GBD 2016 Stroke Collaborators

Summary

Background Stroke is a leading cause of mortality and disability worldwide and the economic costs of treatment and post-stroke care are substantial. The Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) provides a systematic, comparable method of quantifying health loss by disease, age, sex, year, and location to provide information to health systems and policy makers on more than 300 causes of disease and injury, including stroke. The results presented here are the estimates of burden due to overall stroke and ischaemic and haemorrhagic stroke from GBD 2016.

Methods We report estimates and corresponding uncertainty intervals (UIs), from 1990 to 2016, for incidence, prevalence, deaths, years of life lost (YLLs), years lived with disability (YLDs), and disability-adjusted life-years (DALYs). DALYs were generated by summing YLLs and YLDs. Cause-specific mortality was estimated using an ensemble modelling process with vital registration and verbal autopsy data as inputs. Non-fatal estimates were generated using Bayesian meta-regression incorporating data from registries, scientific literature, administrative records, and surveys. The Socio-demographic Index (SDI), a summary indicator generated using educational attainment, lagged distributed income, and total fertility rate, was used to group countries into quintiles.

Findings In 2016, there were 5·5 million (95% UI 5·3 to 5·7) deaths and 116·4 million (111·4 to 121·4) DALYs due to stroke. The global age-standardised mortality rate decreased by 36·2% (–39·3 to –33·6) from 1990 to 2016, with decreases in all SDI quintiles. Over the same period, the global age-standardised DALY rate declined by 34·2% (–37·2 to –31·5), also with decreases in all SDI quintiles. There were 13·7 million (12·7 to 14·7) new stroke cases in 2016. Global age-standardised incidence declined by 8·1% (–10·7 to –5·5) from 1990 to 2016 and decreased in all SDI quintiles except the middle SDI group. There were 80·1 million (74·1 to 86·3) prevalent cases of stroke globally in 2016; 41·1 million (38·0 to 44·3) in women and 39·0 million (36·1 to 42·1) in men.

Interpretation Although age-standardised mortality rates have decreased sharply from 1990 to 2016, the decrease in age-standardised incidence has been less steep, indicating that the burden of stroke is likely to remain high. Planned updates to future GBD iterations include generating separate estimates for subarachnoid haemorrhage and intracerebral haemorrhage, generating estimates of transient ischaemic attack, and including atrial fibrillation as a risk factor.
Global Stroke Burden

- 80.1 Million prevalent cases, 13.7 Million new stroke cases, 5.5 Million deaths
- Recent stroke projections forecast a worldwide rise to 200 million disability adjusted life years lost per annum by 2030.
- Stroke incidence and mortality in low to middle income countries have now exceeded those in high income countries (over 85% of stroke mortality worldwide).
- Urgent need to develop informative, accessible and cost-effective forms of support.

*Lancet 2019*

We are facing worldwide Pandemic of stroke
Sub-Saharan Africa is home to nearly **one billion** people.

- There are **47 countries** in sub-Saharan Africa, including: **6 central**, **17 eastern**, **6 Southern**, and **18 Western**.
The epidemiology of stroke in Africa: A systematic review of existing methods and new approaches

Accurate epidemiological surveillance of the burden of stroke is direly needed to facilitate the development and evaluation of effective interventions in Africa. The authors therefore conducted a systematic review of the methodology of stroke epidemiological studies conducted in Africa from 1970 to 2017 using gold standard criteria obtained from landmark epidemiological publications. Of 1330 articles extracted, only 50
Stroke burden in Africa

- Age-standardized annual stroke incidence rate of up to 316 per 100,000 population
- Age-standardized prevalence rates of up to 981 per 100,000 in Africa.
- Stroke case fatality rates of up to 43% in Africa.
Unchecked industrialization and a rise in many modifiable vascular disease risk factors.

