BIAL – R&D Investments, S.A. Coronado, Portugal; ⁵Department of Neurosurgery, University Medical Center, Goettingen, Germany

Background and aims: Rapid eye movement sleep behavior disorder (RBD) is prevalent in Parkinson's disease (PD). Opicapone improved sleep disturbances in fluctuating PD patients with PD-related sleep disturbances in the exploratory Phase IV Opicapone in Sleep dISorder (OASIS) trial. This OASIS post-hoc analysis evaluates opicapone's effect on sleep disturbances, motor/non-motor symptoms and quality of life in PD patients with and without probable RBD, as determined by their medical history.

Methods: The 6-week, single-arm OASIS trial evaluated opicapone 50 mg in levodopa-treated fluctuating PD patients with sleep disturbances. Assessments included PD Sleep Scale-2 (PDSS-2), Movement Disorder Society-sponsored Non-Motor Symptoms rating scale (MDS-NMS), Patient and Clinician Global Impressions of Change, Parkinson's Fatigue Scale-16 (PFS-16), Parkinson's Disease Questionnaire-8 (PDQ-8).

whether efficacy could be achieved in patients with lower baseline symptom burden (MG-ADL scores: 6–9).

Methods: Analysis included seropositive patients treated with nipocalimab or placebo with baseline MG-ADL score below cohort median score of 9. Efficacy was evaluated by changes in MG-ADL (meaningful clinical improvement [MCI]: ≥ 2 -point improvement; substantial clinical improvement [SCI]: ≥ 3 -point improvement), and QMG (MCI: ≥ 3 -point improvement; SCI: ≥ 4 -point improvement) scores at week (W) 24. Two-sample *t*-tests compared changes-from-baseline between groups.

Results: In this population, baseline demographics were generally balanced between nipocalimab and placebo-treated patients (Table). At W24, MG-ADL reductions (mean [SD]) from baseline were greater with nipocalimab (-4.5 [2.64]) versus placebo (-2.3 [2.37]); difference: -2.23 (standard error [SE]: 0.588); 95%CI (-3.41 ; -1.06); $p < 0.001$. QMG reductions (mean [SD]) were also greater with nipocalimab (-5.2 [4.45]) versus placebo (-1.9 [3.69]); difference: -3.38 (SE: 0.986); 95%CI (-5.34 ; -1.41); $p = 0.001$. A greater proportion of patients receiving nipocalimab met MCI and SCI criteria for MG-ADL and QMG at W24 versus placebo (Table).

Conclusion: In patients with baseline MG ADL scores 6–9, nipocalimab demonstrated greater efficacy versus placebo, achieving MCI and SCI in MG ADL and QMG at W24. These results support the benefit of nipocalimab for sustained disease control in patients with gMG with lower baseline MG-ADL scores.

Patients Receiving Steroids at OLE Baseline (N)	11	78
Baseline Prednisone Equivalent (mg/day), mean (SD)	9.2 (2.46)	19.6 (16.27)
Endpoint Prednisone Equivalent (mg/day), mean (SD)	6.2 (2.92)	14.3 (11.51)
Prednisone Equivalent Change (mg/day), mean (SD)	-3.0 (2.74)	-5.3 (12.38)
Patients with Steroid Reduction* at data cutoff (N)	7	33
Baseline Prednisone Equivalent (mg/day), mean (SD)	10.4 (2.32)	25.1 (20.53)
Endpoint Prednisone Equivalent (mg/day), mean (SD)	5.6 (2.82)	11.2 (10.50)
Prednisone Equivalent Change (mg/day), mean (SD)	-4.8 (1.68)	-13.9 (13.32)
Patients with ≤ 5 mg prednisone mg/day at data cutoff, n (%)	5 (71.4%)	12 (36.4%)
MSE† achieved in first 48 weeks, n (%)	4 (57.1%)	14 (42.4%)

The data (n=off date: August 24, 2024).
*Reduction defined as a decreased dose or discontinuation of steroid.
†Minimum symptom expression (MSE) is defined as MG-ADL total score of 9 or 1.
‡Population size, n=number in group; OLE=open-label extension; SD=standard deviation

expression (MSE; MG-Activities of Daily Living [MG-ADL] score=0/1) and sustained for ≥ 8 weeks. In Japan, achieving minimal gMG symptoms with low corticosteroid doses (target: ≤ 5 mg/day) is an important treatment goal. We characterized the impact of nipocalimab on corticosteroid use in Japanese patients in the VIVACITY-MG3 OLE phase.

Methods: Corticosteroid doses (mg/day prednisone-equivalent) were evaluated through OLE data cut-off (August 2024). Among patients who reduced corticosteroid dose (≤ 5 mg/day), the proportion achieving MSE was evaluated.

Results: Of 11 Japanese patients receiving corticosteroids at OLE baseline, 7 (64%) receiving nipocalimab in OLE reduced/discontinued corticosteroids at data cutoff; of these, 5 (71%) reached ≤ 5 mg/day. Among steroid reducers, mean (SD) steroid dose reduced from 10.4 (2.32) to 5.6 (2.82) mg/day prednisone-equivalent in Japanese patients, while in remaining population dose reduced from 25.1 (20.53) to 11.2 (10.50) mg/day prednisone-equivalent. Among those reducing corticosteroids, 4/7 (57%) patients achieved MSE within 48 weeks (Table 1).

Conclusion: In OLE, over half of Japanese patients reduced/discontinued corticosteroids with substantial proportions tapering to low-dose corticosteroid (≤ 5 mg/day) and achieving MSE within 48 weeks. These results are consistent with the overall population where almost half of patients receiving corticosteroids at baseline, reduced/discontinued steroids and showed sustained disease control with nipocalimab.

Background and aims: Autoantibody-mediated complement activation damages neuromuscular junctions in gMG, resulting in variable muscle weakness. The phase 3 NIMBLE trial evaluated subcutaneous cemisiran (siRNA inhibiting hepatic C5 production) and subcutaneous pozelimab (monoclonal antibody targeting C5) as monotherapies or in combination in patients with gMG.

Methods: NIMBLE is a double-blind, placebo-controlled trial. A total of 288 patients with gMG were randomised to cemisiran (600mg Q12W), pozelimab (200mg Q4W), combination (both 200mg Q4W), or placebo. We present key results for the primary efficacy endpoint, change from baseline in MG-ADL at Week 24, based on August 2025 database lock ($n=239$), and the cumulative rate of TEAEs based on December 2025 database lock ($n=281$).

Results: NIMBLE met its primary endpoint. In the cemisiran ($n=64$) and combination ($n=67$) arms, the least squares mean (SE) of change from baseline at Week 24 in MG-ADL total score was -4.5 (0.4) and -4.0 (0.4), with placebo-adjusted differences of -2.3 ($p=0.0005$) and -1.7 ($p=0.0086$); achieving 76.6% ($n=75$) and 99.6% ($n=75$) terminal complement inhibition, respectively. TEAEs occurred in 74.7% (59/79), 81.6% (40/49), 81.5% (66/81), and 81.9% (59/72) in the cemisiran, pozelimab, combination, and placebo arms, respectively. No meningococcal, serious infections or deaths occurred in the cemisiran arm during the double-blind treatment period (DBTP); SAEs of infections in other arms were low. There were 2 deaths (pneumonia [cemisiran], septic shock [combination]) in patients on concomitant immuno-suppressive therapies and comorbidities after the DBTP.

Conclusion: Quarterly, subcutaneous cemisiran was generally well-tolerated and achieved significant improvement in symptoms with partial complement inhibition among patients with gMG.

EPO-1054 | Corticosteroid and biologic use in a real-world population with generalized myasthenia gravis in the United States and Europe

J. Howard Jr¹; S. Anderson²; B. Canales²; J. Park²; G. Gibson³; H. Connolly³; S. Biriya³; B. Poirrette³; A. Foster³; A. Bhambri²
¹Department of Neurology, The University of North Carolina, Chapel Hill, North Carolina; ²Amgen Inc. Thousand Oaks, USA; ³Adelphi Real World, Bollington, UK

Background and aims: Generalised myasthenia gravis (gMG) is a neuromuscular condition manifesting as fluctuating muscle weaknesses and fatigue. Treatments include corticosteroids and targeted biologic treatments. This study describes corticosteroid and biologic use in a multi-country sample of gMG patients.

Methods: Data were drawn from the Adelphi MG Disease Specific Programme (DSP)[™], a cross-sectional survey of neurologists and their patients with gMG in the France, Germany, Italy,

TABLE 1 Patient age, sex, MG-ADL score and time since gMG diagnosis, split by country.

	All Patients	France	Germany	Italy	Spain	UK	USA
Age, mean (SD)	61.7 (11.3)	59.7 (10.8)	60.4 (11.1)	58.5 (11.8)	61.7 (11.3)	60.1 (10.8)	61.7 (11.3)
Female sex, n (%)	391 (50.2)	111 (51.8)	101 (51.8)	91 (51.8)	111 (51.8)	101 (51.8)	101 (51.8)

Time since gMG diagnosis, mean (SD)	1.8 (2.8)	1.8 (2.8)	1.8 (2.8)	1.8 (2.8)	1.8 (2.8)	1.8 (2.8)	1.8 (2.8)
Time since gMG diagnosis, n (%)	627 (80.7)	127 (60.5)	127 (60.5)	127 (60.5)	127 (60.5)	127 (60.5)	127 (60.5)

TABLE 2 Proportion of gMG patients prescribed maintenance treatment of corticosteroid and biologic treatments, split by country.

	All Patients	France	Germany	Italy	Spain	UK	USA
Patients prescribed maintenance treatment at time of survey, n (%)	391 (50.2)	111 (51.8)	101 (51.8)	91 (51.8)	111 (51.8)	101 (51.8)	101 (51.8)
Patients prescribed corticosteroids at time of survey, n (%)	337 (86.2)	98 (48.1)	98 (48.1)	98 (48.1)	98 (48.1)	98 (48.1)	98 (48.1)
Patients prescribed biologics at time of survey, n (%)	101 (25.8)	101 (48.1)	101 (48.1)	101 (48.1)	101 (48.1)	101 (48.1)	101 (48.1)

Spain, UK and United States, from January 2024 - November 2025. Physicians provided patient-level demographics, clinical characteristics and treatment.

Results: Overall, 146 neurologists reported on 917 gMG patients, patient demographics are shown by country in **TABLE 1** Physicians reported a mean (Standard Deviation; SD) Myasthenia Gravis - Activities of Daily Living (MG-ADL) score of 4.5 (3.3) and 59.8% of patients were in Myasthenia Gravis Foundation of America class II. At time of survey, 88.3% of patients were prescribed a gMG treatment. Of those, 40.4% were prescribed corticosteroids, most commonly prednisone (35.6%). Patients had been prescribed their current regimen of corticosteroids for a mean (SD) 1.8 (2.8) years and 43.1% were prescribed a dosage ≥ 20 mg. Among patients on treatment, 37.2% were prescribed biologics. Patients had been prescribed their current biologic treatment regimen, for a mean (SD) 1.1 (1.2) years at survey and the biologic was administered a mean (SD) 2.3 (4.1) times per month.

Conclusion: Corticosteroid and biologic therapies were frequently prescribed in the six countries included in this analysis. Reducing steroid burden and frequent administrations of biologic therapies whilst maintaining efficacy could benefit this population.

EPO-1055 | Healthcare costs of generalized myasthenia gravis in Germany: A real-world retrospective cohort study

C. Schneider-Gold¹; S. Anderson²; I. Bucholz²; V. Višková³; A. Marzà-Florensa⁴; M. Ludwig³; A. Postema⁴; A. Bhambri²
¹Department of Neurology, St. Josef-Hospital, Bochum, Germany; ²Amgen Inc, Thousand Oaks, USA; ³InGef - Institute for Applied Health Research Berlin GmbH, Berlin, Germany; ⁴PHARMO Institute for Drug Outcomes Research, Utrecht, The Netherlands

Background and aims: Generalized myasthenia gravis (gMG) is a chronic autoimmune neuromuscular disorder characterized by muscle weakness and fatigue affecting daily activities. This study describes patient characteristics and healthcare costs among patients with gMG in Germany.

Methods: We conducted a retrospective cohort study using anonymized secondary healthcare claims data from the InGef database from 2017 to 2024. Patients aged ≥ 18 years with ≥ 1 inpatient or ≥ 2 outpatient diagnoses and ≥ 12 months of continuous enrollment before and after the index date were included. Follow-up was variable length with a minimum of 12 months. Annualized healthcare costs per patient per year (PPPY) were calculated across outpatient, inpatient, emergency department, and pharmacy services.

Results: A total of 4,025 patients with gMG were identified (mean age 61.2 years, standard deviation 16.7 years; 49.3 percent female). Median total healthcare costs were 6,115.06 euros (interquartile range 2,942.54 to 13,011.55 euros) PPPY, with gMG-related costs of 1,279.06 euros (interquartile range 346.74 to 3,238.00 euros). Costs were higher among patients with ≥ 1 exacerbation ($N=2,144$; median total costs 7,757.87 euros PPPY; median gMG-related costs 2,262.18 euros PPPY) and among patients with ≥ 1 myasthenic crisis ($N=93$; median total costs 34,605.52 euros PPPY; median gMG-related costs 14,928.98 euros PPPY).

Conclusion: This real-world study demonstrates the substantial economic burden of gMG in Germany. Higher costs among patients with exacerbations and myasthenic crises emphasize the impact of disease severity and the need for improved disease management.

Disclosure: Christiane Schneider-Gold receives research funding from Amgen. Seth Anderson is an employee of Amgen and

EPO-1056 | Diagnostic utility of anti-SRP54 antibody ELISA in immune-mediated necrotizing myopathy: Experience from a real-world cohort

S. Kim

Department of Neurology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea

Background and aims: Immune-mediated necrotizing myopathy (IMNM) associated with anti-signal recognition particle (SRP) antibodies typically presents with rapidly progressive proximal weakness and markedly elevated creatine kinase levels. In clinical practice, line-blot immunoassays are commonly used to detect anti-SRP antibodies, but their reliability and reproducibility are sometimes questioned. We examined the performance of an enzyme-linked immunosorbent assay (ELISA) targeting anti-SRP54 antibodies and explored its clinical relevance in a real-world IMNM cohort.

Methods: Patients evaluated for idiopathic inflammatory myopathies between 2002 and 2023 were retrospectively reviewed. Eighty-seven patients with inflammatory myopathies and 107 healthy controls were included. Anti-SRP IMNM was defined based on line-blot immunoassay results, and the diagnostic performance of anti-SRP54 ELISA was assessed. Clinical features, laboratory findings, and coexisting autoantibodies were analyzed in ELISA-positive patients.

Results: Among 32 patients diagnosed with anti-SRP IMNM using line-blot immunoassays, 28 (88%) tested positive on anti-SRP54 ELISA. The ELISA demonstrated a sensitivity of 88% and a specificity of 99%, with high test-retest reliability. All ELISA-positive patients showed proximal muscle weakness. Neck weakness, myalgia, dysphagia, or respiratory symptoms were observed in a subset of patients. Extra-muscular involvement, including interstitial lung disease and myocarditis, was uncommon. Serum creatine kinase levels were markedly elevated overall and tended to be higher in patients with coexisting anti-Ro-52 antibodies.

Conclusion: Anti-SRP54 antibody ELISA showed high diagnostic accuracy and good reproducibility in patients with anti-SRP IMNM. In routine clinical practice, this assay can serve as a reliable complementary tool to support the diagnosis of IMNM and may help increase diagnostic confidence in patients with suspected disease.

Disclosure: Nothing to disclose.

EPO-1057 | Do we really need non-steroidal immunosuppressants in generalized myasthenia gravis

treated with new targeted therapies? A pilot study

V. Vera¹; E. Rossini¹; L. Leonardi²; G. Antonini¹; S. Morino²; M. Garibaldi¹; A. Lauletta¹; F. Forcina¹; L. Tufano¹; D. Marando¹; L. Fionda²

¹*Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), SAPIENZA University of Rome, Rome, Italy;*
²*Neuromuscular and Rare Diseases Centre, Neurology Unit, Sant'Andrea Hospital, Rome, Italy*

Background and aims: Targeted biologic therapies, including complement and neonatal Fc receptor (FcRn) inhibitors, have transformed the treatment of generalized myasthenia gravis (gMG). However, the role of concomitant non-steroidal immunosuppressants (NSIST) remains uncertain. This study evaluated whether background NSIST influences clinical outcomes and corticosteroid reduction in gMG patients treated with targeted therapies.

Methods: We conducted a retrospective, observational study including adult gMG patients treated with complement inhibitors or anti-FcRn agents ($n=41$). Clinical outcomes were assessed at baseline and during follow-up using Myasthenia Gravis Activities of Daily Living (MG-ADL) and Quantitative Myasthenia Gravis (QMG) scales. Achievement of Minimal Symptom Expression (MSE), MG Foundation of America Post-Intervention Status (MGFA-PIS), and changes in corticosteroid dose were analyzed.

Results: Twenty patients received background NSIST (Group 1), while 21 did not (Group 2). Baseline MG-ADL scores and corticosteroid doses were comparable between groups (9.10 ± 4.36 vs 8.24 ± 3.38) (22.17 ± 13.81 mg vs 22.06 ± 16.43). Baseline QMG scores were slightly higher in Group 1 (14.0 ± 5.1 vs 10.9 ± 4.8 ; $p=0.049$). Both groups showed significant improvement in MG-ADL and QMG scores at all follow-up time points, without differences in clinical scale improvement comparing the two groups. Rates of MSE achievement, MGFA-PIS improvement, and corticosteroid tapering did not differ between groups.

Conclusion: Our pilot analysis indicates that concomitant use of NSIST does not appear to be associated with greater improvement in clinical outcomes, enhance corticosteroid-sparing effects or increased disease stability. Larger, prospective studies are needed to optimize treatment strategies in gMG.

Disclosure: LF received financial support from Alexion Pharmaceuticals, argenx, UCB, Dianthus, Johnson & Johnson and amgen. GA received conference honoraria, advisory board and travel grants from Kedrion, Alnylam, Alexion, Argenx, Takeda. ER received honoraria from UCB and Alexion.

Background and aims: Understanding patients' preferences for Generalised Myasthenia Gravis (gMG) is essential for informed treatment decisions. However, limited evidence is available regarding how Chinese patients weigh safety, efficacy, onset speed, and convenience when choosing treatments. This study aimed to assess treatment preferences and willingness to pay (WTP) among Chinese patients.

Methods: This multicenter, cross-sectional survey was conducted from March to August 2025 among gMG patients across

FIGURE 1 The selection probability of gMG patients.

China. A discrete choice experiment was used to quantify patient preferences by presenting hypothetical treatment scenarios.

Results: Of 909 analysed patients, treatment safety was a key determinant of patient preferences. Oral administration was most preferred, followed by subcutaneous injection. Less frequent dosing was strongly favoured: once every 6 months, and once daily, compared to 2–3 times daily. Younger patients paid more attention to low-frequency dosing, subcutaneous injection, and liver and kidney function impairment than older patients. Patients with MGFA class II were more concerned about oral administration, once-weekly dosing, infection risk, and myelosuppression. High-income patients (>¥100,000) favoured low risk of metabolic disease, infection, myelosuppression, and liver and kidney function impairment and infrequent (weekly, biweekly, or every-6-month), subcutaneous administration, and were less sensitive to cost compared to low- (< ¥50,000) and medium-income groups (¥50,000–100,000).

Conclusion: Safety, infrequent and convenient administration route (oral/subcutaneous), affordable cost, and rapid onset of action were prioritised. Patients were willing to invest financially in therapies that align with these preferences. Embedding

patient preferences in clinical decision-making and reimbursement policy can improve adherence, reduce disease burden, and enhance quality of life for individuals with gMG in China.

Disclosure: Nothing to disclose.

Neurocritical Care

EPO-1059 | **Aetiology, clinical features, and outcomes of paediatric TBI management in sub-Saharan Africa: A systematic review and meta-analysis of regional data**

A. Moradeyo¹; E. Okoh¹; M. Opabode¹; E. Ibitunde¹;
B. Akinyemi¹; S. Rath²; C. Orazulike¹; H. Bukar¹; D. Oladiran¹;
S. Olatokun¹; D. Lawal¹
¹*Surgical Interest Group Lagos (SURGIL), Lagos, Nigeria;* ²*All India Institute of Medical Sciences Bhubaneswar, India*

Background and aims: Despite the rising burden of paediatric traumatic brain injury (TBI) in sub-Saharan Africa, there is still fragmented evidence on its clinical profile and outcomes. This review evaluated the aetiology, clinical presentation, management, and outcomes of paediatric TBI to establish pooled and regional estimates.

Methods: Articles published between January 2005 and August 2025 on pediatric TBI and neurosurgical management were identified from PubMed, ScienceDirect, Google Scholar, AJOL, and Cochrane Library. Pooled proportions and 95% confidence intervals were calculated using random-effects meta-analyses, with I² statistic for heterogeneity.

Results: A total of 19 studies (n = 4452 patients) were included in this review. Road traffic accidents (RTA) were the primary aetiology (64%; 95% CI 57–70%), followed by falls (20%) and assaults (9%). Computed tomography scan was the dominant imaging

FIGURE 2 Paediatric TBI in sub-Saharan Africa.

FIGURE 1 PRISMA flow diagram for included studies.

modality. Common radiological findings included fracture-related lesions (43.5%), intracranial hemorrhage (33.3%), cerebral contusions (13.70%), and cerebral edema (9.50%). On admission, the GCS (Glasgow Coma Scale) scores for mild, moderate, and severe TBI accounted for 56%, 26%, and 42% of cases, respectively. Neurosurgical intervention was reported in 15.4% of patients. The pooled favorable outcome was 81% (95% CI 67–90%), with the highest in West Africa (89%). The overall pooled mortality was 8% (95% CI 6–11%), with country-specific rates varying from 3% to 13%.

Conclusion: RTAs are the major cause of TBIs, with a significant proportion presenting with a moderate to severe GCS score at admission. Despite relatively favourable functional outcomes among survivors, mortality remains considerably high and varies across regions.

Disclosure: Nothing to disclose.

EPO-1060 | Severe chronic inflammatory demyelinating polyradiculoneuropathy relapses in the ICU: Clinical characteristics, complications and outcome

A. Balcerac¹; C. Benoit¹; C. Marois²; T. Maisonobe³; T. Lenglet³; R. Debs³; D. Psimaras⁴; B. Rohaut⁵; S. Demeret¹; K. Viala³; N. Weiss⁶; L. Le Guennec¹

Background and aims: Severe relapses of chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) requiring intensive care unit (ICU) admission are rare, and data on their presentation and prognosis are limited. This study aimed to describe their characteristics, management, and long-term outcomes.

Methods: We conducted a single-center retrospective study including all neurological ICU admissions for severe CIDP relapse between January 2004 and December 2024. CIDP was diagnosed according to EFNS criteria. Demographic data, indications for ICU admission, treatments, and 1-year modified Rankin Scale (mRS) scores were analyzed. Patients were stratified by the need for invasive mechanical ventilation.

Results: Fifty-two patients were included (median age 62.8 years). Main indications for ICU admission were plasma exchange for refractory disease (35%), acute respiratory failure (33%), and rapid motor worsening (33%). Twelve patients (23%) required invasive ventilation and more frequently presented with respiratory failure, bulbar dysfunction, and severe motor impairment. ICU stay was longer in ventilated patients (30 vs 7 days). Overall ICU mortality was low (3.8%). At ICU discharge,

58% of patients had significant disability (mRS 4–5). Pre-relapse mRS independently predicted 1-year functional outcome, whereas intubation did not.

Conclusion: In this long-term cohort, mortality from severe CIDP relapses was low, and invasive ventilation was not associated with worse 1-year functional outcome. Respiratory and bulbar involvement were the main predictors of intubation.

EPO-1061 | Stimulating consciousness recovery after acute brain injury with psilocybin and apomorphine

A. Eigenbrodt¹; P. Laigaard¹; S. Stücker¹; M. Hassani¹; K. Möller²; J. Kjærgaard³; D. Kondziella¹

¹Department of Neurology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark; ²Department of Neuroanaesthesiology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark; ³Department of Cardiology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark

Background and aims: What can be done to promote recovery of consciousness after brain injury in the intensive care unit (ICU)? We hypothesize that simultaneously targeting the two components of consciousness—awareness with psilocybin and arousal with apomorphine—can promote consciousness after acute brain injury. Here, we assess the safety of this combination in comatose ICU patients.

Methods: Prospective, open-label, phase 1b dose-escalation study ($n=80$). ICU coma patients receive psilocybin at doses of 1 mg (n = the first 26), 10 mg (n = next 27), or 25 mg (n = final 27), together with 2 mg apomorphine 1–2 hours after psilocybin administration (Figure 1).

Results: The first participant was recruited in February 2025, and as of January 2026, 53 (66%) participants have been enrolled, i.e., enrollment of the 1 mg and the 10 mg groups has been completed. In total, 69 serious adverse events were observed as of mid-January 2026 (Table 1). The most common events were

FIGURE 1 Distribution of the modified Rankin Scale (mRS) in the population.

pneumonia ($n=19$), death after withdrawal of life-sustaining support ($n=15$), and urinary tract infection ($n=13$). We identified no serious adverse events related to the study drugs. Occasionally, apparently beneficial effects were noted in the 10 mg group.

Conclusion: No safety concerns have been identified following administration of 1 mg and 10 mg psilocybin in combination with 2 mg apomorphine so far. Pending replication of safety data in the 25 mg psilocybin group, we suggest that this combination appears safe to test in a randomized controlled trial-design to boost arousal (apomorphine) and awareness (psilocybin) in comatose ICU patients.

Disclosure: Nothing to disclose.

EPO-1062 | Evaluation of CAPE rhythm and clinical outcomes: A single-center study

B. Zeybek; K. Aslan-Kara
Neurology Department, Cukurova University, Adana, Türkiye

Background and aims: Cyclic Alternating Pattern of Encephalopathy (CAPE) refers to cyclical fluctuations in background electroencephalography (EEG) activity lasting 10 to 60 seconds, characterized by a spontaneous and regular alternation between two distinct patterns occurring for at least six consecutive cycles. The clinical significance of CAPE remains unclear.

In this study, we aimed to evaluate the electroencephalographic characteristics and clinical relevance of CAPE in critically ill patients.

Methods: We retrospectively reviewed EEG recordings obtained from patients hospitalized in the intensive care units of Cukurova University Hospital between 2022–2025. These patients were categorized according to age, sex, indication for intensive care admission, length of stay, clinical outcome. In addition, CAPE characteristics including the number of cycles, cycle durations, the proportions of pattern 1 and pattern 2 relative to the total CAPE duration and EEG recording time were analyzed.

Results: Among 371 patients with a total of 521 EEG recordings, CAPE rhythm was identified in 3.5% ($n=13$). The mean age was 50.8 years (range 20–79), and 9 patients (69.2%) were female. Etiology for hospitalization were CVD (23.1%), CNS infection (15.4 %), metabolic encephalopathy (23.1%), intoxication (23.1 %), intracranial malignancy and NORCE (15.4%). Mortality rate was 53.8 %. During EEG recording, 53.8% ($n=7$) of patients had a GCS score ≥ 11 . The associations between CAPE ratio, pattern 1, and pattern 2 with mortality were not statistically significant (all $p>0.05$).

Conclusion: CAPE is an increasingly recognized EEG pattern, particularly in critically ill patients. In this retrospective study, the mortality ratio was not affected according to CAPE findings.

Disclosure: Nothing to disclose.

EPO-1063 | Non-convulsive status epilepticus: Treatment adequacy matters more than treatment sequence

F. Misirocchi
University Hospital of Parma, Parma, Italy

Background and aims: Non-convulsive status epilepticus (NCSE) is often managed using algorithms derived from convulsive SE, despite major differences in etiological heterogeneity, diagnostic uncertainty, and patient vulnerability. Benzodiazepines (BZDs) and continuous intravenous anesthetic drugs (CIVADs) are frequently avoided due to comorbidities, respiratory risk, and benefit-risk balance. Although deviation from guideline-recommended SE treatment is associated with adverse outcomes, its clinical relevance in NCSE remains unclear.

Methods: Adult NCSE episodes were extracted from a six-year ambispective non-anoxic SE registry and classified using Salzburg criteria. Etiology was categorized according to ILAE and grouped as potentially fatal or non-potentially fatal; acute etiologies were further classified as primary or secondary CNS pathology. First-line BZD use was defined as administration before any antiseizure medication (ASM). ASMs underdosing was defined as a loading dose $<2/3$ of the recommended weight-adjusted dose. Outcomes included failure of NCSE termination, in-hospital mortality, and worsening of the modified Rankin Scale (mRS).

Results: We analyzed 189 NCSE episodes (median age 74). Failure to NCSE cessation occurred in 12.1%, in-hospital mortality in 31.7%, and mRS worsening in 63.0%. First-line BZDs were used in 50.8% of episodes and were not associated with outcomes. ASM underdosing occurred in 38.6% and was independently associated with failure to NCSE cessation (OR6.56, $p=0.002$) and

FIGURE 1 Conceptual model of NCSE showing the inverse relationship between antiepileptic treatment responsiveness and etiological impact on outcome.

in-hospital mortality (OR 4.38, $p < 0.001$). CIVADs were used in 21.7% and were not independently associated with outcomes. The negative impact of ASMs underdosing was most evident in acute primary CNS and non-potentially fatal etiologies.

Conclusion: In NCSE, adequate ASM dosing is more strongly associated with outcome than adherence to treatment sequence, supporting a personalized, etiology-driven treatment approach.

Disclosure: Nothing to disclose.

EPO-1064 | Altered level of consciousness in a tertiary emergency department: Etiologies, mortality, and predictors of outcome in a contemporary cohort

K. Kim; Y. Cho
Keimyung University School of Medicine, Daegu, Republic of Korea

Background and aims: Altered level of consciousness (ALC) is an emergency department (ED) presentation with diverse etiologies and substantial mortality. This study aimed to describe

FIGURE 1 Flowchart of patients including dispositions and destinations. ALC, altered level of consciousness; ED, emergency department; GCS, Glasgow Coma Scale; GW, general ward; ICU, intensive care unit; Transfer, transferred to another hospital.

TABLE 2 Independent and severity-related factors associated with mortality.

	Adjusted OR (95% CI)	p-value
Age	1.01 (1.01–1.02)	<0.001
GCS	0.94 (0.90–0.98)	<0.001
Usage of vasopressor	19.48 (13.36–27.59)	<0.001
Stay time in ED	1.00 (1.00–1.01)	0.17
Admission to ICU	1.94 (1.52–2.49)	<0.001

the incidence, etiologic distribution, and mortality of ALC in the ED and to identify predictors of death.

Methods: This is a retrospective single-center cohort study of adults presenting with ALC to a tertiary ED between September 2023 and August 2025. ALC was defined as a Glasgow Coma Scale (GCS) score <15 or clearly abnormal orientation or behavior compared with baseline. Etiologies were categorized into ten predefined groups based on structured chart review. Logistic regression analyses were performed to identify baseline clinical predictors of overall mortality.

Results: Among 76,957 ED visits, 2,194 (2.85%) involved ALC. Systemic Infection was the most frequent etiology ($n = 516$, 23.5%), followed by Metabolic Cause ($n = 502$, 22.9%) and Stroke ($n = 325$, 14.8%). Overall mortality of ALC was 20.7%, consisting of 5.6% and 24.3% in the ED and in-hospital, respectively. The highest overall mortality occurred in Central Nervous System Infection (CNS-i) (40.9%), Stroke (31.7%), and Systemic Infection (30.6%). In the multivariable model, older age, lower initial GCS, vasopressor use, and ICU admission were independently associated with increased odds of death, whereas ED length of stay was not.

Conclusion: Mortality varied markedly across etiologic categories, with the highest risk observed for CNS-i and Stroke. These findings highlight the prognostic significance of age, initial neurologic status, and underlying etiology and may assist in risk stratification and early resource allocation.

Disclosure: Nothing to disclose.

¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; ²Azienda USL di Bologna, Bologna, Italy; ³DIBINEM, Università degli Studi di Bologna, Bologna, Italy; ⁴Azienda USL Romagna, Bologna, Italy

Background and aims: Climate change may crucially impact on various neurological diseases, which affect 40% of people globally. Socioeconomic status and green spaces could act as mitigating factors, promoting physical activity, social interaction, and psychological well-being. Objectives: (1) to evaluate the impact of extreme temperatures on emergency department visits (EDVs) among cohorts of Bologna residents with Parkinson's disease, atypical parkinsonism, epilepsy, dementia, amyotrophic lateral sclerosis, obstructive sleep apnoea, migraine, stroke; (2) to investigate the moderating role of socioeconomic status and green spaces.

Methods: Case-crossover design (Figure). Cohorts will be identified through record-linkage systems (Table 1) and compared to the adult resident population of Bologna (2015–2024). The mean daily apparent temperature represents the exposure. The primary outcome is the number of EDVs. Effect modification will be assessed for age, sex, Deprivation Index and Normalized Difference Vegetation Index.

Results: Sample sizes and data sources for the cohorts are reported in Table 1 Preliminary results on the association between

FIGURE 1 Case cross-over design: the control period is selected using a time-stratified approach, in which each case is matched to control values recorded on the same subject in different time points.

TABLE 1 Sample sizes (observed and estimated) and data sources for the cohorts of patients included in the study.

Disorder	Source	Observed/Estimated number of participants
Migraine*	CephalLink	3,200
Stroke*	Validated algorithm applied to administrative databases	9,500
Dementia*	Validated algorithm applied to administrative databases	5,000
Epilepsy**	EpiLink	400
Parkinson's disease and atypical parkinsonism**	ParkLink-Bologna	1,687 (1,311 PD and 376 APS)
Obstructive sleep apnoea syndrome**	OSASLink	380
Amyotrophic lateral sclerosis*	SEALink	80

TABLE 2 Odds ratios (OR) of emergency department visits (EDVs) per 1°C increase in mean apparent temperature, for the entire temperature range and above the 26°C threshold, with corresponding 95% confidence intervals (CI).

Univariate models	Odds ratio	95% CI	p-value
Unit increase of temperature (°C)	1.0026	(1.0015-1.0037)	<0.001
Unit increase of temperature above 26°C (°C)	1.0044	(1.0015-1.0072)	0.003

mean daily apparent temperature and EDVs in the reference population ($N=190,971$) are in Table 2 A one-unit increase in mean apparent temperature was significantly associated with increased odds of EDVs (OR 1.0026, 95%CI 1.0015–1.0037) with a stronger effect observed for each 1°C increase above the 26 °C threshold (1.0044, 1.0015–1.0072). These associations will be further compared across the specific cohorts of patients.

Conclusion: The project's findings may enhance our understanding of the role of extreme temperatures in the progression of neurological conditions and inform public health policies and preventive strategies to mitigate their impact on vulnerable populations.

EPO-1066 | Endothelial activation and stress index (EASIX) as a predictor of delayed cerebral ischemia and functional outcome in subarachnoid hemorrhage

N. Yıldız Akbulut; A. Önalın; E. Gürkaş
Kartal Dr Lutfi Kırdar City Hospital, Istanbul, Türkiye

Background and aims: Endothelial dysfunction contributes to secondary brain injury and poor outcomes following subarachnoid hemorrhage (SAH). The Endothelial Activation and Stress Index (EASIX), derived from routine laboratory parameters, has recently emerged as a marker of endothelial stress. This study aimed to evaluate the relationship between admission EASIX values and clinical outcomes in both aneurysmal and non-aneurysmal SAH.

Methods: We retrospectively analyzed 90 patients admitted to the neurointensive care unit with SAH between January 2020 and June 2025. EASIX was calculated within the first 2 h of admission as: $EASIX = (LDH \times Creatinine) / \text{Platelet count}$. Clinical variables included age, sex, aneurysm presence, Glasgow Coma Scale (GCS), Fisher grade, Hunt-Hess, and WFNS scores. Delayed cerebral ischemia (DCI) was defined according to AHA/ASA guidelines. Logistic regression was used to identify independent predictors of DCI and 3-month functional outcomes (mRS).

Results: DCI occurred in 37.7% of patients, and poor functional outcomes ($mRS \geq 3$) in 35.6%. Patients with DCI had significantly higher EASIX values (median 1.01 [IQR 0.57] vs 0.64 [IQR 0.28], $p=0.001$). Multivariable analysis identified higher EASIX (OR=26.3, $p=0.004$) and aneurysm presence (OR=7.7, $p=0.005$) as independent predictors of DCI. For functional outcome, both EASIX (OR=2.83, $p=0.039$) and age (OR=1.05, $p=0.036$) independently predicted poor prognosis.

Conclusion: EASIX independently predicts delayed cerebral ischemia and poor 3-month functional outcome in SAH, supporting its potential as a simple, readily available biomarker of endothelial stress in neurocritical care.

Disclosure: Nothing to disclose.

EPO-1067 | Precision glycemc management for diabetic neuropathy in the ICU: The HYPO-AWARE score in 96,129 admissions

S. Biswas¹; S. Vasireddy²; Y. Srivastava¹; S. Arora³; J. Rajamani⁴; K. Jindal⁵; F. GOHIL⁶

¹Department of Internal Medicine, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine; ²Department of Neurology, NMC Specialty Hospital, Abu Dhabi, United Arab Emirates; ³Department of Internal Medicine, University of Debrecen, Hungary; ⁴Department of Internal Medicine Medical College, Caucasus University, Tbilisi, Georgia; ⁵Department of Internal Medicine Government Medical College, Patiala, India; ⁶Università Cattolica del Sacro Cuore, Rome, Italy

Background and aims: Diabetic neuropathy affects 50% of diabetic ICU patients, yet current glycemc protocols ignore neuropathy status despite impaired counterregulation and gastroparesis fundamentally altering glucose homeostasis. Existing hypoglycemia prediction tools achieve only modest discrimination (AUC 0.66–0.83) and exclude neuropathy-specific factors.

Methods: We analyzed 96,129 ICU admissions with 3,093,411 glucose measurements from MIMIC-IV v3.1 (2008–2022), comparing diabetic patients with neuropathy ($n=42,672$), diabetic controls ($n=37,202$), and non-diabetics ($n=16,255$). We developed the HYPO-AWARE score incorporating gastroparesis, autonomic dysfunction, hypoglycemia frequency, and glucose variability, then evaluated prediction performance using gradient boosting models with 5-fold cross-validation.

Results: Neuropathy patients exhibited paradoxically lower mean glucose (148.76 vs 156.41 mg/dL, $p<0.001$) but significantly higher coefficient of variation (26.20% vs 22.99%, $p<0.001$). Feature importance analysis revealed glucose variability dominated hypoglycemia prediction (56.6%) over mean glucose (30.9%). The HYPO-AWARE score achieved AUC 0.92 (95% CI: 0.92–0.93), substantially outperforming existing tools. Risk stratification effectively separated hypoglycemia incidence: low-risk 8.2%, moderate-risk 18.4%, high-risk 41.2% ($p<0.001$ for trend). Only 49.0% of neuropathy patients achieved adequate time-in-range ($>70\%$) compared to 81.1% of non-diabetics, representing systematic failure of universal protocols.

FIGURE 2

FIGURE 3

Conclusion: Diabetic neuropathy creates a distinct glycemc phenotype requiring targeted management strategies. The HYPO-AWARE score provides validated risk stratification substantially superior to existing tools. Current one-size-fits-all ICU glucose protocols fail half of neuropathy patients, demanding precision medicine approaches that prioritize variability reduction over mean glucose targets and incorporate neuropathy-specific pathophysiology.

Disclosure: Nothing to disclose.

EPV-0237 | Recurrent transient ischemic attacks associated with long-term Nilotinib: A case of accelerated Atherosclerosis

L. Caballero Sánchez; M. Capra; C. Gómez López de San Román; I. Bermejo Casado; A. De Luca; M. Vargas Cobos; R. Alfonso González; D. Cerdán Santacruz; A. Castrillo Sanz; A. Mendoza Rodríguez
General Hospital of Segovia, Segovia, Spain

EPV-0238 | Repeated intravenous thrombolysis within one day for recurrent ischemic stroke

D. Černík¹; J. Macko²; J. Neumann³

¹Comprehensive Stroke Center, Department of Neurology, Masaryk Hospital, Krajska Zdravotni As, Ústí nad Labem, Comprehensive Stroke Center, Department of Neurology, Palacký University Medical School and University Hospital Olomouc, Czech Republic; ²Stroke Center, Department of Neurology, Most Hospital, Krajska zdravotni as, Most, Czech Republic; ³Stroke Center, Department of Neurology, Chomutov Hospital, Krajska Zdravotni As, Chomutov, Czech Republic

EPV-0239 | Reperfusion therapy in stroke patients over 80 years: Risks and outcomes from a Stroke Center in the Republic of Moldova

T. Stupac¹; V. Spinei¹; A. Levca¹; I. Pregelzu¹; A. Grumeza¹; V. Lisnic³; O. Grosu²

¹Stroke Unit, Department of Neurology and Neurosurgery, Institute of Neurology and Neurosurgery “Diomid Gherman”, Hospital, Chisinau, Republic of Moldova; ²Department of Neurology, Institute of Neurology and Neurosurgery “Diomid Gherman”, Hospital, Chisinau, Republic of Moldova; ³State University of Medicine and Pharmacy “Nicolae Testemitanu”, Chisinau, Republic of Moldova

EPV-0240 | Results of indication for primary air transport of patients with suspected stroke based on telephone verification of FAST+ positivity

J. Bilik²; D. Černík¹

¹Comprehensive Stroke Center, Department of Neurology, Palacký University Medical School and University Hospital Olomouc, Czech Republic; ²Emergency Medical Service of the Usti nad Labem Region, Czech Republic

EPV-0241 | Reversible cerebral vasoconstriction syndrome and non-aneurysmal intracerebral haemorrhage: Diagnostic role of delayed digital subtraction angiography

Z. Jiang; N. Singh; A. Chandratheva
Neurological Institute, Cleveland Clinic London, London, UK

EPV-0242 | Reversible cerebral vasoconstriction syndrome associated with hydrogen sulphide exposure: A rare environmental trigger

J. Aguilera Aguilera; B. Rodriguez Garcia; D. Gómez de la Torre Morales; J. Rodríguez Carrillo; M. Luz Esteve; I. Díaz Díaz; J. Vizcaya Gaona; Í. Esain González; G. Carvalho Monteiro
Salamanca University Hospital, Salamanca, Spain

EPV-0243 | Robotic assisted stroke rehabilitation: Does it improve functional recovery and patient outcomes?