- Smoking, harmful use of alcohol
- Physical inactivity
- Unhealthy diets resulting in an increased prevalence of hypertension, diabetes, and obesity
- Racial (? Genetic factors: gene – environment interactions)
World Stroke Organization (WSO) Stroke Services Framework which consists of six phases of the continuum of stroke care:

- Systems for stroke recognition and response
- Hyper acute stroke care
- Acute inpatient care
- **Stroke rehabilitation**
- Secondary stroke prevention
- Longer-term stroke recovery.
Stroke care in Africa: A systematic review of the literature

Gerard Urimubenshi¹,² , Dominique A Cadilhac³,⁴ , Jeanne N Kagwiza², Olivia Wu⁵ and Peter Langhorne¹

Abstract

Background: Appropriate systems of stroke care are important to manage the increasing death and disability associated with stroke in Africa. Information on existing stroke services in African countries is limited.

Aim: To describe the status of stroke care in Africa.

Summary of review: We undertook a systematic search of the published literature to identify recent (1 January 2006–20 June 2017) publications that described stroke care in any African country. Our initial search yielded 838 potential papers, of which 38 publications were eligible representing 14/54 African countries. Across the publications included for our review, the proportion of stroke patients reported to arrive at hospital within 3 h from stroke onset varied between 10% and 43%. The median time interval between stroke onset and hospital admission was 31 h. Poor awareness of stroke signs and symptoms, shortages of medical transportation, health care personnel, and stroke units, and the high cost of brain imaging, thrombolysis, and outpatient physiotherapy rehabilitation services were reported as major barriers to providing best-practice stroke care in Africa.

The proportion of patients reported to receive inpatient physiotherapy rehabilitation was greatest in South Africa (98%) and smallest in Rwanda (40%).

Low attendance rates to outpatient physiotherapy rehabilitation:

- Lack of finances
- Patient migration to other areas
- Living a long distance from the hospital
- Lack of continuity of care
Stroke Rehabilitation

- In patient
- Home-Based Rehab
- Community-based programs
Stroke Rehabilitation

- **Physiotherapy**: facilitate the improvement of mobility and physical activity
- **Occupational therapy**: identification, engagement, and improved function in activities of daily living
- **Speech-language therapy**: the treatment of language, speech, voice and communication disorders
- **Therapeutic Recreational therapy**: the incorporation of recreation and leisure as essential components to improved quality of life
- **Registered Nurse**: provision of basic medical support and health education
Stroke Patient pathways

- Acute Stroke Care
  - Outpatient Rehabilitation
  - Home-Based Rehabilitation
  - Inpatient Rehabilitation
    - Home-Based Rehabilitation
    - Outpatient Rehabilitation
    - LTC
    - No Service
1- Poor physician **knowledge**.

2- Lack of **rehabilitation component** in the standard of care.

3- The **long interval** from stroke onset to admission to rehabilitation.

4- The infrequent, **unskilled**, and short-lived provision of rehabilitation care.

5- Inadequate public insurance or **financial support** for rehabilitation care.
Barriers to Stroke Rehabilitation

6-Transportation
7-Distance
8-Time constrains
9-Weather
10-Resources
11-The current stroke rehabilitation focuses on improving motor deficit; It ignores cognitive, emotional, and communicative skills.
What is the best model for stroke rehab in less wealthy areas?
The early hospital discharge and home-based rehabilitation scheme was less costly ($8040) than conventional hospital rehab with community care ($10,054) for patients with stroke.

A policy of early hospital discharge and home-based rehabilitation for patients with stroke can reduce the use of hospital rehabilitation beds without compromising clinical patient outcomes.

(Anderson et al, Stroke 2000)
Tele-Rehabilitation
Telemedicine in post Stroke Rehabilitation

RESEARCH

Systematic review

Telerehabilitation in stroke care – a systematic review

Tim Johansson and Claudia Wild
Ludwig Boltzmann Institute for Health Technology Assessment, Vienna, Austria

Summary
We conducted a systematic review of telerehabilitation interventions in stroke care. The following databases were searched: Medline, Embase, DARE-NHSEED-HTA (INAHTA) and the Cochrane Library. Nine studies, all published after 2000, were included in the review. A wide variety of telemedicine interventions in post-stroke rehabilitation care was identified. Four studies had been carried out in the USA, two in the Netherlands, two in Italy and one in China. There were four randomized controlled trials and one qualitative analysis. Four studies used an observational study design/case series. Home-based telerehabilitation interventions showed promising results in improving the health of stroke patients and in supporting caregivers. Telemedicine systems based on a virtual environment for upper extremity exercise can improve the physical health of stroke patients. Health professionals and participants reported high levels of satisfaction and acceptance of telerehabilitation interventions. There was no evidence regarding the effects on resource utilization or cost-effectiveness. Most studies showed promising results, although overall, the quality of the evidence on telerehabilitation in post-stroke care was low.

Telemedicine in post Stroke Rehabilitation

- The feasibility, effectiveness, cost-effectiveness and quality of tele-rehabilitation interventions in post-stroke care.
- The effect of post-stroke tele-rehabilitation initiatives on health outcomes, health-care processes, the use of health resources, and user/patient satisfaction and Acceptance.
- Six studies reported user and patient satisfaction of telemedicine interventions in stroke rehabilitation settings.
- Overall, participants, caregivers and health professionals were satisfied and accepted the use of telerehabilitation services

Journal of Telemedicine and Telecare 2011
Family-led rehabilitation after stroke in India (ATTEND): a randomised controlled trial

The ATTEND Collaborative Group

Summary

Background Most people with stroke in India have no access to organised rehabilitation services. The effectiveness of training family members to provide stroke rehabilitation is uncertain. Our primary objective was to determine whether family-led stroke rehabilitation, initiated in hospital and continued at home, would be superior to usual care in a low-resource setting.

Methods The Family-led Rehabilitation after Stroke in India (ATTEND) trial was a prospectively randomised open trial with blinded endpoint done across 14 hospitals in India. Patients aged 18 years or older who had a stroke within the past month, had residual disability and reasonable expectation of survival, and who had an informal family-nominated caregiver were randomly assigned to intervention or usual care by site coordinators using a secure web-based system with minimisation by site and stroke severity. The family members of participants in the intervention group received additional structured rehabilitation training—including information provision, joint goal setting, carer training, and task-specific training—that was started in hospital and continued at home for up to 2 months. The primary outcome was death or dependency at 6 months, defined by scores 3–6 on the modified Rankin scale (range, 0 [no symptoms] to 6 [death]) as assessed by masked observers. Analyses were by intention to treat. This trial is registered with Clinical Trials Registry-India (CTRI/2013/04/003557), Australian New Zealand Clinical Trials Registry (ACTRN12613000078752), and Universal Trial Number (U1111-1138-6707).

Findings Between Jan 13, 2014, and Feb 12, 2016, 1250 patients were randomly assigned to intervention (n=623) or control (n=627) groups. 32 patients were lost to follow-up (14 intervention, 19 control) and five patients withdrew (two intervention, three control). At 6 months, 285 (47%) of 607 patients in the intervention group and 287 (47%) of 605 controls were dead or dependent (odds ratio 0·98, 95% CI 0·78–1·23, p=0·87). 72 (12%) patients in the intervention group and 86 (14%) in the control group died (p=0·27), and we observed no difference in rehospitalisation (89 [14%] patients in the intervention group vs 82 [13%] in the control group; p=0·56). We also found no difference in total non-fatal events (112 events in 82 [13%] intervention patients vs 110 events in 79 [13%] control patients; p=0·80).

Interpretation Although task shifting is an attractive solution for health-care sustainability, our results do not support investment in new stroke rehabilitation services that shift tasks to family caregivers, unless new evidence emerges. A future avenue of research should be to investigate the effects of task shifting to health-care assistants or team-based community care.

ATTEND was a prospectively randomized open trial with blinded endpoint (PROBE) done across 14 hospitals in India.

It involved training family members to provide a simplified version of evidence-based rehabilitation.

A written intervention guide was available for the coordinators and an intervention manual for the patient and caregiver.