A. Ahmad; E. Ademeta
Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

EPV-0244 | Routine coagulation parameters and severity of neurological deficit in women with ischemic stroke

K. Manysheva
Dagestan State Medical University, Russian Federation

EPV-0245 | Screening for poststroke Screening for poststroke cognitive impairment (PSCI) in real practice

Z. Gdovinova¹; D. Koren²; M. Slavkovska²
¹Department of Neurology, P. J. Safarik University, Faculty of Medicine, Kosice, Slovakia; ²Department of Neurology, University Hospital L. Pasteur, Kosice, Slovakia

EPV-0246 | Seeds from another source: Iatrogenic cerebral amyloid angiopathy

F. Duca¹; A. Bettinelli¹; E. Scelzo²; K. Khouri Chalouhi²; A. Priori¹; L. Tancredi²
¹Department of Biomedical and Clinical Science, University of Milan, Milan, Italy; ²Department of Neuroscience, ASST Santi Paolo e Carlo, Milan, Italy

EPV-0247 | Sex differences in acute ischaemic stroke treated with reperfusion therapy: A retrospective registry analysis

M. Pfister¹; M. Peycheva²; C. Berger¹; M. Costa¹; L. Siegenthaler¹; F. Huber¹; I. Rizzo¹; M. Krasteva³; M. Beyeler¹; T. Bremova-Ertl¹; N. Slavova¹; P. Mordasini⁴; R. Umarova¹; P. Bücke¹; K. Antonenko¹; A. Hoffmann⁵; S. Pilgram-Pastor⁴; M. Heldner¹
¹Department of Neurology, Inselspital, Bern University hospital and University of Bern, Bern, Switzerland; ²Department of Neurology, University Hospital “Saint George”, Medical University Plovdiv, Plovdiv, Bulgaria; ³University Children’s Hospital, Sofia, Bulgaria; ⁴Department of Neuroradiologie, Kantonsspital Aarau, Aarau, Switzerland; ⁵Institute of Diagnostic and Interventional Neuroradiologie, Inselspital, University Hospital and University of Bern, Bern, Switzerland

EPV-0248 | Sex differences in acute ischemic stroke thrombolysis: Insights from a real-world registry

A. Levca¹; V. Spinei¹; T. Stupac¹; A. Grumeza¹; V. Lisnic²; O. Grosu¹
¹Emergency Department, Diomid Gherman Institute of Neurology and Neurosurgery, Chişinău, Republic of Moldova; ²Nicolae Testemitanu State University of Medicine and Pharmacy, Chişinău, Republic of Moldova

EPV-0249 | Sex differences in mechanical thrombectomy timing and early outcomes in acute ischemic stroke: A single-center retrospective cohort study

E. Costru-Tasnic¹; E. Manole²; A. Arabadji²; I. Teaca²; I. Pregeluz¹; M. Arion¹; O. Gavriluc¹; O. Odainic¹
¹Diomid Gherman Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova; ²Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Republic of Moldova

EPV-0250 | Sneezing-induced sudden headache as an initial manifestation of convexity subarachnoid hemorrhage: A case report

C. Gomez López de San Román¹; M. Vargas Cobos¹; A. De Luca¹; R. Alfonso González¹; M. Capra¹; S. Arribas Bernardo²; L. Caballero Sánchez¹; I. Bermejo Casado¹; D. Cerdán Santacruz¹; A. Castrillo Sanz¹; A. Mendoza Rodriguez¹
¹Neurology Department, Segovia Hospital, Segovia, Spain; ²Health Emergencies, Management of Castilla and León, Spain

EPV-0251 | Splenial ischemic stroke in a young woman with systemic inflammation and probable serotonergic toxicity

K. Paposhvili¹; N. Rizhamadze²; T. Margania³
¹Department of Neurology, LTD New Hospitals, Tbilisi, Georgia; ²Department of Neurology, LTD New Hospitals, Tbilisi, Georgia; ³Department of Neurology, LTD New Hospitals, Tbilisi, Georgia

EPV-0252 | Spontaneous triple flexion after thalamo-capsular haemorrhagic stroke

I. Carmo e Pinto; J. Blazer Costa; A. Sobral Pinho; F. Serrazina
Neurology Department, ULS Lisboa Ocidental, Lisbon, Portugal

EPV-0253 | Stress, autonomic dysfunction, and cortisol profile in chronic cerebral ischemia with and without somatovegetative syndrome

D. Mirzaeva; D. Tolibov; S. Shokirov
Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0254 | Stroke burden and risk factors in India, 1990–2023: Age–sex stratified GBD analysis

M. Nath¹; P. Kumar²; D. Vibha¹
¹Department of Neurology, Neurosciences Center, All India Institute of Medical Sciences, New Delhi, India; ²Clinical Research Unit, All India Institute of Medical Sciences, New Delhi, India

EPV-0255 | Stroke characteristics and outcomes in two neurology units in a Sub-Saharan African country

M. Njohjam
Department of Neurology, National University Hospital Center, Dakar, Senegal

EPV-0256 | Temporal trends in particulate matter-attributable stroke across Europe. Insights from the global burden of disease 2023 study (1990–2023)

S. Wasti¹; A. Wasti²; M. Javed¹
¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0257 | Tenecteplase versus alteplase before mechanical thrombectomy in acute ischaemic stroke: A retrospective comparative study

P. Diaz-Corta; B. Lara-Rodríguez; A. Paipa-Merchan; H. Quesada-García; A. Núñez-Guillén; P. Cardona-Portela
Neurology, Hospital Universitario de Bellvitge, Barcelona, Spain

EPV-0258 | Tenecteplase vs alteplase for large vessel occlusion stroke: An updated systematic review and meta-analysis

M. Cierny¹; D. Vodak²; C. Moore¹; C. Herath¹; H. Attar¹; R. Licenik³
¹Medical College of Wisconsin, Milwaukee, WI, USA; ²Department of Neurology, St. Anne's University Hospital and Faculty of Medicine, Masaryk University, Brno, Czech Republic; ³Acute Stroke Centre, North West Anglia NHS Foundation Trust, Peterborough, England, UK

EPV-0259 | The beta-blocker nebivolol therapy in acute ischemic stroke: Effects on nitric oxide metabolism

M. Ibodullaeva; K. Daminova

Department of Neurology and Clinical Psychology, Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0260 | The evolving epidemiology of ischemic heart disease and ischemic stroke in Europe: Observational and genetic evidence from GBD 2023

H. Hu; F. Yang

The First Medical Center, Chinese PLA General Hospital, Beijing, China

EPV-0261 | The predictive value of the stroke oxidative-inflammatory index in hemorrhagic stroke: A retrospective cohort study

A. Sönmezler; E. Altunışık; B. Yılmaz; S. Parlak; D. Alpar

Department of Neurology, Gaziantep City Research and Training Hospital, Gaziantep, Türkiye

EPV-0262 | The prevalence of cerebral amyloid angiopathy among the causes of hemorrhagic stroke

O. Novosadova; T. Semenova; V. Grigoryeva

Privolzhsky Research Medical University, Nizhny Novgorod, Russian Federation

EPV-0263 | The relationship between dehydration levels on admission, blood viscosity, and early neurological deterioration in patients with lacunar strokes

S. Han

Department of Neurology, Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea

EPV-0264 | The role of inflammatory cytokine IL-6 in cognitive impairment after acute ischemic stroke: A preliminary study

A. Sarnataro¹; A. Smimmo²; G. Riccio¹; E. Spina¹;

F. Manganelli¹

¹University of Naples Federico II, Naples, Italy; ²Università della Campania Luigi Vanvitelli, Naples, Italy

EPV-0265 | The Role of undiagnosed obstructive sleep apnea in recurrence of transient ischemic attacks and progression of Leukoaraiosis: A pilot cohort study

O. Kasimova; H. Daminova

Department of Neurology, Tashkent Medical University Hospital, Tashkent, Uzbekistan

EPV-0266 | Tocilizumab for the treatment of cerebral amyloid angiopathy-related inflammation with elevated IL-6: A case report

J. Huang; R. Guo; Z. Jia; Y. Sun; B. Li

Department of Neurology, The Second Hospital of Hebei Medical University, Shijiazhuang, China; Key Laboratory of Neurology (Hebei Medical University), Ministry of Education, China; Key Laboratory of Neurology of Hebei Province, Shijiazhuang, China

EPV-0267 | Trends and disparities in colon cancer and stroke-related mortality in the United States: A retrospective study

S. Wasti¹; A. Wasti²; F. Rizwan¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0268 | Trends and disparities in stroke-related mortality in inflammatory bowel disease patients

S. Wasti¹; A. Wasti²; E. Shafquat¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0269 | Umbrella review of endovascular thrombectomy time windows and outcomes in acute ischemic stroke

F. Aljamea¹; N. Aderinto²; D. Babalola³; A. Onyia⁴; E. Mbah⁵; E. Motimbe⁶; E. Ogungbemi⁷; S. Kallah⁸

¹College of Medicine, Vision College, Riyadh, Saudi Arabia;

²Department of Medicine and Surgery, Ladoko Akintola

University of Technology, Ogbomosho, Nigeria; ³University of Ilorin Teaching Hospital, Nigeria; ⁴University of Nigeria Nsukka, Nigeria; ⁵Ahmadu Bello University (ABU) Zaria, Nigeria;

⁶University of Buea, Cameroon; ⁷Rostov State Medical University, Rostov-on-Don, Russian Federation; ⁸AMA School of Medicine, Philippines

EPV-0270 | Using an artificial intelligence-based machine learning approach to understand the future of declining burden of stroke in the United Kingdom

S. Wasti¹; A. Wasti²; F. Rizwan¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0271 | Vascular risk burden as a predictor of clinical outcomes after thrombolysis in acute ischemic stroke: Single-centre study

A. Solodjankina

Riga Stradiņš University, Riga East Clinical University Hospital, Riga, Latvia

EPV-0272 | Vasospasm after aneurysmal subarachnoid hemorrhage: Triggering factors and clinical outcomes

G. Hatzidaki; A. Tsamourelis¹; I. Tyrovolas; G. Tagaris

Department of Neurology, Georgios Gennimatas General Hospital, Athens, Greece

EPV-0273 | Venous sinus stenosis in idiopathic intracranial hypertension: Intracranial compliance after best medical therapy versus venous sinus stenting

L. Souza Viana; F. Moulin de Moraes; S. Luiz De Andrade Matas; G. Sampaio Silva

Federal University of São Paulo, São Paulo, Brazil

EPV-0274 | Very late-onset HTRA1-related autosomal dominant cerebral small vessel disease misdiagnosed as multiple sclerosis

M. Mora Conde¹; M. Calvellido²; S. Antonarakis³; A. Batté³; E. Ranza³; G. Padlina⁴; M. Raimondi⁴

¹Department of Geriatrics, Gruppo Ospedaliero Moncucco, Lugano, Switzerland; ²Oncology Competence Center, Gruppo Ospedaliero Moncucco, Lugano, Switzerland; ³Medigenome, Swiss Genomic Institute of Genomic Medicine, Geneva, Switzerland; ⁴Department of Neurology, Gruppo Ospedaliero Moncucco, Lugano, Switzerland

EPV-0275 | Werneck's syndrome: A case report

M. González Gómez; E. Gismera Fontes; F. Sánchez García; L. Cabral Esquea; L. Ballesteros Plaza

Department of Neurology, Guadalajara's University Hospital, Guadalajara, Spain

EPV-0276 | White blood cells to HDL ratio as a superior predictor of ischemic stroke clinical severity

F. Hakim; S. Daoud; S. Sakka; K. Moalla; N. Bouattour;

N. Charfi; E. Smaoui; M. Damak

Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia

Child neurology/developmental neurology

EPV-0277 | A Network meta-analysis of stem cell for cerebral Palsy: Does route of administration and stem cell type matters?

K. Siregar¹; Y. Ramli²; S. Tanumihardja³

¹School of Medicine Maranatha Christian University, Bandung, Indonesia; ²Department of Neurology, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia; ³Department of Neurology, Faculty of Medicine, Maranatha Christian University, Bandung, Indonesia

EPV-0278 | A study of the clinical characteristics, etiology and predictors of severity of global developmental delay in children

A. Srivastava; V. Mani; A. Mishra; P. Chaurasiya

Department of Neurology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

EPV-0279 | Acute peripheral facial palsy of neurological origin in the pediatric population

F. Dridi; M. Jamoussi; H. Klai; Z. Miladi; A. Zioudi; M. Ben Hafsa; H. Benrhouma; T. Ben Younes; I. Kraoua

Pediatric Neurology Department, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia

EPV-0280 | Age and diagnosis determine TMS Efficacy in preschoolers with developmental disorders

M. Askar

Kazakh National Medical University named after S.D. Asfendiyarov, Almaty, Kazakhstan

EPV-0281 | An investigation of stuttering prevalence in children in Tashkent, Uzbekistan

D. Nurmukhamedova; M. Nurmukhamedova

Department of Neurology, Child neurology and Medical Genetics, Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0282 | Clinical and functional manifestations of diabetic cardiovascular autonomic neuropathy in children with type 1 diabetes

A. Sadirkhodjaeva; D. Ashurova; A. Malikova

Department of Propedeutics of Childhood Diseases No. 2, Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0283 | Clinical and instrumental phenotyping of gait in subjects with Cri du Chat syndrome

B. Agostini¹; G. Vaghi¹; M. Corrado²; V. Grillo¹; L. Martinis²; M. Gjini²; I. Campese²; M. Giraud¹; F. Cammarota¹; S. Ravaglia²; M. Croce¹; V. De Giorgis¹; D. Politano¹; S. Castiglia³; D. Trabassi³; M. Serrao³; C. Danesino⁴; A. Guala⁵; C. Tassorelli¹; R. De Icco¹

EPV-0404 | Climatic predisposing factors for posterior circulation aneurysm rupture

K. Yarova; Y. Solodovnikova

Department of Neurology and Neurosurgery, Odesa National Medical University, Odesa, Ukraine

EPV-0405 | Clinical and neuropsychological characteristics of chronic cerebral ischemia in patients living in the Aral environmental crisis region

N. Dosbergenova; D. Usmanova

¹Department of Neurology, Tashkent State Medical University, Uzbekistan

EPV-0406 | Environmental factors in multiple sclerosis focusing climate change

A. Landtblom

Department of Medical Sciences, Uppsala University, Uppsala, Sweden

EPV-0407 | Increasing incidence of Lyme disease in the Republic of Moldova: National data and potential neurological implications in climate change context

E. Mamolea¹; V. Lisnic¹; E. Manole¹; O. Grosu²

¹Neurology Department No 1, Nicolae Testemitanu State University of Medicine and Pharmacy; Chisinau, Republic of Moldova; ²Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova

EPV-0408 | Neuroplasticity in spaceflight: Adaptive and maladaptive brain changes in microgravity

F. Seifar; L. Speicher; D. Herrigel; M. Harrison; M. Freeman
Mayo Clinic, Jacksonville, Florida, USA

EPV-0409 | Rising temperatures, rising risks: Heatwave effects on Parkinson's disease

M. Auffret
France Développement Electronique (FDE), Monswiller, France

Epilepsy

EPV-0410 | “The Silent Rust of the Brain”: A case of delayed diagnosis of idiopathic superficial siderosis of the CNS

K. Duve; S. Shkrobot; R. Nasalyk
I. Horbachevsky Ternopil National Medical University, Ternopil, Ukraine

EPV-0411 | “Seizure-like phenomena (SLP)” in the context of propofol sedation after recovered cardiac arrest: A case report

I. Ruiz Salcedo; V. Carmona Bravo; A. Torres Moral; F. Sánchez Fernández; C. Conde Velasco; A. Rincón Valencia; J. Montaner Villalonga; S. Pérez Sánchez
Neurology Department, Hospital Universitario Virgen Macarena, Seville, Spain

EPV-0412 | A multimodal automated seizure diagnosis model for seizure detection and type classification using video-electroencephalogram data

N. Lin¹; Z. Liang²; L. Li²; W. Gao¹; Y. Gao¹; H. Sun¹; Q. Lu¹
¹Department of Neurology, Peking Union Medical College Hospital, Beijing, China; ²NetEase Media Technology Co., Ltd., Beijing, China

EPV-0413 | A rare complication of radiotherapy: SMART syndrome

S. Dirkeç; İ. Bilgi; S. Üstün Özek
Department of Neurology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Türkiye

EPV-0414 | A review of the burden of status epilepticus, approaches to its treatment, and any gaps in the Asia-Oceanic region

K. Subramaniam¹; P. Purushottamahanti²; T. Kumagai³
¹Viatris, New Zealand; ²Viatris, India; ³Viatris, Japan

EPV-0415 | A systematic review of health economic evaluations of treatments for patients with drug-resistant epilepsy

D. Elabbasy²; S. Jowett¹; A. Gouveia¹; I. Pokhilenko¹; S. Evers²; M. Majoie³; G. van Mastrigt²
¹Health Economics Unit, Department of Applied Health Sciences, College of Medicine and Health, University of Birmingham, UK; ²Care and Public Health Research Institute, Department of Health Services Research, Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, the Netherlands; ³Academic Center for Epileptology (ACE), Maastricht University Medical Center and Kempenhaeghe, Maastricht, Heeze, the Netherlands

EPV-0416 | A systematic review of human status epilepticus in organophosphate poisoning: A real-world stage 1 plus model?

G. Magro; O. Marsico; F. Tosto; L. Rapisarda; G. Bilotti; G. Mastroianni; C. Ermio
Neurology Department, Lamezia Terme Hospital, Catanzaro, Italy

EPV-0417 | ABCC2 polymorphisms and antiseizure medication resistance: A systematic review and meta-analysis with power assessment

A. Daskeviciute¹; E. Zaboras²; J. Navalinskas³; R. Mameniskiene¹
¹Clinic of Neurology and Neurosurgery, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; ²Faculty of Medicine, Vilnius University, Vilnius, Lithuania; ³Clinic of Cardiac and Vascular Diseases, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Lithuania

EPV-0418 | Age and sex disparities in healthcare utilization and costs among epilepsy patients: A population-based study in Korea

E. Jung
Chonnam National University Hospital, Gwangju, Korea

EPV-0419 | Applications of machine learning in predicting valproic acid pharmacokinetics, safety and treatment response in epilepsy

S. Wasti¹; E. Shafquat¹; A. Wasti²

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0420 | Beyond Drug Resistance: Rethinking Early Surgery in Lesional Focal Epilepsy

F. Benninger; I. Goldberg

Epilepsy and EEG at Beilinson Hospital, Rabin Medical Center, Petach Tikva, Israel

EPV-0421 | Brain arteriovenous malformations and epilepsy – A retrospective analysis from a tertiary centre

M. Brás Monteiro¹; N. Ramniclăl²; R. Armindo²; A. Santos³; A. Sobral-Pinho¹; F. Sá¹

¹Serviço de Neurologia, Hospital Egas Moniz, Lisbon, Portugal;

²Serviço de Neurorradiologia, Hospital Egas Moniz, Lisbon,

Portugal; ³Serviço de Neurocirurgia, Hospital Egas Moniz, Lisbon, Portugal

EPV-0422 | Clinical and neurophysiological diagnosis and surgical treatment of post-traumatic drug-resistant temporal lobe epilepsy

S. Kravtsova; A. Vasilenko; A. Ulitin

Almazov National Medical Research Centre, St. Petersburg, Russian Federation

EPV-0423 | Clinical characteristics and outcomes of patients with refractory/super refractory status epilepticus: A retrospective analysis

D. Çoban; K. Aslan-Kara; T. Demir; Ş. Bıçakçı

Çukurova University Balcalı Hospital Department of Neurology, Adana, Türkiye

EPV-0424 | Clinical characteristics, etiology, and outcomes of motor Epilepsia Partialis continua: A 12-patient cohort study

S. Dirkeç; S. Üstün Özek

Department of Neurology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Türkiye

EPV-0425 | Clinical correlates of depressive symptoms and the treatment gap of depression among adults with epilepsy

S. Kasradze

Caucasus International University, Tbilisi, Georgia

EPV-0426 | Clinical outcomes of adult-initiated cenobamate in developmental and epileptic encephalopathy versus other drug-resistant epilepsies

D. Rivero-Rodríguez; R. Almansa-Castillo; C. Cabeza-Alvarez

Neurology department, Complejo Hospitalario Universitario de Toledo, Spanish Ministry of Health, Toledo, Spain

EPV-0427 | Clinical, EEG and CSF predictors of outcome in status epilepticus: A retrospective study

K. Stanzelova; M. Kalinova; P. Marusic; D. Krysl

Department of Neurology, Second Faculty of Medicine, Charles University, Motol and Homolka University Hospital, Prague

EPV-0428 | Comparative analysis of wearable machine learning-based and EEG-based seizure detection methods

G. Bambal

University of Buckingham, Buckinghamshire, UK

EPV-0429 | Comparative performance of the Montreal cognitive assessment and the mini-mental state examination for cognitive screening in patients with epilepsy

R. Ben Dhia; L. Bouafia; M. Mhiri; N. Daoussi; M. Frih Ayed
Neurology department, Fatouma Bourguiba Hospital Monastir, Tunisia

EPV-0430 | Comparison of prognostic score performance in refractory status epilepticus treated with continuous intravenous anesthetic drugs at 90 days

D. Rivero-Rodríguez¹; Y. Pernas-Sánchez²; C. Cabeza-Alvarez¹; D. DiCapua-Sacoto³; G. Pluck⁴; M. Morales Casado¹

¹Neurology Department, Complejo Hospitalario Universitario de Toledo, Spanish Ministry of Health, Toledo, Spain; ²Oncology department, Hospital Universitario Fundación Alcorcón, Spanish Ministry of Health, Madrid, Spain; ³Department of Neurology, Hospital de Especialidades Eugenio Espejo, Ministry of Public Health of Ecuador, Quito, Ecuador; ⁴Department of Psychology, College of Human Sciences and Education, KIMEP University, Almaty, Kazakhstan

EPV-0431 | Correlation of EEG findings outcome in Juvenile Myoclonic Epilepsy (JME) – A multi-centric retrospective study

R. Bansal¹; A. Bansal¹; C. Rathore²; N. Baheti³

¹Institute of Neurosciences, Medanta-The Medicity, Gurugram, India; ²Neurology Department, Zydus Hospital, Vadodara, India; ³Neurology Department, Dr. Gm Taori Ciims Hospital, Nagpur, India

EPV-0432 | Deep brain stimulation in drug-resistant epilepsy: Our experience in clinical practice

E. Cañada Lahoz¹; P. Iriarte Uribe-Echeverria¹; A. Vieira Campos¹; S. Lozano Veiga¹; R. Berbegal Serralta¹; M. Navas²; P. Pulido²; C. Torres²; L. Vega³; J. Pastor³; M. De Toledo Heras¹

¹Neurología, Hospital Universitario de La Princesa, Madrid, Spain; ²Neurocirugía, Hospital Universitario de La Princesa, Madrid, Spain; ³Neurofisiología, Hospital Universitario de La Princesa, Madrid, Spain

EPV-0433 | Detection of anxiety disorders in tension-type headache and evaluation of the effectiveness of cognitive behavioral therapy

S. Gafurova; N. Maxamatjanova; S. Yusuphodjayeva; G. Ernayeva

Tashkent State Medical University, Neurology and Medical Psychology Department, Tashkent, Uzbekistan

EPV-0434 | Detection of anxiety-phobic disorders in epilepsy and evaluation of the effectiveness of medical-psychological intervention

S. Gafurova; Z. Ibodullayev; N. Maxamatjanova;

S. Yusuphodjayeva; G. Ernayeva

Tashkent State Medical University, Neurology and Medical Psychology Department, Uzbekistan, Tashkent

EPV-0435 | Dynamics of epilepsy in patients with supratentorial brain ventricular system tumours depending on surgical approach

S. Ahmedov¹; R. Egamberdiev¹; B. Muminov²

¹Republican Specialized Scientific and Practical Medical Center of Neurosurgery; ²Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0436 | Early cenobamate as a third-line option in drug-resistant focal epilepsy: A paradigm shift?