The primary outcome was death or dependency at 6 months defined as 3-6 score on MRS.
**Figure 2**: Patients achieving each mRS score at 6 months.

mRS = modified Rankin Scale.

Stroke Self-Management and Rehabilitation Trial (SMART-DVD): An International, Multi-Site Pilot Trial

Objective:
To assess the feasibility of conducting a randomized controlled trial of an instructional and educational stroke DVD and determine the feasibility and preliminary efficacy of this intervention in a multinational context.

Kelly M Jones¹, Rohit Bhattacharjee¹, Rita Krishnamurthi¹, Sarah Blanton¹, Suzanne Barker-Collo¹, Alice Theadom¹, Amanda G Thrift¹, Steven L Wolf¹, Narayanaswamy Venkatasubramanian⁵, Priya Parmar¹, Annick Maujean⁴, Annemarei Ranta⁷, Dominique Cadilhac¹, Emmanuel O Sanya⁸, Marilyn MacKay-Lyons¹, Jeyaraj D Pandian¹⁰, Deepti Arora¹⁰, Reginald O Obiako¹¹, Gustavo Saposnik¹², Shivanthi Balalla¹³, Natan M Bornstein¹⁴, Peter Langhorne¹⁵, Bo Norrving¹⁶, Nita Brown¹⁷, Michael Brainin¹⁸,¹⁹, Denise Taylor¹⁰,¹⁹ and Valery L Feigin¹
SMART Study design & Participants

- **Design:** Non-funded, international multicenter pilot randomized controlled trial of intervention versus usual care.

- **Participants:** Community-living adults up to three years post stroke with moderate to severe disability and their nominated informal caregivers.
14 recruitment sites were established across eight countries.

Recruitment was achieved at nine (64%) sites.

66 patients were recruited over 16 months.

Patients randomized to intervention (n = 34) and control (n = 32) groups.

**Reasons for non-recruitment included:**
- Administrative delays (ethics)
- Inadequate resourcing (non-funded trial)
- Non-English-speaking patients
- Clash with changing treatment guidelines

All other study processes successfully implemented at international level (localized randomization, intervention delivery, screening tests, baseline and follow-up assessments).
Intervention Group

- Role model observational learning tool DVD offering >40 care and rehabilitation techniques Based on best available evidence
- Features people from a variety of ethnic backgrounds
- Baseline assessment at 4 weeks – 9 months post-stroke
- Weekly Phone Assessments
- Two-month follow-up assessment
Intervention

Six Segments:

1. Understanding Stroke
2. Early Care and Hygiene
3. Rehabilitation Exercises
4. Moving Around
5. Coping with Stroke Aftermath
6. Experience of Caregivers
Usual Care Group

• Receive usual care
• No Weekly Phone Call
• Baseline Assessment
• Two-month follow-up assessment
• Option to access treatment DVD after participation in the trial has ended
Study Endpoints

• **Primary endpoint:** implementation of study processes at all sites

• **Secondary endpoints:** Process measures about benefits of the intervention, barriers to adherence, suggested improvements, and preliminary efficacy at 3-months
### Feasibility of setting up and running study centres.

</table>
• An instructional and educational intervention focusing on common problems post stroke and delivered by DVD may be acceptable, with a range of benefits reported by stroke patients and/or their family caregivers.

• Instructional and educational interventions must be individualized to meet the needs, and learning preferences of stroke patients and their family caregivers.
Conclusion

• There are some attractive and equal alternatives for in hospital and community based stroke rehabilitation.

• Home-Based Rehabilitation is a feasible and cost-effective measure for stroke rehab and recovery in LMIC and improves outcomes, eliminates wait times, saves money.

• Tele-Rehabilitation has significant improvement with acceptable level of satisfaction for both patient and caregiver.

• An instructional and educational intervention focusing on common problems post stroke and delivered by DVD may be acceptable, with a range of benefits reported by stroke patients and/or their family caregivers.
STAY SAFE AND HEALTHY