F. Dono¹; M. Russo¹; R. Agosto¹; G. Evangelista¹; B. Nucera²; G. Falcicchio³; S. Sensi¹

¹Department of Neuroscience, Imaging and Clinical Science, “G. d’Annunzio” University of Chieti-Pescara, Chieti, Italy;

Ethics in neurology

EPV-0494 | Decision-making capacity and safeguards in voluntary assisted dying for neurodegenerative disorders

C. Gericke
School of Medicine, Australian National University, Canberra, Australia & Canberra Epilepsy Specialist Centre, Deakin Private Hospital, Canberra, Australia

EPV-0495 | Epistemic authority in adaptive DBS: When neural metrics compete with lived experience

A. Vila¹; E. Mejia¹; B. Carr²
¹University of Florida College of Medicine, Gainesville, FL, USA;
²University of Florida Department of Psychiatry, Gainesville, FL, USA

EPV-0496 | Ethical and Governance Challenges in Neurotechnology: Implications for Clinical Neurology

T. Roth¹; M. Ienca¹; L. Cabrera²; E. Schiller¹; J. Illes³
¹Laboratory of Ethics of AI & Neuroscience, Institute for History and Ethics in Medicine, Technical University of Munich, Munich, Germany; ²Neuroethics Lab, Rock Ethics Institute, and Department of Engineering Science and Mechanics, Pennsylvania State University, University Park, USA; ³National Core for Neuroethics, Division of Neurology, Department of Medicine, University of British Columbia, Vancouver, Canada

EPV-0497 | Presymptomatic disease-modifying therapies in neurodegenerative disorders: Clinical promise and ethical challenges

A. Klein¹; J. Luker²; R. Harris³; J. Hearn⁴
¹UCB, Monheim am Rhein, Germany; ²UCB, Slough, UK;
³Customer Faithful Limited, Peterborough, UK; ⁴Manchester Metropolitan University, Manchester, UK

EPV-0498 | The ethics of chiropractic cervical spinal manipulation

C. Gericke
School of Medicine, Australian National University, Canberra, Australia & Canberra Epilepsy Specialist Centre, Deakin Private Hospital, Canberra, Australia

EPV-0499 | “Interictal photophobia as a potential risk factor for migraine chronification and treatment resistance: A prospective study proposal”

M. Alkhawaja; M. Fragoso; J. Paz; P. Comes; G. Salazar
Consorci sanitari de Terrassa (CST), Barcelona, Spain

EPV-0500 | A Comparison of the efficacy, tolerability and adverse effects of two Anti-CGRP (Erenumab and Galcanezumab) in migraine prevention

M. El-Lahawi; S. Ibrahim
Neurology Department, SKMC, Abu Dhabi, UAE

EPV-0501 | Absenteeism caused by migraine among Norwegian hospital nurses

K. Alstadhaug¹; A. Wisth¹; R. Jensen²; S. Ose³
¹Department of Neurology/Nordland Hospital, Bodo, Norway;
²Danish Headache Centre, Rigshospitalet-Glostrup, University of Copenhagen, Copenhagen, Denmark.; ³SINTEF, Trondheim, Norway

EPV-0502 | Achieving higher standards for migraine prevention in a series of 639 patients with chronic migraine treated with OnabotulinumtoxinA

C. Sánchez-Rodríguez; E. Varas-Martín; C. Montero Grande; P. Jiménez Caballero; Á. Sierra-Mencía; A. Recio-García; P. Caballero-Lillo; M. Peñas-Martínez; A. Gonzalez-Martinez; Á. Guerrero-Peral
Headache Unit, Neurology Department, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

EPV-0503 | Alterations in interoception among patients with medication-overuse headache

G. Ustun¹; S. Aksu²; S. Bek¹; G. Kutlu¹
¹Mugla SK University, School of Medicine, Department of Neurology, Muğla, Turkey; ²Mugla SK University, School of Medicine, Department of Physiology, Muğla, Turkey

EPV-0504 | Atogepant for migraine prevention, including patients previously treated with anti-CGRP therapies: A real-world cohort

R. Nunes Rato; A. Neves; C. Sousa; R. Dias; M. Pinto; M. Pinto; A. Costa
Department of Neurology, Unidade Local de Saúde São João, Porto

EPV-0505 | Beyond headache freedom: Crystal-clear and unclear days to assess residual interictal burden in migraine treated with CGRP monoclonal antibodies

F. Chianese¹; M. Silvestro¹; I. Orologio¹; R. Ornello²; F. Trojsi¹; A. Tessitore¹; S. Sacco²; A. Russo¹
¹Headache Centre, Department of Advanced Medical and Surgical Sciences, University of Campania “Luigi Vanvitelli”, Naples, Italy; ²Department of Biotechnological and Applied Clinical Sciences, University of L’Aquila, L’Aquila, Italy

EPV-0506 | Beyond headache frequency: Sex-specific clinical and lifestyle signatures of migraine chronicity

D. Onan¹; E. Uludüz²; S. Eyüboğlu³; M. İskender²; D. Sucu⁴; S. Evin⁵; A. Özge⁶; D. Uludüz⁷
¹Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Yozgat Bozok University, Yozgat, Türkiye; ²Koc University Medical Faculty, Grade III Medical Student, Istanbul, Türkiye; ³Department of Psychology, Brain 360 Holistic Approach Center, Istanbul, Türkiye; ⁴Mersin University School of Medicine, Department of Biostatistics and Medical Informatics, Mersin University, Mersin, Türkiye; ⁵İslahiye Public Hospital, Gaziantep, Türkiye; ⁶Mersin University School of Medicine, Department of Neurology, Algology and Clinical Neurophysiology, Mersin, Türkiye; ⁷Department of Neurology, Cerrahpaşa Faculty of Medicine, Istanbul University Cerrahpaşa, Istanbul, Türkiye

EPV-0507 | Beyond pain: impact of atogepant on migraine-related symptoms

C. Sousa; A. Neves; R. Rato; R. Dias; M. Pinto; M. Pinto; A. Costa
Department of Neurology, São João University Hospital, Porto, Portugal

EPV-0508 | Breath holding cerebrovascular responses in migraine: longitudinal fNIRS comparison of CGRP mAb and oral preventives

Y. Kim

Department of Neurology, Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Anyang, Republic of Korea

EPV-0509 | Cerebrospinal fluid biomarkers in idiopathic intracranial hypertension: Targeted proteomics analysis

B. Arora; A. Pandit; S. Shree; P. Tangri; R. Singh; M. Nath
Department of Neurology, AIIMS, New Delhi, India

EPV-0510 | CGRP level in patients with vestibular migraine and the therapeutic effect of onabotulinumtoxinA

B. Holmuratova; N. Rashidova; K. Khalimova
Department of Neurology, Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0511 | Changes in muscle tone after electrotherapy in patients with chronic migraine and cervicalgia

L. Zharashueva¹; M. Naprienko²; L. Smekalkina²
¹Department of Nervous Diseases and Neurosurgery, Sechenov University, Moscow, Russian Federation; ²Department of Sports medicine and medical rehabilitation, Sechenov University, Moscow, Russian Federation

EPV-0512 | Characterisation of patients with new daily persistent headache treated at a tertiary care hospital

S. Sánchez Gamino; J. Pérez Ceballos; I. Rodríguez Lavado; L. García Trujillo; M. Castro Sánchez
Hospital Regional Universitario de Málaga, Málaga, Spain

EPV-0513 | Clinical characteristics and outcomes of patients with idiopathic intracranial hypertension treated by transvenous venous sinus stenting

R. Nadig¹; S. Deepalam²; S. GG¹; S. Shivde¹; S. Badachi¹; A. Huddar¹; T. Mathew¹; G. Sarma¹

¹Department of Neurology, St Johns Medical College Hospital Bengaluru, India; ²Department of Radiology, St Johns Medical College Hospital Bengaluru, India

EPV-0514 | Clinical outcomes of rimegepant in acute and prophylactic migraine therapy in a real-world setting

N. Öksüz¹; E. Ekizoğlu²; N. Tepe³; R. Karacı⁴; T. Cerrahoğlu Şirin⁵; A. Atalar⁶; E. Acıman Demirel⁷; B. Polat⁸; P. Yalınay Dikmen⁹; D. Vurallı¹⁰; H. Genç¹¹; F. Domaç⁴; E. Ilgaz Aydınlar⁹; E. Kocasoy Orhan²; A. Özge¹

¹Department of Neurology, Mersin University, School of Medicine, Mersin, Türkiye; ²Department of Neurology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Türkiye; ³Department of Neurology, Balıkesir University, School of Medicine, Balıkesir, Türkiye; ⁴Department of Neurology, University of Health Sciences, Erenköy Psychiatry and Neurological Diseases Training and Research Hospital, Istanbul, Türkiye; ⁵Department of Neurology, University of Health Sciences, Şişli Hamidiye Etfal Training and Research Hospital, Istanbul, Türkiye; ⁶Department of Neurology, Istanbul Physical Therapy and Rehabilitation Training and Research Hospital, Istanbul, Türkiye; ⁷School of Medicine, Neurology Department, Zonguldak Bülent Ecevit University, School of Medicine, Zonguldak, Türkiye; ⁸Department of Neurology, Düzce University, School of Medicine, Düzce, Türkiye; ⁹Department of Neurology, Acıbadem University, School of Medicine, Istanbul, Türkiye; ¹⁰Department of Neurology and Algology, Neuropsychiatry Center, Neuroscience and Neurotechnology Center of Excellence (NÖROM) Gazi University, Faculty of Medicine, Ankara, Türkiye; ¹¹Department of Neurology, Gaziantep City Hospital, Health Application and Research Center, Gaziantep, Türkiye

EPV-0515 | Clinical outcomes of topiramate and onabotulinumtoxinA in chronic migraine prophylaxis

B. Holmuratova¹; N. Rashidova¹; K. Khalimova¹; Z. Muminova²

¹Neurology Department, Tashkent State Medical University, Tashkent, Uzbekistan; ²Department of Obstetrics and Gynecology, Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0516 | Cluster headache and sleep: A questionnaire-based cross-sectional study on the bidirectional relationship between attacks and sleep disturbances

A. Chotoura¹; H. Göbel²; K. Heinze-Kuhn²; A. Heinze²; C. Göbel³

¹Faculty of Medicine, Kiel University, Kiel, Germany; ²Kiel Migraine and Headache Centre, Kiel, Germany; ³Department of Neurology, University Hospital Schleswig-Holstein, Campus, Kiel, Germany

EPV-0517 | Cluster-BIO: Cross-sectional study of plasma biomarkers (CGRP, PACAP-38, and VIP) in patients with cluster headache

L. Portocarrero-Sánchez¹; F. Laso-García²; N. Díaz-Gamero²; A. Calzado-González²; M. Ruiz-Castrillo¹; L. Zaballa-Pérez¹; J. Díaz-de-Terán²

¹Department of Neurology, Hospital Universitario La Paz, Madrid, Spain; ²Department of Neurology, Hospital Universitario La Paz, Hospital La Paz Institute for Health Research – IdiPAZ (La Paz University Hospital – Universidad Autónoma de Madrid), Madrid, Spain

EPV-0518 | COACT study: CGRPmAbs + OnabotulinumtoxinA assessment of chronic migraine treatments study

B. Torphy; M. Smith; S. Lamba; S. Koseli; A. Rakhangi; S. Dairo

Chicago Headache Center and Research Institute, Chicago, USA

EPV-0519 | Cognitive complaints in migraine: response to preventive treatment with atogepant

M. Costa Taveira; F. Dourado Sotero; M. Dias da Costa; R. Rodrigues; I. Pavão Martins

Serviço de Neurologia, Departamento de Neurociências e Saúde Mental, ULS Santa Maria, Lisbon, Portugal

EPV-0520 | Cognitive flexibility, resilience and executive control in chronic migraine with and without medication overuse

Y. Şengül¹; E. Gülhan²; F. Ülker¹

¹Department of Neurology, Faculty of Medicine, Çanakkale Onsekiz Mart University, Çanakkale, Türkiye; ²Faculty of Medicine, Çanakkale Onsekiz Mart University, Çanakkale, Türkiye

EPV-0521 | Comparative efficacy and safety of magnesium sulfate versus metoclopramide for treating acute migraines: A systematic review and meta-analysis

S. Wasti¹; A. Wasti²; M. Abdullah¹; Y. Mir¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0522 | Comparative efficacy and safety of metoclopramide versus sumatriptan in acute management of migraine: A systematic review and meta-analysis

S. Wasti¹; A. Wasti²; M. Shahid¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0523 | Comparative efficacy and safety of propranolol versus flunarizine for migraine prophylaxis: A systematic review and meta-analysis

S. Wasti¹; A. Wasti²; S. Waqas¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0524 | Comparing neurologist and neurologist-customised semantic search engine management plans for chronic migraine: A prospective pilot study from Kenya

A. Vakil¹; J. Shah²; H. Ekea¹; D. Sokhi²

¹Department of Medicine, Aga Khan University Medical College of East Africa (Nairobi Campus); ²Brain and Mind Institute, Aga Khan University, Kenya

EPV-0525 | Data of efficacy and safety of Atogepant in the preventive treatment of migraine in a cohort of highly treatment-refractory migraine patients

M. Morra; R. Ferri; E. Virgilio; F. Masuzzo; F. De Mattei; M. Matta; M. Torrieri; M. Clerico

SSD Specialist Neurological Pathologies, University Hospital San Luigi Gonzaga, Orbassano, Italy

EPV-0526 | Diagnostic yield of non-contrast cranial CT in chronic tension-type headache: A retrospective cohort

M. Acharya¹; A. Debnath²; S. Rana¹

¹Dr. B C Roy Multispecialty Medical Research Centre, IIT Kharagpur, Kharagpur, India; ²Department of Neuromedicine, Bankura Sammilani Medical College, Bankura, India

EPV-0527 | Distinct clinical features in adult and pediatric HaNDL syndrome: A literature-based analysis

G. Cabral¹; M. Brás Monteiro¹; M. Viana Baptista¹

¹Neurology Department, Hospital de Egas Moniz, Unidade Local Saúde Lisboa Ocidente, Portugal; ²Chronic Diseases Research Center (CEDOC), NOVA Medical School, Universidade NOVA de Lisboa, Lisbon, Portugal

EPV-0528 | Effectiveness and safety in patients receiving atogepant

P. López-Grueiro Valcarce; M. Ruiz Castrillo; F. Díaz de Terán Velasco; L. Portocarrero Sánchez
Neurology, Hospital Universitario La Paz, Madrid, Spain

EPV-0529 | Effectiveness of pulsed radiofrequency for migraine: A systematic review and meta-analysis

H. Hussien; A. Hegazi; M. SeragEldin
Faculty of Medicine Mansoura University, Mansoura, Egypt

EPV-0530 | Effects of astrocytic metabolic dysfunction and glucose stress on gene expression during cortical spreading depression

S. Khan
Wayne State University, Detroit; USA

EPV-0531 | Efficacy and safety of Eptinezumab 100 mg and 300 mg for migraine prevention: A systematic review and meta-analysis of randomized trials

M. Koirala; A. Pandit
Department of Internal Medicine, Chitwan Medical College Teaching Hospital, Bharatpur, Nepal

EPV-0532 | Efficacy and safety of fentanyl for prophylaxis against postdural puncture headache in cesarean section: A meta-analysis

S. Wasti¹; A. Wasti²; M. Shahid¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0533 | Efficacy and safety of Gabapentin versus placebo against postdural puncture headache: A systematic review and meta-analysis

S. Wasti¹; A. Wasti²; F. Amin¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0534 | Efficacy and safety of magnesium in preventing post-dural puncture headache after cesarean delivery: A systematic review

S. Wasti¹; A. Wasti²; S. Waqas¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0535 | Efficacy and safety of ondansetron versus conservative treatment in post-dural puncture headache prophylaxis in cesarean section: A meta-analysis

S. Wasti¹; A. Wasti²; F. Amin¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan

EPV-0536 | Efficacy and safety of Rimegepant 75 mg for migraine prevention: A meta-analysis of randomized controlled trials

A. Pandit; M. Koirala
Department of Internal Medicine, Chitwan Medical College Teaching Hospital, Bharatpur, Nepal

EPV-0537 | Efficacy and safety of valproate versus topiramate for pediatric migraine prophylaxis: A systematic review

S. Wasti¹; A. Wasti²; M. Berkinbayeva³; S. Cano-Reyes⁴; V. Kuo⁵; M. Iqbal¹; M. Saddique¹

¹Department of Neurology, King Edward Medical University, Lahore, Pakistan; ²Department of Neurology, Continental Medical College, Lahore, Pakistan; ³Department of Neurology, Asfendiyarov Kazakh National Medical University, Almaty, Kazakhstan; ⁴Department of Neurology, Hospital de la Misericordia/Universidad Nacional de Colombia, Bogotá D.C., Colombia; ⁵Department of Neurology, National Taiwan University, Taipei City, Taiwan

EPV-0538 | Efficacy of coenzyme Q10 for migraine: a systematic review, meta-analysis, and trial sequential analysis

K. Alidreesi¹; G. Alsamiri¹; M. Bukari¹; M. Almutairy¹; R. Alharthi¹; R. Abuhadi¹; M. Halabi¹; A. Attar²; A. Alsabban³
¹College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Jeddah, Kingdom of Saudi Arabia; ²Neurology Department, King Abdulaziz Medical City, Jeddah, Kingdom of Saudi Arabia; ³Family Medicine Department, King Abdulaziz Medical City, Jeddah, Kingdom of Saudi Arabia

EPV-0539 | Efficacy of Rimegepant 75 mg for acute migraine treatment: A systematic review and meta-analysis of randomized controlled trials

A. Pandit; M. Koirala
Department of Internal Medicine, Chitwan Medical College Teaching Hospital, Bharatpur, Nepal

EPV-0540 | Eptinezumab for difficult to treat migraine: Who responds and who need more

A. Visentini; E. Ratto; F. Genovese; B. Colombo; R. Messina; M. Filippi
Neurology Unit IRCCS San Raffaele Scientific Institute, Milan, Italy

EPV-0541 | Frequency of migraine phenotype in individuals at risk for MEFV variations: A neuroinflammatory reflection of familial mediterranean fever

Y. Guldiken¹; M. Attaalla²; A. Bakan³; F. Silan⁴

EPV-0911 | Exploring the effect of cerebrospinal fluid cytokine levels on MRI biomarkers of inflammation and neurodegeneration in multiple sclerosis

I. Addazio¹; E. De Meo¹; M. Betti¹; C. Ballerini¹; R. Amoriello²; O. Maghrebi²; C. Ballerini²; E. Fainardi³; E. Portaccio¹; M. Amato¹
¹Department of NEUROFARBA, University of Florence, Florence, Italy; ²Laboratory of Neuroimmunology Department of Experimental and Clinical Medicine University of Florence, Florence, Italy; ³Neuroradiology Unit, Careggi University Hospital, Florence, Italy

EPV-0912 | Fatigue and depression in multiple sclerosis: A bidirectional relationship

A. Alhajmabrouk¹; H. Derbali¹; I. Bedeoui¹; Y. Mrad¹; M. Messelmani¹; M. Mansour¹; N. Fakih Mrissa²; J. Zaoueli¹
¹Neurology Department, The Military Hospital of Tunis, Tunis, Tunisia; ²Molecular Biology Research Laboratory, The Military Hospital of Tunis, Tunis, Tunisia

EPV-0913 | Fatigue and disability drive sexual dysfunction in multiple sclerosis: a cross-sectional study in Spain using the MSISQ-15

C. Lapeña López¹; E. Ginés Murcia¹; L. Moreno Navarro¹; Á. Pérez Sempere¹; G. Pérez Paz²; P. Mahiques Ochoa¹; M. Warnken Miralles¹; A. Benavent Rojas¹; L. Montero Pardo¹; D. López Ros¹; A. Muñoz Ambit¹; L. Ruiz-Escribano Menchén¹
¹Neurology, Hospital General Universitario de Alicante, Spain; ²Preventive Medicine, Hospital General Universitario de Alicante, Spain

EPV-0914 | Fatigue severity in multiple sclerosis: preliminary results of a cross-sectional study

F. Sarıdaş; F. Hojjati; S. Albak; E. Koç
Bursa Uludağ University, Faculty of Medicine, Department of Neurology, Bursa, Türkiye

EPV-0915 | Fatigue, depression and anxiety as determinants of physical and mental quality of life in MS types

K. Ntoskas¹; T. Doskas²
¹Department of Neurology, 251 Hellenic Air Force General Hospital, Athens, Greece; ²Department of Neurology, Athens Naval Hospital, Athens, Greece

EPV-0916 | Feasibility and neurological safety of a ketogenic dietary intervention in relapsing-remitting multiple sclerosis: A pilot study

F. Filippi¹; S. Lorenzut²; R. Garbo³; E. Lamon⁴; I. Del Negro⁴; A. Nilo¹; S. Pez⁴; G. Gigli⁴; M. Valente⁴
¹Department of Medicine (DMED), University of Udine, Via Colugna 50, 33100 Udine, Italy; ²Neurology Unit, Head Neck and Neuroscience Department, Santa Maria della Misericordia University Hospital, Udine, Italy; ³SC Neurology of Gorizia Monfalcone, Azienda Sanitaria Universitaria Giuliano Isontina (ASUGI), Udine, Italy; ⁴Clinical Neurology Unit, Udine University Hospital, Piazzale Santa Maria della Misericordia, Udine, Italy

EPV-0917 | Features of cognitive and neuropsychological disorders in multiple sclerosis

M. Nazarova¹; R. Matmurodov¹; S. Nazarov²
¹Department of Neurology and medical psychology, Tashkent State Medical University, Tashkent, Uzbekistan; ²Department of Otorhinolaryngology, Tashkent State Medical University, Tashkent, Uzbekistan

EPV-0918 | Frailty in elderly patients with Multiple Sclerosis (MS)

V. Lizhdvoy
Department of Neurology, IMoscow Regional Research Clinical Institute N.A. M.F. Vladimirskiy, Moscow, Russian Federation

EPV-0919 | From biomarker to a new clinical perspective: Kappa free light chain index and disability progression in multiple sclerosis

M. Bruno; G. Romano; G. Lus; S. Bonavita; E. Signoriello
Multiple Sclerosis Centre, Second Division of Neurology,
University of Campania “Luigi Vanvitelli”, Naples, Italy

EPV-0920 | Functional outcomes after immune reconstitution therapy: A multidimensional evaluation of multiple sclerosis patients treated with cladribine

S. Ocak; B. Tasdelen; D. Cetinkaya Tezer; I. Gungor Dogan; S. Demir
Neurology Department, Sancaktepe Ilhan Varank Sancaktepe
Sehit Prof. Dr. Ilhan Varank Training and Research Hospital,
Istanbul, Türkiye

EPV-0921 | Gastric diffuse large B-cell lymphoma in a multiple sclerosis patient undergoing treatment with natalizumab: A case-report and literature review

L. de Castro Rocha; H. Felgueiras
Serviço de Neurologia, Unidade Local de Saúde de Gaia e
Espinho, Portugal

EPV-0922 | Gastrointestinal symptoms and health-related quality of life in relapsing-remitting multiple sclerosis: A GSRS and SF-36 based study

S. Talapbek kyzy; M. Tardov; N. Sturov; T. Mansur; A. Mikhailov
Department of General Medicine, RUDN University, Moscow,
Russian Federation

EPV-0923 | Hemifacial spasm as the initial manifestation of multiple sclerosis: a diagnostic pitfall

H. Hadji; S. Demuth; P. Sunsovan; M. Verin; C. Ciumas
Gaumond
Neurology Unit, CHU d'Orleans, Orleans, France

EPV-0924 | Hidden disabilities in multiple sclerosis: Incontinence and sexual dysfunction

M. Seferoğlu¹; M. Köktürk¹; A. Görgül¹; A. Sıvacı¹; M. Güzelsoy²
¹Bursa Yüksek İhtisas Training and Research Hospital, Neurology Clinic, Türkiye; ²Bursa Yüksek İhtisas Training and Research Hospital, Urology Clinic, Türkiye

EPV-0925 | How will climate change impact severity and incidence of multiple sclerosis?

S. Jalal; N. Nantheswaran; D. Neal; H. Rahman
Anglia Ruskin University, Cambridge, UK

EPV-0926 | Hyper-reflecting foci in multiple sclerosis: Association with clinical, optical coherence tomography, and laboratory markers

A. Castiello¹; A. Esposito¹; V. Nicoletta¹; G. Corsini¹; L. Corsaro¹; G. Cennamo¹; C. Polito³; D. Terracciano³; D. Ranucci¹; G. Moiese¹; C. Costagliola¹; M. Petracca⁴; R. Lanzillo¹; M. Moccia²; V. Brescia Morra²; A. Carotenuto¹

EPV-1100 | Phenotype distribution and differential disease burden in multiple sclerosis: Real-world data from the apolo study

C. Oreja-Guevara¹; I. González-Suarez²; S. Eichau Madueño³; S. Otero Romero⁴; M. Calvo Díez⁵; C. Engroba Teijeiro⁶; A. Casado Gómez⁷; P. Castro Albarrán⁷; J. Meca-Lallana⁸

¹Neurology Department, Hospital Universitario Clínico San Carlos, Madrid, Spain; ²Neurology Department, Hospital Álvaro Cunqueiro, Vigo, Spain; ³Neurology Department, Hospital Universitario Virgen Macarena, Seville, Spain; ⁴Preventive Medicine and Epidemiology Department, Hospital Universitario Vall d'Hebron, Barcelona, Spain; ⁵Health Economics & Pricing Business, Sanofi, Barcelona, Spain; ⁶Market Access, Sanofi, Barcelona, Spain; ⁷Pharmacoeconomics & Outcomes Research Iberia (PORIB), Madrid, Spain; ⁸Neurology Department, Hospital Universitario Clínico Virgen de la Arrixaca, Murcia, Spain

EPV-1101 | Post-COVID changes in thyroid cancer incidence: Possible neuroendocrine and ACE2-mediated mechanisms

Z. Khalimova; B. Kamildjanova; M. Omiljonov; I. Khakimov
Republican Specialized Scientific and Practical Medical Center of Endocrinology named after Acad. E.Kh. Turakulov, Tashkent, Uzbekistan

EPV-1102 | Serum S100B protein levels in neurodegenerative diseases

J. Tana¹; A. Mitre²; I. Zekja¹; J. Kruja¹

¹Neurology Department, UHC Mother Teresa, Tirana; ²Intermedica Laboratory, Tirana

EPV-1103 | Sex differences in ischemic stroke among young adults: A North African cohort study

I. Khiyel¹; H. Gutteche¹; L. Rouabah¹; B. Fekraoui²

¹Molecular and Cellular Biology Laboratory, University of Brothers Mentouri Constantine 1, Constantine, Algeria; ²Department of Neurology, University of Salah Bounider Constantine 3, Constantine, Algeria

EPV-1104 | Sex-specific trends in multiple sclerosis burden in India, 1990–2023: A GBD 2023 analysis

A. Sharma¹; P. Kola²; A. Paruchuri²

¹Government Medical College, Omandurar, Chennai, India; ²All India Institute of Medical Sciences, New Delhi, India

EPV-1105 | Sociodemographic and clinical profile of an outpatient population with functional neurological disorder over a decade

B. Fasching; G. Hennig; C. Mueller; B. Ludwig

Department of Neurology, Medical University of Vienna, Vienna, Austria

EPV-1106 | Superficial siderosis of the central nervous system: An underdiagnosed cause of hearing loss and progressive ataxia

I. Saurina Navarro¹; C. Martínez Follana¹; M. Marín Rubio¹; E. Campaña Martí¹; M. García Huguet¹; B. Alemany Perna²; D. López Domínguez²

¹Department of Neurology, Hospital Doctor Josep Trueta, Girona, Spain; ²Ataxia Unit – Hospital Doctor Josep Trueta, Girona/Hospital Santa Caterina, Salt, Spain

EPV-1107 | The impact of psychological stress on epileptic seizure frequency during wartime: A study following the “Swords of Iron” War in October 2023

A. Eilam; M. Arar; Y. Balash; V. Samogalsky; N. Khmeliov
Neurology Department, Kaplan Medical Center, Rechovot, Israel

EPV-1108 | A 62-year-old woman with hyperorality and apathy drug resistant, A new variant of CHMP2B mutation

A. Sangiorgio; C. Manco; D. Righi; S. Bianchi; N. De Stefano; D. Plantone

Department of Medicine, Surgery and Neuroscience, University of Siena, Italy

EPV-1109 | A novel mutation in the RNF216 gene associated with gordon holmes syndrome: Two Turkish sibling cases

Z. Baykan Biyikli; C. Boz

Karadeniz Technical University, Department of Neurology, Trabzon, Türkiye

EPV-1110 | A recurrent pathogenic MTM1 variant manifesting as hereditary spastic paraplegia (HSP) expands the phenotypic spectrum of X-linked myotubular myopathy

C. Koniari¹; Z. Kontogeorgiou¹; N. Ragazos¹; C. Kartanou¹; E. Anagnostou²; G. Pepe³; G. Nasioulas³; G. Karadima¹; G. Koutsis¹

¹Neurogenetics Unit, 1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece; ²1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece; ³Genekor Medical S.A., Athens, Greece

EPV-1111 | Accelerated brain aging and anatomical substrates in spinocerebellar ataxia type 3

G. Shirui

Department of Neurology and Institute of Neurology of First Affiliated Hospital, Institute of Neuroscience, and Fujian Key Laboratory of Molecular Neurology, Fujian Medical University, Fuzhou, China

EPV-1112 | Adult-onset congenital myasthenic syndrome: Genetic variability and clinical phenotype

A. Sousa

Unidade Local de Saúde de Aveiro, Portugal

EPV-1113 | Application of genetic tests in clinical practice: challenges in dealing with atypical phenotypes in neurodegenerative diseases

M. Anselmi¹; E. Monfrini²; A. Di Fonzo²; R. Di Giacomo³

¹Interdepartmental Centre of Medical Science, University of Trento, Trento, Italy; ²Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ³Neurology Unit, Santa Maria del Carmine Hospital, Rovereto, Italy

EPV-1114 | Association study between polymorphisms of the PTH gene and the morphology of the Sella Turcica

C. Nagai¹; J. Armando Brancher²; M. Gonçalves Fauth¹; E. Calvano Küchler³

¹Department of Anatomy, Federal University of Paraná, Curitiba, Paraná, Brazil; ²Postgraduate Program in Cell and Molecular Biology, Federal University of Paraná, Curitiba, Paraná, Brazil; ³Department of Orthodontics, University of Bonn, Medical Faculty, Bonn, Germany

EPV-1115 | Atypical presentation of spinocerebellar Ataxia 34 associated with a Novel Elov14 mutation

F. Usta; S. Usta; M. Mercan; V. Yayla

Neurology Clinics, University of Health Sciences, Dr. Sadi Konuk Training and Research Hospital, Istanbul Türkiye

EPV-1116 | Autosomal dominant cerebellar ataxia in siblings with a shared PDYN frameshift variant

R. Rodrigues¹; M. Rosário¹; V. Carvalho¹; L. Correia Guedes²

¹Neurology, Department of Neurosciences and Mental Health, Unidade Local de Saúde de Santa Maria, Lisbon, Portugal; ²Centro de Estudos Egas Moniz, Clínica Universitária de Neurologia, Faculty of Medicine, University of Lisbon, Lisbon, Portugal

EPV-1117 | Beyond ALS genes: Identification of causative variants associated with neurodegenerative disorders in Greek ALS patients

C. Kartanou¹; V. Eliades¹; Z. Kontogeorgiou¹; N. Ragazos¹; T. Loupis²; D. Vrachnos²; I. Spyropoulou¹; M. Petraki¹; C. Koniari¹; S. Aristeidou³; E. Koropouli³; A. Daponte³; V. Zouvelou³; M. Rentzos³; E. Kapaki³; M. Panas¹; P. Makrythanasis⁴; L. Stefanis³; G. Koutsis¹; G. Karadima¹
¹Neurogenetics Unit, 1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece; ²Hematology Research Lab, Clinical, Experimental and Translational Research Center, Biomedical Research Foundation, Academy of Athens, Athens, Greece; ³1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece; ⁴Laboratory of Medical Genetics, Medical School, National and Kapodistrian University of Athens, St. Sophia's Children's Hospital, Athens, Greece

EPV-1118 | CADASIL atypical motor presentation

M. Seco¹; F. Assis Jacinto¹; A. André²; A. Ferreira³; P. Salgado⁴; S. Duarte⁴
¹Neurology Department, Hospital Pedro Hispano, Portugal; ²Neurology Department, Faro Hospital, Faro, Portugal; ³Neurology Department, Horta Hospital, Portugal; ⁴Neurology Department, Portuguese Institute of Oncology of Porto, Porto, Portugal; ⁵Neurology Department, Horta Hospital, Portugal; ⁶Neurology Department, Hospital Pedro Hispano; ⁷Neurology Department, Horta Hospital, Portugal

EPV-1119 | Challenges in diagnosing pediatric neurodegeneration with brain iron accumulation: A case report

A. Condrea¹; D. Secu²; N. Balica²; I. Istratuc¹; S. Hadjiu³; V. Sacara²
¹Pediatrics Clinic, Mother and Child Institute, Chisinau, Republic of Moldova; ²Human Molecular Genetics Laboratory, Mother and Child Institute, Chisinau, Republic of Moldova; ³Nicolae Testemițanu State University of Medicine and Pharmacy, Chisinau, Republic of Moldova

EPV-1120 | Clinical and genetic characterization of a Portuguese cohort with familial multiple cavernous malformations

T. Morais¹; C. Silva²; A. Santos³; P. Vicente⁴; M. Almeida³; I. Santana⁴; J. Durães⁴
¹Neurology Department, Divino Espírito Santo Hospital, Ponta Delgada, Azores, Portugal; ²Neurology Department, Local Health Unit of Leiria, Leiria, Portugal; ³Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal; ⁴Neurology Department, Local Health Unit of Coimbra, Coimbra, Portugal

EPV-1121 | Decoding Parkinson's genetics: Causal mutations, risk factors, and clinical phenotypes

G. Frías Reyes¹; E. González Vilchis²; L. Adalid Peralta³
¹Multidisciplinary Academic Division of Comalcalco DAMC-UJAT, Comalcalco, Mexico; ²Faculty of Medicine, National Autonomous University of Mexico (UNAM), Ciudad de México, México; ³Laboratorio de Reprogramación Celular, Instituto de Fisiología, National Autonomous University of Mexico (UNAM), en el Instituto Nacional de Neurología y Neurocirugía, Ciudad de México, México

EPV-1122 | Defining a rare mtDNA phenotype: MELAS-like presentation and status epilepticus linked to MT-TT m.15933G>A

S. Chowdhury; M. Tiet
Neurology, University Hospitals Leicester NHS Foundation Trust, Derby, UK

EPV-1123 | Determination of genotype-phenotype characteristics in 194 cases with hereditary ataxia

M. Gultekin
Erciyes University Faculty of Medicine, Department of Neurology, Kayseri, Türkiye

EPV-1124 | Early-onset parkinsonism associated with intermediate CAG/CAA expansion in the TBP gene

G. Soares¹; S. Moreira¹; J. Oliveira²
¹Department of Neurology, Hospital Pedro Hispano, Matosinhos, Portugal; ²Centre for Predictive and Preventive Genetics, IBMC – Instituto de Biologia Molecular e Celular, University of Porto, Porto, Portugal

EPV-1125 | Epileptic and developmental encephalopathy associated with wdr45 mutation

I. Istratuc²; C. Calci¹; A. Condrea¹; E. Capestru¹; I. Calistru³; M. Sprincean³; S. Hadjiu¹

¹Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Republic of Moldova; ²PHMI Mother and Child Institute, Chisinau, Republic of Moldova; ³Laboratory of Neurobiology and Medical Genetics, Nicolae Testemitanu State University of Medicine and Pharmacy, Chişinău, Republic of Moldova

EPV-1126 | Evaluation of inflammatory and neurotrophic gene expression profiles in the epileptogenesis process

H. Soytürk¹; P. Bakkal²; T. Bakkal³; Ü. Kılıç⁴; Ş. Aydın Türkoğlu²

¹Interdisciplinary PhD Program in Neuroscience, Bolu Abant İzzet Baysal University, Bolu, Türkiye; ²Department of Neurology, Bolu Abant İzzet Baysal University Faculty of Medicine, Bolu, Türkiye; ³Department of Neurology, İzzet Baysal State Hospital, Bolu, Türkiye; ⁴First and Emergency Aid Program, Vocational School of Health Services, Düzce University, Düzce, Türkiye

EPV-1127 | Exploring the clinical spectrum of LRSAM1-related disorder: A Greek case series

C. Koniari¹; Z. Kontogeorgiou¹; C. Tzembetzi¹; C. Kartanou¹; E. Anagnostou²; V. Mouratoglou³; P. Kokotis²; V. Zouvelou²; N. Fakas³; Z. Lygerou⁴; M. Rentzos²; L. Stefanis²; G. Karadima¹; G. Koutsis¹

¹Neurogenetics Unit, 1st Department of Neurology, National and Kapodistrian University of Athens, Eginition Hospital, Athens, Greece; ²1st Department of Neurology, National and Kapodistrian University of Athens, Eginition Hospital, Athens, Greece; ³Department of Neurology; 401 General Military Hospital of Athens, Athens, Greece; ⁴Molecular Genetics Unit, Department of General Biology, School of Medicine, University of Patras, Patras, Greece

EPV-1128 | Fabry's disease: Rare symptom in a rare disease

S. Bourokba; N. Toubal; M. Louanchi
Department of Neurology CHU Annaba, Annaba, Algeria

EPV-1129 | Fragile X-associated tremor/ataxia syndrome (FXTAS) with mosaicism in genetic testing and different clinical course in two female siblings

E. Zeis; P. Kalligerou; A. Daskalaki; C. Koros; V. Konstantinidis; N. Skarmas; S. Papageorgiou
1st Department of Neurology, Aiginiteio University Hospital, Athens, Greece

EPV-1130 | Genetic evaluation of hereditary ataxia patients in Türkiye using targeted next-generation sequencing: The impact of consanguinity

E. Soker¹; D. Yorulmaz¹; D. Agirbasli²; A. Kalayci²
¹Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Türkiye; ²Department of Medical Genetics, Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Türkiye

EPV-1131 | Genetic risk factors in neurodegenerative parkinsonism

T. Strnadová¹; K. Menšíková¹; K. Kolaříková²; R. Vodička²; P. Kaňovský¹
¹Department of Neurology and Clinical Neuroscience Center, Faculty of Medicine and Dentistry, Palacký University, Olomouc, Czech Republic; ²Department of Clinical and Molecular Genetics, Faculty of Medicine and Dentistry, Palacký University, Olomouc, Czech Republic

EPV-1132 | Genetic spectrum and phenotypic heterogeneity in Parkinson's disease patients undergoing whole-exome sequencing in a tertiary referral center

A. Alexandratou¹; G. Vatselas²; R. Antonellou¹; A. Simitsi¹; N. Papagiannakis¹; C. Koros¹; E. Sfikas¹; I. Alefanti¹; M. Maniati²; K. Lourentzos³; A. Bonakis³; P. Makrythanasis⁴; L. Stefanis¹
¹First Dept of Neurology, NKUA Medical School, Athens, Greece; ²BRFAA, Greece; ³Second Dept of Neurology, NKUA Medical School, Athens, Greece; ⁴Laboratory of Medical Genetics, NKUA Medical School, Athens, Greece

EPV-1133 | Hemiplegic migraine with epileptic seizures and reversible cortical abnormalities in a male adolescent: A case report

A. Baz Cárdenas

Barbara Gutierrez Ruano, Hospital Central de la Defensa Gómez Ulla, Madrid, Spain

EPV-1134 | Hypercapnic respiratory failure in familial cavernous cavernoma: Neurogenetic diagnostic criteria and significance of lesion progression – A rare case

T. Balraj Singh¹; C. Chan¹; K. Teo²

¹Department of Medicine, National University Hospital, Singapore; ²Division of Neurology, Department of Medicine, National University Hospital, Singapore

EPV-1135 | Identification of genetic modifiers in adult Moyamoya disease using whole-exome sequencing

J. Kim¹; J. Jeon²

¹Department of Neurosurgery, Seoul National University College of Medicine, Seoul, Republic of Korea; ²Department of Neurosurgery, Hallym University College of Medicine, Chuncheon-si, Gangwon-do, Republic of Korea

EPV-1136 | Inflammation-related genetic variants and copy number changes in Alzheimer's disease in a Saudi cohort

L. Sorour¹; M. Alkhateeb³; N. Qadi¹; M. Al Rajeh²; F. El Bitar¹
¹King Faisal Specialist Hospital and Research Center (KFSHRC), Riyadh, Kingdom Saudi Arabia; ²Al Habib Medical Center, Riyadh, Kingdom Saudi Arabia; ³Princess Nourah bint Abdulrahman University (PNU), Riyadh, Kingdom Saudi Arabia

EPV-1137 | Late presentation of megalencephalic leukoencephalopathy with subcortical cysts (MLC) in a female patient with ataxia, dystonia and seizure

I. Sarac¹; F. Borovecki¹; H. Sarac²

¹University of Zagreb, Croatia; ²University Hospital Center Zagreb, Croatia

EPV-1138 | Machine learning applications in Huntington's disease genomics: A systematic review

G. Uzoechina; T. Osajiuba

Faculty of Clinical Sciences, University of Nigeria Teaching Hospital, Enugu, Nigeria

EPV-1139 | Measuring functional abilities and assistance level in niemann-pick disease type C, GM2 gangliosidosis, and ataxia

B. Zandrucha¹; M. Patterson¹; J. Kerthi¹; J. Raymond¹;

A. Hatcher¹; M. Grosso¹; J. Caines²; S. Rounds²

¹IntraBio Inc., Austin, Texas, USA; ²Curant Health LLC., Smyrna, Georgia, USA

EPV-1140 | Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes: A case series

M. Majoul; Y. Memmich; D. Ben Mohamed; R. Zouari;

A. Rachdi; Z. Saied; F. Nebli; S. Ben Sassi

Department of Neurology, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia

EPV-1141 | Molecular diagnosis of trinucleotide repeat expansion disorders in Singapore (1996–2024)

A. Raheja¹; K. Narasimhalu¹; H. Law²

¹National Neuroscience Institute (SGH Campus), Singapore; ²KK Women's and Children's Hospital, Singapore

EPV-1142 | Neuromuscular manifestations in patients with lipodystrophy

N. Varga¹; Z. Grosz¹; A. Takacs²; P. Reismann³; A. Jobbagy⁴; V. Molnar¹; M. Molnar¹

¹Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary; ²Department of Ophthalmology, Semmelweis University, Budapest, Hungary; ³Department of Internal Medicine and Oncology, Semmelweis University, Budapest, Hungary; ⁴Department of Dermatology, Dermatoooncology and Venerology, Semmelweis University, Budapest, Hungary

EPV-1143 | Peak expiratory flow causally affects brain neuronal activity: A Mendelian randomization study

Y. Mao; R. Wu

Department of Radiology, Second Affiliated Hospital, Shantou University Medical College, Shantou, Guangdong, China

EPV-1144 | Persistent sleep disturbance in youth: A clue to Wilson disease

V. Mouratoglou¹; N. Papageorgiou¹; M. Thomas¹; I. Vamvakaris¹; G. Pepe³; G. Nasioulas³; A. Simitsi²; C. Koniari¹; L. Stefanis²; N. Fakas¹

¹Neurology Department; 401 General Military Hospital of Athens, Athens, Greece; ²1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece; ³Genekor Medical S.A, Athens, Greece

EPV-1145 | Progressive external ophthalmoplegia due to a POLG gene mutation: A case report

C. Segura Sanz

Department of Neurology, University Hospital Virgen de la Victoria, Málaga

EPV-1146 | Progressive spastic paraparesis misdiagnosed as cerebral palsy: a case of ARSACS

M. Nezval¹; T. Doriňák¹; L. Satke¹; M. Nevrlý¹; L. Osičková²; P. Kaňovský¹

¹Department of Neurology and Clinical Neuroscience Center, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic; ²Department of Clinical and Molecular Genetics, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

EPV-1147 | Pseudodemyelinating MRI changes in neurofibromatosis type 1: Clinical significance of UBO/FASI

K. Kovalchuk; T. Nehrych; M. Shorobura; N. Nehrych; N. Bozhenko; Y. Matviyenko

Department of Neurology, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

EPV-1148 | Rare case of neuromuscular oculauditory syndrome: Genetic challenges

A. Frontistis¹; S. Kalampokini¹; D. Goulis²; G. Pepe³; S. Koukoulas⁴; M. Moschou¹; M. Arnaoutoglou¹; V. Papaliagkas⁵; V. Kimiskidis¹

¹First Department of Neurology, AHEPA University Hospital, Aristotle University of Thessaloniki; ²Unit of Reproductive Endocrinology, First Department of Obstetrics-Gynaecology, Aristotle University of Thessaloniki; ³Genekor Medical S.A., Athens, Greece; ⁴Vitreoretinal Department, Ophthalmica Eye Institute, Thessaloniki, Greece; ⁵Department of Biomedical Sciences, School of Health Sciences, International Hellenic University, Thessaloniki, Greece

EPV-1149 | RORA-Related IDDECA with cerebellar atrophy: Marked clinical response to valproate in an adult patient

V. Busco¹; G. Di Lazzaro²; A. Cimmino¹; M. Petracca²; D. Genovese²; A. De Biase²; F. Musso¹; A. Calarco¹; P. Calabresi²; A. Bentivoglio²

¹Catholic University of the Sacred Heart, Rome, Italy; ²Neurology Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

EPV-1150 | Transcranial alternating current stimulation for treatment of multiple system atrophy cerebellar type: A randomized controlled trial

G. Shirui

Department of Neurology and Institute of Neurology of First Affiliated Hospital, Institute of Neuroscience, and Fujian Key Laboratory of Molecular Neurology, Fujian Medical University, Fuzhou, China

EPV-1151 | VPS16-dystonia linked pathogenic variant in Parkinson's disease: Expanding the phenotype?

M. Ostrožovičová¹; T. Lorincova¹; R. Jech²; M. Zech³; M. Skorvanek¹

¹Department of Neurology, P.J. Safarik University, and University Hospital of L. Pasteur, Kosice, Slovakia; Laboratory of Clinical Neurosciences, University Science Park MEDIPARK, P. J. Safarik University, Kosice, Slovakia; ²Department of Neurology and Center of Clinical Neuroscience, First Faculty of Medicine Charles University and General University Hospital in Prague, Prague, Czech Republic; ³Institute of Human Genetics, School of Medicine and Health, Technical University of Munich, Munich, Germany. Institute of Neurogenomics, Helmholtz Zentrum München, Institute for Advanced Study, Technical University of Munich, Munich, Germany

EPV-1152 | AI in healthcare: The potential of ChatGPT as an assisting tool in diagnosing stroke

N. Abdelmaksoud¹; H. Hussien²; M. Mamdouh³; Y. Fathy⁴; N. Eldmrdash⁵; A. Gamal⁶; H. Elsharkawy⁷; M. Hossam⁸
¹Neurology Department, Misr University for Science and Technology, Giza, Egypt; ²5th year student, Faculty of Medicine, Mansoura University, Mansoura, Egypt; ³5th year student, Faculty of Medicine, Sohag University, Sohag, Egypt; ⁴3rd year student, Faculty of Medicine, Mansoura National University, Mansoura, Egypt; ⁵5th year student, Faculty of Medicine, Delta University, Mansoura, Egypt; ⁶Medical intern, Sohag University Hospital, Sohag, Egypt; ⁷Physical Therapy intern, Mansoura University Hospital, Kafr-Elshiekh, Egypt; ⁸5th year student Faculty of Physical Therapy, October 6th University, Giza, Egypt

EPV-1153 | Beyond the classical triad: Cerebral and spinal cord involvement in Kearns-Sayre syndrome

A. Correia¹; D. Cruz¹; C. Cunha²; A. Antunes¹; L. Albuquerque¹; V. Carvalho¹
¹Neurology Department, Department of Neurosciences and Mental Health, Santa Maria Hospital, Lisbon, Portugal; ²Neuroradiology Department, Department of Neurosciences and Mental Health, Santa Maria Hospital, Lisbon, Portugal

EPV-1154 | Changes in brain morphometry in post COVID-19 patients: An exploratory study

S. Panda¹; R. Naik¹; S. Tiwari²; G. Bohra³; P. Khera²
¹Department of Neurology All India Institute of Medical Sciences, Jodhpur, India; ²Department of Diagnostic and Interventional Radiology All India Institute of Medical Sciences, Jodhpur, India; ³Department of Medicine All India Institute of Medical Sciences, Jodhpur, India

EPV-1155 | CHANTER syndrome: An emerging diagnosis in toxic encephalopathy

I. Córdoba Bueno; M. Mesa Hernández; M. Jimenez Arenas; P. Blanco Ramírez; M. García Falcón; J. Gómez Moreno; M. Molina López; A. Parejo Olivera; A. Roa Montero
Department of Neurology, Badajoz University Hospital, Badajoz, Spain

EPV-1156 | Characterizing the cellular distribution of iron in Parkinson's disease from MRI data

A. Oliveira²; Q. Raynaud¹; M. Castro Jiménez³; C. Hubsch³; E. Accolla⁴; J. Bally³; A. Lutti¹
¹Laboratory for Research in Neuroimaging, Department of Clinical Neuroscience, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; ²Department of Radiology, Lausanne University Hospital (CHUV), Lausanne, Switzerland; ³Service of Neurology, Department of Clinical Neuroscience, Lausanne University Hospital (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland; ⁴Service de Neurology, HFR – Hôpital Cantonal Fribourg, Fribourg, Switzerland

EPV-1157 | Clinical and radiological features of autoimmune encephalitis: A monocentric study from Tunisia

O. Sakli; R. Zouari; Z. Saied; A. Rachdi; D. Ben Mohamed; F. Nabli; L. Bouafia; S. Ben Sassi
Department of Neurology, Mongi Ben Hamida Hospital, Tunis, Tunisia

EPV-1158 | Clinical utility of DaTscan in detecting neurodegenerative causes of Parkinsonism

A. Teo¹; K. Teo¹; S. Ng¹; C. Tan²
¹Division of Neurology, Department of Medicine, National University Hospital, Singapore; ²Division of Neurology, Department of Medicine, Alexandra Hospital, Singapore

EPV-1159 | Correlation between FDG and amyloid-beta PET uptake in patients with neurodegenerative diseases

M. Bonacci; M. Caligiuri; C. Calomino; R. Nisticò; M. Bianco; V. Prigitano; A. Quattrone; A. Quattrone; F. Novellino
Neuroscience Research Center, University “Magna Graecia”, Catanzaro, Italy; Department of Medical and Surgical Sciences, University “Magna Graecia”, Catanzaro, Italy

EPV-1160 | Deep learning-based synthesis of [11C]PiB MicroPET images from [18F]FDF in an Alzheimer's disease animal model

M. Becerril
Universidad Nacional Autónoma de México, Mexico

EPV-1161 | Diencephalo-mesencephalic Junction Dysplasia Type B: Diagnostic challenges and clinico-imaging correlations

M. Ursoi¹; M. Sangheli¹; G. Corcea²

¹University of Medicine and Pharmacy “Nicolae Testemițanu”, Chișinău, Republic of Moldova; ²Institute of Neurology and Neurosurgery “Diomid Gherman”, Chișinău, Republic of Moldova

EPV-1162 | Differentiating neurovascular conflict in classical trigeminal neuralgia: A 15-year study on the use of multispiral computed tomographic angiography

O. Zykova; E. Balyazina; A. Afanasyeva

Rostov State Medical University, Rostov-on-Don, Russian Federation

EPV-1163 | Distinct cerebral perfusion patterns in drug-induced parkinsonism versus Parkinson's disease: A dual-phase 18F-FP-CIT PET analysis

E. Jung

Chonnam National University Hospital, Gwangju, Republic of Korea

EPV-1164 | Enlarged perivascular spaces alongside white matter hyperintensities predict poor MoCA outcomes among elderly individuals

M. Abdi¹; K. Hassaninia¹; M. Almasi-Dooghaee²; F. Akhoundi²

¹Medicine Faculty, Iran University of Medical Sciences, Tehran, Iran; ²Neurology department, Iran University of Medical sciences, Tehran, Iran

EPV-1165 | Evaluation of the correlation of neuromelanin loss in the Substantia Nigra on MRI

S. Aydeniz; S. Özkaynak; K. Karaali

Neurology, Akdeniz University/Antalya, Türkiye

EPV-1166 | Fahr disease diagnosed in an elderly patient: A puzzling clinical case

A. Quka¹; I. Zekja¹; E. Ranxha²; A. Hoxha¹; A. Kuqo¹

¹Department of Neurology, UHC Mother Teresa, Tirana, Albania; ²Stroke Unit, UHC Mother Teresa, Tirana, Albania

EPV-1167 | FDG-PET in Creutzfeldt-Jakob disease presenting as corticobasal syndrome

A. Vătămănelu¹; I. Ion¹; B. Chambert²; G. Taieb¹;

G. Castelnovo¹; D. Renard¹

¹Department of Neurology, CHU Nîmes, Univ. Montpellier, France; ²Department of Nuclear Medicine, CHU Nîmes, Univ. Montpellier, France

EPV-1168 | Hypertrophic olivary degeneration secondary to venous infarction: a previously unreported presentation

M. Bonnin Bravo; M. García Ruiz; E. López Valdés; M. Álvarez

Gutiérrez; L. Domínguez Jiménez; Á. Lafuente Almadén;

J. Melgar Jara; P. Mayo Rodríguez

Neurology Department, Hospital Clínico San Carlos, Madrid, Spain

EPV-1169 | Hypomagnesemia-associated cerebellar syndrome: A reversible cause of acute ataxia

M. Filipa Graça; A. Ferreira; M. Calejo; S. Duarte

Neurology Department, Unidade Local de Saúde Matosinhos, Matosinhos, Portugal

EPV-1170 | Improving diagnostic sensitivity for temporal lobe epilepsy by using deep learning-based MRI reconstruction

D. Jung

Ajou University School of Medicine, Suwon, Republic of Korea

EPV-1171 | Inflammatory cerebral amyloid angiopathy: Report of two clinical cases

M. Ruiz Perelló; F. Salazar Hernandez; B. Gómez González;

D. Lopez Segura; A. Maija Savolainenhg; M. Lorente;

A. Sancho; A. Gomez Esteban; D. Vidal Mena; M. Lopez Lopez;

E. Fages Caravaca; M. Ortega Ortega; M. Ruiz Perelló

Department of Neurology, Santa Lucía University Hospital, Cartagena, Spain

EPV-1172 | Intermittent diplopia revealing an aneurysmal persistent trigeminal artery

A. Kalfat¹; I. Dkhil²; S. Jelassi²; A. Ben Lakhal²; N. Hammami²; S. Nagi²

¹LR18SP04 and Pediatric Neurology Department, National Mongi Ben Hmida Institute of Neurology, Tunis, Tunisia;

²Neuroradiology Department, National Mongi Ben Hmida Institute of Neurology, Tunis, Tunisia

EPV-1173 | Intravenous thrombolysis in wake-up and unknown-onset ischemic stroke selected by CT-based imaging: A systematic review and meta-analysis

H. Atwan

Faculty of Medicine, Assiut University, Assiut, Egypt

EPV-1174 | Intravenous thrombolysis in wake-up and unknown-onset ischemic stroke selected by MRI-based imaging: A systematic review and meta-analysis

H. Atwan

Faculty of Medicine, Assiut University, Assiut, Egypt

EPV-1175 | Longitudinal neuroimaging evidence of cognitive changes in essential tremor

C. Calomino; A. Quattrone; M. Bianco; R. Nisticò; M. Bonacci; V. Prigitano; F. Novellino

Neuroscience Research Center, Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro, Italy

EPV-1176 | Neuroimaging spectrum of central nervous system tuberculosis – A retrospective cohort study

A. Pathirage; V. Velumylum; P. Ruwanpathirana; B. Senanayake

Institute of Neurology, National Hospital, Sri Lanka

EPV-1177 | Not everything is as it seems: Pseudo–midbrain atrophy on neuroimaging

E. Gismera Fontes; M. González Sánchez; F. Sánchez García; M. González Gómez; L. Cabral Esquea

Neurology Department, University Hospital Guadalajara, Guadalajara, Spain

EPV-1178 | Persistent trigeminal artery causing transient oculomotor nerve palsy: A neuroimaging case

O. Cibuku¹; V. Thimjo¹; E. Xhukellari¹; A. Rroji²; E. Ranxha¹

¹Neuro vascular Service, University Hospital “Mother Teresa” Tirane, Albania; ²Neuro radiology Department, University Hospital “Mother Teresa” Tirane, Albania

EPV-1179 | Preserved global topology with frontoparietal control–centered cross-network coupling alterations after carbon monoxide poisoning

Y. Li¹; T. Wang²

¹Lanzhou University, Lanzhou, China; ²The First Hospital of Lanzhou University, Lanzhou, China

EPV-1180 | pyogenic cerebellar abscesses leading to ataxia and intractable hiccups

A. Elsaddig

Neurology Department, Sheikh Tahnoon Bin Mohammed Medical City, Al Ain, United Arab Emirates

EPV-1181 | Radscale score and clinical response to tap-test in patients with normal pressure hydrocephalus

J. Camacho Velasquez; B. Lobo Minuve; E. Franquet Gomez; M. Bea Sintes; V. Adell Ortega; P. Bermell Campos

Department Of Neurology. Consorci Sanitari Alt-Penedes-Garraf. Barcelona, Spain

EPV-1182 | Reversible splenial lesion syndrome after fentanyl exposure: Expanding the etiological spectrum

P. Nieto Palomares¹; M. El Harmochi Doud²; P. Gómez Ramírez²; A. García Maruenda³; I. Martín Sobrino⁴; L. Quirós Illán⁶; A. Sánchez Gómez²; A. Herrera Ortega²

¹Neurology, Neurotraumatological Hospital of Jaén, Jaén, Spain;

EPV-1250 | Ofatumumab in refractory anti-GABABR encephalitis with active infection

J. Wang

Department of Neurology, Chongqing University Affiliated Sanxia Hospital, Chongqing, China

EPV-1251 | Optimization of treatment of autonomic disorders and vegetative dysfunction in patients with rheumatoid arthritis

S. Kalandarova; S. Kuranbayeva; S. Rustambekova;

A. Amriddinov

Tashkent State Medical University, Tashkent, Uzbekistan

EPV-1252 | Outcomes within 5 years following different immunosuppressive treatment protocols in cerebral amyloid angiopathy-related inflammation: A case series

C. Morgan¹; N. Gupta¹; A. Siegel²; A. Nevares³; F. Sweeney¹; C. Roy-Hewitson¹

¹Neurology, University of Vermont Medical Center, Burlington, USA; ²Larner College of Medicine, University of Vermont, Burlington, USA; ³Rheumatology, University of Vermont Medical Center, Burlington, USA

EPV-1253 | Overlap between anti-NMDAR encephalitis and multiple sclerosis: A rare neuroimmunological overlap

C. Conde Velasco; J. Arzalluz Luque; I. Ruiz Salcedo; A. Rincón Valencia; S. Eichau Madueño
Department of Neurology, Hospital Virgen Macarena, Sevilla, Spain

EPV-1254 | Overlap syndrome of myositis, myocarditis, and myasthenia gravis secondary to immune checkpoint inhibitors (ICI): A tertiary-center case series

C. Conde Velasco; Á. Laviana Marín; A. Rincón Valencia; I. Ruiz Salcedo; Y. Morgado Linares; E. Martínez Fernández
Department of Neurology. Hospital Virgen Macarena. Sevilla. Spain

EPV-1255 | Pediatric MOGAD atypical fulminant or insidious presentations: monophasic or relapsing conditions?

S. Garcia-Tarodo¹; A. Bordessoule²; C. Habre³; J. Fluss¹; K. Deiva⁴
¹Neuropediatric Unit, Department of Child, Adolescent and Women, Geneva University Hospitals, Switzerland; ²Pediatric intensive care, Department of Child, Adolescent and Women, Geneva University Hospitals, Switzerland; ³Pediatric Radiology Unit, Department of Diagnostic, Geneva University Hospitals, Switzerland; ⁴Pediatric Neurology department, Paris Saclay University Hospitals, Le Kremlin Bicêtre, Paris, France

EPV-1256 | Posterior cortical atrophy caused by antiphospholipid syndrome Identified by the “railroad track” sign on brain PET

A. Aksamit
Mayo Clinic, Rochester MN, USA

EPV-1257 | Pre-diagnostic disease trajectories preceding central nervous system inflammation: A UK Biobank Study

D. Kook¹; H. Kim²; K. Kim³; Y. Park²; W. Kim¹; B. Choi¹
¹Department of Neurology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; ²Department of Biomedical Systems Informatics, Yonsei University College of Medicine, Seoul, Republic of Korea; ³Department of Neurology, Yonsei University College of Medicine, Seoul, Republic of Korea

EPV-1258 | Prognostic significance of thyroid autoantibodies in MOGAD and NMOSD: A biomarker for disease activity

T. Fidan Çolak; S. Şen; M. Terzi
Department of Neurology, Faculty of Medicine, Ondokuz Mayıs University, Samsun, Türkiye

EPV-1259 | Progressive Hemifacial Atrophy (Parry-Romberg Syndrome): Long-term clinical course with traumatic onset and late stabilization

N. Bozhenko; M. Bozhenko
Neurology Department, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

EPV-1260 | Real-life study of multiple sclerosis patients under treatment with cladribine

A. Costa; S. Gomes; S. Moreira; J. Ferreira Pinto; A. Santos; F. Sousa; J. Cerqueira
Neurology Department – Local Health Unit Braga, Braga, Portugal

EPV-1261 | Recurrent aseptic meningitis associated with nivolumab: A rare immune-related neurological adverse event

L. Caballero Sánchez; M. Vargas Cobos; A. De Luca; R. Alfonso González; M. Capra; C. Gómez López de San Román; I. Bermejo Casado; D. Cerdán Santacruz; A. Castrillo Sanz; A. Mendoza Rodríguez
General Hospital of Segovia, Segovia, Spain

EPV-1262 | Reduction of immune cell subsets and autoantibodies by cladribine in generalised myasthenia gravis peripheral blood mononuclear cell-based assays

Y. Wu¹; E. Järvinen²; D. Jack³; T. Derfuss⁴; C. Sun¹
¹EMD Serono Research & Development Institute, Inc., Billerica, MA, USA (an affiliate of Merck KGaA); ²Merck OY, Espoo, Finland (an affiliate of Merck KGaA); ³Merck Serono Ltd., Feltham, UK (an affiliate of Merck KGaA); ⁴Department of Biomedicine, University of Basel, Switzerland

EPV-1263 | Role of anti-HBs antibody titers in HBV reactivation risk stratification in pOBI patients with multiple sclerosis treated with anti-CD20 therapy

L. Corsaro¹; A. Esposito¹; A. Buonomo²; F. Cuccurullo²; G. Viceconte²; V. Fotticchia²; E. Scivico¹; R. Scotto²; I. Gentile²; A. Carotenuto¹; M. Moccia³; V. Brescia Morra¹; R. Lanzillo¹

Background and aims: To identify non-cataplexy symptoms indicating hypocretin-1 deficiency, and to investigate the association between CDH symptom presentation and varying CSF hypocretin-1 levels.

Methods: We included 302 CDH individuals from the European Narcolepsy Network database. Hypocretin-1 levels were categorized as ≤ 40 , 41–110, 111–200, and > 200 pg/mL. Machine learning (stochastic gradient boosting) was used to explore non-cataplexy predictors of hypocretin-1 deficiency. Logistic and quantile regression models examined associations between absolute hypocretin-1 levels and demographic, subjective symptom, polysomnography, and multiple sleep latency test (MSLT) measures, adjusted for age, sex, and body mass index. Cataplexy features were analyzed among individuals with cataplexy and hypocretin-1 levels ≤ 200 pg/mL.

Results: Non-cataplexy variables predicted degrees of hypocretin-1 deficiency with moderate certainty. In all individuals, lower hypocretin-1 levels were associated with shorter sleep latency and rapid eye movement sleep latency on both polysomnography and MSLT, more MSLT sleep-onset rapid eye movement periods, higher Epworth Sleepiness Scale scores, increased periodic limb movement index, and more frequent disturbed nocturnal sleep. Among individuals with cataplexy and hypocretin-1 levels ≤ 200 pg/mL, lower levels were associated with earlier excessive daytime sleepiness onset, younger age at diagnosis, greater diagnostic certainty of hypnagogic hallucinations and sleep paralysis, and more frequent and complete cataplexy attacks.

Conclusion: Lower hypocretin-1 levels were associated with more severe symptoms, both in the overall CDH population and in individuals with cataplexy and low hypocretin. Even within the deficient range, hypocretin-1 variation contributed to individual differences in symptom presence and severity.

LB_02 | Apathy marks brain network and genetic vulnerability to cognitive decline in Parkinson's disease

B. Attaallah
Imperial College London, UK

Background and aims: Motivational deficits such as apathy and impulse-control behaviours (ICBs) are common in Parkinson's disease (PD), with increasing evidence suggesting their relevance to cognitive function. However, the mechanisms by which they influence cognitive trajectories remain under investigation.

Methods: Using the Parkinson's Progression Markers Initiative (PPMI), we examined apathy and ICBs in relation to longitudinal cognition, resting-state functional connectivity, structural imaging, and genetic susceptibility in early PD.

Results: In 1502 participants at baseline, apathy-containing phenotypes were comparatively stable over time, whereas isolated ICB was more transient, consistent with a stronger medication-linked component. Across up to 15 years of follow-up, higher baseline apathy robustly predicted steeper decline in both latent global cognition and Montreal Cognitive Assessment performance, independent of demographic, motor, depressive, and treatment covariates; ICB-related effects on decline were weak and not robust. In resting-state functional MRI ($n=310$), the Network-Based Statistic identified an apathy-related somato-motor–dorsal-attention connectivity signature independent of disease severity and dopaminergic medication, whereas any ICB-related connectivity attenuated after levodopa-equivalent dose adjustment. Lower connectivity within this subnetwork predicted steeper cognitive decline, mediated the apathy–decline association in an age-dependent manner, and tracked smaller hippocampal volume and faster subsequent atrophy. Apathy-related cognitive decline was selectively amplified in GBA-associated PD, with apathetic GBA carriers declining approximately five-fold faster than non-apathetic sporadic cases.

FIGURE 1 Apathy-ICB co-occurrence and longitudinal stability in early Parkinson's disease.

FIGURE 2 Apathy preferentially predicts faster global cognitive decline in early Parkinson's disease.

Conclusion: pathy, rather than ICB severity, identifies a stable and clinically meaningful motivational marker of adverse cognitive trajectory in early PD, linked to a specific connectivity phenotype and amplified by GBA status.

Disclosure: None.

S. Patel, R. Maroofian, H. Houlden

Department of Neuromuscular Diseases, National Hospital of Neurology and Neurosurgery, Queen Square, London, UK

Background and aims: Hypomyelinating leukodystrophies (HLDs) are traditionally defined radiologically by persistent hypomyelination on brain MRI. However, many rare HLD-associated genes remain represented only by isolated reports or very small case series, limiting understanding of their full clinical, radiological, and biological spectrum.

Methods: We performed retrospective multicentre deep phenotyping and neuroradiological review of individuals with pathogenic variants in several rare HLD-associated genes, including FAM177A1, AIMP1, AIMP2, HSPD1, EPRS1, and NKX6.2.

Results: Cross-cohort analysis identified reproducible clinical subgroups, including classic Pelizaeus–Merzbacher disease-like HLD, movement-predominant HLD, epileptic HLD, peripheral neuropathy-associated HLD, and syndromic/systemic HLD phenotypes. Notably, approximately one-third of individuals with EPRS1-related disease lacked hypomyelination despite significant neurological involvement. Prominent movement disorders, particularly dystonia and tremor, were frequent in HSPD1- and NKX6.2-related disease. Seizures, often severe or refractory and associated with developmental impairment, were core features in AIMP1- and AIMP2-related disease. Progressive macrocephaly emerged as a consistent feature in individuals with FAM177A1 deficiency.

Conclusion: These findings suggest that MRI-defined HLD classifications do not fully capture the clinical and biological heterogeneity of these disorders. An integrated framework combining clinical subgrouping with imaging and molecular diagnosis may better reflect disease mechanisms, improve diagnostic interpretation, and guide future research.

Disclosure: Nothing to disclose.

Background and aims: The temporal relationship between disease-specific autoantibodies and biomarkers of CNS injury before diagnosis of multiple sclerosis (MS), myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD), and aquaporin-4-IgG-positive neuromyelitis optica spectrum disorder (NMOSD) remains unknown. The objective was to elucidate the preclinical trajectory of EBNA-1-specific, AQP4 as well as MOG antibodies and their association with CNS injury to improve understanding of early pathobiology and biomarker-based risk stratification.

Methods: We performed a multicenter, retrospective, longitudinal case-control study with pre-diagnostic plasma samples from 362 individuals who later developed MS, 145 who later developed MOGAD, and 60 who later developed NMOSD. Plasma IgG levels directed against CNS antigens, MOG, and AQP4, as well as plasma concentrations of neurofilament light chain (pNfL), were quantified, and temporal relationships between immune activation and neuroaxonal injury and clinical disease onset were modeled using linear mixed-effects models and survival analyses.

Results: In MS, EBNA-1-specific and CNS-cross-reactive IgG were elevated up to 77.8 months before diagnosis and preceded first increases in pNfL by mean intervals of 44.9 months, respectively. In NMOSD, AQP4-IgG seroconversion occurred a mean of 32.5 months before diagnosis and preceded elevations in pNfL by 40.4 months, respectively. In contrast, in MOGAD, elevations in pNfL preceded MOG-IgG seroconversion by 11.2 months, respectively.

Conclusion: In MS and NMOSD, disease-specific humoral autoimmunity precedes detectable blood biomarkers of CNS injury, whereas in MOGAD, neuroaxonal and astroglial injury becomes evident before circulating MOG-IgG. These distinct temporal patterns suggest different early pathophysiological mechanisms and may inform early diagnosis and intervention strategies.

Disclosure: The study was funded by the Center for Virology (Medical University of Vienna, Vienna), the Department of Neurology (Medical University of Vienna, Vienna), the Austrian Science Fund (FWF): SYNABS, I6565-B, the Austrian Research Promotion Agency (FFG, project number FO999920011) and the Austrian Society of Neurology, Austria.

B. Joubert, A. Lebrun, M. Benaïteau, A. Farina, L. Comperat, J. Honnorat

CFrench Reference Center for Autoimmune Encephalitis, Hospices Civils de Lyon – MeLiS CNRS UMR 5284 – INSERM U1314, Université Claude Bernard Lyon 1, Lyon, France

Background and aims: CASPR2-associated disease (CASPR2-ad) is a rare autoimmune neurological disorder characterized by recurrent clinical events and frequent long-term disability. We aimed to assess the effect of baseline features and treatments on disease course and neurological outcomes.

Methods: All patients testing positive for anti-CASPR2 antibodies at the French Reference Centre for Autoimmune Encephalitis (2011–2025) were retrospectively included. Neurological outcomes, mortality, and clinical event rate were analyzed using generalized linear mixed models, stratified Cox models, and Andersen-Gill counting-process models, with treatments as time-varying covariates.

Results: Among 171 patients (89% male; median age 66 years; median follow-up, 3 years [IQR 1.3–4.8]), the predominant phenotypes were limbic encephalitis (73%), Morvan syndrome (12%), and Isaacs syndrome (9%). Mortality differed markedly across syndromes ($p < 0.001$; Fig. 1A), with thymoma as the only independent predictor (HR 4.59 [1.26–16.73], $p = 0.021$; Fig. 1B). In two-year survivors, higher baseline mRS and female sex were independently associated with worse neurological outcome (OR 0.19 [0.09–0.39], $p < 0.001$ and OR 0.12 [0.02–0.71], $p = 0.02$) while Morvan syndrome was associated with higher odds of favorable outcomes (OR 12.06 [1.24–117.35], $p = 0.032$; AUC 0.868; Fig. 2). Active rituximab therapy was independently associated with a 56% reduction in clinical event rate (HR 0.44 [0.25–0.77], $p = 0.004$; Fig. 3), with a stronger effect in limbic encephalitis patients (HR 0.35 [0.18–0.66], $p = 0.001$).

FIGURE 1 Mortality.

FIGURE 2 Neurological outcomes at 2 years.

FIGURE 3 Rate of clinical events (patients with ≥ 6 months follow-up).

Conclusion: Baseline severity and thymoma are the main determinants of neurological outcome and mortality, respectively. Rituximab markedly reduces clinical event rate, supporting its use to control CASPR2-ad activity. These findings are limited by the retrospective design and potential confounding by indication.

Disclosure: This study has been developed within the BETPSY project (ANR-18-RHUS-0012).

LB_06 | Clemastine as remyelinating treatment in patients with multiple sclerosis and internuclear ophthalmoplegia

S. Hof¹, D. de Jong¹, P. Molenaar¹, J. Twisk², L. van Rijn³, B. Uitdehaag¹, A. Petzold⁴

¹Neuro-ophthalmology Expertise Center Amsterdam, Amsterdam UMC location Vrije Universiteit Amsterdam, Neurology, De Boelelaan 1117, Amsterdam, The Netherlands & Amsterdam Neuroscience, Neuroinfection & -inflammation, Amsterdam, The Netherlands, ²Department of Epidemiology and Data Science, Amsterdam UMC, Amsterdam, The Netherlands, ³Neuro-ophthalmology Expertise Center Amsterdam, Amsterdam UMC location Vrije Universiteit Amsterdam, Ophthalmology, De Boelelaan 1117, Amsterdam, The Netherlands & Onze Lieve Vrouwe Gasthuis, Ophthalmology, Amsterdam, The Netherlands, ⁴The National Hospital for Neurology and Neurosurgery, Moorfields Eye Hospital and the Queen Square Institute of Neurology, UCL, London, United Kingdom

Background and aims: Remyelination failure contributes to disability and disease progression in multiple sclerosis (MS). Clemastine has shown promise for therapeutic remyelination in optic neuropathy, but its efficacy in other neural pathways remains uncertain. A key area to explore is the brainstem where lesions cause internuclear ophthalmoplegia (INO) in 25% of people with MS, which can transiently improve with fampridine. We investigated whether clemastine promotes brainstem remyelination and evaluated fampridine response as a remyelination predictor.

Methods: In this RCT, 47 people with MS and INO received 4 mg clemastine or placebo twice daily for 6 months. Horizontal saccades conjugacy, a measure of brainstem myelination, was quantified by infrared oculography at baseline, 3, 6, 12, 24 and 36 months. The primary outcome measure was the Versional

Figure 1 consists of three panels, A, B, and C, each showing a graph of Horizontal eye position (degrees) on the y-axis (ranging from 0 to 16) versus Time (ms) on the x-axis (ranging from 0 to 600). The legend indicates that the red line represents the Left eye and the blue line represents the Right eye. Panel A shows the Left eye (red) rising to a steady state of approximately 14 degrees, while the Right eye (blue) rises more rapidly to a peak of about 15.5 degrees at 100 ms before settling at the same level. Panel B shows both eyes rising to a steady state of approximately 14 degrees, with the Right eye (blue) rising slightly faster than the Left eye (red). Panel C shows both eyes rising to a steady state of approximately 14 degrees, with the Right eye (blue) rising very rapidly to the steady state within about 50 ms.

Results: The trial ended on 15-Aug-2025. Positive fampridine response was observed in 23 subjects (49%), with a balanced distribution between clemastine ($n=12$) and placebo ($n=11$) groups (Table 1). Fampridine response was associated with VDI improvement over time ($p=0.004$). Full treatment efficacy data will be presented at the EAN conference.

Late-breaking ePoster Session

F. Nuti¹, M. Valletta¹, D. Vetrano¹, E. Laukka¹, G. Kalpouzos¹,
M. Canevelli¹, C. Fredolini³, G. Bruno², G. Grande¹

Background and aims: Growth differentiation factor 15 (GDF-15) is a circulating cytokine reflecting biological aging linked to cognitive decline. Evidence on brain structural correlates is limited. We investigated the associations of blood GDF-15 with brain volumes and cerebrovascular burden in community-dwelling older adults free from dementia.

Methods: We included 400 community-dwelling participants from the Swedish National Study on Aging and Care in Kungsholmen (SNAC-K), free from major baseline cerebrovascular and neurological diseases. GDF-15 was measured at baseline and analyzed in tertiles. Brain MRI was performed at baseline and after 3 and/or 6 years. Linear mixed models were adjusted for age, sex, education, and chronic comorbidities; secondary analyses further accounted for blood p-tau217.

Fluorometer	Overall N = 362	T1 N = 154	T2 N = 153	T3 N = 155	p-value

Volume (mL)	31.0 (4.5)	31.0 (4.5)	31.0 (4.5)	31.0 (4.5)	0.98
Myocardial mass (g)	5.5 (0.45)	5.5 (0.45)	5.5 (0.45)	5.5 (0.45)	0.98
Left atrial volume (mL)	150 (39.5)	140 (91.5%)	139 (91.5%)	135 (87.1%)	<0.001
Left atrial volume index (mL/m ²)	3.7 (0.5)	3.7 (0.5)	3.7 (0.5)	3.7 (0.5)	0.98

Results: Mean age was 70 (SD 9) years; 58% women. Higher GDF-15 tertiles, adjusted for multiple confounders, showed an association with faster atrophy of total brain tissue (T3 vs T1: β -year = -0.026, 95% CI -0.041, -0.010), hippocampus

FIGURE 1 Annual rate of change in volumes of total brain tissue (TBT), lateral ventricles, hippocampus, amygdala, and white matter hyperintensities (WMH) accumulation over time, by baseline tertiles levels of GDF-15.

FIGURE 2 Annual rate of change in volumes of total brain tissue (TBT), lateral ventricles, hippocampus, amygdala, and white matter hyperintensities (WMH) accumulation over time, by baseline tertiles levels of GDF-15 adjusted for baseline ptau217 levels.

(β -year = -0.054 , 95% CI -0.081 , -0.027), and amygdala (β -year = -0.048 , 95% CI -0.085 , -0.011), and with faster enlargement of the ventricles (β -year = $+0.026$, 95% CI 0.006 , 0.045) and accumulation of white matter hyperintensities (WMH) (β -year = $+0.032$, 95% CI 0.003 , 0.061) over time. Findings were robust to comorbidity adjustment and APOE $\epsilon 4$; associations with total brain tissue, hippocampal, and ventricular trajectories remained significant after adjustment for blood p-tau217.

Conclusion: Higher GDF-15 levels were associated with faster atrophy of total brain tissue, hippocampus, and amygdala, and with ventricular enlargement and WMH over 6 years, supporting GDF-15 as a biomarker of accelerated age-related brain atrophy.

Disclosure: Nothing to disclose.

Background and aims: Real-world data describing lecanemab clinical and safety outcomes by apolipoprotein E (APOE $\epsilon 4$) status, including amyloid-related imaging abnormalities (ARIA) incidence, remain limited. This interim analysis from LEADER characterizes clinical outcomes with lecanemab in APOE $\epsilon 4$ heterozygotes and non-carriers (APOE $\epsilon 4$ homozygotes were excluded to align with the ex-US label).

Methods: LEADER is a multicenter, retrospective, real-world study conducted across 15 geographically diverse U.S. neurology practices. Sites abstracted deidentified medical chart data for patients who received ≥ 7 biweekly intravenous lecanemab infusions. This descriptive analysis assessed clinician-reported

Results: Of 309 patients in LEADER, 256 were included in this analysis (excluding APOE $\epsilon 4$ homozygotes): 155 (50.2%) were heterozygous and 101 (32.7%) were noncarriers. ARIA—edema/effusion (ARIA-E) occurred in 12 (7.7%) heterozygotes and 7 (6.9%) noncarriers. No intracerebral hemorrhages (> 1 cm) occurred. Mean treatment duration at last follow-up was 471.3 and 437.6 days, respectively. Over the observation period, 85.2% of heterozygotes were stable or improved (80.0% stable; 5.2% improved) and 87.1% of noncarriers were stable or improved (81.2% stable; 5.9% improved).

LB_09 | Bocunebart (anti-PACAP monoclonal antibody Lu AG09222) in adults with migraine and prior preventive treatment failures: Phase 2 program outcomes

J. Ailani¹, R. Phul², I. Florea², M. Josiassen², S. Schmidt², A. Blumenfeld³, M. Ashina^{4,5}
¹Department of Neurology, Medstar Georgetown University Hospital, Headache Center, Washington, DC, USA, ²H. Lundbeck A/S, Valby, Copenhagen, Denmark, ³The Los Angeles Headache Center, Los Angeles, CA, USA, ⁴Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, ⁵Department of Neurology, Center for Discoveries in Migraine, Danish Headache Center, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark

Methods: The phase 2 program comprised the proof-of-concept phase 2a HOPE trial (NCT05133323) and the adaptive phase 2b PROCEED trial (NCT06323928), evaluating dose and route of administration. The PROCEED primary endpoint was change from baseline in monthly migraine days (MMDs) over Weeks

1–12. Efficacy in participants with chronic migraine (CM) was evaluated in pooled post-hoc analyses across all doses and parts of PROCEED+HOPE.

Results: For PROCEED (intravenous part), the primary endpoint was met; a statistically significant reduction in MMDs was observed with bocunebart dose A versus placebo over Weeks 1–12 (−4.24 [standard error 0.63] vs −2.86 [0.53]; $p=0.0178$ [2-sided]). Over Weeks 9–12, in the pooled CM subgroup (PROCEED+HOPE), pooled bocunebart doses demonstrated greater improvements from baseline versus placebo in MMDs (−5.94, [0.42] vs −3.63 [0.53]; $p<0.001$), monthly headache days (−6.90, [0.42] vs −4.32 [0.54]; $p<0.001$) and MMDs with acute medication use (−5.21, [0.39] vs −3.53 [0.50]; $p<0.05$). Bocunebart was generally well tolerated; no new safety signals were identified.

Conclusion: Positive phase 2 findings support PACAP inhibition as a novel approach in migraine prevention. Overall, bocunebart reduced migraine burden in a severely impacted population with high unmet need. These findings support bocunebart's continued development as a potential first-in-class anti-PACAP mAb.

Background and aims: Foslevodopa/foscarbidopa (LDp/CDp) is a nonsurgical 24-hour/day continuous subcutaneous infusion for patients with advanced Parkinson's disease (aPD) whose motor fluctuations are uncontrolled on oral medications. Twelve-month safety and effectiveness data from routine clinical practice were captured.

Methods: ROSSINI (NCT06107426) is an ongoing 3-year multi-country, prospective, observational study of adults with aPD who are LDp/CDp-naïve (cohort A) or transitioning from LDp/CDp

TABLE 1 Baseline characteristics and overview of adverse events through 12 months of LDp/CDp treatment in the second interim analysis population (SAS).

Baseline characteristic	n	Cohort A (n = 205)
Age, years, mean (SD)	72.1	68.1 (8.1)
< 65 years, %	66	32.8
≥ 65 years, %	125	67.2
Sex, male, %	122	65.7
Country, %		
Austria	13	6.0

BDI, Depressive symptoms	132 13.8 (3.5)	122 11.8 (3.5)**	86 11.2 (3.4)**	106 10.7 (3.5)**	101 12.1 (3.5)**	81 12.3 (3.4)*	-0.8 (-2.0, 0.1)
MCSI, Cognitive symptoms	81 8.8 (3.0)	55 8.4 (3.0)	48 8.1 (3.0)	40 8.0 (3.0)	48 8.9 (3.0)	41 8.4 (3.1)	0.0 (-1.7, 2.0)

* $P < .05$, ** $P < .01$, *** $P < .001$ for LS mean difference from baseline to time point. CFB values represent LS mean change from baseline to M12, estimated from a mixed model for repeated measures that includes visit and country as fixed effects. Abbreviations: BDI, Beck Depression Inventory; CFB, change from baseline; ESS, Epworth Sleepiness Scale; FAS, full analysis set; PDQ-39, Freedom of Gal Questionnaire; LDp/CDp, levodopa/carbidopa; GDS-PD, Gastrointestinal Dysfunction Scale in Parkinson's disease; LS, least squares; MCSI, Modified Caregiver Strain Index; mCS, motor symptoms of daily living; MDS-UPDRS-II, III, or IV, Movement Disorder Society Unified Parkinson's Disease Rating Scale Part II, III, or IV; PD, Parkinson's disease; PDQ-39, 39-item Parkinson's Disease Questionnaire.

open-label extension studies (NCT04379050/NCT04750226, cohort B). Second interim results for cohort A patients (N=202) enrolled ≥ 12 months (M) before 16December2025 are presented. Adjusted mixed-effects models for repeated measurements (continuous outcomes) were utilized.

Results: At baseline, patients had a mean (SD) age of 68.1 y (9.1 y), PD duration of 12.1 y (5.7 y), and OFF time of 4.8 h (2.6 h, Table 1). From initial prescription to M12, mean daily LD equivalent dose during infusion (1414.7 mg–1471.9 mg) and LDp/CDp base infusion rates (58.9 mg/h LD–67.1 mg/h LD) moderately increased; 21/201 (10.4%) patients received LDp/CDp as a monotherapy until final visit/M12. Patients on LDp/CDp showed statistically significant sustained reductions in motor fluctuations and nonmotor symptoms by M12, including in King's Parkinson's Disease Pain Scale scores (–8.4; Figure 1, Table 2). Patients < 65 y of age and < 10 y PD duration ($n = 22$) showed numerically larger reductions in 39-item Parkinson's Disease Questionnaire scores than the overall population (Figure 1). For safety, 149/201 (74.1%) patients reported ≥ 1 adverse event, mostly nonserious and mild-moderate, with hallucinations and infusion site events most frequent (Table 1).

Conclusion: ROSSINI interim results demonstrate sustained reductions in PD symptoms following 12M of LDp/CDp treatment with an acceptable safety profile.

Background and aims: There is an unmet need for approved and effective treatments for patients with ocular myasthenia gravis (oMG). Subcutaneous (SC) efgartigimod PH20 is a human immunoglobulin G1 (IgG1) antibody Fc fragment coformulated with recombinant human hyaluronidase PH20 that selectively reduces IgG levels by blocking neonatal Fc receptor-mediated IgG recycling. Retrospective data analyses supporting the approval of efgartigimod for treatment of generalized MG indicated improvements in ocular symptoms. Here, we present interim results from the Phase 3 ADAPT OCULUS trial (NCT06558279) evaluating the efficacy and safety of efgartigimod PH20 SC in adults with oMG.

Methods: Adults with oMG (MGFA Class I) and Myasthenia Gravis Impairment Index (patient-reported outcome; MGII [PRO]) ocular score ≥ 6 were randomized 1:1 to receive 4 once-weekly efgartigimod PH20 SC 1000 mg or placebo injections via prefilled syringe, with 4 weeks of follow-up. Participants could continue to Part B, a ≤ 2 -year open-label period.

Results: The primary endpoint was met with statistically significant ($p = 0.012$) improvement from baseline in MGII (PRO) ocular score at Week 4 with efgartigimod compared with placebo. Least squares mean change from baseline to Week 4 in MGII

(PRO) ocular score was -4.04 points with efgartigimod versus -1.99 for placebo. A reduction in all ocular symptoms was reported, and no new safety concerns were identified.

Conclusion: ADAPT OCULUS is the first registrational trial designed specifically to evaluate a targeted therapy for patients with oMG. These results support the efficacy and safety of efgartigimod PH20 SC treatment across multiple cycles in participants with oMG.

LB_12 | Neuronal apoptosis redirects disease-associated microglial states in presymptomatic Alzheimer's iPSC models

A. Dapkute¹, K. Lee², D. Agarwal³, M. Cader¹

¹Nuffield Department of Clinical Neurosciences, University of Oxford, UK, ²Nuffield Department of Medicine, Centre for Human Genetics, University of Oxford, UK, ³Kennedy Institute of Rheumatology, University of Oxford, UK

Background and aims: This study investigated how microglia from presymptomatic AD patients respond to an AD-like neuronal environment using patient-derived induced pluripotent stem cell (iPSC) models.

Methods: Twenty iPSC lines from presymptomatic AD participants from the Deep and Frequent Phenotyping study were differentiated into microglia. iPSC-microglia were exposed to non-apoptotic (NAN) or apoptotic neurons (AN) and analysed by scRNA-sequencing. Following quality control, 14 lines (11 APOE3/E4, 3 APOE4/E4) were retained. Data were preprocessed using Panpipes and annotated using a published microglia atlas. Clustering and batch correction were performed with Monocle3, while trajectory inference and pseudotime-associated gene analysis were performed using Slingshot and tradeSeq. Differential expression and gene ontology enrichment analyses were conducted using Seurat and ClusterProfiler.

Results: Trajectory analysis identified two trajectories leading from cycling to disease-associated microglia (DAM). Trajectory towards GPNMB-high CXCR4+ TREM2+ Lipox-DAM via TREM2+ IFN responsive microglia was preferred in NAN environment. Alternatively, when subjected to AN, trajectory towards LPL-high TREM2+ DAM via MITO-high DAM was more prominent. Comparing microglia subtype ratios between NAN and AN environments showed a decrease in TREM2+ IFN responsive microglia (14.2% in NAN to 1.0% in AN) and an increase in MITO-high DAM (7.2% in NAN to 15.3% in AN). Compared with TREM2+ IFN-responsive microglia, MITO-high DAM showed enrichment of endocytosis-related pathways and reduced immune-response signatures.

Conclusion: Our findings suggest that neuronal apoptosis redirects presymptomatic AD microglia toward a metabolically active, endocytosis-associated DAM state while reducing IFN-responsive immune programs. These results raise the possibility that AD-related neuronal damage may impair protective microglial immune responses early in disease pathogenesis.

Disclosure: Nothing to disclose.

LB_13 | How did Pyridostigmine gain its reputation with POTS? A systematic review and head-to-head intervention meta-analysis

L. Überall, A. Pavelic, W. Struhal

Department of Neurology, University Hospital Tulln, Tulln, Austria

Background and aims: Pharmacotherapy of postural orthostatic tachycardia syndrome (POTS) commonly includes beta-blockers, ivabradine, midodrine, fludrocortisone and pyridostigmine. However, the use of pyridostigmine in POTS is still largely based on limited evidence.

To perform a systematic review and head-to-head intervention meta-analysis of studies evaluating the efficacy of pyridostigmine in reduction of heart rate in standardized autonomic function testing in comparison to beta-blockers, ivabradine and midodrine.

Methods: We searched PubMed, Embase, CINAHL as well as Cochrane Library for results up to May 25th, 2026, and evaluated full text articles for 38 of 443 search results. Six articles met all selection criteria. The respective heart rate change results (before and after intervention) of these 6 articles were pooled together and analyzed in a head-to-head manner (Pyridostigmine vs. beta-blockers and Pyridostigmine vs. ivabradine). All analyses were carried out using Review Manager 5.4.

Results: In the 6 articles, pyridostigmine showed no superiority in comparison to beta-blockers or ivabradine. The standardized mean difference (SMD) was -10.38 (95% confidence interval (CI) -47.90 to 27.14) for pyridostigmine vs. beta-blockers, and -3.63 (CI -56.54 to 49.27) for pyridostigmine vs. ivabradine.

Conclusion: Based on the currently available literature, pyridostigmine should not be considered a first-line therapy in patients with POTS. Our head-to-head meta-analysis and systematic review showed that the available literature is highly heterogeneous and published studies reported diverse primary endpoints. Our findings highlight the need for unanimous and standardized reporting of results (including symptomatologic questionnaires) to accurately evaluate the success of POTS pharmacological interventions.

Disclosure: Nothing to disclose.

LB_14 | AI-Augmented EEG interpretation: Unlocking timely diagnosis for new-onset epilepsy patients

E. Ménétré¹, S. Rayatdoost¹, A. Lage¹, M. Seeck², S. Gallotto¹

¹dEEGtal Insights SA, Geneva, Switzerland, ²EEG and Epilepsy Unit, University Hospitals and Faculty of Medicine, Geneva, Switzerland

Background and aims: Approximately five million individuals are diagnosed with epilepsy each year, while many others present with uncertain first-seizure events. Early diagnosis is essential because timely treatment improves outcomes, yet delays are common due to limited access to electroencephalography (EEG) expertise. Interictal epileptiform discharges (IEDs), the only routinely used EEG biomarker, are highly specific but have low sensitivity. This study aimed to develop and validate an artificial intelligence (AI)-based diagnostic classifier using resting-state

EEG and routinely available clinical variables to improve early differentiation between epileptic and non-epileptic first-seizure presentations.

Methods: A transformer-based model was trained on approximately 10-minute resting-state EEG recordings from a real-world cohort. Patients were classified as having epilepsy or non-epileptic events after a standardized 2-year follow-up. Model inputs included EEG features, expert-marked IEDs, and clinical variables (age, sex, lesion status). A subject-level 5-fold cross-validation framework was used, with performance assessed using the area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, and accuracy.

Results: The cohort included 1248 patients (621 epilepsy; 627 non-epilepsy). EEG alone yielded an AUROC of 0.72, decreasing to 0.67 in patients without IEDs or epileptogenic lesions. Adding clinical variables improved performance to 0.79. A fusion model combining EEG, IEDs, and clinical data achieved the highest performance (AUROC = 0.82; accuracy = 0.74; specificity = 0.86; sensitivity = 0.61).

Conclusion: AI-derived resting-state EEG in combination with routinely available clinical variables provides diagnostic value beyond conventional interpretation and may reduce diagnostic uncertainty and treatment delays after a first seizure.

Disclosure: This research was co-financed through a combination of public and private funding sources. Some authors are shareholders and/or full-time employees of dEEGtal Insights SA.

LB_15 | Long-term safety and tolerability of del-desiran in myotonic dystrophy type 1: Final results from MARINA-OLE™

N. Johnson¹, J. Hamel², S. Subramony³, P. Soltanzadeh⁴, J. Statland⁵, M. Freimer⁶, D. Quan⁷, S. Vaziri⁸, B. McEvoy⁸, M. Fowler⁸, E. Ackermann⁸, A. Davidson⁸, D. Schmitt⁹
¹Virginia Commonwealth University, Richmond, USA, ²University of Rochester Medical Center, Rochester, USA, ³University of Florida, Gainesville, USA, ⁴University of California, Los Angeles, Los Angeles, USA, ⁵University of Kansas Medical Center, Kansas City, USA, ⁶The Ohio State University, Columbus, USA, ⁷University of Colorado Anschutz, Aurora, USA, ⁸Avidity Biosciences, A Novartis Company, San Diego, USA, ⁹Avidity Biosciences, A Novartis Company, Non-author Presenter, San Diego, USA

Background and aims: Myotonic dystrophy type 1 (DM1) is a rare, progressive neuromuscular disorder caused by DMPK mutations, leading to toxic mRNA accumulation, muscle dysfunction, and reduced life expectancy. Delpacibart etedesiran (del-desiran; AOC 1001) is an investigational antibody oligonucleotide conjugate comprised of a monoclonal antibody targeting transferrin receptor 1 for muscle delivery and an siRNA that induces degradation of DMPK mRNA to treat the underlying cause of DM1.

Methods: MARINA-OLE™ was a phase 2, open-label extension study assessing long-term safety and tolerability of del-desiran in adults with DM1, with follow-up extending to 37 months. Participants received del-desiran at either 2 or 4 mg/kg every 13 weeks and later transitioned to 4 mg/kg every 8 weeks, consistent with the phase 3 trial regimen. All participants completed approximately 1 year on this regimen.

Results: 37 participants received del-desiran, 101.3 patient-years of cumulative exposure with 506 infusions. Most treatment-emergent adverse events (TEAEs) were mild/moderate. No severe or serious TEAEs were treatment-related, and none led to treatment discontinuation or death. Laboratory values, including hematology parameters, were stable over time.

Conclusion: Del-desiran showed favorable long-term safety and tolerability in adults with DM1. These data represent the longest safety results for a DMPK-targeted therapy and highlight potential of del-desiran to drive a new treatment paradigm for DM1.

Disclosure: Funding: This study was supported by Avidity Biosciences, A Novartis Company.

NEJ has received grant funding from NINDS (R01NS104010, U01NS124974), NCATS (R21TR003184), CDC (U01DD001242), and the FDA (2R01FD006071); receives royalties from the CCMDHI and the CMTHI, and research funds from Avidity Biosciences, A Novartis Company, Takeda, Sanofi Genzyme, Dyne, Novartis, Vertex Pharmaceuticals, Fulcrum Therapeutics, ML Bio, and Sarepta; provided consultation for Arthex, Novartis, AMO Pharma, Takeda.

JH served on Clinical Advisory Committees for Dyne Therapeutics and Vertex Pharmaceuticals; provided disease specific information to Design Therapeutics; as a Q&A panel member for Avidity Biosciences, A Novartis Company, at the MDA Conference; and as the overall Principal Investigator for the PepGen Freedom DM1 Study.

SHS has participated in Advisory Boards for Amicus Therapeutics, Inc., Fulcrum Therapeutics, PTC Therapeutics, Inc., and Reata; is a Principal Investigator for clinical trials by Avidity Biosciences, A Novartis Company, Biogen, Inc., Biohaven Pharmaceuticals, Inc., Fulcrum Therapeutics, Harmony Biosciences, PTC Therapeutics, Inc., Reata, Reneo, and Retrotope; and has discussed forthcoming trials with Solid Biosciences.

PS has a Research Contract Grant through UCLA to perform del-desiran clinical trials with Avidity Biosciences, A Novartis Company.

JS has served as a Consultant on trial design (Armatus Bio and Epic Bio), Advisory Boards (Avidity Biosciences, A Novartis Company, Dyne, F. Hoffmann-La Roche, Fulcrum Therapeutics, and Vertex Pharmaceuticals), and for Kate Therapeutics; received funding for clinical studies from Avidity Biosciences, A Novartis Company, Dyne, F. Hoffman-La Roche, FSHD Canada, and NINDS; received a grant for Muscular Dystrophy Clinical Research Network from MDA; and receives options as part of a non-employee compensation plan from Dyne.

MF received research support from Alnylam, Argenx, Catalyst Pharmaceuticals, Fulcrum Therapeutics, Momenta Pharmaceuticals, Inc., and UCB, Inc.; has been provided consulting fees by Argenx, Johnson & Johnson, and UCB Inc. for participation in Advisory Boards and by UCB Inc. for serving as a faculty member for speakers bureau training; and has served as Principal Investigator in clinical trials sponsored by Avidity Biosciences, A Novartis Company.

DQ receives clinical research support from Alnylam, Bridge Bio, Momenta, and Avidity; serves on a data safety monitoring board for Argenx; and has received payment from Astra Zeneca for a speaking engagement.

SV, AD, BM, MF, and EJA are employees of Avidity Biosciences, A Novartis Company.

LB_16 | Safety and efficacy of SR750 in patients with trigeminal neuralgia: A double-blind, randomized, placebo-controlled, phase 2 study

B. Fan¹, Q. Han², L. Jin², X. Gong², F. Wang², C. Fei², L. Wang², Y. Chen², S. Li²

¹Department of Pain Management, China-Japan Friendship Hospital, Beijing, China, ²Shanghai SIMR Biotechnology Co., Ltd, Shanghai, China

Background and aims: Trigeminal neuralgia (TN) is a severely disabling disorder featuring sudden, recurrent, electric shock-like facial pain in the trigeminal nerve distribution. SR750, a first-in-class alpha5-GABAA receptors negative allosteric modulator (NAM) developed for neuropathic pain, has the potential to improve the condition of TN. This study assessed the efficacy and safety of SR750 in Chinese patients with TN.

Methods: A phase 2 randomized, double-blind and placebo-controlled study (NCT06571448) was initiated in July 2024. Patients diagnosed with primary TN were recruited and randomized into three arms at 1:1:1 ratio to receive SR750 50 mg, 150 mg or placebo twice a day (BID) for 6 weeks. The primary endpoint was change from baseline at week 6 in the weekly average of the daily average pain score (DAPS) of paroxysms using pain intensity numerical rating scale.

FIGURE 1 Study design.

Results: A total of 138 patients were enrolled, with 45 patients treated with SR750 50 mg BID, 47 treated with SR750 150 mg BID, and 46 treated with placebo. For the primary endpoint, the least square mean (LSM) change from baseline were -0.89 , -1.83 , and -1.97 in the placebo, SR750 50 mg BID and SR750 150 mg BID groups, respectively. Both SR750 treatment groups were superior to placebo, with between-group LSM differences of -0.94 (90% CI -1.66 , -0.23 , $p=0.031$) and -1.08 (90% CI -1.78 , -0.37 , $p=0.012$), respectively.

Conclusion: Overall, SR750 low dose and high dose demonstrated statistically and clinically significant efficacy versus placebo, with a favorable safety and tolerability profile, supporting its further investigation in late-stage trials.

Disclosure: Funded by SIMR. B. Fan reports no conflicts of interest. All other authors are employees of SIMR, including S. Li, the CEO, who participated in study oversight and approval. The funder was involved in study design, data analysis and manuscript preparation.

²Uzhhorod National University, Ukraine

Background and aims: Upper limb injuries and amputations in military personnel are associated with PTSD, anxiety, depression, and cognitive impairment. While standard rehabilitation is effective, the additional effects of robotic systems require further study.

Methods: Sixty military personnel with upper limb amputations were enrolled. Group 1 ($n=30$) received standard rehabilitation, while Group 2 ($n=30$) additionally underwent robotic therapy (DIEGO®). Assessments at baseline, 14, 30, and 120 days included PCL-5, GAD-7, PHQ-9, and MoCA. Data were analyzed using repeated-measures ANOVA, Cohen's d , and η^2 .

Results: At baseline, both groups had high psychoemotional distress and moderate cognitive impairment without significant differences: PCL-5 58.2 ± 6.1 vs. 57.9 ± 5.8 ($p=0.84$), GAD-7 15.3 ± 3.4 vs. 15.1 ± 3.2 ($p=0.79$), PHQ-9 17.8 ± 4.0 vs. 18.0 ± 3.8 ($p=0.88$), MoCA 23.1 ± 2.3 vs. 23.3 ± 2.5 ($p=0.67$).

PCL-5 scores improved: day 14 51.6 ± 5.7 vs. 45.9 ± 5.4 ($p=0.04$), day 30 43.8 ± 5.4 vs. 35.2 ± 4.9 ($p=0.003$), day 120 34.5 ± 5.2 vs. 26.1 ± 4.8 ($p=0.002$; $d=1.68$; $\eta^2=0.31$).

GAD-7 differences were significant only at day 120: 9.2 ± 2.6 vs. 6.3 ± 2.1 ($p=0.004$; $d=1.22$; $\eta^2=0.24$).

PHQ-9 improvement: day 14 15.0 ± 3.6 vs. 13.6 ± 3.3 ($p=0.06$), day 30 12.8 ± 3.3 vs. 9.6 ± 2.9 ($p=0.01$), day 120 10.4 ± 3.1 vs. 7.2 ± 2.5 ($p=0.006$; $d=1.13$; $\eta^2=0.21$).

MoCA: day 14 23.8 ± 2.2 vs. 25.1 ± 2.0 ($p=0.02$), day 30 24.4 ± 2.1 vs. 26.3 ± 1.9 ($p=0.01$), day 120 25.0 ± 2.1 vs. 27.4 ± 1.8 ($p=0.001$; $d=1.25$; $\eta^2=0.28$).

Conclusion: Robotic therapy (DIEGO®) added to standard rehabilitation leads to faster and greater improvement in psychoemotional and cognitive functions, supporting its integration into military rehabilitation.

Supported by the National Research Foundation of Ukraine (Project No. 2025.07/0021).

USA, ⁸Nationwide Children's Hospital, Columbus, Ohio, USA, ⁹University of Padova, Padova, Italy, ¹⁰University of Florida, Gainesville, Florida, USA, ¹¹Arkansas Children's Hospital, University of Arkansas for Medical Sciences, Little Rock, Arkansas, USA, ¹²Edgewise Therapeutics, Boulder, Colorado, USA

Background and aims: There are no currently approved BMD therapies. Sevasseten, an investigational skeletal myosin inhibitor, is designed to protect muscle against contraction-induced damage in Becker muscular dystrophy (BMD). GRAND CANYON (NCT05291091), a double-blind, placebo-controlled cohort, evaluates sevasseten efficacy and safety.

Methods: Ambulatory BMD adults were randomized and stratified by NSAA and rise from floor (RFF). Primary endpoint is NSAA change from baseline at 18 months; secondary endpoints are TFTs, stride velocity 95th percentile (SV95C), and MRI fat fraction.

Results: 175 participants enrolled (mean age (SD): 33 (9) years; baseline NSAA: 19.6 (7.6); 58% with NSAA <22). 4-Stair Climb (4SC), 10-meter walk run (10MWR), and 100-m walk run (100MWR) tests were 6.3 (6.1), 8.2 (6.5), and 83.1 (33.8) seconds, respectively. RFF was 5.4 (3.0) seconds. SV95C was 1.2 (0.24) meters/second. Upper limb function was largely maintained, with 15% having entry level PUL 2.0 <6. In the initial CGI-S, 51% of participants had moderately or markedly severe disease and 48% reported moderate or severe disease per PGI-S. Pre-treatment NSAA strongly correlated with 4SC ($r=0.90$), 10MWR ($r=0.89$), 100MWR ($r=0.82$), RFF ($r=0.87$), and SV95C ($r=0.83$), all $p \leq 0.001$.

Conclusion: GRAND CANYON is the largest BMD interventional trial; results could support approval as the first targeted BMD therapy. Pre-treatment NSAA correlation analysis provides initial insight into potential alternatives to assessing functional status.

Disclosure: The GRAND CANYON trial is sponsored by Edgewise Therapeutics. Craig McDonald, Eugenio Mercuri, Kristl Claey's, Michela Guglieri, Erik H. Niks, Katherine Mathews, Anne M. Connolly, Luca Bello, Barry Byrne, Aravindhan Veerapandian are consultants for Edgewise. Jim MacDougall, Roxana Donisa Dreghici, and Joanne Donovan are employees and shareholders of Edgewise Therapeutics. All non-Edgewise authors are investigators in the GRAND CANYON trial.
